ENVIRONMENTAL IMPACT STATEMENT

The Sea Lion Field
Northern Development Area, Phase 1 & 2

July 2025

Environmental Impact Statement: The Sea Lion Field Northern Development Area, Phase 1 & 2

Navitas Petroleum Development and Production Limited.

Project	Area	Discipline	Doc Type	Doc. Number	Sheet

Acknowledgements

Thanks are extended to the Falkland Islands Government, particularly to the following personnel: Andrea Clausen, James Wilson, Chris Moorey, Nomali Port, Steuart Barlow, Francis J Hart, Dani Baigorri, Robert King, Hayden Eldridge, Rebecca Piontek, Debbie Barlow, Maeve Daly-Llamosa, Roddy Cordeiro, Zac Stephenson, James Greenland. Thanks are also extended to: Laura Yon (Stanley Services), Craig Paice (Atlink Limited) and SAERI staff who provided additional data used in the assessment.

Thanks go to the Joint Nature Conservation Committee and Falklands Conservation allowing access to the Seabirds at-Sea Team survey dataset in previous Sea Lion EIAs. These data are presented again here but no re-analyses were conducted for this current EIS submission. The original project was sponsored by Falklands Conservation with funding coming from Falkland Islands Government and FOSA (Falklands Offshore Sharing Agreement) in the first year.

This document has been prepared by SAERI (Falklands) Ltd. SAERI is the South Atlantic Environmental Research Institute.

TABLE OF CONTENTS

1 NON-TECHNICAL SUMMARY 26
1.1 Introduction 28
1.2 The Sea Lion Field 29
1.3 EIA Context 31
1.4 Consideration of alternatives 33
1.5 The Sea Lion Field Northern Area Phase 1 & 2 - Development description 35
1.6 Scoping consultation 39
1.7 Environmental and social baseline description 40
1.8 Environmental and social impact and risk assessment 46
1.9 Environmental Monitoring and Management 70
1.10 Overall conclusion 74
1.11 Formal stakeholder consultation 75
2 INTRODUCTION 76
2.1 Introduction 77
2.2 Overview of the Sea Lion Field Development 78
2.3 EIA process overview 85
2.4 Scope of the EIA 85
2.5 Purpose and structure of this Environmental Impact Statement 86
3 EIA CONTEXT 90
3.1 Regulatory overview and legislation 92
3.2 Navitas Operating Management System 103
4 CONSIDERATION OF ALTERNATIVES 117
4.1 Introduction 118
4.2 Project development process 118
4.3 Historical consideration of alternatives 118
4.4 Development optimisation by Navitas 127
4.5 Mitigations not used 130
5 SEA LION FIELD, PHASE 1 & 2 DEVELOPMENT DESCRIPTION 132
5.1 Introduction 136
5.2 Project overview 136
5.3 Sea Lion reservoir characteristics 145
5.4 Phase 1 & 2 Drilling operations 145
5.5 Construction: Installation of drilling, production and export facilities 163
5.6 FPSO Hook-up and commissioning 172
5.7 Simultaneous Operations (SIMOPS): drilling and production 172
5.8 Production facilities 173
5.9 Steady state production 191
5.10 Oil export process and facilities 193
5.11 Logistics and infrastructure 196
5.12 Decommissioning 222

5.13 Development resilience to the effects of climate change 224
5.14 Phase 1 & 2 base-case mitigation technologies 225
5.15 Estimated quantities of residues and emissions resulting from the project 228
6 SCOPING AND STATUTORY CONSULTATIONS 230
6.1 Introduction 231
6.2 Historical scoping and statutory consultations 236
6.3 Navitas informal scoping consultation 2023 242
6.4 Summary of all informal scoping consultation outcomes 242
6.5 Navitas statutory 42-day public consultation 247
7 ENVIRONMENTAL AND SOCIAL BASELINE 248
7.1 Introduction 256
7.2 Data Sources 259
7.3 Physical Environment 267
7.4 Biological Environment 307
7.5 Conservation Designations for sites, species and habitats 484
7.6 Coastal Sensitivity to Oil Spills 499
7.7 Social Environment 506
7.8 Summary of Key Environmental and Social Sensitivities 550
8 ENVIRONMENTAL IMPACT AND RISK ASSESSMENT METHODOLOGY 554
8.1 Introduction 555
8.2 Overview of the environmental impact and risk assessment process 555
8.3 Aspect, impact and risk identification 556
8.4 Environmental baseline and receptor identification 558
8.5 Impact assessment methodology for planned events 558
8.6 Risk assessment methodology for unplanned and accidental events 568
8.7 Impact and risk mitigation 571
8.8 Residual assessments 572
8.9 Cumulative impact assessment and impact interactions 573
8.10 Confidence in the assessment 575
8.11 Offsetting of impacts 576
9 ENVIRONMENTAL IMPACT AND RISK IDENTIFICATION AND SCREENING 581
9.1 ENVIID workshop 582
9.2 ENVIID outcomes - preliminary impact assessment and screening 586
10 ENVIRONMENTAL IMPACT AND RISK ASSESSMENT 612
10.1 Artificial light 613
10.2 Onshore disturbance to wildlife from helicopter use 646
10.3 Disturbance to seabed 659
10.4 Underwater noise - Offshore 682
10.5 Underwater noise inshore 721
10.6 Discharge of drilling fluid and cuttings 740
10.7 Operational Discharges 773

10.8 Thermal discharges 817
10.9 Atmospheric emissions 829
10.10 Waste Generation and Management 888
10.11 Collision / entanglement between cetaceans, vessels and moorings 920
10.12 Introduction of marine non-native species 939
10.13 Introduction of terrestrial non-native species 964
11 SOCIAL IMPACT AND RISK ASSESSMENT 975
11.1 Other Users of the Sea - Offshore 976
11.2 Other users of the sea – Inshore 994
11.3 Competition for resources – Accommodation 1016
11.4 Competition for resources – Freshwater 1028
11.5 Competition for resources – Electricity 1047
11.6 Competition for resources – Air links 1059
11.7 Competition for resources – Road networks 1065
11.8 Disturbance to human population - Light 1085
11.9 Disturbance to human population – Helicopters and Noise 1096
12 ACCIDENTAL AND CHRONIC OIL POLLUTION IMPACT AND RISK ASSESSMENT 1120
12.1 Accidental and chronic oil pollution offshore 1121
12.2 Inshore fuel oil spill 1234
12.3 At-shore and onshore fuel oil and chemical spills 1266
13 CUMULATIVE IMPACTS AND IMPACT INTERACTIONS 1284
13.1 Introduction 1285
13.2 Cumulative impacts 1285
13.3 Indication of impact interactions 1286
14 SUMMARY OF EIS FINDINGS 1289
14.1 Introduction 1289
15 OUTLINE ENVIRONMENTAL MONITORING AND MANAGEMENT PLAN 1312
15.1 Introduction 1313
15.2 EMMP Workshop 1313
15.3 EMMP Scope 1314
15.4 Legislative and corporate monitoring 1318
15.5 Governance 1327
15.6 Baseline data and survey work 1327
15.7 Research and studies 1337
16 FINAL REVIEW AND CONCLUSION 1341
16.1 Introduction 1342
16.2 Significant impacts and risks of planned activities and unplanned events 1342
16.3 Significant risks associated with accidental events 1343
16.4 Overall conclusion 1344
17 POST-SUBMISSION CONSULTATION OUTCOMES 1345

1.1 Introduction

Navitas Petroleum Development and Production Ltd. (hereafter referred to as Navitas) is proposing to develop the Sea Lion Field Northern Development Area in the North Falkland Basin (NFB) with a view to the long-term production and export of oil. A phased development process is proposed.

Navitas will conduct all operations in compliance with its Health, Safety and Security Policy (HS&S) and its Environment and Biodiversity (E&B) Policy (see EIS Section 3.2.1), which requires that Navitas does all that is reasonably practicable to prevent major accidents and minimise environmental impacts.

In line with Falkland Islands legislation and its Operating Management System (OMS), Navitas has conducted a full Environmental Impact Assessment (EIA) of The Sea Lion Field Northern Area Development, Phase 1 & 2 (hereafter referred to as the 'Phase 1 & 2 Development').

The EIA was carried out in line with:

- Falkland Islands Government (FIG) Hydrocarbons Environmental Impact Assessment Guidance Note (FIG, 2016e).

The detailed outcomes of the EIA process are reported in the Environmental Impact Statement (EIS) and the key outcomes are summarised in this Non-Technical Summary (NTS). Following submission to FIG a copy of the full EIS is available on request from the Navitas office in Stanley (sealion.enviro@navitaspet.com).

1.1.1 Historical context

The NFB licences were previously held by Premier Oil Exploration and Production Limited (POEPL) working with their Joint Venture partner Rockhopper Exploration. Exploration drilling campaigns were carried out by Rockhopper in 2010 - 11 and by POEPL in 2015-16. Plans for the development of the Sea Lion project, with a view to production, commenced in 2012. An EIS for POEPL's plan for the Sea Lion Development was submitted and formally accepted by FIG in 2020 (Premier, 2020). However, in 2020 the parent company of POEPL (Premier Oil) and Chrysaor merged to form Harbour Energy Plc. Harbour Energy Plc. then sold POEPL to Navitas Petroleum in September 2022. At this time, POEPL was renamed Navitas Petroleum Development and Production Limited (hereafter referred to as Navitas).

All intellectual property previously owned by POEPL in relation to the Sea Lion Project is now owned by Navitas. As a result, Navitas has access to all preparatory processes and documentation developed under POEPL, all reports and surveys commissioned in support of the Sea Lion Development, as well as all 'lessons learned' throughout the process.

Since Navitas acquired the NFB licences, the proposed Sea Lion Development has further evolved and has been optimised in terms of:

- A reduction in number of wells and subsea infrastructure,
- The design of the wells uses 'Open Hole Gravel Pack' (OHGP) completions in the production wells, which are installed where the well meets the hydrocarbon reservoir, and which do not require conventional explosive perforation guns,
- The proposed daily production figures and hence the size and efficiency of the Floating Production, Storage and Offload (FPSO) vessel such that the forecast atmospheric emissions per barrel are reduced, and
- A longer proposed Field Life with increased recoverable resources.

As a result of these changes, it is necessary to conduct another EIA and submit a revised EIS to FIG.

1.1.2 Purpose of the EIA

The main purpose of the EIA is to answer the following six questions:

1. What is the context within which the proposed Development is being carried out?
    a. What do the '**Regulations**' and the '**Navitas OMS**' require?
2. What does the Phase 1 & 2 Development involve?
    a. What activities are involved in the proposed Development? In other words, what is the '**Phase 1 & 2 Development Description**'?
    b. Are any mitigation measures built-in to the basis of design to minimise interactions with the environment and the human population? In other words, what are the '**Base-Case Mitigations**'?
3. What do the stakeholders think about the proposed Development?
    a. What do the Falkland Islands Government (FIG) and its expected consultees think? What do the Falkland Islands public think? The answers to these questions were invited during '**Scoping and Previous Statutory Consultations**'.
4. What are the existing environmental and social attributes and sensitivities in the area?
    a. What is known about the local environment and the local human population? For example, what species of marine mammals or seabirds are found in the area? When are they there? What are they doing there? How important is the population that could be impacted upon? Do they have international or local protected status? This is called the '**Environmental and Social Baseline**'.
5. What are the environmental and social impacts and risks associated with the project activities?
    a. How might the Development interact with the environment and / or the human population? In other words, what are the associated '**Environmental and Social Aspects**'?
    b. How are the impacts and risks assessed? In other words, what is the '**Impact and Risk Assessment Methodology**'?
    c. What impacts and risks are associated with the planned activities and accidental or unplanned events? Are the potential impacts and risks significant? What are the '**Key Findings of the EIA**'?
6. What is Navitas doing to reduce the potential impacts and risks?
    a. What if an impact or risk is considered to be significant despite compliance with legislation, the use of industry-standard practice and the 'base-case' mitigation measures? Will additional actions be taken to remove, minimise or monitor the impact or risk?
    b. All mitigations and monitoring commitments will be summarised in the '**Project-Specific Environmental Monitoring and Management Plan (EMMP)**' which will remain 'live' (be continually reviewed and updated) for the life of the field.

Numerous steps are involved in conducting an EIA and in answering the questions above. This NTS briefly outlines the planned Development and describes the key outcomes of the EIA.

1.2 The Sea Lion Field

The Sea Lion Field is an oil field. Oil and gas are trapped in underground sandstone rocks approximately 2.5 km below the seabed, in water depths of approximately 450 m. It is likely that there is a gas accumulation (or 'gas cap') overlying some of the oil. The existence of the gas cap will be determined

during the Development drilling operations. The field is located approximately 220 km to the north of the Falkland Islands in Block 14 / 10 and is 480 km from Argentina, the closest point on the South American coastline (Figure 1-1). Navitas propose the development of the Sea Lion Field in accordance with the Production Licence areas PL032 and PL004b granted by the Falkland Islands Government (Figure 1-1).

The Sea Lion Field is the first potentially commercially viable hydrocarbon discovery in the NFB and was discovered by Rockhopper Exploration plc in 2010. With regard to oil production, a Field Life of 30 years has been projected and it is estimated that the Phase 1 & 2 Development can recover approximately 310.5 million stock tank barrels (MMstb) of oil in this time.

The crude oil discovered in the Sea Lion Field has a high wax content such that it needs to be kept at an elevated temperature throughout the production and export process to ensure that it can flow.

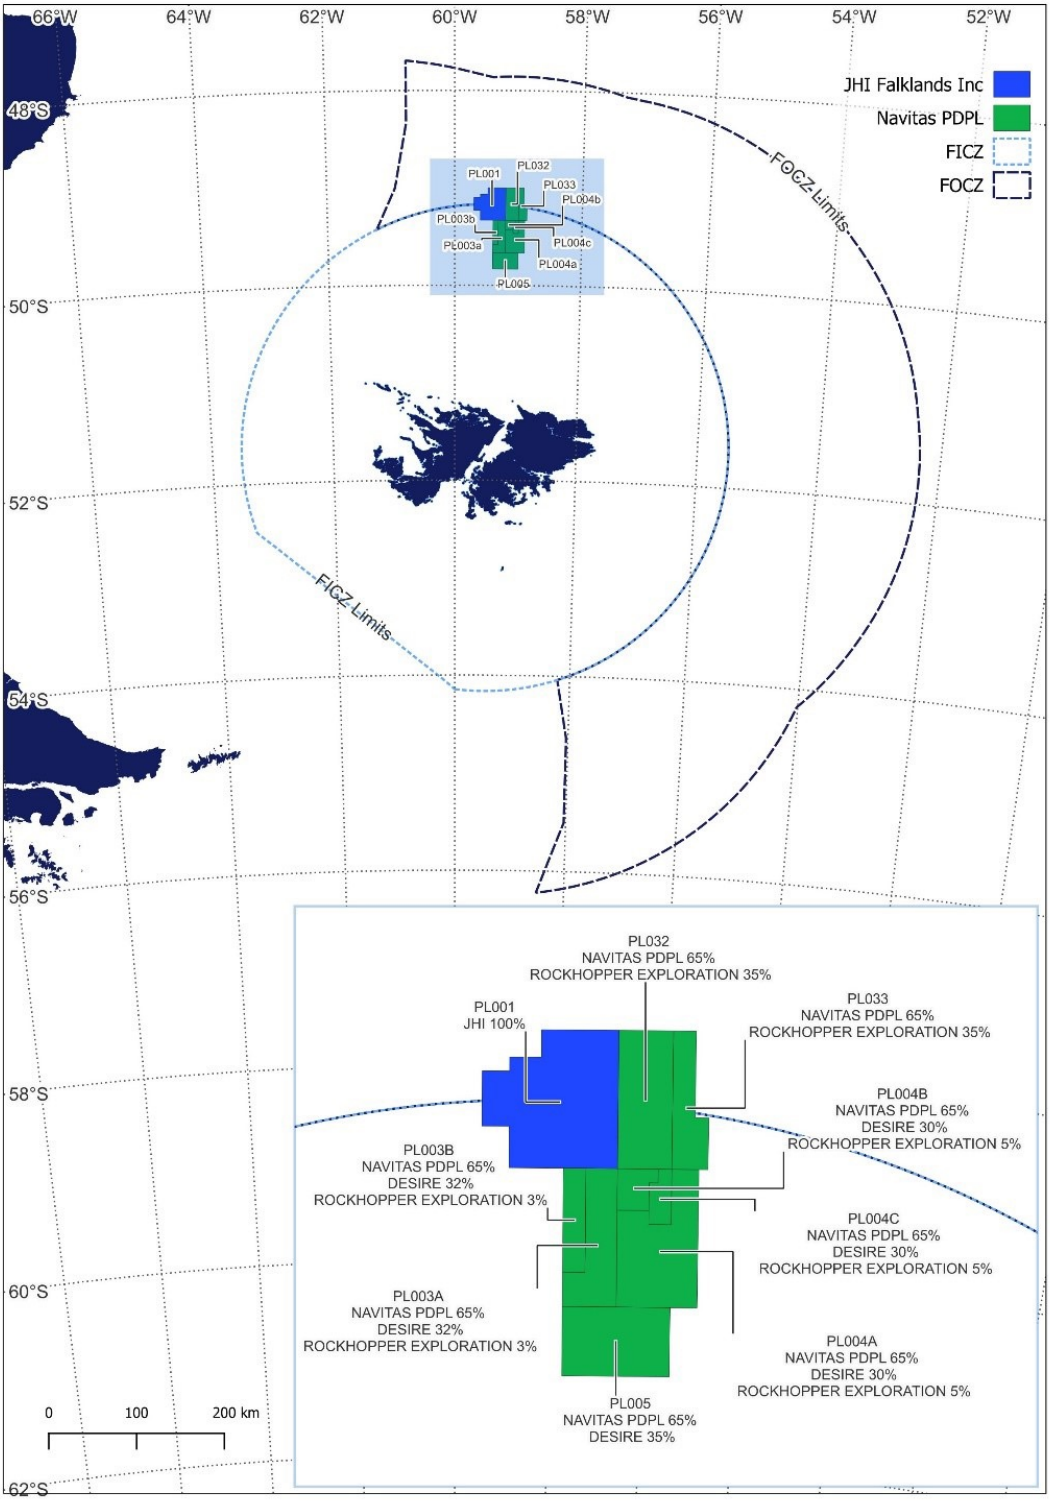

Figure 1-1: North Falklands Basin Licence Block Locations

1.3 EIA Context

To answer 'Question 1' above, the following information summarises FIG's regulatory requirements, and those of the Navitas OMS, both of which define the context within which the EIA has been carried out. Full details on both are provided in Chapter 3 of the EIS.

1.3.1 Regulatory overview

The Falkland Islands is one of 14 UK Overseas Territories (UKOT) as defined under the British Overseas Territories Act 2002.

The Environmental Charter is a joint agreement between FIG and the UK Government that was signed in 2001. The Charter lists ten guiding principles and 11 commitments therein. All commitments are intended to ensure effective environmental management within the Islands.

Falkland Islands environmental legislation that applies to Oil and Gas (O&G) activities is largely based upon the regulatory requirements for the United Kingdom Continental Shelf (UKCS).

Legal compliance and the preparation of all required consents will be based on current FIG legislation (where it exists) with reference to UK legislation and guidance. In the event that FIG legislation is enacted in the future, reference to UK legislation will not be required.

Existing Falkland Islands legislation relevant to the O&G industry is as follows:

- Offshore Minerals Ordinance 1994 (1997 and 2011 Amendments).
- Offshore Petroleum (Licensing) Regulations 1995.
- The Offshore Petroleum (Licensing) Regulations 2000 (as amended).
- Petroleum Survey Licences (Model Clauses) Regulations 1992.
- Maritime (Amendment) Ordinance 2019.
- Maritime (Oil Pollution Preparedness, Response and Co-operation Convention) Regulations 2019.
- Deposits in the Sea (Exemptions) Order 1995.
- Marine Mammals Ordinance 1992.
- Maritime Ordinance 2017.
- Maritime (Amendment) Ordinance 2019.
- Conservation of Wildlife and Nature Ordinance 1999.
- Fisheries (Conservation and Management) Ordinance 2005.
- Endangered Species Protection Ordinance 2015.
- Planning Ordinance 1991.
- Planning (Environmental Impact Assessment) Regulations 2015.
- Falklands Interim Port And Storage System (FIPASS) Ordinance 1989.
- Harbours and Ports Ordinance 2017.
- Maritime (Registration of Ships) Regulations 2019.
- Merchant Shipping (Confirmation of Legislation) (Falkland Islands) Order 2018.
- Offshore Installations (Prevention of Fire, Explosion and Emergency Response) Order 2008
- Offshore Installations (Safety Case) Order 2008.
- Falkland Islands Environmental Trust Ordinance 2021.
- Maritime (Port State Control) Regulations 2021.

Specific guidance on the Falkland Islands EIA process and the development of the EIS is provided in:

- FIG Hydrocarbons Environmental Impact Assessment Guidance Note (FIG, 2016e).

1.3.2 Navitas Operating Management System

As in all of its O&G activities, Navitas will, as a minimum, adhere to its own corporate Health, Safety and Security (HS&S) Policy and Environment and Biodiversity (E&B) Policy *via* the processes set out in the OMS. The application of the OMS framework throughout the lifecycle of the Phase 1 & 2 Development will ensure environmental management is considered at every stage.

With regard to managing environmental impacts, the OMS provides a framework for operational controls to prevent and reduce impacts and risks by:

- Preventing, minimising or remediating an impact,
- Preventing, or reducing the likelihood of unplanned events, and
- Minimising the severity of effects in the event of an incident.

Operational controls include a hierarchy of Elimination, Substitution, Engineering and Administrative Controls. Elimination and substitution controls are built-in to the project basis of design such that the project will always endeavour to minimise impacts and risks. During the EIA process, where impacts or risks are deemed significant despite the base-case mitigations and industry-standard safeguards, it is necessary to determine what additional, project-specific, controls may be required. All additional project-specific controls intended to prevent or mitigate impacts and risks will be utilised where they are deemed to be 'reasonably practicable'.

The OMS provides for incident management and monitoring, emergency response and safety and environmentally critical equipment with regular measurement and reporting against plans and objectives.

The OMS will apply through all subsequent Phases of the Development. Full details on the Navitas OMS are provided in Section 3.2 of the EIS.

1.4 Consideration of alternatives

The basis of design for the production of the Sea Lion field has been under development since 2011. Between 2012 and 2020, the relevant licences were owned by POEPL with their Joint Venture partner Rockhopper Exploration (Section 2.1.1 of the EIS). An EIS for POEPL's proposal for the Sea Lion Development was submitted and formally accepted in 2020 (Premier, 2020). However, in 2020 the parent company of POEPL (Premier Oil) and Chrysaor merged to form Harbour Energy Plc. Harbour Energy Plc. then sold POEPL to Navitas Petroleum in September 2022. At this time, POEPL was renamed Navitas Petroleum Development and Production Limited (hereafter referred to as Navitas). Navitas now operates the licences and has further optimised the proposed basis of design

Detail on the history of the project development and option selection is provided in Chapter 4. However, in summary, numerous options were considered by POEPL and the majority of the options selected were carried over into the Navitas basis of design although some key activities have been optimised by Navitas (Table 1.1).

Table 1.1. Providing a basic summary of the options considered for the Development basis of design.

Development option	Selected by POEPL					Selected by Navitas	Optimised by Navitas
	2014/15	2016	2018	2020	2023		
Drilling and Production							
Semi-submersible	Rejected	No change	No change	No change	No change	Rejected	N/A
TLP with FSO and Electric Submersible Pumps (ESPs) for dry wells and gas lift to subsea wells.	Considered	Rejected	No change	No change	No change	Rejected	N/A
TLP with FSO and subsea wells with Hydraulic submersible pumps (HSPs)	Considered	Rejected	No change	No change	No change	Rejected	N/A
FPSO with subsea wells and artificial lift from downhole HSPs	Considered	Rejected	No change	No change	No change	Rejected	N/A
FPSO with subsea wells and gas lift	Considered	**Selected**	No change	No change	No change	**Selected**	Yes. Fewer wells and smaller FPSO.
Well completion design	Cement and perforation	No change	No change	No change	No change	Rejected	Yes. Open Hole Gravel Pack.
Oil export							
Offload from the FPSO directly to the export vessel for transport to market	Considered	Rejected	No change	**Selected**	No change	**Selected**	Unchanged
Offload from the FPSO to an Offshore Loading Shuttle Tanker (OLST) and Transfer to a CTT elsewhere							
At an offshore / nearshore location	Considered	Rejected	No change	No change	No change	Rejected	N/A
At a sheltered location in another country	Considered	Rejected	No change	No change	No change	Rejected	N/A
At a sheltered location in the Falkland Islands	Considered	**Selected**	No change	Rejected	No change	Rejected	N/A

1.5 The Sea Lion Field Northern Area Phase 1 & 2 - Development description

To answer 'Question 2' above, the following sections provide a summary of:

- The activities that will be required during the proposed Phase 1 & 2 Development to enable the production of oil from the Sea Lion Field, and
- The base-case mitigations that are built-in to the basis of design.

The full Phase 1 & 2 Development Description is provided in Chapter 5 of the EIS.

1.5.1 Activities associated with the Development

1.5.1.1 Drilling and installation of subsea infrastructure

The proposed Phase 1 & 2 Development is expected to consist of 23 completed wells comprising 16 Oil Production (OP) wells, six Water Injection (WI) wells and a remote Gas Injection (GI) well, drilled by a Mobile Offshore Drilling Unit (MODU) over six drill centres. If the remote GI well has insufficient gas flow, an additional remote GI well will be drilled, although only one of these will be completed. Further, based on historical data from drilling in the Sea Lion Field, there is a contingency for two potential redrills in the event of technical problems. Therefore, while there may be up to 26 penetrations, only 23 wells will actually be completed and operated. The MODU will be anchored to the seabed and surrounded by a 500 m exclusion zone, supported by up to two support vessels and an Emergency Response and Rescue Vessel (ERRV).

An FPSO vessel (Figure 1-2 below) will be used to produce the fluids from the wells. The FPSO will be anchored to the seabed, within a 1,275 m radius exclusion zone. The OP and WI well drill centres will all be within a 2 - 5.5 km radius around the FPSO and the remote GI well location is approximately 8 km from the FPSO.

After First-Oil there will follow two periods of Simultaneous Operations (SIMOPS) as the FPSO commences with production from the first tranche of wells while the MODU continues to drill the remaining wells and installation of subsea equipment takes place.

Wells are normally 'cleaned up' once completed to remove unwanted solids and liquids. With the use of Open Hole Gravel Pack (OHGP) completions, it is anticipated that the wells will be cleaned up by flowing them directly to the FPSO prior to being brought on for production. However, a contingency is retained to flow four wells (3 x OP and 1 x GI well) back to the MODU should it be considered necessary. Flow-back / testing of these wells will require flaring off of the product from the MODU, for approximately one day per well.

To support the Development, ten subsea manifolds and an array of subsea pipelines, 'umbilicals', 'risers' and associated supports (e.g., sandbags, clump weights etc.) will be installed to connect the wells at the seabed with the FPSO at the surface.

While drilling of the wells is underway, installation of the subsea production facilities will be undertaken by dedicated installation vessels.

It is anticipated that four Large Transport Vessels (LTVs) will be used to support the construction and installation operations, with a maximum of two vessels anchored in Berkeley Sound at any one time, for a combined total period of *c.* 13 months. These LTVs will act as 'floating storage barges' from which equipment will be collected and taken out to the Sea Lion Field for installation.

It is anticipated that drilling will start approximately 17- 20 months after project sanction. Up to nine wells will be drilled pre-First-Oil (including the contingency GI well if needed, noting that only one GI well will be operated) and the remaining 15 wells will be drilled during SIMOPS. When drilling starts, only the MODU, its support vessels and the installation vessels will be in the Field.

1.5.1.2 Hook up and commissioning of the FPSO vessel and First-Oil

Oil production and processing will be carried out from the FPSO ship-shaped vessel which will be anchored to the seabed *via* a turret and surrounded by a 1,275 m radius exclusion zone, which is effectively 500 m beyond the installation extremities (including the hose and tanker during crude oil offload). The term 'Hook Up and Commissioning' (HUC) refers to the process by which the FPSO is connected to the subsea wells, *via* the manifolds and the pipelines, umbilicals and risers through the turret mooring buoy (Figure 1-2).

During the commissioning process, the gas injection system will also be commissioned which will involve flaring gas from the GI well for 30 days.

It is expected that 'First-Oil' will occur approximately 33 months after project sanction.

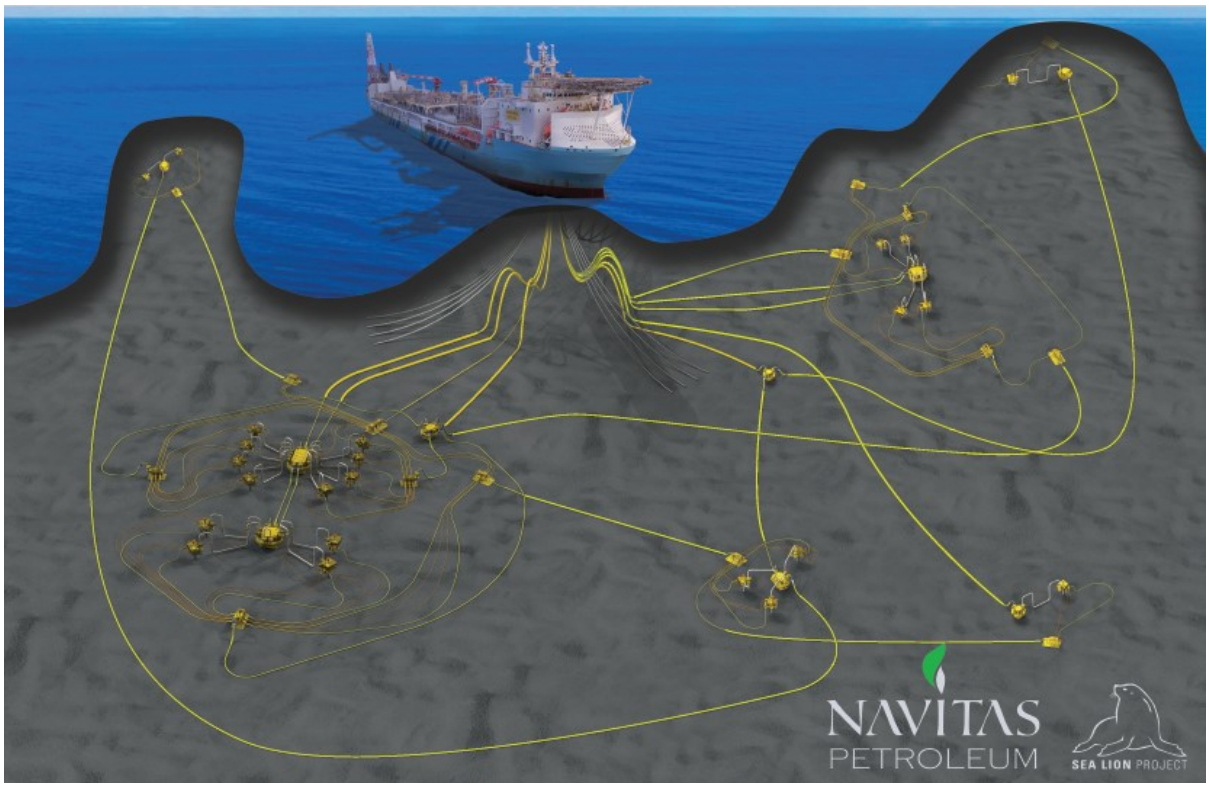

Figure 1-2: Showing the FPSO and the Phase 1 & 2 Development Field layout

1.5.1.3 Simultaneous operations (SIMOPS)

After 'First-Oil' there will follow a period of SIMOPS with the MODU continuing to drill the remaining wells while the FPSO produces from the wells which have already been drilled. During SIMOPS, both the MODU and the FPSO will be supported by two support vessels and an ERRV.

Once all the wells have been drilled, the MODU will leave the Sea Lion Field and only the FPSO and its support vessels will remain.

1.5.1.4 Production

The OP wells will produce reservoir fluids to the FPSO. The total produced fluids will consist of:

- Crude oil (the desired product),
- Associated hydrocarbon gas (arising from the gas cap in the reservoir, (if present) and gas dissolved in the oil which is liberated as the oil flows to surface i.e., the gas that is 'associated' with the oil production), and

- Water (a by-product of the oil production which is referred to as 'produced water').

These three products will be separated and treated on the FPSO:

- The oil will be stabilised (i.e., made ready for export) and transferred to storage tanks within the FPSO hull for subsequent offloading and export (Section 5.10),
- The associated gas from the production wells will be used:
  - As fuel to heat and power the FPSO, and
  - For 'gas lift' in the oil production wells, which reduces the density of the oil enabling it to flow at higher production rates.

Note: During normal operations any excess associated gas will be re-injected back into the reservoir *via* the remote GI well. In the event of a deficit in associated gas, the required gas volumes will be supplemented with gas brought back up from the designated GI well.

Note: The produced water will be cleaned to remove dispersed oil and any solids (e.g., sand, if present). During normal operations, produced water will be re-injected *via* the WI wells (in combination with treated seawater) to maintain pressure in the reservoir, thereby optimising oil recovery.

1.5.1.5 Oil export

The crude oil will be directly offloaded from the FPSO to the purchasers' Conventional Trading Tankers (CTT) at the Sea Lion location and from there will be exported to market. To ensure that the offloading operating conditions are maintained within strict limits, direct offtake will require an Offshore Support Vessel (OSV, i.e., a pull-back tug) to attend the CTT offshore, in addition to the presence of the ERRV, which is always on standby.

1.5.1.6 Logistical support

The logistics and infrastructure support required by the Sea Lion Phase 1 & 2 project includes:

- Port facilities and onshore supply base: including the Temporary Dock Facility (TDF) already established in Stanley Harbour together with onshore laydown yards, storage bases and offices in the Gordon Lines area of east Stanley,
- Use of vessels: for the movement of materials and equipment, installation of the infrastructure and support,
- Personnel transportation facilities: including fixed-wing flights, helicopters and land transportation, and
- Use of resources: e.g., accommodation, freshwater, electricity, fuel, roads and waste management / disposal facilities.

1.5.1.7 Decommissioning

At the end of Field Life, expected to be 30 years after commencement of production, the FPSO and all associated subsea infrastructure and pipelines, will be decommissioned and removed from the NFB in accordance with regulatory requirements in place at that time. Decommissioning will be subject to a separate EIA, submitted at a time to be agreed with FIG (most commonly a few years prior to the cessation of production).

1.5.2 Base-case mitigations

FIG legislation, Navitas' corporate standards and industry-standard practices will be followed to reduce the potential impacts associated with the above planned activities, and to minimise the likelihood and / or consequences of unplanned events or accidents. The legislation and industry-standard practices relevant to each activity are detailed in the impact and risk assessment chapters of the EIS (Chapters 10, 11 and 12).

It is important to note that, where possible, a number of best-practice mitigations are built-in to the design of the facilities. These serve to minimise the impacts of the Development by reducing the outputs or activities that might lead to impacts in the first place (e.g., technologies to reduce the amount of gaseous emissions). These are referred to as the base-case mitigations and are summarised in Table 1.2.

Table 1.2: Summary of the mitigations built-in to the Phase 1 & 2 Development basis of design

Project activity	Mitigations built-in to the Phase 1 & 2 basis of design
General	• All materials, fittings and system contents contained in the FPSO hull will be non-toxic, non-smoke emitting, fire retardant or 'low flame spread'.
Drilling and production	**The following will reduce the amount of atmospheric emissions:** • The main fuel supply for the FPSO will be produced gas, use of which will be facilitated by the availability of three Dual Fuel GTG Turbines, • Use of waste heat recovery to reduce the need for active heat generation and therefore to reduce fuel consumption / CO_2 emissions, • No planned flaring during ongoing well testing throughout Field Life, • No routine flaring during normal production (notwithstanding the flare pilot light), • Use of a Flare Recovery Package during normal operations, • No venting from the FPSO during normal production, • Follow international standards for piping, valves etc. and best practises for integrity management e.g., UK Step Change Hydrocarbon Toolkit, • Use of Vapour Recovery Package (VRP) during normal operations, • Use of a vapour balancing system to pass blanket gases from the FPSO cargo tanks to the CTT cargo tanks, when available, during transfer of oil, • The use of passive heat retention systems wherever possible to maintain working temperatures and flow assurance, thereby preventing energy expenditure, and its associated emissions, on active heating systems, • Use of Open Hole Gravel Pack (OHGP) completions which minimise downhole debris and reduce the requirement for well clean-up to the MODU, and thus the likelihood of associated flaring. The base-case is for the wells to be flowed straight back to the FPSO (**Note:** there is a contingency flow / test four wells to the MODU if considered necessary which would require flaring), • Use of F-Gases with the lowest Global Warming Potential, • Back-up inert gas generator for use as gas blanket in the event that the VRP malfunctions to prevent venting of hydrocarbon gas, and • Use of Marine Gas Oil (MGO) instead of Intermediate Fuel Oil (i.e., a lighter fuel) when operating inshore. **The following will reduce the volumes of drilling discharges:** • Use of seawater sweeps, bentonite and WBM for tophole drilling, and • Batch drilling to optimise drilling mud use. **The following will reduce the volumes of, or negate the need for, discharges of oil and chemicals to sea:** • Produced Water Reinjection (PWRI) as a base-case to alleviate the need to discharge produced water to sea during normal production operations, • Subsea and topside technical flow assurance measures, e.g., insulation and heating, will minimise the use of flow assurance chemicals, • Diversion of produced water to slops / off-spec tanks for retreatment in the event that PWRI is down and produced water is out-with discharge specifications, and • Oil in ballast tank detection on the FPSO. **The following will reduce the volume of oily waste returned to shore:**

Project activity	Mitigations built-in to the Phase 1 & 2 basis of design
	• Use of a Thermomechanical Cuttings Cleaner (TCC) during drilling which will clean-up drill cuttings on the rig so they may be discharged to sea, reducing the amount of oily waste sent to shore for treatment. **The following will reduce the volume of waste being returned to the UK for disposal:** • Use of FIG municipal waste facilities. **The following will reduce the competition for resources:** • Use of buffer storage water tanks at the TDF, the mud plant and potentially the at-shore bulk supply base to ensure management of peak water use requirements.
Oil spill prevention measures	**Note:** many industry-standard preventative mitigation measures must be built-in to the basis of design. Therefore, there are very few 'extra' base-case mitigation options available and the standard requirements are summarised below: **Preventative measures built-in to the FPSO include:** • Cargo and fuel tanks of the vessel will be double skinned, • Bunding of all liquid containing equipment and chemicals, • Open deck drains to catch and collect spills to a dedicated slops tank, • High level tank filling alarm and emergency shutdown of the process, • FPSO offloading hose quick-break connectors to prevent spills on unplanned disconnection, and • Automatic Identification Systems and Marine Procedures to prevent collisions. **Preventative measures built-in to the well design include:** • Development of the appropriate, and peer reviewed, well design, • Use of appropriately weighted drilling muds, • The use of appropriate mud additives to ensure over-balanced drilling, and • Use of Blow-Out Preventers and production X-mas trees. **Preventative measures built-in to the CTT nomination and selection include:** • Cargo tanks, and potentially the fuel tanks, of the vessel will be double-skinned, • Vetting and auditing prior to acceptance of the nominated vessel, • Transfer of Falkland Islands' authorised Berthing Master / Pilot and assistant to CTT to manage the offshore direct offtake operation, • Cargo tank hi level and hi-hi level alarms to prevent overfilling, • Bunding of all liquid containing equipment and chemicals, and • Open deck drains to catch and collect spills to a dedicated slops tank.

1.6 Scoping consultation

To answer 'Question 3' above, the following section describes the scoping consultation processes which were carried out to identify any concerns that the stakeholders (including the Falkland Islands public and consultees) had regarding the Phase 1 & 2 Development. The consultations were carried out in line with the FIG EIA Guidance (2016e) and were intended to:

- Inform the stakeholders about the proposed Development,
- Identify stakeholder concerns, and
- Ensure that the EIA adequately addresses stakeholder concerns.

As advised by the FIG EIA Guidance (2016e), the stakeholders consulted by Navitas included:

- Falkland Islands Government (FIG),
- Conservation groups,
- Naturalists,
- Special interest groups,
- Other users of the sea, and

- The general public.

Scoping consultations for the (then) Phase 1 Development proposed by POEPL were carried out between 2014 and 2016, prior to formal submission/s of the EIS and the statutory consultations that followed in 2018 and 2020. Further scoping consultations were carried out by Navitas in 2023 to present detail on, and elicit response to, the optimised development basis of design (presented in this EIS). Details on the pre-submission scoping consultations and their outcomes, are provided in Chapter 6 of the EIS.

During scoping consultations, numerous questions were asked, and issues raised by the stakeholders. All representations were taken into account during the EIA process and are recorded in the EIS. The key issues that were identified as areas of concern over the course of the scoping consultations (2014 – 2023) were:

- Control of vessels and general management in Berkeley Sound,
- Oil spill mitigations and clean-up:
  - The impact of this particular type of crude on the marine environment.
- Onshore infrastructure,
- Environmental offsetting,
- Decommissioning,
- Jobs, employment and numbers of people, and
- Standards and governance.

1.7 Environmental and social baseline description

To answer 'Question 4' above, the following sections aim to summarise the current environmental and social baseline information. It is necessary to describe the baseline in sufficient detail to:

- Understand what is currently present i.e., the 'baseline'. For example, what benthic (seabed) communities, fish, birds, marine mammals are in the area? What is the current condition of the seabed? What resources are available in the Falkland Islands for the local human population, and who else uses the offshore and inshore locations?
- Understand the sensitivity of the receptors. For example, what are the population sizes of the species present? What are they doing there? Are they vulnerable, are they protected, are they commercially important or of value for other users? Are stakeholders concerned?
- Determine whether there are data gaps and if, or how, these could affect confidence in the impact and risk assessments, and
- Provide a reference point of comparison for future monitoring that will be carried out by Navitas to determine whether or not the Phase 1 & 2 Development has had any discernible environmental or social impacts, and to validate the results of the EIA.

1.7.1 Key environmental sensitivities

Understanding the attributes of the NFB, the Sea Lion Field and Berkeley Sound area was informed by:

- Extensive literature reviews,
- Historical environmental surveys conducted in the area by various parties since the mid-1990's, and
- Further surveys carried out by Rockhopper and POEPL between 2012 and 2019.

Note: The survey reports can be requested from sealion.enviro@navitaspet.com.

The Patagonian Shelf, on which the Falkland Islands archipelago is located, is one of the most biologically productive areas in the South Atlantic. Two marine ecosystems, the sub-Antarctic ecosystem and the southern temperate ecosystem, are separated by a transition zone, which runs through the Falkland Islands. Further, the area is dominated by two different oceanic currents.

The resulting mixing of water masses produces areas of high biological productivity, including one on the edge of the Continental Shelf to the south of the Sea Lion Field. This productivity supports a high biomass of plankton in the NFB, which forms the basis of marine ecosystem food chains, upon which many species of larger animals such as fish, seabirds and marine mammals depend.

The inshore area of Berkeley Sound is important given its regular use by the fishing and tourism industries, as well as by wildlife. The Sound is used by a variety of protected marine mammals and protected birds. Moreover, the entrance to Berkeley Sound is flanked by two National Nature Reserves (Volunteer Point and Cow Bay, and the Kidney Island Group), which are also classified as Important Bird Areas (IBAs).

Potentially sensitive habitats identified within Berkeley Sound that are equivalent to those of conservation significance in the UK, as defined by the Offshore Marine Conservation of Habitats Regulations (which implement the EC Habitats Directive), include biogenic reefs (reefs created by living organisms), geogenic reefs (created by geological processes) and kelp forests.

The key biological sensitivities of the Falkland Islands offshore environment and Berkeley Sound are summarised in Table 1.3 and Table 1.4, respectively. In order to provide an overview of the environmental sensitivities, the tables indicate the relative importance of each month, regardless of the particular species, fishery or site that is driving the sensitivity.

Table 1.3: Summary of key environmental sensitivities in the Sea Lion Phase 1 & 2 Development area

Environmental baseline and sensitivity at Sea Lion											
Low[1]				Medium[1]				High[1]			
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Plankton: Plankton comprises of small to microscopic plants (phytoplankton) and animals (zooplankton) that drift in the surface layers of the sea. Phytoplankton require sunlight, like all other plants, to survive, and zooplankton graze upon the phytoplankton or prey on other zooplankton. The oceanic fronts around the Falkland Islands result in nutrient rich waters which create an area of very high phytoplankton productivity immediately to the north of the Islands (and approx. 60 km to the south of the Sea Lion Field). This phytoplankton productivity is seasonal and in turn supports complex communities of zooplankton, which then support complex pelagic (in the water column) and demersal (near the seabed) ecosystems.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine flora: Not applicable to offshore location.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Benthic fauna: Benthic fauna are those animals which live on, or below, the seabed. Overall, benthic fauna around the Sea Lion area is very uniform, with polychaetes (i.e., marine worms) and crustaceans (e.g., crabs) being the two most abundant groups present, followed by molluscs (e.g., clams).											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Fish and shellfish: The convergence of the temperate and sub-Antarctic regions in the Falkland Islands archipelago results in the presence of species belonging to both. The six sub-Antarctic, and seven temperate, fish and squid species found in abundance in Falkland Islands' waters primarily utilise the NFB as feeding grounds, migrating in and out of the area as food availability changes and to follow seasonal spawning migrations. Other species feed in the area as juveniles and move to deeper waters as they mature and become adults. This results in seasonal changes in the fish assemblages across the ecosystem.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Seabirds: Over 70 % of the global population of black-browed albatross breed on the Falkland Islands with a significant proportion of the global populations of gentoo and rockhopper penguins doing the same. The waters surrounding the Falklands also support numerous species that breed elsewhere. Of the species recorded in the Sea Lion area, the Atlantic petrel, grey-headed albatross, and northern royal albatross are all listed as 'Endangered' on the IUCN Red List, and the southern rockhopper penguin, white-chinned petrel, southern royal albatross and the wandering albatross are listed as 'Vulnerable'.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine mammals: Confirmed records indicate that 25 species of cetacean (whales, dolphins and porpoises) occur within Falkland Islands waters and three species of pinniped (seals) breed on the Islands. Many of the cetacean species are rare and inconspicuous and some are only known from stranded animals. Of these 25 cetacean species, two species are listed as 'Endangered' on the IUCN Red List, namely the sei whale and the less common blue whale, two species, the fin and sperm whales, are listed as 'Vulnerable' and the southern right whale is listed as being of regional conservation concern.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Conservation sites: There are no designated marine protected areas in Falkland Islands waters. The Falkland Islands Government (FIG) has identified several areas as proposed Marine Managed Areas, for which a public consultation was held in 2022[2]. Policy work is ongoing (as of 2024) but it is anticipated the proposed Marine Managed Areas will be designated. Non-statutory Key Biodiversity Areas (KBAs) have also been identified for sei whales and seabirds around the Falkland Islands. On land, a number of Important Bird Areas (IBAs) have been designated. Additionally, a network of National Nature Reserves (NNR) and Important Plant Areas (IPAs) protect many of the most important seabird breeding sites and areas supporting native flora respectively.											

[1] Note that the terms Low, Medium and High in this context provide a guide only as to the general sensitivity / abundance as it is relevant to each receptor. Specific sensitivities of each receptor to each environmental impact are explored in full within the EIS.

[2] Consultation report and scientific evidence to support Marine Managed Areas is available *via* FIG website https://www.falklands.gov.fk/policy/environment/marine-managed-areas-consultation-report.

Table 1.4: Summary of key environmental sensitivities in Berkeley Sound

Environmental baseline and sensitivity in Berkeley Sound											
Low[1]				Medium[1]				High[1]			
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Plankton: Plankton comprises small to microscopic plants (phytoplankton) and animals (zooplankton) that drift in the surface layers of the sea. The most conspicuous component of the inshore zooplankton community is lobster krill, which is an important prey species for higher predators (such as penguins and whales).											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine flora: Marine plants are the major primary producers in the marine environment. The most common species of seaweed within the Falklands are the giant kelp and the tree kelp, which are found around the entire Falklands coastline. Kelp is a habitat forming species and is a very important part of the inshore ecology.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Benthic Fauna: Benthic fauna are those animals which live on, or below, the seabed. Berkeley Sound supports a wide range of benthic habitats (including biogenic and geogenic reefs), each supporting a characteristic range of species. Although none of the species found is rare or protected under any Falkland Islands legislation. Work is ongoing to identify important marine areas, and as such work develops, new designations can be incorporated in the ongoing management of the project *via* the EMMP and the 5-yearly review of the EIS.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Fish and shellfish: The most conspicuous species found inshore off the east coast is loligo squid, which play a key role in the inshore ecology as predator and prey. In addition, loligo support the second largest fishery in the Falklands. Loligo are known to migrate inshore to spawn, although the key spawning sites remain unknown. Periods of 'high sensitivity' reflect the spawning periods of the two loligo cohorts. There are several species of shellfish found within Berkeley Sound that are commercially exploited elsewhere but not currently in the Falklands.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Seabirds: Berkeley Sound encompasses significant breeding populations (>1 % of the national population) of gentoo and rockhopper penguins and a far higher proportion of the national populations of king penguins, sooty shearwaters and white-chinned petrels. In addition to king and gentoo penguins, there are large resident populations of imperial and rock shags and Falkland steamer ducks, which are present year-round. Of the species breeding in Berkeley Sound the white-chinned petrel and southern rockhopper penguin are listed as 'Vulnerable' on the IUCN Red List.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine mammals: Berkeley Sound supports small breeding populations of South American sea lions (Diamond Cove), South American fur seals (Volunteer Rocks) and is likely to have breeding populations of Commerson's and Peale's dolphins. Conspicuous seasonal visitors include sei whales, which are most numerous in the late summer and autumn. Several other species of large whale have been recorded within Berkeley Sound including southern right and Antarctic minke whales. An influx of southern right whales was first *recorded* during the winter of 2017 and seems to have sustained since.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Conservation sites: The entrance to Berkeley Sound is flanked by two National Nature Reserves (Volunteer Point and Cow Bay, and the Kidney Island Group), which are also classed as Important Bird Areas, and a proposed Marine Management Area has also been proposed. Further, the importance of sei and southern right whales in Berkeley Sound and surrounds has resulted in a Key Biodiversity Area and two Important Marine Mammal Areas to be adopted.											

[1] Note that the terms Low, Medium and High in this context provide a guide only as to the general sensitivity / abundance as it is relevant to each receptor. Specific sensitivities of each receptor to each environmental impact are explored in full within the EIS.

1.7.1.1 Data gaps

1.7.1.1.1 The Gap Analyses Programme

The Falkland Islands Offshore Hydrocarbons Environmental Forum (FIOHEF) was established in 2011 to facilitate discussion of environmental issues relating to current and future hydrocarbon activities in the Falkland Islands. FIOHEF established a subcommittee, the Gap Analyses Group, to examine the data gaps that needed to be filled in order to better inform and monitor the potential environmental impacts from offshore hydrocarbon activities in the Falkland Islands.

Data gaps of most relevance to the Development were identified and prioritised according to the urgency with which it was perceived that the data was required:

- Offshore benthic ecosystems with regard to collation of data, infaunal sampling, sedimentology and chemistry,
- Oceanography in relation to oil spill modelling with regard to hydrographic dynamics, temporal and water column dynamics,
- Seabirds with regard to priority species and temporal movements, and
- Marine mammals (seals, dolphins and whales) with regard to populations and breeding activity, spatial and temporal distributions.

This programme is now complete.

1.7.1.1.2 Key data gaps relevant to the Sea Lion EIA

The GAP project is complete and it is considered necessary to acknowledge the outstanding and project-specific data gaps that have been identified during the Sea Lion EIA process. Note that most of the below were out of the scope of the GAP project.

The remaining key data gaps of relevance to the Sea Lion EIA, and associated actions, are:

- General
  - Predicting the likelihood of introducing invasive species:
    - Settlement plates will be positioned in Berkeley Sound prior to and during the construction phase of the project. Settlement plates will also be positioned at the Temporary Dock Facility / Stanley Harbour for sampling throughout the duration of the project. In the event that a new marine invasive species is discovered, a pathway analysis will be conducted to attempt to determine where / how the species had been brought into the Islands. Marine invasive species will be confirmed using genetic barcoding.
  - Auditory sensitivity of penguins and marine mammals:
    - The specific experimental measurement of the auditory sensitivity of penguins and marine mammals is outwith Navitas' responsibility. However, Navitas is committed to the measurement of underwater noise levels *via* hydrophones as a monitoring exercise.
  - Quantifying the impact of bird strikes:
    - Navitas is committed to collecting data on bird-strike on all its vessels. Navitas will also investigate the use of alternative spectrum lighting on the FPSO and vessels operating in the field.
  - Impact of long-term noise and actual noise outputs from the operations:
    - Navitas is committed to the measurement of underwater noise levels *via* hydrophones as a monitoring exercise.

- Impact of Sea Lion crude on pinniped fur:
  - Investigation of Sea Lion crude impacts on seal fur will be conducted prior to drilling commencing.

- Offshore environment (NFB and Sea Lion Field):
  - Inter-annual distribution and abundance of marine mammals in the NFB,
  - Seabird distribution and abundance,
  - Seasonal abundance of fish and squid in the deeper areas of the Northern Slope (NS), and
  - Benthic habitats and fauna at the Sea Lion drill centre and flowline locations specifically.
- Inshore environment (Berkeley Sound):
  - Location(s) of Loligo (*Doryteuthis gahi*) spawning grounds (this work has been progressed through the GAP project and other projects, but the delineation of the spawning grounds remains a gap in knowledge. Survey data shows that Loligo do lay their egg clusters on hard surfaced down to approximately 80 m), and
  - Inter-annual distribution and abundance of marine mammals.
  - Given the limited operations in Berkeley Sound, the distribution and abundance of Loligo inshore *and* the Inter-annual distribution and abundance of marine mammals will not be specifically investigated by Navitas.

1.7.1.1.3 Management of data gaps within the Sea Lion EIA

Data gaps identified during the EIA process are specified in the respective impact and risk assessment chapters in the EIS (Chapters 10, 11 and 12). While a precautionary approach was taken during all the impact and risk assessments, it is important to note that the identification of data gaps was pivotal in determining the level of confidence in the assessment, as is described in the EIA Methodology (Chapter 8 of the EIS).

Where data gaps had the potential to undermine assessments of the 'Sensitivity of Receptor' or the potential 'Severity of Effect' associated with an activity, the confidence in the assessment was indicated to be either 'Probable' or 'Uncertain' (as opposed to 'Certain'). In turn, the level of confidence in the assessment was used to inform the monitoring requirements for each potential impact / risk (see again the EIA Methodology in Chapter 8 of the EIS).

To enable identification and agreement on reasonably practicable monitoring options, a workshop to consider the contents of an Environmental Monitoring and Management Plan (EMMP) to accompany the Sea Lion oil field Environmental Impact Statement (EIS) was held in Stanley, Falkland Islands on 23-25 April 2019. It was attended by 25 interested stakeholders, comprising FIG, POEPL, industry bodies and NGOs. Consideration was given to eleven environmental impacts from the Sea Lion development where there was potentially a need for further certainty as to the actual impact. The Summary EMMP tables, which have been reviewed and updated by Navitas, are provided below (Section 1.9; Chapter 15 in the full EIS). International researchers will continue to be engaged in the EMMP process through workshops and collaborative peer review so the work has international standing and transparency.

1.7.2 Key social sensitivities

As of the 2021 census, the permanent population of the Islands stands at 3,142 (2,818 excluding residents at the Mount Pleasant Complex (MPC)). The majority of the population resides in the capital, Stanley, which is the main town on the Islands and is situated on East Falkland. The key social sensitivities of the Falkland Islands are summarised in Table 1.5.

Table 1.5: Summary of key social sensitivities in the Sea Lion Phase 1 & 2 Development area

Social baseline and sensitivity											
Low[1]				Medium[1]				High[1]			
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Commercial fisheries: The four most important fisheries within the Falklands Economic Exclusion Zone (EEZ) are the jig fishery for Argentine shortfin squid, Loligo squid and the trawl fishery for hake and Patagonian rock cod, which accounted for 49.5 %, 25.1 %, 12.9 % and 5.2 % of the 2013-2022 catches by weight respectively[2]. There is also a fleet of trawlers that operate over the Falklands continental shelf that target a range of finfish species. Currently, the only other fishery in the Falklands EEZ is the longline fishery for Patagonian toothfish, which operates in deeper waters (> 600 m).											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Tangible property and resources: There is a range of onshore infrastructure on the Falkland Islands that will be utilised during the Phase 1 & 2 Development, which could lead to competition for resources with other users of these facilities. The main areas of potential impact include the use of: port facilities, supply routes, airports and airlinks, the road network, accommodation, freshwater and electricity supply. During the austral summer period, accommodation, flight availability and freshwater may all be less available.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Tourism: The majority of tourists visiting the Falkland Islands arrive on cruise ships. Many cruise ships visit locations in the west of the Islands to see wildlife and most vessels visit Stanley. Within Stanley, there are a number of businesses and individuals that support tourist excursions to locations within driving distance of the city. Many of these sites are important for the wildlife that they support; however, they are also important recreational sites for residents.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine archaeology: The UK Hydrographic Office Wreck site database indicates that there are 177 wrecks recorded within Falkland Islands waters, with records dating from the 1800's to present day. There are six recorded wrecks within 100 nautical miles of the proposed drilling sites; the closest of these wrecks is located approximately 50 nautical miles from the nearest well site. Two wrecks were identified within the Berkeley Sound survey area: the trawler Ocean 8 to the north-west, and the Blakeney to the south-east.											

[1] Note that the terms Low, Medium and High in this context provide a guide only as to the general sensitivity as it is relevant to each receptor. Specific sensitivities of each receptor to each social impact are explored in full within the EIS.

[2] Although rock cod has not been targeted in recent years and is not a commercial species any more, it is still abundant and important to ecosystem function.

1.8 Environmental and social impact and risk assessment

To answer 'Question 5' above, the following section provides:

- A description of how the activities associated with the proposed Phase 1 & 2 Development may interact with the environment e.g., the environmental and social aspects, impacts and risks,
- A brief summary of the EIA methodology,
- Key findings of the EIA including:
  - An overview of the overall EIA findings with regard to the initial and residual assessments, and
  - Narratives on the residual impacts (planned activities) and risks (unplanned / accidental activities) which remain of '**Moderate**' significance or above.
- A summary of all residual impacts and risks from all activities.

1.8.1 Environmental and social aspects, impacts and risks

All of the activities that will be carried out in the proposed Development have the potential to interact with the environment and the human population. The ways in which the Development activities may

interact, and the potential impacts and risks associated with these interactions, were identified during an ENVironmental Impact IDentification (ENVIID) workshop (see Chapter 9 of the EIS).

In summary, the ways in which the planned Phase 1 & 2 activities and unplanned / accidental activities may interact with the environment and the human population are as follows:

- Environmental aspects:
  - Artificial light,
  - Disturbance to wildlife from use of helicopters,
  - Disturbance to the seabed / placement and removal of objects on the seabed,
  - Underwater noise offshore,
  - Underwater noise inshore,
  - Drill cuttings and mud discharges to sea,
  - Operational discharges to sea,
  - Thermal discharges,
  - Atmospheric emissions,
  - Waste,
  - Collisions / entanglements with cetaceans,
  - Introduction marine non-native species, and / or
  - Introduction of terrestrial non-native species.
- Social aspects:
  - Disturbance to other users of the sea offshore,
  - Disturbance to other users of the sea inshore,
  - Competition for resources:
    - Accommodation,
    - Freshwater,
    - Electricity,
    - Air-links, and
    - Use of roads network.
  - Disturbance to the human population through:
    - Light, and
    - Helicopters and noise.
- Accidental events offshore, inshore and at-shore:
  - Loss of control leading to oil / chemical spill,
  - Small spills contributing to chronic oil pollution, and / or
  - Fuel spill either from bunkering operations or from an accidental event.

Each activity carried out during the Development may lead to one or more of the aspects above and one or more associated impact or risk. For example, the use of vessels will result in the presence of artificial light, underwater noise, discharges to sea, the creation of waste, impacts to other users of the sea and atmospheric emissions whilst also carrying the risk of collisions / entanglement with cetaceans, and the introduction of marine invasives and oil / MGO (diesel) spills. Therefore, the project activities, their associated environmental aspects and the environmental receptors on which they may impact upon, as identified in the ENVIID workshop, are presented in Figure 1-3. Details on the ENVIID process and indication of which impacts have been scoped out are provided in Chapter 9 of the EIS.

Note: under the FIG EIA Guidance Notes (FIG, 2016e) and in consultation with FIG (November, 2015) socio-economic impacts, such as tax revenues, wages, land values, were considered to fall outwith the scope of an EIA (see full EIS Section 6.2.2.1.1).

Identification of Environmental Aspects

Figure 1-3: Project activities and the identification of environmental aspects and the receptors, upon which they may impact. Please note that the impacts of each aspect may be covered in different chapters (see EIS Table 2.2). Note that this figure shows only those impacts that were scoped in for further assessment ('F) in the ENVIID outcomes tables (Chapter 9)

1.8.2 Impact and risk assessment methodology

To understand the impact and risk assessment process and the summary results presented below, it is necessary to appreciate that:

- Impacts to the environmental and human population may result from planned activities, and
- Each activity carries the risk of impacts occurring during unplanned and / or accidental events.

As shown in Figure 1-4, the impact is assessed by considering the 'Sensitivity of the Receptor' and the 'Severity of Effect' on that receptor. This then leads to an overall 'Impact significance Rating' ranging from '**Very Low**' to '**High**'.

Impacts of unplanned or accidental events are assessed in the same way while the significance of the risk associated with these events takes account of the 'Likelihood' of the event occurring. Taking account of both the Impact Significance and the 'Likelihood of Occurrence' the 'Significance of Risk' is then rated, again ranging from '**Very Low**' to '**High**'.

*Significance of the **impact***	=	*The **sensitivity** of the receptor to the environmental aspect*	x	*The **severity** of the effect on the receptor*		
*Significance of the **risk***	=	*(----------Impact----------) The **sensitivity** of the receptor to the environmental aspect*	x	*The **severity** of the effect on the receptor*	x	*The **likelihood** that an unplanned or accidental event will occur*

Figure 1-4: Illustration of the impact assessment for planned events and the risk assessment for unplanned and accidental events

When carrying out the EIA, the impact and risk assessments are each conducted twice:

- The first assessment takes account of the legal requirements and industry-standard practices as well as the mitigations which are built into the base-case (see Section 1.5.2 above). The latter are included as these are already in place and are often included to minimise outputs e.g., emissions, discharges etc. This assessment describes the significance of the initial impact or risk (i.e., '**Very Low**' to '**High**').
- The second assessment takes account of any additional project-specific mitigations which are considered reasonably practical to further reduce the initial impacts and risks which were considered to be significant (i.e., '**Moderate**' or above). Project-specific mitigations are those which are used in addition to any mitigations required by legislation either in the Falklands or the UK and / or are currently considered to be standard industry practice in the Falklands. This second assessment describes the significance of the residual impacts and risks.

All residual impacts and risks will be reduced to a level that is 'As Low As is Reasonably Practicable' (ALARP) throughout the EIA process and throughout the life of the Development.

The mitigation measures and commitments are listed in the Environmental Monitoring and Management Plan (EMMP) described in Section 1.9.1 below.

1.8.3 Offsetting

Section 64C of the Offshore Minerals Ordinance states that EISs must contain a description of measures proposed to "*eliminate or reduce significant adverse effects…remedy those effects and offset them*." Appendix 2 to the FIG Hydrocarbons Environmental Impact Assessment Guidance Note (FIG, 2016e) provides offsetting guidance. ExCo paper 124/16 (FIG, 2016d) details FIG's recommendations for further developing offsetting guidance and suggested the establishment of an Environmental Fund.

ExCo paper 124/16 (FIG, 2016d) states that hydrocarbon development should seek meaningful offsetting of any impacts that cannot be avoided or mitigated, specifically in relation to greenhouse gas emissions and biodiversity. The options for offsetting these impacts include:

- Direct offsetting, i.e., the operator develops local projects to offset, like-for-like, the impacts arising from the Development that cannot be avoided or mitigated,
- Indirect offsetting, i.e., implementing measures that do not directly compensate for the impacts / risks identified, but may provide opportunities to achieve environmental benefits and improve the environment in the longer-term, or
- An environmental fund whereby the operator contributes to a fund with a governance panel to direct, manage and oversee various offsetting projects.

The Operator is required to demonstrate how offsetting measures have been considered which may further reduce significant adverse residual impacts identified in the EIS.

Navitas has ambitions for significant future local offsetting programmes, however these need to be informed by feasibility along with empirical data. Navitas will commit to a Carbon and Biodiversity offsetting Fund that will lay the foundations to inform scaling for island-wide restoration to achieve carbon and biodiversity benefits. Therefore, the Environmental Carbon and Biodiversity offsetting Fund is a precursor to inform any offsetting initiatives.

The section below details the offsetting options considered by Navitas and the reasons for the approach being proposed.

1.8.3.1 Review of offsetting options

Following elimination and / or reduction of all the impacts and risks identified for the Sea Lion Field, Navitas conclude that only tangible significant impacts /risks (impacts / risks assessed as ‘Moderate’ or above), may be offset.

Navitas has reviewed its significant residual impacts / risks (Section 1.8.4.2), and explored practicable, effective and locally beneficial direct offsetting measures in relation to these.

Direct or ‘like-for-like’ offsetting means compensating for impacts / risks to the environment at one site through activities that specifically address the nature of the impact in the local area. For example, this might include re-forestation of a nearby area where trees have been cleared for a construction site. For each residual impacts / risks assessed as ‘Moderate’ or above, Navitas has looked for practicable, local, environmentally beneficial and effective opportunities to directly offset them (see Section 8.11 of the full EIS). However, for each of the significant residual impacts / risks, Navitas has not at this time identified direct ‘like-for-like’ offsetting that is feasible, effective or reasonably practicable. The reasons for this are:

- It has not been possible to sufficiently quantify the impact / risk, and / or
- Navitas has not been able to conceive of a suitable project to achieve like-for-like offsetting,
- Navitas has conceived of but has not yet been able to determine feasibility, empirically define or formulate direct offsetting projects.

In addition, Navitas concludes it is not possible to plan to offset accidental events; that is where the impact may or may not happen, such as an oil spill. There is the risk of a spill occurring, but it is not possible to state if, when and what the impact of that spill might be, thus the impact is assessed in terms of the likelihood of it occurring. The impact itself is very difficult to quantify, and any efforts to remediate an impact that has arisen as the result of a risk, e.g., an oil spill, is considered ‘remediation’ as opposed to offsetting.

While potential offset initiatives have been identified in relation to atmospheric emissions, it has not been possible at this time for Navitas to determine the feasibility of these projects to confirm and quantify the benefit to the local environment, and that they are practicable for Navitas to implement. As such, while Navitas is committed to offsetting where practicable and to securing a positive environmental legacy, Navitas will not commence direct, like-for-like, offsetting for the residual significant impacts / risks from the Sea Lion Development until such time that identified initiatives have been further developed and proved, and it has been demonstrated that they are practicable and achievable within the Falkland Islands environment[1].

Where, following feasibility studies, direct offsetting activities or opportunities are not available, Navitas is also committed to exploring indirect offsetting opportunities onshore and offshore in the Falklands. Indirect offsetting refers to implementing measures that do not directly compensate for the impacts / risks identified above but may provide opportunities to achieve environmental benefits and improve the environment of the Falklands in the longer-term. These may include habitat restoration projects, pest and invasive species eradiation / control and conservation, biodiversity educational initiatives and the research required to inform them.

FIG's offsetting guidance requires proposed offsetting projects to be; described in detail (including costs and timelines), to be realistic, practicable and effective, be as quantitative as possible, additional to current projects / schemes or funding sources, and to provide a level of redundancy. Navitas cannot make *ad hoc* commitments to indirect offsetting projects that are not fully understood, and at this stage it has not been practicable to develop potential indirect offsetting projects to the level of maturity required by the EIA guidance. Given this, as a first step Navitas is working in close collaboration with FIG to initially identify schemes, undertake research as necessary and develop local indirect offsetting initiatives for future funding support.

Navitas will undertake operator-led direct and indirect offsetting in the Falkland Islands including carbon and biodiversity offsetting that includes Falklands-specific habitat restoration projects. To enable this Navitas will make contributions to a fund which will initially be used to commission research and feasibility studies that lead to pilot offsetting schemes that can be expanded to enable large scale in-Falklands habitat restoration (e.g., carbon sequestration) and biodiversity offsetting. Navitas will provide further funding to the viable projects identified. Navitas will monitor opportunities to fund / undertake direct and indirect offsetting throughout Field Life. There will be regular monitoring and reporting on performance of offsetting initiatives.

1.8.4 Key findings of the EIA

1.8.4.1 Overview of EIA findings - initial and residual assessments

A total of 134 impacts and risks were assessed.

During the initial assessment:

- 66.4 % of the impacts and risks assessed were considered to be **Very Low** or **Low**. While no additional, project-specific, mitigations were considered necessary for these impacts and risks, all will be subject to ongoing reviews to ensure that they remain ALARP,
- 27.6 % of the impacts and risks were considered to be of **Moderate** significance,
- 3.7 % were **Upper Moderate**,
- 1.5 % were **High**, and

[1] Since the public consultation, Navitas has agreed with FIG that it will make payments to a fund which will support local offsetting projects.

- 0.7 % were considered **Beneficial**.

Where initial impacts and risks were Moderate or above, project-specific mitigations were identified and those that were considered to be 'reasonably practicable' were factored into the residual assessment to reduce all the impacts / risks to ALARP. This resulted in an overall reduction in the number of 'High' impacts and risks (Figure 1-5).

Based on the residual assessment:

- The number of **Very Low** and **Low** impacts / risks increased to 67.9 %,
- The number of **Moderate** impact / risks remained at 27.6 % because two Upper Moderates were reduced to Moderate,
- The number of **Upper Moderate** impacts / risks remained at 3.7 % because two High risks were reduced to Upper Moderate,
- The number of **High** impacts / risks was reduced to 0 %, and
- The number of **Beneficial** impacts remained at 0.7 %.

A summary of the impacts and risks that were **Moderate** or above during the initial assessment and were reduced in the residual assessment due to the project-specific mitigation commitments is provided in Table 1.6.

The impacts and risks, which remained significant despite the use of industry-standard mitigations and the commitment to reasonably practical project-specific mitigations, are described in more detail below and summarised in Table 1.7.

A summary table showing all the residual impacts and risks to all the receptors is provided in Table 1.8 (in Section 1.8.5) below[2].

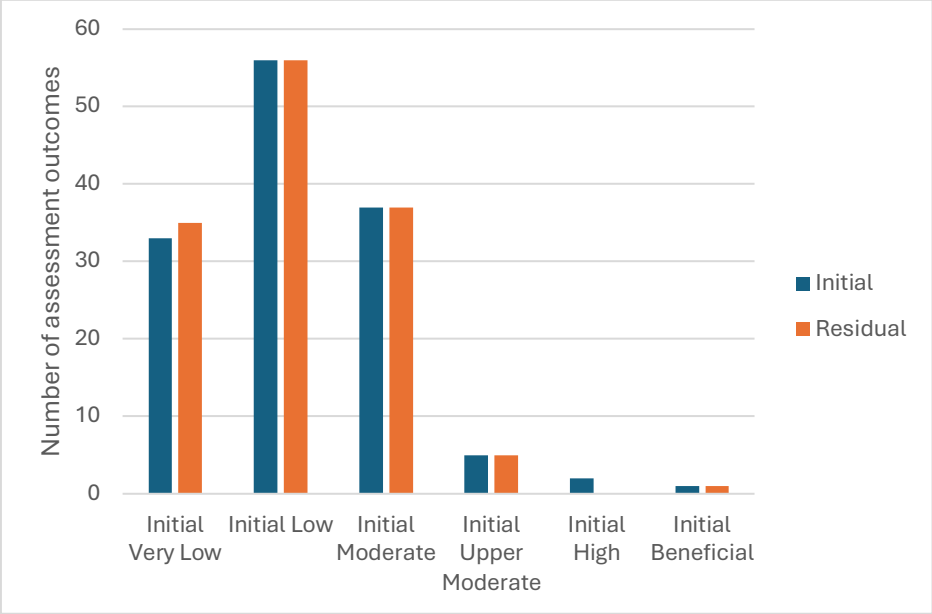

Figure 1-5: Illustrating the difference between the initial and residual impact and risk assessment outcomes

[2] Please note that Figure 1-3 above summarises the outcomes of the ENVIID while Table 1.8 below presents the worst-case outcomes of the assessment chapters. While individual receptors may be highlighted within Figure 1-3, for some activities, the impact assessment may, to avoid repetition, refer to biodiversity as a whole to assess the broad and primary impact rather than to itemise each individual receptor.

Table 1.6: A summary of the impacts and risks that were initially identified as being of Moderate significance or above and which were reduced following commitment to reasonably practical project-specific mitigations

Impact / risk	Initial assessment[1]	Key project-specific mitigation summary	Residual assessment[2]	Section
Collision between cetaceans and vessels inshore.	**Upper Moderate**	Reduction of vessel speed to maximum eight knots.	**Moderate**	**Section 10.11**
Risk of marine invasive species from biofouling on LTVs.	**Upper Moderate**	Hull inspection of LTVs and potential hull cleaning if necessary.	**Moderate**	**Section 10.12**
Use of freshwater resources during Stages 1 and 2 (a & b)	**High**	Ensuring reliability of water supply, offtake limits, pre-filling of MODU and vessels and re-stocking from incoming vessels. Use of seawater where possible.	**Upper Moderate**	**Section 11.4**
Competition with domestic energy needs	**High**	Sustainable and energy efficient design, Off-peak power utilisation, and standby diesel fueled electricity generators.	**Upper Moderate**	**Section 11.5**
Disturbance to the human population from operations noise at the TDF and supply base	**Moderate**	Activity restrictions and minimising noise at night	**Very Low**	**Section 11.9**
Disturbance to the human population from the Large Transport Vessel (LTV) and Offshore Construction Vessel (OCV) operations noise in Berkeley Sound	**Moderate**	Activity restrictions and minimising noise at night	**Very Low**	

[1] Taking account of regulatory requirements, industry-standard practices and base-case mitigations.
[2] Taking account of reasonably practicable project-specific mitigations.

1.8.4.2 Significant residual impacts and risks

The significant residual impacts and risks are summarised in Table 1.7. The sections below summarise only the residual impacts and risks that remained significant following project-specific mitigation. Note that the full EIS describes the initial and residual assessment outcomes for all the environmental and social aspects (Chapters 10, 11 and 12).

Significant residual impacts and risks are those that have been reduced to ALARP but are still considered to be '**Moderate**' or '**Upper Moderate**', primarily because of:

- The limited options for effective and reasonably practicable project-specific mitigations, and / or
- The use of a precautionary approach during the assessment when faced with data gaps, which leads to higher levels of uncertainty.

In each summary below, only the highest impact or risk is presented. For example, where underwater noise may affect diving seabirds and marine mammals, only the impact to marine mammals is described in the sections below as this was assessed as the greatest potential impact.

Table 1.7: A summary of the residual impacts and risks that, while considered to be ALARP, remain significant

Impact / risk	Residual assessment[1]	Section
Impacts and risks associated with planned activities		
Risk of large-scale bird-strikes due to artificial light offshore.	**Moderate**	Section 10.1
Risk of small-scale bird-strikes due to artificial light offshore.	**Moderate**	
Risk of large-scale bird-strikes due to artificial light inshore.	**Moderate**	
Behavioural disturbance to marine mammals from underwater noise offshore.	**Moderate**	Section 10.4
Impacts of drill cuttings discharge on benthos including burial of benthic fauna, modification of habitat, toxicity and oxygen depletion.	**Moderate**	Section 10.6
Impacts from Phase 1 & 2 atmospheric emissions on global warming.	**Moderate**	Section 10.9
Impacts from Phase 1 & 2 atmospheric emissions on ocean acidification	**Moderate**	
Indirect impact from atmospheric emissions associated with the combustion of sold product.	**Upper Moderate**	Section 10.9
Use of regulated landfill for waste disposal (while following the waste hierarchy as far as possible)	**Moderate**	Section 10.10
Risk of collision between cetaceans and vessels *en route* between the field and Stanley	**Moderate**	Section 10.11
Risk of collision between cetaceans and vessels in Berkeley Sound	**Moderate**	
Risk of introducing marine invasive species in Sea Lion in-field vessels	**Moderate**	Section 10.12
Risk of introducing marine invasive species in by *ad hoc* freighters	**Moderate**	
Risk of introducing marine invasive species to Berkeley Sound *via* LTVs	**Moderate**	
Risk of introducing marine invasive species in-field by CTTs	**Moderate**	
Risk associated with non-native terrestrial species arriving on air freight	**Upper Moderate**	Section 10.13
Competition for freshwater resources – water use for MODU drilling and vessel top-up and for onshore yards and accommodation (Stages 1 and 2)	**Upper Moderate**	Section 11.4
Competition for freshwater resources – water use for offshore vessel top-up and onshore yards and accommodation (Stage 3)	**Upper Moderate**	
Competition with domestic electricity needs	**Upper Moderate**	Section 11.5
Competition for use of road network	**Moderate**	Section 11.7
Disturbance to the human population from light at supply bases and TDF	**Moderate**	Section 11.8
Disturbance to the human population from light in Berkeley Sound	**Moderate**	
Risks associated with accidental events		
Accidental releases of Sea Lion oil to sea offshore	**Moderate**	Section 12.1
Accidental releases of inshore Marine Gas Oil (MGO) to sea offshore	**Moderate**	
Accidental release of MGO inshore	**Moderate**	Section 12.2
Day-to-day small leaks and spills at-shore	**Moderate**	Section 12.3

[1] Taking account of regulatory requirements, base-case mitigations, industry-standard mitigation *and* reasonably practicable project-specific mitigations.

1.8.4.2.1 Artificial lights offshore and inshore

Throughout the Phase 1 & 2 Development, installations and vessels will add to the existing levels of artificial light both offshore and inshore, and this was raised as a concern by stakeholders during consultations in 2014, 2015 and 2016 (see EIS Chapter 6). Further, while flaring is not expected to occur during normal operations, a pilot light will be permanently lit, and flaring may be necessary during planned or unplanned equipment outages. Flaring during well tests and well clean-up may also be

required for all production wells and is retained within the Development Description (Chapter 5) as a contingency.

During the hours of darkness, artificial light will attract plankton, fish and squid and potentially marine mammals, but the impact upon seabirds is considered to be of greatest concern. Lights will attract and / or disorientate seabirds (small petrels) and there is the potential for these birds to collide with the lights or vessel superstructures. This phenomenon is known as 'bird-strike'.

Bird-strikes may result in mortality through direct collision. Birds may suffer injuries or hypothermia, should feathers become contaminated with residues on the deck of a vessel. The occurrence of seabird collisions will depend upon a combination of factors including the species and abundance of birds in the area at the time, and local weather conditions. Small nocturnally active petrels are most susceptible during periods of poor visibility.

Taking account of the sensitivity of bird species which may be susceptible, the potential severity of effect of multiple bird-strikes, the fact that some artificial lighting on vessels and installations cannot be reduced or altered without compromising safety, and also adopting a precautionary approach, the residual risk of bird-strikes is considered to be '**Moderate**' (see EIS Section 10.1).

1.8.4.2.2 Underwater noise offshore

Underwater noise will be generated by the use of vessels throughout the Phase 1 & 2 Development and will be continuous throughout the life of the project. Noise pollution and its effects on sensitive receptors was raised as a concern by stakeholders during consultations in 2014 and 2015 (see EIS Chapter 6). While underwater vessel noise has the potential to impact upon plankton, invertebrates, fish and diving birds, it is most likely to have a consequential impact upon fish, seabirds and marine mammals, through disturbance and / or changes in behaviour. In other areas with greater marine actives, impacts on other parts of the ecosystem can also be expected with ramifications for acoustically sensitive marine organisms and the functioning of marine ecosystems.

When assessing the impact of sound on any animal, it is necessary to compare the sounds being made with the thresholds above which the animal may exhibit behavioural reactions to disturbance or experience hearing loss / injury. It is also necessary to consider how close the animal needs to be to the source of the noise for it to experience the sound at levels above the disturbance and injury thresholds.

Modelling was carried out to assess the impact of different sound sources on the different receptors e.g., fish and marine mammals[3], at different distances. Based on the modelling results and available information, the worst-case impact of underwater noise is that of a spread of near-stationary sources of vessel noise at the Phase 1 & 2 Development site (e.g., from the dynamically positioned tug tending the CTT, or the CTT accelerating / decelerating on approach or exit) and its potential long-term effect on marine mammals.

Given the conservation status of the whale species that may be affected, data gaps in marine mammal distribution in the NFB, lack of knowledge of the long-term impact of continuous noise and difficulties in effectively mitigating this impact, the precautionary approach dictates that the residual impact rating remains '**Moderate**' (see EIS Section 10.4).

[3] Note that there are no recorded injury or behavioural disturbance thresholds for plankton, invertebrates or seabirds against which to compare modelling outputs such that impacts to these receptors are not considered within the chapter. However, research has shown that some species of squid are similar to fish in their ability to detect sound (Mooney *et al.,* 2010; OSPAR, 2009b) and a qualitative assessment of the impacts to squid is carried out.

1.8.4.2.3 Discharge of drill cuttings

Drilling of the Development wells will result in the discharge of drilling muds and rock cuttings in the proximity of the well. Water-based Mud (WBM) and cuttings will be discharged directly to seabed whilst drilling the top sections of the wells. Cleaned Non-Aqueous Drill Fluid (NADF) cuttings will be discharged from the bottom sections of each well. Prior to discharge, NADF (see Section 10.6.4.1.3.1) cuttings will be returned to the MODU where they will be cleaned by a Thermo-mechanical Cuttings Cleaner (TCC). The cuttings will be cleaned to ensure there is <0.5 % oil (by weight on dry cuttings) remaining, following which the cuttings will be discharged to sea.

Whilst the discharge of cuttings may impact water quality, plankton, fish and squid, the greatest impact will be to the benthic community in the area. These impacts can arise from smothering, changes to habitat, reduction in oxygen availability and the toxic effects of residues associated with the cuttings.

Modelling was carried out to determine the extent of the impacts of the cuttings in the vicinity of the wells. Although there are no known species of conservation importance in the area, the specific location of the Sea Lion Development has not yet been surveyed such that there are minor data gaps and thus a precautionary approach was taken. Using the precautionary approach, and due to the extent and duration of the impacts, the residual impact to benthic fauna is considered to be '**Moderate**' (see EIS Section 10.6).

1.8.4.2.4 Atmospheric emissions (climatic factors)

Nearly all activities associated with the Phase 1 & 2 Development will result in atmospheric emissions and this was raised as a concern by stakeholders during consultations in 2015 and 2016 (see EIS Chapter 6). Emissions will result from power generation on the MODU and FPSO, the flare pilot light on the FPSO and the use of all vessels, fixed-wing flights and helicopters. There is also a contingency to flow / test four wells to the MODU if this is considered necessary and the potential for non-routine flaring as a result of process upset or emergency shutdowns throughout Field Life.

Atmospheric emissions include gases which lead to global warming and ocean acidification, the best known of which is Carbon Dioxide (CO_2).

A number of emissions reduction measures are built-in to the Phase 1 & 2 project, as shown Table 1.2 above. Moreover, in line with its HS&S and E&B Policies (see Section 3.2.1), and in recognition of Net Zero, Navitas will endeavour to minimise emissions, where possible, through operational control measures, monitoring and reporting and periodic reviews to determine whether or not the emissions remain ALARP. Worst-case emissions estimates based upon the Phase 1 & 2 Development (P10 – P90) indicate a carbon intensity of 21.8 - 30.3 kg CO_2 equivalent per barrel of oil produced. When the worst-case emissions are compared to the NSTA data (i.e., by removing emissions associated with personnel transportation, drilling and vessel use), the carbon intensity estimates range from 17.2 - 23.8 kgCO_2e/boe and the 'currently expected' emissions range from 13.1 - 18.2 kgCO_2e/boe.

The estimated worst-case percentage contribution of Sea Lion emissions is minimal when compared to the 2021 UK emissions (0.06 %) and amounts to 53 % of the Falklands Islands 2021 emissions (noting that the Falkland Islands dataset is currently incomplete as it does not include emissions from aviation, shipping or previous offshore O&G activity and includes only small-scale fishing within the IPPC 'transport' sector). While the new development has been designed with efficiency in mind, owing to the sensitivity of the global environment as a receptor, the residual impacts of the contribution of atmospheric emissions to both global warming and ocean acidification are considered to be '**Moderate**' (see EIS Section 10.9).

Emissions associated with the combustion of sold product are beyond the ability of Navitas to influence. Nonetheless, these were estimated for the P10, P50 and P90 production cases under the

worst-case assumption that 100 % of the sold product will be combusted. These emissions were compared over Field Life to two future projection scenarios for global demand and to the currently known global demand. Comparison with the global daily emissions of the two future projections indicated that the daily contribution of Sea Lion (at the P10 production case, 336.7 MMstb over Field Life) to global emissions ranged from 0.014 – 0.087 % and when compared to the current known demand, was 0.031 % (assuming all globally produced oil is similarly combusted). In absolute terms this is still a significant contribution and to take a precautionary approach, the impact was considered to be '**Upper Moderate**' (see EIS Section 10.9).

1.8.4.2.5 Waste management

Waste by-products will result from nearly every activity carried out during the Phase 1 & 2 Development and waste management was raised as a concern by stakeholders during consultations in 2015 and 2016 (see EIS Section 10.10). Waste from the Development will include domestic and marine wastes, solid wastes, produced water, drainage water, ballast water, domestic wastewater, food, sewage discharges and drill cuttings. Some of these wastes are hazardous, some are non-hazardous and some may be legally discharged to sea provided they undergo proper treatment. Produced water, drainage water, ballast water and drill cuttings are all described in separate chapters. With the exception of drill cuttings (see above) the associated impacts were '**Low**' such that they are not detailed in this NTS beyond their inclusion in Table 1.8 below.

Of greater significance, is the generation of solid operational wastes, all of which will be returned to shore for disposal at the FIG waste management facility or, in the event that the planned municipal facility is not yet available, for incineration at the supply base or deposition to landfill in the UK. To ensure the responsible management of waste, and compliance with Navitas' Duty of Care obligations, Navitas will develop and implement a project-specific Waste Management Plan (WMP) prior to the start of operations.

Navitas is committed to using the planned FIG Waste Management Facility to treat and dispose of all incinerable project wastes that have no re-use or recycling outlet locally. In the event that the FIG Waste Management Facility is unavailable, Navitas will discuss other options with FIG, such as the possibility to install a temporary incinerator at the supply base for the burning of suitable waste streams with resultant ash from the incineration process returned to the UK for disposal.

Navitas will not make use of the Eliza Cove or Mary Hill Quarry sites and will export wastes, if necessary, in compliance with all applicable international and national waste shipment regulations. Throughout the Development the 'Waste Hierarchy' will be utilised and annual waste targets will be set, to maximise waste reduction and recovery.

Waste facilities in the Falkland Islands are currently very limited. Plans approved by FIG should deliver a new municipal integrated waste facility that is capable of receiving the waste from the Sea Lion Phase 1 & 2 Development. Although it is not Navitas' preferred option for the disposal of wastes, should the municipal facilities not be ready when the project starts, some waste will need to be sent to landfill in the UK. Landfill is an unsustainable practice and therefore, although the quantities of waste are comparatively small, landfill space in the UK remains limited such that the worst-case residual impact of waste generation is considered to be '**Moderate**' (see EIS Section 10.10).

1.8.4.2.6 Risk of injury to cetaceans

1.8.4.2.6.1 Injury via collisions in-transit and inshore

There is a risk of vessel collision with cetaceans and this was raised as a concern by stakeholders in the 2016 scoping consultations (see EIS Chapter 6). Concerns about vessel collisions with marine animals is increasing worldwide. However, most publications focus on larger whales. While Schoeman *et al.*

(2020) found that smaller animals are also affected and recommend the establishment of a species-specific necropsy protocol and a database for smaller species, there is a paucity of documented evidence / data on vessel collisions and smaller cetaceans generally. In the Falklands Islands, recent collisions have been reported with sei whales and a Commerson's dolphin (Falklands Conservation, 2020). However, there is little detail on the circumstances. Anecdotally the collision with the dolphin was with a fast-moving launch. According to van Waerebeek *et al.* (2007), most collisions between small cetacean and vessels tend to occur in enclosed inshore, estuarine or freshwater environments where there is a high-density of smaller fast-moving vessels. Navitas will use large ocean-going vessels in Berkeley Sound and in the Sea Lion Field and for this reason, collisions with small cetaceans are not considered further. The impact assessment focuses on the potential for collisions with the larger cetaceans only.

Offshore vessels will transit from the Sea Lion Field into Stanley on a regular basis and though they are some of the smaller vessels used in the project, they will be operational year-round and so there is a possibility they will overlap with large whales, e.g., sei whales (IUCN 'Endangered') and southern right whales.

Some of the inshore vessels involved in the construction phase (e.g., the LTVs) will be considerably larger than vessels employed in the offshore aspect of the project. These vessels are required to transit to, and anchor in, Berkeley Sound where there is a seasonally high likelihood of encountering sei and southern right whales.

In line with the industry-standard guidelines, all vessels coming into Stanley, *via* Port William, will be limited to 10 knots on entering the proposed Marine Management Area (pMMA). However, in line with project-specific mitigations, vessels entering Berkeley Sound will reduce their speed further to eight knots. These relatively slow vessel speeds will reduce the likelihood of collisions and the energy behind any impacts, thus reducing the potential for lethal injury.

While the use of industry-standard guidelines, reduced vessel speeds and the use of Marine Mammal Observers will all lessen the likelihood and impact of collisions, the sensitivity of the large whale species that may be affected (e.g., sei whales), the limited maneuverability of very large whales (e.g., right whales), the unpredictable nature of cetacean behaviour in general and data gaps in the knowledge of whale distribution mean that while the risk has been reduced to ALARP, the residual risk remains '**Moderate**' for both offshore and inshore vessels (see EIS Section 10.11).

1.8.4.2.6.2 Risk of entanglement with subsea infrastructure

A review of the literature indicated that the majority of incidents of entanglement of cetaceans with man-made subsea structures involve fixed and static fishing gears. These usually have a considerable amount of slack in the lines and are generally of a small gauge. This slack enables the lines to wrap around whale body parts, which ultimately leads to entanglement and often drowning.

The anchor chains and cables associated with the MODU / FPSO, other large vessels and subsea risers would be high gauge and taut under most circumstances and would not have enough slack to allow cetaceans to become entangled. In the absence of records for entanglements with this type of gear, coupled with the lack of evidence for entanglement with high gauge moorings in the literature, this risk is not assessed further within this EIS.

1.8.4.2.7 Risk of introducing marine invasive species

The arrival of vessels into Falkland Islands waters from elsewhere in the world may lead to the introduction of non-native marine species and biosecurity was raised as a concern by stakeholders during consultations in 2014, 2015 and 2016 (see EIS Chapter 6). The introduction of non-native species can result from discharged ballast waters or from biofouling present in the 'nooks and crannies' of a

ship's hull. In the event that non-native species are introduced, there is then the potential that they may become established and spread. If this occurs, they are referred to as 'invasive species' and can dramatically alter the local ecosystem and / or outcompete native species altogether, negatively impacting the local biodiversity. Once established, marine invasive species are virtually impossible to eradicate.

The likelihood of such a species being introduced, and then becoming invasive, depends upon numerous factors e.g., whether the species comes from a similar climate and ecosystem, whether the ship passed through different climates *en route* (e.g., the Tropics) and whether or not the vessel is repeatedly 'new' to the Falkland Islands.

Industry-standard and project-specific mitigation measures regarding ballast water management and antifouling of vessels (which will be detailed in the Biosecurity Management Plan) go a long way to reducing the likelihood of species introduction, which may or may not then become invasive. However, the greatest risk comes from third-party vessels such as the purchaser's CTT over which Navitas does not have full control over and above contractor vetting and selection processes. On balance, given that species invasion can be difficult to detect in the short-term and can have severe effects on biodiversity which are almost impossible to reverse, the worst-case residual risk of marine species invasion is considered to be '**Moderate**' (see EIS Section 10.12).

1.8.4.2.8 Risk associated with non-native terrestrial species arriving on freight

Bringing freight into the Islands to support Navitas' operations carries the risk of introducing non-native, potentially invasive species in the cargo. As with marine invasives, if invasive species were introduced during the Phase 1 & 2 Development the impact on the ecology of the Islands through parasites, disease, competitors or predators may not be immediately evident but may have long-term implications. Initially the impact may not be felt locally, however, once established invasive species may spread 'naturally' or with anthropogenic assistance to other parts of the Falklands archipelago. If found, potentially invasive species can be removed but they can be very difficult to detect and then eradicate.

Vessels and charter flights will be arriving in Stanley and Mount Pleasant throughout the life of the Development and a large amount of cargo will be taken onshore. The transportation of invasive species to the Falklands has happened in recent years, and the introduction of invasive species has occurred in the O&G industry elsewhere in the world, such that the risk is considered possible during the Phase 1 & 2 Development. A Biosecurity Management Plan will be implemented during the Phase 1 & 2 Development to help prevent non-native and potentially invasive species being introduced. However, due to the potential impacts of invasive species and the fact that invasives have been introduced in the past, the risk of non-native species introduction is considered '**Upper Moderate**' (see EIS Section 10.13).

1.8.4.2.9 Competition for freshwater resources

Onshore infrastructure associated with the Development (e.g., the onshore supply base and the TDF) will require connection to the existing Stanley water utilities. In addition, the onshore water supply will be required to support a proportion of water use by offshore assets including vessels, the MODU's drilling requirements for muds, cements, brines and domestic use.

The FIG owned Stanley water filtration plant is the single water supplier and has a fixed capacity which is limited by the existing utility infrastructure[4]. Water is therefore considered a limited resource. Any

[4] Navitas is aware that FIG plans to increase water supply and treatment capacity. If these improvements are realised the impact of water use by the Development will be significantly lower. However, these planned improvements are not currently factored into the impact assessment in order to assume the worst-case.

use of water by the Development activities or assets which is above the current baseline Stanley usage has the potential to lead to competition with the local users in Stanley.

Competition for water resources will be particularly high during the drilling stages of the Phase 1 & 2 Development and in the event that demands during these stages exceed supply, impacts upon volume will be immediately apparent to consumers and businesses. The Stanley water supply is already near capacity and, to accommodate the Development, the existing system may need to operate at a temporary deficit for short durations if no changes are made to the current FIG system.

Throughout the project, the water supply to Stanley will always be prioritised over that provided to the TDF such that the impacts of any water shortage will be felt by the Phase 1 & 2 Development rather than the Stanley users. Nonetheless, the overall significance of the impact of water competition on the human population is '**Upper Moderate**' (see EIS Section 11.4).

All additional project-specific mitigation measures, including providing a freshwater buffer tank at the TDF and planning and logistics to reduce water use during the drilling phases, will be discussed further with FIG.

1.8.4.2.10 Competition for electricity

Onshore and at-shore infrastructure in support of the Phase 1 & 2 Development will require connection to the existing electrical power grid of Stanley. FIG is the single energy utility supplier and has a fixed power capacity from a finite number of generators at the Stanley power station and wind turbines located a few miles out of town.

Electricity is an essential utility upon which almost all daily activity depends in an increasingly electronic age. Stanley's current baseline capacity is such that it may be unable to sustain peak demand spikes in the short-term and therefore must be considered a finite resource. The use of electricity by Navitas therefore has the potential to be unsustainable in the immediate term. Overall demand from Stanley plus the Phase 1 & 2 Development has the potential to exceed the available capacity in the system. While Navitas will have back-up generators available at the onshore base, Navitas will liaise closely with FIG to ensure that energy supply and demand are in balance. These discussions will include those based on FIG's planned future development of power capacity.

Nevertheless, while development of a new FIG power station may alter the impact assessment by altering the baseline capacity against which usage is compared, these changes are currently outwith Navitas' control and cannot be used as a mitigation within this assessment. Therefore, the impact of competition for electrical energy on the human population of the Falkland Islands is considered to be '**Upper Moderate**' (see EIS Section 11.5).

1.8.4.2.11 Competition for use of road network

All stages of the Sea Lion Phase 1 & 2 Development will require the use of the existing road network for the movement of personnel to, from and within Stanley, for the haulage of equipment, and transport of supplies and waste between a range of different locations. Whilst road capacity and use cannot be accurately quantified, increased utilisation may be detrimental to the road surfaces and may also result in increased necessity for remedial repairs. Further, additional traffic, congestion and vehicles seeking parking may also create a nuisance to the local population and the issue of road use was raised as a concern during scoping consultations (see EIS Chapter 6).

An increase in traffic of up to 17 % in Stage 1 and Stage 2 (a & b), and 11 % in Stage 3 (up to 30 years) is predicted, which could result in some degree of congestion at peak times and lessen parking availability which may cause inconvenience to other road users.

A Traffic Management Plan (TMP) will be put in place for operations, as was done for the exploration campaigns, to minimise the impacts from operational road use in this area. The TMP will highlight operating hours, signage, allowable routes, warning devices, clothing and pedestrian precautions for Navitas staff and contractors. However, owing to the sensitivity of the receptor and the extent and duration of traffic increases, the residual significance of the impact of road use on the human population is still considered to be '**Moderate**' (see EIS Section 11.7).

1.8.4.2.12 Disturbance to the human population from light

Throughout the Phase 1 & 2 Development the onshore supply base and port facilities in Stanley, as well as the vessels in Berkeley Sound, will create artificial light. All of these sources have the potential to create light pollution and a nuisance to local residents. It was noted during previous scoping consultations that light from the TDF, vessels and yard is noticeable to Stanley residents (see EIS Chapter 6).

To ensure a safe operation, minimum levels of lighting are required on the TDF and at the supply base as well as in Berkeley Sound on the LTV storage vessels. In compliance with safety legislation, the light levels may not be reduced below that minimum. However, mitigation measures are proposed to ensure all lights are facing inwards and to reduce light pollution both by directionally blocking lights and turning them off when not required.

Nonetheless, due to the sensitivity of the receptor (the residents of Stanley and Berkeley Sound), the longevity of the potential disturbance in Stanley and the fact that proposed mitigation measures have not proven to be fully effective during previous campaigns, the residual impact of light pollution and nuisance to the human population is considered to be '**Moderate**' (see EIS Section 11.8).

1.8.4.3 Significant residual risks associated with accidental events

1.8.4.3.1 Accidental releases of crude oil or MGO to sea offshore

All offshore O&G operations carry the risk of oil spills and this was raised as a concern by stakeholders during consultations in 2014, 2015 and 2016 (see EIS Chapter 6). The impacts of any given spill depend upon the type of the oil, the size and source of the spill, the prevailing winds and currents, water depth, proximity to the shoreline or to concentrations of receptors offshore, and numerous other factors. Depending upon these factors, the spill may impact upon biological, social and environmental receptors.

Lessons learned from oil spill events around the world have led to stringent industry-standard practices that are required to minimise both the likelihood of occurrence of an oil spill and the consequences of such an event should it occur. Many of these preventative industry-standard practices are built into the design of the facilities (Section 1.5.2 above) and were therefore taken into account during the initial risk assessment.

With regard to the wells, industry-standard oil spill prevention measures range from the way the wells are designed to the use of blow-out preventers and operational control procedures that ensure that good oilfield practice is followed in all activities that could carry the risk of a large or small spill. Further, the well designs will be peer reviewed by an independent well examiner and the UK Health and Safety Executive (HSEx) to ensure that the risk of an uncontrolled release is minimised.

With regard to the FPSO, the industry-standard preventative requirements built-in to the design range from double-skinned and double-bottomed cargo and fuel tanks to the use of Automated Information Systems (AIS) and marine procedures intended to prevent collisions (Section 1.5.2 above). The FPSO is detachable should there be a risk from iceberg movement.

A range of different offshore oil spill scenarios were modelled to determine the behaviour of spills that could occur if the above preventative mitigation measures fail. The modelled scenarios included spills of reservoir oil from a well blow-out, loss of the FPSO cargo tank inventory, and spills of MGO during bunkering operations. The results of these models were used to inform the impact assessments with regard to the 'Severity of Effect' of a spill.

The measures intended to minimise the consequences of an oil spill are based upon the outcomes of the spill models, as well as industry-standard practice. An Oil Pollution Emergency Plan (OPEP) that covers the offshore operations will be submitted to FIG before operations commence and will detail the organisational responsibilities, immediate and long-term actions, reporting requirements and resources available to ensure the effective and timely management of any spills. The Sea Lion OPEP will be compatible with the FIG National Oil Spill Contingency Plan (NOSCP). Resources available, and described within the OPEP, will range from equipment held on-site by Navitas to international resources which can be brought in to track and monitor spill trajectories and / or equipment that will be deployed to stem the release of oil if necessary.

Mitigation measures to prevent the occurrence of spills and to minimise the consequences are designed based on the outcomes of the modelled oil spill scenarios, the full details of which are provided in Section 12.1 of the EIS.

Taking account of the predicted fate of Sea Lion crude and MGO in the event of a release (as indicated by the models), the worst-case potential impacts of an oil spill would be to fish, seabirds, marine mammals, fisheries and the human population (in terms of potential impact upon tourism through public perception of a spill, even if none were to reach the shore). The sensitivity of each of these receptors to an oil spill was assessed during the EIA and ranged from '**High**' to '**Very High**' (see EIS Section 12.1).

The impact of spills (i.e., the 'Sensitivity of Receptors' x 'Severity of Effect') on all the potential receptors was assessed for each spill scenario. The large volume crude spills (e.g., well blow-out, crude inventory loss) and spills that create a 'sheen' on the water (e.g., fuel spills) resulted in impacts of '**Upper Moderate**' and '**High**' significance to the more sensitive receptors.

As described in Section 1.8.2, the risk assessment process applies the likelihood of a spill occurring to the impacts associated with the spill. In the case of offshore spills, the 'Likelihood of Occurrence' was estimated based on statistical information on the frequency of incidents as well as specific Collision Risk Assessments for the Sea Lion Field activities. Based on these statistics, the likelihood of offshore spills ranges from '**Very Unlikely**' (e.g., for full loss of the FPSO crude inventory) to '**Possible**' (e.g., for a spill during transfer of crude from the FPSO to the CTT). Therefore, the assessment results in a worst-case residual risk of '**Moderate**' (see EIS Section 12.1).

1.8.4.3.2 Accidental releases of MGO to sea inshore

The risk of oil spill in Berkeley Sound was raised by stakeholders during consultations in 2014, 2015 and 2016 (see EIS Chapter 6). The potential sources of inshore spill include the arrival and manoeuvring of the LTVs prior to anchoring, intermittent visits from Offshore Construction Vessels (OCVs), and the presence of non-Navitas third-party vessels. Therefore, the events that may result in an MGO spill in Berkeley Sound include fuel bunkering incidents and potential vessel collisions.

With regard to mitigation, industry-standard collision prevention measures, AIS and marine procedures will be used (Section 1.5.2 above). Also, Navitas will 'vet' all vessels prior to their use for project activities.

The LTVs will be vetted and audited to assess:

- Verification of compliance with all relevant MARPOL Annex requirements and other IMO requirements,
- Verification of compliance with mandatory shipping requirements e.g., The Oil Companies International Marine Forum Ship Inspection Report Programme (SIRE), International Association of Classification Societies (IACS) etc.,
- Verification of the Shipboard Oil Pollution Emergency Plan (SOPEP), and
- Specific checks to ensure the vessel's equipment is suitable for the operation with regard to risk management and insurance requirements.

Two inshore oil spill scenarios were modelled to determine the behaviour of spills that could occur if the above preventative mitigation measures fail. The modelled scenarios were spills of MGO from bunkering incidents and vessel collisions. The results of the modelling were used to inform the impact assessment with regard to the 'Severity of Effect' of a spill.

An OPEP that covers the inshore operations will be submitted to FIG before operations commence.

Mitigation measures to prevent the occurrence of spills and to minimise the consequences are designed based on the outcomes of the modelled oil spill scenarios and full details are provided in Section 12.2 of the EIS.

Taking account of the predicted fate of MGO in the event of a release in the Sound (as indicated by the models), the worst-case potential impacts of spills are to fish and squid, fisheries, seabirds, marine mammals, coastal ecology and the human population (in terms of potential impact upon tourism). The sensitivity of each receptor within Berkeley Sound was assessed during the EIA and ranged from '**High**' to '**Very High**'.

The impact (i.e., the 'Sensitivity of Receptor' x 'Severity of Effect') on all the potential receptors in and around Berkeley Sound was assessed for both spill scenarios. The larger volume spill resulted in residual impacts of '**High**' and '**Upper Moderate**' significance to the more sensitive receptors.

Estimation of the 'Likelihood of Occurrence' of inshore spills was based on statistical information on the frequency of incidents. The assessment of the worst-case residual risk was '**Moderate**' for a spill of MGO (see EIS Section 12.2).

1.8.4.3.3 Day-to-day small leaks and spills at-shore

Small scale spills and leaks may occur through the presence and / or the day-to-day use of equipment onshore and at-shore (e.g., cranes, generators, vehicles etc.). Specifically, spills and leaks that may result from the presence and / or use of equipment include losses of chemicals or fuel oil (MGO). Any unintentional at-shore release which reaches the water, however small, will contribute to chronic pollution of the marine environment. Stanley Harbour supports a population of flightless Falkland steamer ducks, and is utilised by Commerson's and Peale's dolphins and South American sea lions. Although the number of animals present is not significant in terms of the Falklands populations, all of these are included in the list of priority conservation species and therefore the sensitivity of receptors is considered to be '**High**'.

While any such leaks are likely to be contained on the superstructure of the TDF where they will rapidly evaporate and are amenable to clean-up, some may reach the water. The scale of such leaks / spills is unlikely to warrant the deployment of a full oil spill response, although localised spill kits would be utilised to reduce the severity of any effect. While there is some uncertainty regarding the potential impacts of some of the fluids used during operations on the TDF, the environmental impact of any small leak or spill will be localised, short-term and fully reversible once activity ceases and, on balance, the severity of effect is considered to be '**Minor**'.

During the 2015 exploration campaign, two small incidents occurred which lead to leaks which did not reach the water. These events may occur less than once per year but could occur more than once over 10 years in the event that operational controls failed; therefore, the likelihood of small-scale spills or leaks occurring and contaminating the environment is '**Possible**'.

Therefore, the residual risk associated with day-to-day small spills is assessed as '**Moderate (9)**'.

1.8.5 EIA outcomes summary

Table 1.8 shows the significance of the worst-case residual impacts and risks associated with all activities on all receptors. The overall significance of impacts associated with each activity is based upon the greatest impact / risk. In other words, if an oil spill is identified as having a greater impact on seabirds than on the benthos, then the impact to seabirds dictates the overall significance of oil spills. Definitions of each significance category are provided in Table 1.9.

Table 1.8 also indicates which of the aspects were initially raised as a concern by stakeholders during the scoping consultations (EIS Chapter 6) to enable easier review by stakeholders of the EIA outcomes for their particular area of concern.

Table 1.8: Summary of the worst-case residual impacts / risks to each receptor for all The Sea Lion Northern Area Development, Phase 1 & 2 activities, and an indication of whether they were raised as a concern by stakeholders during informal scoping consultations[1]

Activity	Residual Environmental Impact / Risk[2]																	Worst-case Residual Impact / Risk	Raised by stakeholder during scoping
	Physical						Biological						Social						
	Seabed (and soil)	Water quality	Regional air quality	Global atmosphere	Marine flora	Plankton	Benthos / habitats	Fish / cephalopods	Seabirds	Marine mammals	Designated sites	Biosecurity / biodiversity	Land / seascape	Human population	Other sea users	Tangible property / resources	Archaeological		
Residual environmental impacts and risks associated with planned activities and unplanned events																			
Artificial light and the risk of bird-strikes inshore and offshore										n/a									✓
Disturbance to wildlife from helicopter use																			✓
Disturbance to seabed																			-
Seabed disturbance - risk of dropped objects																			-
Underwater noise offshore																			✓
Underwater noise inshore																			✓
Discharge of drilling mud and cuttings																			✓
Operational discharges																			✓
Operational discharges – risk of PWRI malfunction																			✓
Thermal discharges																			✓
Atmospheric emissions (climatic factors)																			✓
Atmospheric emissions from combustion of sold product																			-
Atmospheric emissions – risk of blowdown / venting / release of F-Gas																			✓

Activity	Residual Environmental Impact / Risk[2]																	Worst-case Residual Impact / Risk	Raised by stakeholder during scoping
	Physical						Biological						Social						
	Seabed (and soil)	Water quality	Regional air quality	Global atmosphere	Marine flora	Plankton	Benthos / habitats	Fish / cephalopods	Seabirds	Marine mammals	Designated sites	Biosecurity / biodiversity	Land / seascape	Human population	Other sea users	Tangible property / resources	Archaeological		
Waste generation																			✓
Waste - risk of loss of waste / improper segregation																			✓
Risk of large cetacean collision inshore and offshore																			✓
Risk of small cetacean collision inshore and offshore										n/a								n/a	-
Risk of cetacean entanglement										n/a								n/a	-
Risk of introducing marine invasive species																			✓
Risk of introducing terrestrial invasive species																			✓
Residual social impacts and risks associated with planned activities and unplanned events																			
Presence of FPSO / MODU and vessels offshore and impact on other users																			✓
Collision between vessels and FPSO / MODU																			✓
Presence of vessels inshore and impact on other users																			✓
Collision between vessels inshore																			✓
Competition for resources – accommodation																			✓
Competition for resources – freshwater																			✓
Competition for resources – electricity																			✓

Activity	Residual Environmental Impact / Risk[2]																	Worst-case Residual Impact / Risk	Raised by stakeholder during scoping
	Physical						Biological						Social						
	Seabed (and soil)	Water quality	Regional air quality	Global atmosphere	Marine flora	Plankton	Benthos / habitats	Fish / cephalopods	Seabirds	Marine mammals	Designated sites	Biosecurity / biodiversity	Land / seascape	Human population	Other sea users	Tangible property / resources	Archaeological		
Competition for resources – air links																			✓
Competition for resources - Use of road network																			✓
Disturbance to the human population – light																			✓
Disturbance to the human population – noise																			✓
Residual risks associated with accidental events																			
Oil spill - offshore																			✓
Fuel Oil spill - inshore (MGO)																			✓
At-shore spill of liquid fuel or chemicals																			✓
Spill of chemical at onshore supply base																			✓

Very Low | **Low** | **Moderate** | **Upper Moderate** | **High** | **Beneficial**

[1] Assessment of the Impact Significance is detailed in this EIS. Initial views of key stakeholders were sought during the scoping consultation process (Chapter 6) and thereafter, the EIS was updated wherever applicable in response to comments / information received from the previous public consultation. Comments received through the formal communication and consultation process are detailed in Chapter 0.

[2] Please note that this table summarises the worst-case impact / risk assessment outcomes. While some impacts may have been identified as requiring further assessment ('F') in the ENVIID outcome tables (Chapter 9), the further assessment carried out may have concluded that there would be no impact. This is indicated where necessary in the individual assessment chapters (Chapters 10, 11 & 12). Further, while individual receptors may be highlighted within Figure 1-3 above, for some activities the actual impact assessment may refer to biodiversity as a whole in order to assess the broad and primary impact rather than to itemise each individual receptor, thereby avoiding excessive repetition.

Table 1.9: Definitions of significance categories

Significance Level		Impact / Risk Definition
Unacceptable	High	Action required to eliminate impact or risk *via* project design or to reduce it to an acceptable level *via* additional mitigation measures and controls which aim to minimise consequence where feasible, effective and reasonably practicable. If impact cannot be reduced, the project cannot proceed.
ALARP Region (Impact tolerable if demonstrably ALARP)	Upper Moderate	Impacts assessed as "Upper moderate" may not be tolerable. Action is required to eliminate or reduce impact *via* project design and / or additional mitigation measures and controls, which aim to minimise consequence where feasible, effective and reasonably practicable. Impacts remaining within this category are considered to be within the upper reaches of tolerability and are placed here owing to the combination of a precautionary approach based upon data gaps and / or a lack of further reasonable mitigation options. Where the impact is ALARP and remains within this category, regular reviews (at a minimum of annually) will be held to determine whether the impact can be further reduced based upon the availability of new data and / or new technology. If the impact cannot be further reduced, consideration may also be given to offsetting of the impact (see Section 1.8.3).
	Moderate	Impacts assessed as "Moderate" require action to identify opportunities for improvement *via* project design, additional mitigation measures and controls which aim to minimise consequence where feasible, effective and reasonably practicable. Where the impact is ALARP and remains within this category, it will be subject to regular ALARP reviews as described above.
	Low	Impacts assessed as "Low" are with the levels of existing natural environmental variability. No project-specific mitigations will be implemented over and above industry-standard measures and controls unless it is stated as a requirement in conditions to approval or Falkland Islands Legislation and / or approved policy. Nonetheless, impacts shall be regularly reviewed to ensure that suitable controls remain in place and shall be subject to continuous improvement where opportunities exist.
Broadly acceptable	Very Low	Impact barely detectable. No additional actions required beyond industry-standard measures and controls. Nonetheless, impacts shall be periodically reviewed to ensure that suitable controls remain in place and shall be subject to continuous improvement where opportunities exist.
	Beneficial	Has a positive effect.

1.9 Environmental Monitoring and Management

To answer 'Question 6' above, the following sections describe what Navitas propose with regard to mitigating, monitoring and managing the potentially significant impacts and risks associated with the Phase 1 & 2 Development throughout its lifecycle.

In support of the EIS submission, Navitas has, to date, developed:

- A Waste Management Procedure,
- Preliminary offshore, inshore and onshore Oil Pollution Emergency Plans, and
- A preliminary Environmental Monitoring and Management Plan (Chapter 15).

These documents will be used to develop more detailed project-specific management plans in the event of approval and sanction of the project, and before operations commence.

The following project-specific management plans will be in place by the time operations commence and are under development:

- EMMP (see Section 1.9.1 below),
- Bird Strike Management Plan (BSMP),
- Waste Management Plan (WMP),
- Harbour Management Plan (HMP),
- Biosecurity Management Plan (BMP),
- Traffic Management Plan (TMP),
- Oil Pollution Emergency Plan (OPEP),
- Wildlife Response Plan (WRP), and
- Iceberg Management Plan (IMP).

1.9.1 Environmental Monitoring and Management Plan

Various commitments have been made by Navitas which aim to reduce the residual environmental impacts and risks. These commitments are detailed in the impact and risk assessment chapters of the EIS (Chapters 10, 11 and 12), and will be recorded in the overarching EMMP.

These commitments are in addition to the mitigation measures built-in to the design of the facilities (Section 1.5.2 above) and the industry-standard and legislative requirements (detailed within the EIS) all of which are considered to be a 'given'.

The specific purpose of the EMMP is to detail the actions / plans required to:

- Measure and monitor the impacts (primarily the 'Severity of Effect') of the Development, thus ground-truthing the EIA,
- Check the efficacy of the project-specific mitigations in place,
- Apply adaptive management options to further reduce impacts, and
- Fill spatial / temporal data gaps, where needed, to increase the level of confidence in the impact / risk assessment outcomes.

Should the monitoring of impacts indicate that the significance of the impacts and risks predicted in the EIS are not appropriate, and / or that mitigation is not effective, a revised mitigation measure and / or monitoring regime will be required.

1.9.2 EMMP Workshop

A workshop to consider the contents of an Environmental Monitoring and Management Plan (EMMP) was held in Stanley, Falkland Islands on 23-25 April 2019. It was attended by 25 interested stakeholders, comprising FIG, POEPL, industry bodies and NGOs.

The keys aims of the EMMP workshop were to agree:

- Priorities for monitoring,
- Planned surveys, monitoring and data collection,
- Regularity of surveys, monitoring and data collection,
- Methods for surveys, monitoring and data collection,
- Reporting of data,
- Intervention thresholds and the associated adaptive management options, and
- Governance (who will oversee the work).

At the Workshop, consideration was given to environmental and social impacts from the Sea Lion Development where there was potentially a need for further certainty as to the actual impact.

The Summary EMMP tables are provided in Section 1.9.3 and Chapter 15 in the full EIS.

In the event that the Development is approved and sanctioned, the EMMP will be transferred into a live document, which will provide details on:

- Specific roles and responsibilities,
- Timelines, deadlines and 'frequency of execution' for actions identified, and
- Progress and completion for use throughout the life of the field.

1.9.3 Preliminary EMMP

While the EMMP is ultimately a live document throughout the life of the Development, Table 1.10 provides a summary of the commitments made by Navitas which have been identified during the EIA process. As described above, a full copy of the EMMP will be made available prior to commencement of the project, upon request from Navitas (sealion.enviro@navitaspet.com).

Information arising from the EMMP commitments will be reported to the EMMP group[5] *via* agreed reporting protocols. Where necessary, amendments will be discussed and the EMMP actions updated accordingly.

[5] As agreed in the EMMP workshop held in 2019. This group will be supported by an advisory forum including both non-technical stakeholders and relevant individuals with expertise in the subjects being monitored and managed.

Table 1.10: Summary of environmental monitoring and management commitments

Environmental Aspect	Key monitoring and management commitments
Environmental impacts and risks associated with planned activities and unplanned events	
Physical presence - artificial light	• Investigate use of alternative spectrum ('green') lighting, • Investigate pilot-free flare design using an automated ignition system, • Seabird and Marine Mammal Observers (SMMOs) regularly on board project vessels, and • Development and implementation of the Bird-Strike Management Plan (BSMP).
Physical presence - helicopter use	• Monitor regularity of complaints received.
Physical presence - Disturbance to seabed	• Visual (ROV) pre-drill survey before drilling. • Seabed surveys of benthos and sediment chemistry throughout the Development.
Underwater noise	• Measurement of underwater noise during construction, • Ground truthing of noise levels once into production, • Investigate low noise thrusters and propellers on any Navitas operated vessels, and • SMMOs on board specific vessels and during certain activities.
Discharge of drilling mud / fluid and cuttings	• Seabed surveys of benthos and sediment chemistry throughout the Development, • Visual (ROV) pre-drill surveying, • Post-drilling cuttings pile analysis, and • Use and discharge of muds will be monitored on board throughout drilling.
Operational discharges	• Monitoring of all chemical discharges, • Oil in produced water (not normally discharged) concentrations included in environmental Key Performance Indicators (KPIs), • Risk Based Approach to ascertain the composition of produced water, • DREAM modelling of produced water once sampled and composition known, and • Produced water re-injection uptime included in environmental KPIs.
Waste generation	• Work collaboratively with FIG on the potential for development of improved waste facilities in the Falkland Islands, • Compliance with the specific requirements of the Phase 1 & 2 Waste Management Plan, • Education of offshore and onshore personnel e.g., inclusion in all personnel inductions, • Education of all personnel on the consequences for wildlife and landscape that can result from loss of waste to sea and inclusion of this in all FPSO and MODU inductions, • Use of educational posters about the potential consequence of loss of waste, • Potential for litter pick-up drives / incentives for local beauty spots and protected sites, and

Environmental Aspect	Key monitoring and management commitments
	• Periodic reviews on whether or not impacts of waste remains ALARP.
Atmospheric emissions	• Recording and monitoring of all emissions and fuel use, and • Uptime of gas re-injection included in environmental KPIs.
Marine mammal collision	• SMMOs regularly on board project vessels, and • Education and awareness for mariners. All collisions will be reported to FIG and the IWC via: www.iwc.int\ship-strikes or shipstrikes@iwc.int.
Introduction of non-native marine species	• Specific inclusion of each vessel's ballast water management system, exchange plan, record book and biofouling management plan (BFMP) and logbook in selection and pre-mobilisation HSE audits, • Ballast water sampling programme for OCV / PSVs entering the Falklands nearshore environment, • Implementation of the Biosecurity Management Plan (BMP), • Non-native species monitoring programme, and • Settlement plates and pathways analysis in the event of any incursions.
Introduction of non-native terrestrial species	• Implementation of the Biosecurity Management Plan (BMP).
Social impacts and risks associated with planned activities and unplanned events	
Competition for resources	• Monitoring of accommodation use and socio-economic impact on the rental market, • Use of onshore water supply will be monitored at all infrastructure locations, • Energy use will be monitored onshore and at the TDF, • Any incidental usage of existing air-links will be recorded, and • Off peak power utilisation.
Disturbance to the human population	• Monitor regularity of complaints received from local residents, • Noise and light monitoring during operations to validate predictions and inform ongoing practices, • Baseline levels of noise, and light to be better established, • Routine sampling and quality tests will be undertaken on all fuel supplies as part of procurement processes and audits, and • AIS based survey of shipping traffic at the Sea Lion location.
Risks associated with accidental events	
Oil spills	• Further research into the effect of Sea Lion crude on pinniped fur, • Regular oil spill response equipment exercises to be conducted, • Efficacy tests of oil spill response equipment, • Maintain continuous and live hydrodynamic model, once into production compare modelled rates with actual flowrates, and • Survey effort to improve knowledge of species distributions of seabirds and marine mammals *via* SMMOs on project vessels.

1.10 Overall conclusion

The use of vessels, fossil fuels and onshore resources (e.g., water and electricity) is necessary to carry out any O&G operation and the generation of some waste, which cannot be re-used, recycled or converted to energy is unavoidable. Similarly, the use of third-party vessels from elsewhere in the world will always carry some risk of non-native species introduction and all oil production and export operations carry the risk of oil spill events. It is, therefore, not possible to carry out O&G operations without some degree of environmental and / or social risk and impact.

In summary following the EIA process, and the adoption of ALARP mitigations, thirteen residual impacts and risks have been assessed as significant:

- Impacts - Planned activities:
  - Artificial light offshore and inshore - **Moderate**,
  - Underwater vessel noise offshore - **Moderate**,
  - Drill cuttings discharges – **Moderate**,
  - Atmospheric emissions (climatic factors) - **Moderate**,
  - Waste management (contingent export to UK with unrecoverable waste going to UK landfill) – **Moderate**,
  - Collisions with cetaceans inshore and offshore – **Moderate**,
  - Introduction of marine invasive species - **Moderate**,
  - Introduction of terrestrial invasive species – **Upper Moderate**,
  - Competition for freshwater resources – **Upper Moderate**,
  - Competition for energy resources – **Upper Moderate**,
  - Competition for use of roads – **Moderate**, and
  - Disturbance to the human population from light – **Moderate**.
- Indirect impacts beyond Navitas' ability to influence:
  - Atmospheric emissions associated with the combustion of sold product – Upper Moderate.
- Risks - Unplanned / accidental events:
  - Oil spill offshore, inshore and at-shore - Moderate.

Navitas believe that:

- All impacts and risks associated with The Sea Lion Field Northern Area Development, Phase 1 & 2 have been identified and robustly assessed,
- Impacts and risks which are ALARP and are considered to be of low significance are sufficiently controlled, and
- Impacts and risks that are currently ALARP but remain significant will be further reduced wherever practicable throughout the life of the Development.

Navitas will continue to do all that is reasonably practicable with regard to monitoring and management to minimise environmental impacts / risks during the Phase 1 & 2 Development.

All impact and risk assessments will be periodically reviewed to ensure that the controls remain in place and that activities leading to potentially significant impacts and risks are subject to continuous improvement where opportunities exist.

1.11 Formal stakeholder consultation

1.11.1 Representations by stakeholders

Following review by FIG DMR, and confirmation by the Executive Council that the EIS complied with the Schedule 4 of the FIG Offshore Minerals Ordinance, the EIS was formally submitted and underwent formal consultation in July - August 2024.

1.11.2 Responses by Navitas

Following the 42-day consultation, all material representations were provided to Navitas by DMR and recorded within this EIS (Chapter 0). This chapter also contains Navitas' responses and, where necessary, indicates what changes have been made to this post-consultation EIA / EIS in response to the representations made.

2.5.1 Structure of the EIS impact and risk assessment chapters 87

2.1 Introduction

Navitas Petroleum Development and Production Ltd (Navitas) is proposing to develop the Sea Lion field ('Sea Lion') with a view to the long-term, responsible and sustainable production of hydrocarbons. Therefore, it is necessary to conduct an Environmental Impact Assessment (EIA) and to present the outcomes in an Environmental Impact Statement (EIS).

The EIA and the development of this EIS were carried out in compliance with the:

- Falkland Islands Government (FIG) Directorate of Policy, Economy and Corporate Services (Formally the FIG Environmental Planning Department (EPD)) Hydrocarbons Environmental Impact Assessment Guidance Note (FIG, 2016e), and
- Navitas Operating Management System (SEL-REG-OPM-PLN-00001-00).

The purpose of this introduction is to:

- Provide an overview of the historical context in which this EIS has been developed,
- Provide a brief overview of:
  - The Sea Lion Northern Development Area, Phase 1 & 2 Field Development,
  - The current areas of uncertainty within The Sea Lion Northern Development Area, Phase 1 & 2, and
  - The potential to further develop the basin in the future.
- Describe the purpose of the EIA and structure of this EIS.

2.1.1 Historical context

The North Falklands Basin (NFB) licences were previously held by Premier Oil Exploration and Production Limited (POEPL) working with their Joint Venture partner Rockhopper Exploration. Exploration drilling campaigns were carried out by Rockhopper in 2010-11 and by Premier in 2015-16. Plans for the development of the Sea Lion project, with a view to production, commenced in 2012. An EIS for POEPL's plan for the Sea Lion Development was submitted and formally accepted in 2020 (Premier, 2020). However, in 2020 the parent company of POEPL (Premier Oil) and Chrysaor merged to form Harbour Energy Plc. Harbour Energy Plc. then sold POEPL to Navitas Petroleum in September 2022. At this time, POEPL was renamed Navitas Petroleum Development and Production Limited (hereafter referred to as Navitas). All intellectual property previously owned by POEPL in relation to the Sea Lion Project is now owned by Navitas. As a result, Navitas has access to all preparatory processes and documentation developed under POEPL, all reports and surveys commissioned in support of the Sea Lion Development, as well as all 'lessons learned' throughout the process.

This is of particular importance in the context of:

- The Consideration of Alternatives (Chapter 4) which describes the evolution of the Development, the consideration of all technical options available and ultimately the rationale for the rejection of some options and the selection of others,
- The Scoping Consultation process (Chapter 6) which describes the various consultations carried out as the Development evolved over time,
- The Environmental Impact Identification (ENVIID) process (Chapter 9) which describes the outcome of numerous multidisciplinary ENVIID workshops, and
- Reference to POEPL commissioned surveys and reports.

Since Navitas acquired the NFB licences, the proposed Sea Lion Development has further evolved and has been optimised in terms of:

- The number and layout of the wells,
- The use of Open Hole Gravel Pack (OHGP) completions in the production wells (which do not require explosive perforation guns),
- The proposed daily production figures and hence the size and efficiency of the Floating Production, Storage and Offload (FPSO) vessel such that the forecast atmospheric emissions per barrel are reduced, and
- An extension to the proposed Field Life.

As a result, it is necessary to conduct another EIA and submit a revised EIS to FIG.

In order to avoid confusion regarding reference to work carried out under POEPL's operatorship, and that carried out since by Navitas, which now has ownership of all previous data, the relevant chapters will be managed as follows:

- The Consideration of Alternatives (Chapter 4):
  - An overview of the historical option selection process, as carried out under POEPL, is provided in order to retain understanding of the overall context. Detail on additional variations within the options, as considered by Navitas, is also provided.
- The Scoping Consultation process (Chapter 6):
  - Detail on all previous scoping consultations carried out under POEPL have been retained within the chapter as many of the representations made by the public and other stakeholders (and the relevant outcomes of these discussions) are still relevant to the current project. In order to avoid confusion to the readership (who may have attended the previous scoping sessions), the description of the earlier scoping consultations will remain the same and be referred to as historical consultations carried out under POEPL operatorship. An additional section has been included to describe the scoping process carried out by Navitas in December 2023.
- Reference to POEPL commissioned surveys and reports:
  - Where a given report, survey or review was carried out prior to Navitas' acquisition of POEPL, it is important to recognise that the information is still held within the Company and Navitas now owns the intellectual property rights. To ensure legal validity, sentences will state that 'POEPL (now Navitas) commissioned xyz etc.' but reference to the associated reports will remain as, for example, 'Premier 2016a'. Where necessary, details are provided in a footnote.

2.2 Overview of the Sea Lion Field Development

2.2.1 The Falkland Islands

The Falkland Islands are a UK Overseas Territory located on the edge of the Patagonian Shelf in the South Atlantic Ocean, approximately 480 km from the South American mainland. The Islands have a total land area of 12,173 km^2 (East Falkland approximately 6,700 km^2, West Falkland approximately 5,300 km^2, plus over 700 smaller islands) and a permanent population of approximately 3,000.

2.2.2 The Sea Lion Field

The Sea Lion Field, as determined by FIG in 2024, lies in water depths of approximately 450 m and is located in Block 14/10 in hydrocarbon license areas PL032, PL033, PL003, PL004 and PL005, approximately 220 km north of the Falkland Islands (Figure 2-1). It is the first commercially viable hydrocarbon discovery in the NFB and was discovered by Rockhopper Exploration PLC (Rockhopper) in 2010.

In October 2012, Premier Oil plc farmed in for 60 % of Rockhopper's licence interests in the Falkland Islands which included the Sea Lion Development and incorporated Premier Oil Exploration and Production Limited (POEPL). POEPL successfully submitted an EIS which was accepted in 2020 (Section 2.1.1 above). However, prior to consideration of field development approval, production consent and commencement of the Development, Navitas acquired POEPL in 2022. As such, Navitas is now Operator of licences PL032, PL033 and PL004 (a, b and c) in which the Greater Sea Lion Field is located.

Navitas' aim is to produce Oil and Gas (O&G) from the Sea Lion Field in a phased development and this EIS describes the EIA for the Sea Lion Northern Development Area Phases 1 & 2 (hereafter referred to as the Phase 1 & 2 Development throughout the document).

The Phase 1 & 2 Development is described in more detail in the Field Development Plan (SLN-GEN-PMA-PLN-00001-10).

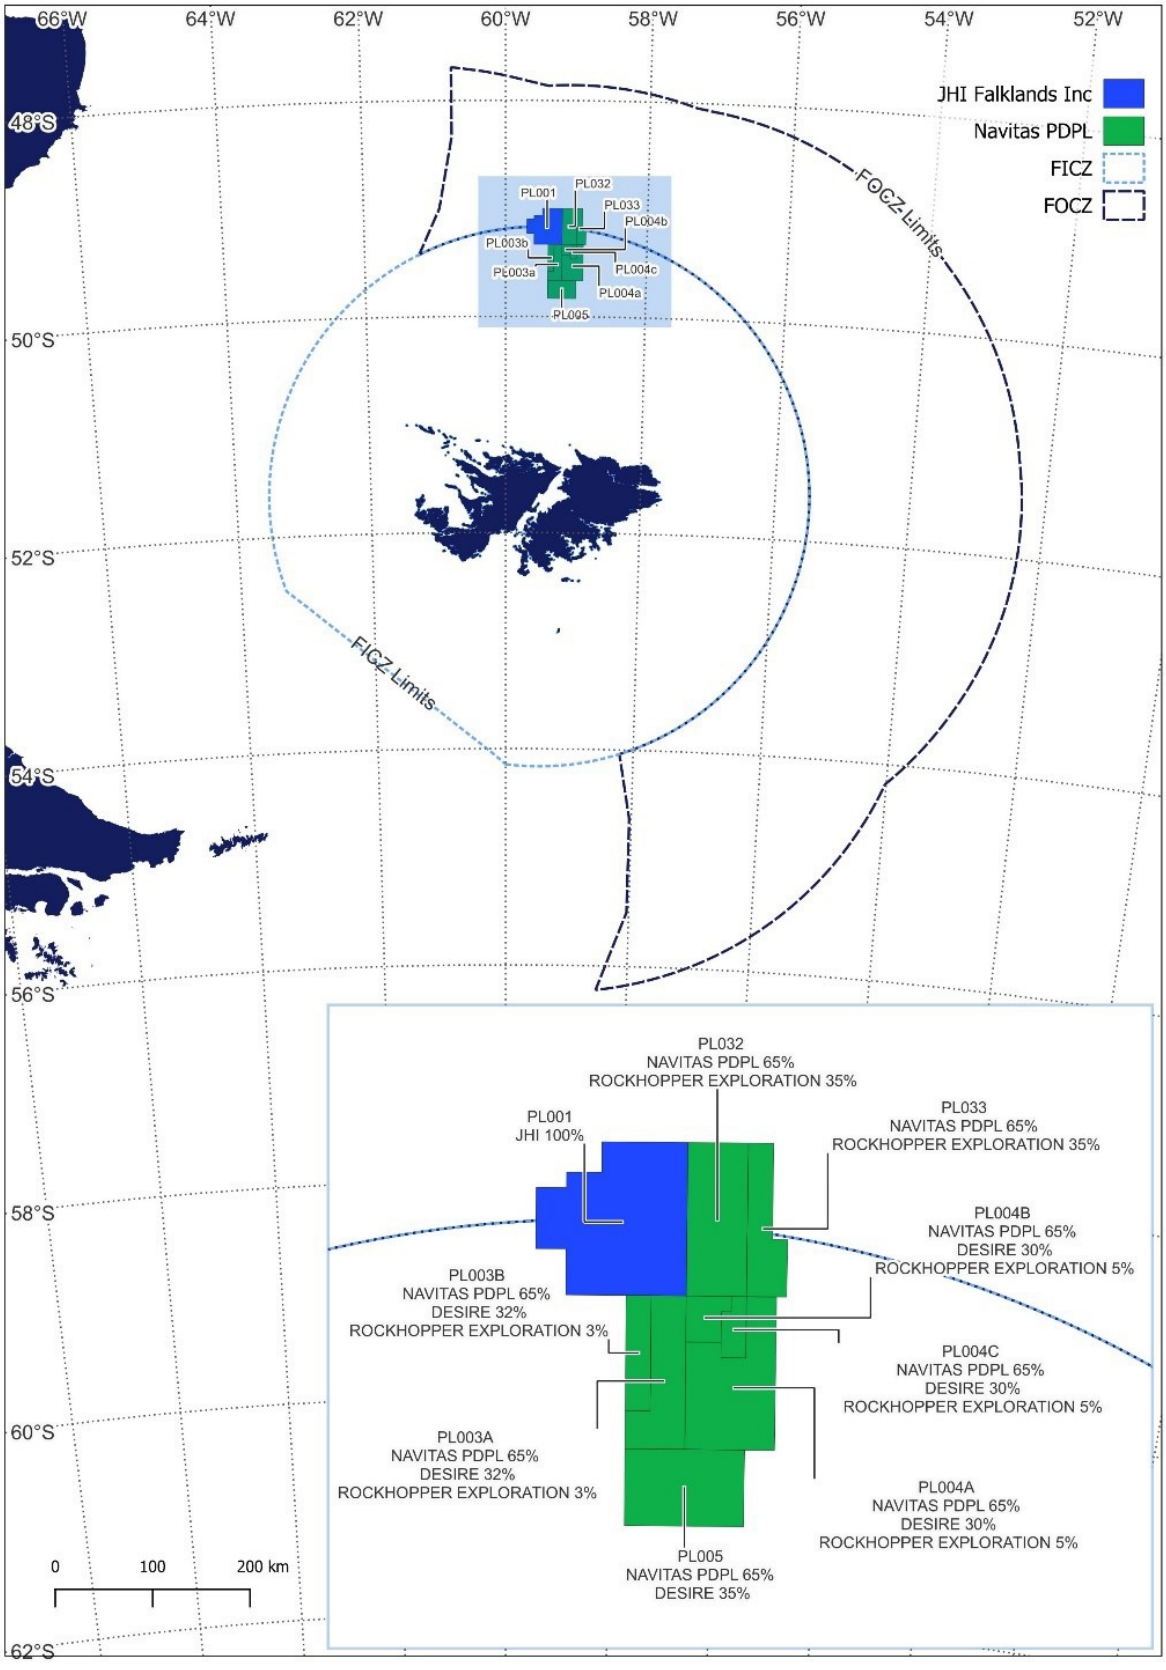

Figure 2-1: Sea Lion Field and Licence Block Locations

2.2.3 The Sea Lion Field Phase 1 & 2 - Development overview

The proposed Phase 1 & 2 Development is located in licence blocks PL032 and PL004. A Field Life of 30 years has been projected and it is estimated that approximately 310.5 million standard barrels (MMstb) of oil can be recovered during Phases 1 & 2.

2.2.3.1 Drilling (Stages 1, 2a & 2b)

The proposed drilling of these wells will occur as follows:

- Stage 1 – drilling of the first batch of the Phase 1 wells (eight wells (potentially nine if it is necessary to drill the contingency GI well)) up to First-Oil,
- Stage 2a – drilling of the second batch of the Phase 1 wells (three wells) while the FPSO simultaneously produces from the first batch (the first period of Simultaneous Operations (SIMOPS) (Section 2.2.3.4)),
- (Interim Stage 3 – steady state production with no drilling),
- Stage 2 b – drilling of the Phase 2 wells (12 wells) with ongoing production (the second stage of SIMOPS), and
- Stage 3 continued steady state production for Field Life (no drilling).

If approved by the Falkland Islands Government (FIG), the Phase 1 & 2 Development will comprise of up to 23 operational subsea wells. The Development is expected to consist of 16 Oil Production (OP) wells, six Water Injection (WI) wells and a single remote Gas Injection (GI) well. These 23 wells will be drilled across six Drill Centres to the north, east and south of the FPSO. There is a contingency to drill an additional GI well should the primary GI location prove unsuitable, and also for two redrills such that while there will only be 23 operational wells, the project may include up to 26 penetrations. To assume the environmental worst-case, this EIS assesses the impact of drilling the maximum number (26) of wells.

The single remote West Flank GI well is the first well in the drilling programme. This well will confirm the presence or absence of a gas cap in the SL20 reservoir and therefore establish whether or not the location is suited for gas disposal. Should this well confirm that the gas cap is absent or significantly smaller than expected, the GI well will be drilled at a contingent location, targeting the known gas cap in the Casper reservoir north of the PL032 / PL004 licence boundary.

All wells will be drilled using a Mobile Offshore Drilling Unit (MODU) located within a 500 m exclusion zone. The drilling operation will be supported by two Anchor Handling Supply Vessels (AHTS), as supply vessels) and an Emergency Response and Rescue Vessel (ERRV). The vessels will also have surveillance and response equipment onboard for monitoring and responding to oil spills should they occur.

The wells will be completed using an Open Hole Gravel Pack (OHGP) which will minimise debris within the wellbore. Therefore, the base-case is to flow the wells back to the FPSO, rather than clean them-up to the MODU beforehand. However, there is a contingency for three of the OP wells and the GI well to be flowed back, tested, to the MODU, which means four wells could be flared offshore for short periods of *c.* 1 day each. It is anticipated that drilling will start approximately 20 months after project sanction.

2.2.3.2 Installation (Stages 1, 2a & 2b)

Whilst drilling is ongoing, installation of subsea facilities will be undertaken by installation vessels, prior to the arrival and 'Hook-Up and Commissioning' (HUC) of the FPSO vessel.

During the installation phase, up to four Large Transport Vessels (LTVs) will be used as floating storage vessels to support the subsea installation operations. The LTVs will be anchored in Berkeley Sound and

each LTV will require its own individual 500 m exclusion zone. At any one time, there will be a maximum of two LTVs present in Berkeley Sound for short periods up to a total of 13 months. Navitas will work with the Falkland Islands Maritime Authority (FIMA) to identify optimum locations within Berkeley Sound that will cause the least disruption to other users during periods of high marine traffic in the Sound.

The FPSO will be anchored to the seabed at the Sea Lion location and will be surrounded by a 1,275 m exclusion zone, which is effectively 500 m beyond the installation extremities (including the hose and tanker during crude oil offload). The FPSO will be located approximately 2 km from the main Production Drill Centre (DC), 3.5km from the Water Injection DC, 5.3 km from the Gas Injection DC, 3.5 km from the Southern Production DC, 2.7 km from the East Water Injection DC and approximately 4.5 km from the Southern Water Injection DC. The contingent Gas Injection well is approximately 7.9 km from FPSO.

The DC's will comprise a number of subsea manifolds (for example, water injection or production) depending upon location (Section 5.5.3). An array of subsea pipelines and risers will be installed to connect the wells at the seabed to the FPSO. An illustrative layout of the installation is provided in Figure 2-2.

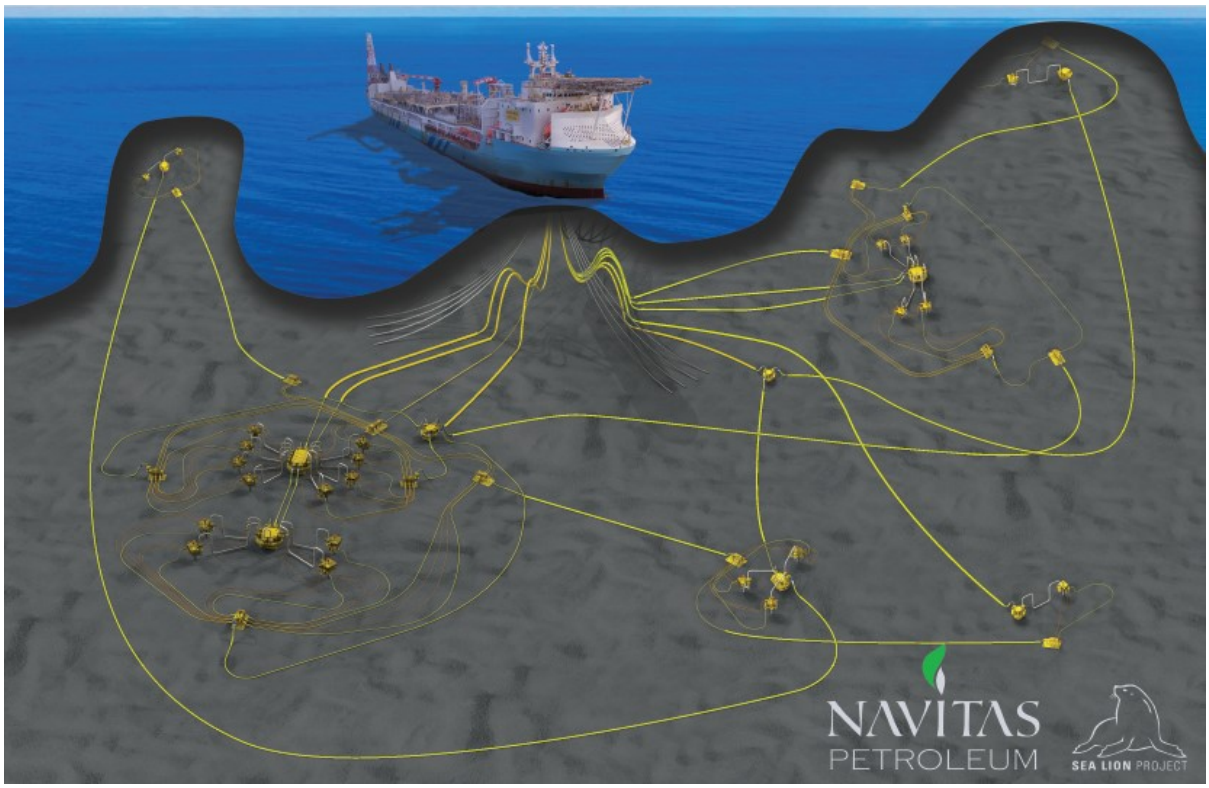

Figure 2-2: The Sea Lion Field Northern Development Area Phase 1 & 2 field configuration (illustrative only)

2.2.3.3 Production (Stages 2a, 2b and 3)

Following HUC of the FPSO, hydrocarbons will be introduced onto the vessel. HUC refers to the process by which the FPSO is connected to the subsea wells, *via* the manifolds and the pipelines, umbilicals and risers. During the commissioning process, the gas injection system will also need to be commissioned. This will potentially involve flaring produced gas for up to 30 days.

Once operational, the production wells will produce reservoir fluids to the FPSO. Oil production and processing carried out onboard the FPSO will stabilise the oil prior to its export. The produced fluids will consist of oil, water and gas which will be separated and treated on the FPSO. Once stabilised the oil will be transferred to storage tanks within the hull structure for subsequent offloading and export to market. Gas will be used for fuel, heat and power on the FPSO and for 'gas lift' in the oil production wells to enhance oil flow by reducing the density of the fluids in the well, thereby enabling a higher production rate from the reservoir. During normal operations, any excess gas will be re-injected into the GI well. Produced water will be cleaned and, during normal operations, will be re-injected *via* the WI wells, in combination with seawater (which has been treated with, for example, biocides and oxygen scavengers to ensure it doesn't foul the system), again to enhance / optimise oil recovery.

It is anticipated that 'First-Oil' will occur approximately 33 months after sanction.

2.2.3.4 Simultaneous Operations (SIMOPS) (Stages 2a & 2b)

Periods when both the MODU and the FPSO are operational in-field is referred to as Simultaneous Operations (SIMOPS). SIMOPS will occur over two periods of time.

After First-Oil, the MODU continues to drill the remaining Phase 1 wells (in Stage 2a) as the FPSO begins production. After this there will follow a period of steady state production (Stage 3) while performance is evaluated. Following this, the second period of SIMOPS will occur in Stage 2b when the Phase 2 wells are drilled. Once all the wells have been drilled, the MODU will leave, and in steady state production, only the FPSO, and its support vessels, will remain.

2.2.3.5 Oil export

The project oil export route involves the direct offtake of oil from the FPSO to a purchaser's Conventional Trading Tanker (CTT) at the Sea Lion location and from there the crude will be exported to market. The direct offtake process will be supported by an Offshore Support Vessel (OSV, i.e., a pull-back tug), in addition to the presence of the ERRV, which is always on standby.

Oil offtakes at peak production rates are expected approximately every 7-10 days. As the rate of oil production reduces over time, it is expected that the oil export operation will occur less frequently and/or smaller parcel offtakes will occur over time.

The direct offtake operation of crude to the CTT is described below.

- The CTT will arrive in Falkland Islands' waters and, dependent on metocean conditions / final risk assessments / approvals, a berthing crew will be transferred to the CTT either by pilot's boarding ladder or helicopter, at a safe distance from the FPSO,
- The CTT will rendezvous with the hold back tug (OSV), which will connect to the stern of the CTT,
- The Multi-Role Support Vessel (MRSV), (acting as an Emergency Response and Rescue Vessel (ERRV)) will be on standby duty in-field throughout the operation,
- The OSV will apply light power to control the heading of the CTT through approach,
- The CTT and connected OSV will approach the stern of the FPSO and connect to the FPSO by a taught hawser. The hose will be unreeled from the FPSO and transferred to the CTT where it will make a connection at the midship manifold and the transfer will begin,
- The OSV will remain attached during connection to the FPSO as well as during pumping, disconnect and departure,
- Once the transfer is complete, the CTT and OSV will disconnect from the FPSO and move away,

- At a safe distance, the OSV will detach and the berthing crew will disembark, and
- The CTT will proceed to deliver the crude to market without entering inshore waters.

2.2.3.6 Logistical Support

The drilling, installation, production and oil export operations will all be supported by an onshore supply base, liquid mud plant, and a Temporary Dock Facility (TDF) located to the east of Stanley. The offshore crew will fly to the Islands on fixed wing charter flights and will be transported from Mount Pleasant to Stanley by road and helicoptered to the Sea Lion Field.

2.2.3.7 Decommissioning

At the end of Field Life, expected to be 30 years after First-Oil, the FPSO and all associated subsea infrastructure and pipelines, will be decommissioned and removed from the NFB in accordance with requirements at that time. Decommissioning will be subject to a separate EIA, submitted at a time to be agreed with FIG (most commonly a few years prior to the cessation of production).

2.2.4 Areas of uncertainty

At the time of conducting the EIA, the following areas have not yet been fully defined:

- Final selection of the MODU to be used,
- Final selection of offshore drilling chemicals,
- The detailed drilling schedule,
- The source/s of equipment and materials e.g., Europe, Asia etc.,
- The specific vessels to be used for transportation, installation and support,
- Final selection of offshore production and utility chemicals,
- The frequency of dedicated charter flights throughout the Field Life,
- The frequency and source of *ad hoc* freighter vessels,
- Fine details on the accommodation arrangements on the Islands,
- Precise infrastructure requirements for power, water and roads, and
- Final selection of oil spill response equipment.

These project details will be finalised following project sanction and contract award. Where project details are subject to change, the 'worst-case' options have been assumed for the purposes of the EIA. Where the different options may impose different impacts and / or risks, either both options, or the worst-case, were assessed.

Therefore, as per the Hydrocarbons EIA Guidance Note (FIG, 2016e), this EIS includes a 'wider range / level of activity to accommodate areas of uncertainty'.

Importantly however, further changes may also occur before commissioning of the field. If post-sanction changes occur, discussions will be held with FIG to determine the most appropriate way to manage and assess the change.

2.2.5 Subsequent phases of development

The potential for subsequent phases of development to produce the remainder of the reserves in Licence Blocks PL032 and PL004 is currently under evaluation. The outcome of this evaluation will depend upon learnings from the Phase 1 & 2 Development, knowledge gained from the 2015 exploration campaign and the forecast for global oil demand and associated prices.

Subsequent phases are, as yet, undefined and are not within the scope of this EIA which assesses the proposal to develop the Sea Lion Field Northern Development Area, Phase 1 & 2 only.

2.3 EIA process overview

Numerous preparatory and data gathering steps are involved in conducting an EIA. These steps aim to:

- Understand the context within which the EIA is being carried out by:
  - Identifying the legal and regulatory context within which the proposed project is to occur (Section 3.1), and
  - Understanding Navitas' Operating Management System (SEL-REG-OPM-PLN-00001-00) which supports the proposed Development (Section 3.2).
- Ensure consideration has been given to alternative approaches to the proposed Development (Chapter 4),
- Understand the proposed Development and all the activities that may interact with the environment (Chapter 5),
- Identify any concerns that stakeholders may have regarding the proposed Development (Chapter 6),
- Understand the environment in which the proposed Development is to occur in order to identify key environmental and social sensitivities (Chapter 7),
- Develop a methodology for assessing the environmental and social impacts of planned activities and the risks associated with unplanned and accidental events (Chapter 8),
- Conduct an ENVironmental Impact IDentification (ENVIID) workshop to specifically identity the impacts and risks associated with the project activities that warrant further investigation, and those that can be 'scoped out' following preliminary assessment (Chapter 9),
- Assess the significance of all environmental and social impacts and risks that were not scoped out, taking account of the base-case (built-in) mitigations as well as the industry-standard, legal and Navitas OMS requirements (Chapters 10, 11 and 12),
- Identify the need for additional project-specific mitigation measures that may be reasonably practicable to reduce any *significant* impacts or risks to 'As Low As is Reasonably Practicable' (ALARP) (Chapters 10 and 11),
- Assess the significance of the residual impacts and risks which take account of the project-specific mitigation (Chapters 10 and 11),
- Identify the level of confidence in the assessments above to inform monitoring and measuring requirements (Chapters 10 and 11),
- Develop a project-specific Environmental Monitoring and Management Plan (EMMP) (Chapter 15) to list all the commitments made by Navitas to reduce impacts and risks, which have been agreed in a workshop and will be reviewed by key stakeholders, and
- Address any concerns raised by stakeholders during the post-submission statutory consultation process (Chapter 0).

2.4 Scope of the EIA

The environmental and societal impacts and risks assessed within this EIS are those associated with:

- Development drilling,
- Transportation and installation of all production facilities,
- Hook-up and commissioning of all production facilities,
- Production of O&G,
- Offloading of crude from the FPSO *via* direct offtake to the CTT,

- The presence of LTVs in Berkeley Sound,
- Associated supporting logistics and the use of onshore facilities e.g., the onshore supply base, and the 'at-shore' facilities e.g., the TDF and other port facilities, and
- Combustion of sold product.

The above are assessed to determine the impacts and risks associated with normal and planned operations as well as unplanned and emergency situations.

Following consultation with FIG (Chapter 6), and in line with FIG EIA Guidance (FIG, 2016e), areas that fall outwith the scope of this EIS include:

- Construction (as opposed to use) of the short-term and long-term onshore supply base and any upgrades that may be required to the TDF:
  - These will be covered by planning applications and separate EIAs as necessary.
- Decommissioning of the short-term onshore infrastructure associated with development drilling,
- Socio-economic impacts of the Development (e.g., revenue, employment etc.):
  - An independent socio-economic assessment of O&G development in the Falkland Islands was previously commissioned by Rockhopper Exploration (Plexus Energy, 2012).
  - FIG commissioned a Socio-Economic Impact Assessment (SIA) to identify potential impacts and any mitigation measures required to minimise any negative impacts that could be associated with O&G development (Regeneris, 2013).
  - An additional separate SIA, building on, and updating, the previous work undertaken for FIG and Rockhopper by Regeneris (2013 & 2015) and Plexus Energy (2012), was completed by POEPL (Maplecroft, 2019).
  - Navitas has commissioned an update to this SIA which will be completed in Q1 2025.
- Offshore decommissioning impacts:
  - These will be covered in a decommissioning-specific EIA prior to the Cessation of Production (CoP) and in support of the decommissioning programme (as agreed in discussion with FIG, and / or in accordance with extant FIG regulation in force at the time, or the approach taken in the UK with regard to developments on the UK continental Shelf (UKCS) and the BEIS (now DESNZ) Decommissioning Guidelines (BEIS, 2018)).

2.5 Purpose and structure of this Environmental Impact Statement

The EIA must be carried out in compliance with the requirements of the:

- Offshore Minerals Ordinance 1994 (and all amendments).

The EIS summarises the outcomes of the EIA and enables informed decisions to be made on whether or not the proposed Development may proceed based on the acceptability, tolerability or otherwise, of the impacts and risks.

Specifically, the EIS informs:

- The Navitas project development and design process; and
- The FIG review process.

Should the FIG Department of Mineral Resources (DMR) indicate to FIG Executive Council (ExCo) that a valid EIS has been submitted which is compliant with Schedule 4 of the Minerals Ordinance, a 42-day consultation period will follow. This will comprise formal consultation with FIG, its expected consultees

and the general public. Prior to any decision being made by FIG, Navitas will respond to comments received from the 42-day consultation by updating the EIS and/or submitting additional information, if required.

2.5.1 Structure of the EIS impact and risk assessment chapters

Within this EIS, each impact and risk assessment chapter (Chapters 10, 11 and 12) follows a consistent structure as summarised in Table 2.1.

Note that many of the Phase 1 & 2 Development activities, e.g., the use of vessels, may have numerous impacts or associated risks and thus need to be described in more than one chapter. Table 2.2 provides an overview of which activities are included in each assessment chapter.

Table 2.1: Impact and risk assessment chapter structure

Impact / risk chapter sub-headers	Description of content
Introduction	This section describes the purpose of the chapter and gives a brief account of the subject-specific legislation and associated compliance requirements.
Sources of impact and / or risk	This section lists Phase 1 & 2 Development activities that may result in the impact and / or risk and provides further detail where necessary and / or reference to the relevant section within the Development Description (Chapter 5).
Potential receptors	This section lists the environmental and social receptors that may be affected by the impact or risk (e.g., water quality, seabirds, human population etc.). Reference is made to the relevant section in the Environmental and Social Baseline (Chapter 7) for detail on the receptors, and a very brief summary of why these are considered to be receptors of the impact and / or risk in question is provided.
Characterising and quantifying the impacts and / or risks	This section provides the specific data necessary to inform the impact and / or risk assessment. Data is drawn from: subject-specific literature reviews to understand the nature of the impact; the Environmental and Social Baseline (Chapter 7) to understand what may be impacted and how sensitive it may be; and the Development Description (Chapter 5) to quantify the relevant project outputs (e.g., emissions, seabed footprint), thus informing the potential severity of the effect. The content within this section varies and is structured as appropriate to the specific impact / risk. **Note:** the estimation of the Phase 1 & 2 Development outputs (e.g., the amount of CO_2 emitted, the area of footprint on the seabed etc.,) takes account of the mitigations which are built-in to the project basis of design which are described in the Development Description (Section 5.14).
Industry-standard mitigation	This section lists the industry-standard mitigation measures that are factored into the initial impact and / or risk assessment and any requirements within the Navitas OMS.
Impact and / or risk assessment	This section draws on all the information above to assess the significance of the impacts and / or risks using the 'Sensitivity of Receptor', 'Severity of Effect' and 'Likelihood of Occurrence' (where applicable) guidelines provided in the EIA Methodology (Chapter 8). This initial assessment takes account of the industry-standard mitigation and a precautionary approach is taken. **Note:** this section aims to provide a concise assessment and refers back to previous sections within the chapter to support the statements made and the rationale behind the evaluation of impact / risk significance.
Project-specific mitigation	This section describes project-specific mitigation measures that may be deployed where necessary, and reasonably practicable, to reduce significant impacts and risks to ALARP.

Impact / risk chapter sub-headers	Description of content
Residual impacts and / or risks	This section describes the residual significance of the impact and / or risk following re-assessment with any project-specific mitigation measures taken into account.
Cumulative impacts	This section assesses the Phase 1 & 2 Development impacts in combination with inputs from other sources as per the EIA Methodology (Chapter 8).
Confidence	This section indicates the level of confidence in the overall assessment, taking account of any data gaps etc.
Offsetting	Where impacts are significant, this section refers back to Section 8.11 and the overarching section on the Carbon and Biodiversity Offsetting Fund.
Findings summary	This section summarises the complete impact and / or risk assessment chapter in a standardised table format.

Table 2.2: Summary of the assessment chapters and which project activities are included within each

Assessment chapters			Drilling operations	Installation	FPSO HUC	SIMOPS	Production	Offloading from FPSO to CTT	LTVs in Berkeley Sound	Use of the onshore supply base and TDF	Fixed-wing flights	Helicopter use	General vessel use	Onshore activity	Decom-missioning
Environmental	10.1	Artificial light	✓	✓	✓	✓	✓	✓	✓				✓		n/a
	10.2	Disturbance to wildlife from helicopter use										✓			n/a

3.1 Regulatory overview and legislation

This section provides a brief overview of the system of governance within the Falkland Islands and current legislation that governs Oil and Gas (O&G) activities in the Islands. The information presented is based upon a review carried out by Genesis (2013), updated in 2023 by SFL.

3.1.1 Falkland Islands territorial status

The Falkland Islands is one of 14 United Kingdom Overseas Territories (UKOT), which are managed under the British Overseas Territories Act 2002.

3.1.2 Falkland Islands governance

The Islands are self-governed although supreme authority is vested in His Majesty the King who is represented in the Falkland Islands by Her Excellency the Governor. Defence and foreign affairs remain the responsibility of the British Government.

The Constitution of the Falkland Islands, the present version having been in place since 2008, lays out the rights and freedoms of the individual as well as setting out the ways in which the Falklands are governed and how its laws are made.

The Falkland Islands' system of government follows the Westminster Model and is divided into:

- Elected Members of the Legislative Assembly (MLA) and associated Legislative and Executive Councils:
  - Eight MLAs are elected as independents by the Falkland Islands' Community to serve a four-year term.
- *Ex officio* members from the Falkland Islands Government (FIG), British Forces and the Governor:
  - The Governor is appointed by the Foreign, Commonwealth and Development Office (FCDO).

Legislative Assembly meetings are held in public (FIG, 2023a) and are chaired by a Speaker chosen from the community by Assembly Members. The meetings are attended by the MLAs and two *ex officio* members, namely the Chief Executive and the Financial Secretary. The Attorney General and the Commander of the British Forces South Atlantic Islands (CBFSAI) are also entitled to attend.

The Legislative Assembly is empowered to pass legislation for the peace, order and good governance of the Falkland Islands, subject to the approval of His Majesty the King and acting through his Secretary of State for Foreign Affairs.

Each year, the MLAs elect three of their number to the policy-making body of the Government known as the Executive Council (ExCo) which is chaired by the Governor. Membership includes the same *ex officio* members who sit on the Legislative Assembly. In addition, the Attorney General and CBFSAI may attend and speak on any matter although only the three elected MLAs are able to vote on ExCo (FIG, 2023a).

3.1.3 Governing bodies for O&G activities in the Falkland Islands

The Falkland Islands offshore hydrocarbons industry is regulated by the FIG's Department of Mineral Resources (DMR). The Department obtains specialist advice from a number of UK Government organisations, such as: the Health & Safety Executive (HSE), the Offshore Petroleum Regulator for Environment and Decommissioning (OPRED), and the British Geological Survey (BGS). However, the DMR has limited executive approval powers and makes recommendations for approval to ExCo. Ultimate approval for a number of Mineral Resources-related matters, such as the granting of licences and changes of licence ownership, is retained by the UK Secretary of State for the FCDO.

The Planning and Building Committee is the authority responsible for statutory planning determinations within the Falklands. Any aspects of a hydrocarbon development occurring within the 12 nm limit or onshore will fall under statutory planning regulations.

Ultimate power in mineral regulatory matters lies with the Governor. The Governor consults with the ExCo, which in turn is advised by the DMR, the Policy Unit[6] and Planning and Building Services[7]. The DMR is responsible for leading on the assessment of the EIS and ultimately makes a recommendation to ExCo as to whether the EIS meets the requirements of the Offshore Minerals Ordinance 1994 (as amended) (Section 3.1.7.3.1).

3.1.4 The Environmental Charter

The Environmental Charter is a joint agreement between FIG and the UK Government and was signed in 2001 (FIG, 2023b). The Charter lists ten guiding principles and the UK and Falkland Islands Governments have each made eleven commitments therein, all intended to ensure environmental management within the Islands.

One of the UK commitments within the Environmental Charter is to 'assist the Falkland Islands in reviewing and updating legislation'. Environmental legislation that applies to O&G activities within the Falkland Islands is based on that for the United Kingdom Continental Shelf (UKCS). However, given that the O&G industry within the Falklands is in its infancy, guiding legislation specific to the Falklands is currently limited. FIG are undertaking a review to ensure the development of appropriate offshore environmental legislation (Section 3.1.6.1). While this process is underway however, and in the absence of specific Falklands legislation, the preparation of required consents shall be based on UK guidance.

3.1.5 Falkland Islands Environmental Strategy 2021-2040

The Falkland Islands Environmental Strategy was published in 2021 to address a broad range of environmental issues and is to be used as a vision to guide priorities, policy creation and work for the Falkland Islands in the long-term. The process included across-government consultation as well as public engagement. With specific reference to the O&G industry, the strategy aims to:

- Conduct the extraction of non-renewable resources, including hydrocarbon development, in a way that values and conserves our unique biodiversity and ecology, supported by effective regulation, and
- Promote and encourage investment in the Falkland Islands Environment Trust and support projects funded by that Trust (see Section 3.1.7.3.17) (FIG, 2021a).

3.1.6 Falklands Islands policies and codes of practice

3.1.6.1 Offshore environmental policy review (2016)

As part of its 'oil readiness planning', the FIG has reviewed its current legislative structure in respect of environmental regulation of offshore hydrocarbon activities and several crucial gaps have been identified. Consequently, a consultation was held on proposed offshore environmental legislation. This proposed legislation should provide the Falkland Islands with a modern regulatory regime, granting regulatory powers that are appropriate to the Falkland Islands' constitutional obligations. Further, the proposed legislation will ensure that environmental impacts and risks are appropriately regulated given the logistical and operational challenges inherent in operating in the South Atlantic. Therefore,

[6] Now known as the Policy Department which sits within the new Directorate of Policy, Economy and Corporate Services (as at 2023).
[7] Now part of the Department of Development and Commercial Services.

it is likely that offshore environmental legislation will be updated prior to the commencement of in-field work on the Phase 1 & 2 Development.

3.1.6.2 Hydrocarbons Development Policy Statement 2013

In order to plan for the future development of the hydrocarbons industry in the Falklands, a Policy Statement was prepared to provide clarity on the purpose of hydrocarbon development and how the implications of developments will be managed. In 2013, the Falkland Islands Hydrocarbon Development Policy Statement (158/13) was released with the following recommendations:

- Hydrocarbons in Falkland Islands waters belong to the people of the Falkland Islands and their exploitation must be to the benefit of the people of the Falkland Islands, both those of today and future generations,
- The FIG will maintain constant supervision and control over all hydrocarbon activities within the Falkland Islands Designated Area,
- Petroleum discoveries must be efficiently managed and exploited to maximise economic recovery and to ensure the development of a long-term industry presence that will benefit the Islands for decades to come,
- Development of the hydrocarbons industry must ensure the protection and conservation of the Falkland Islands environment and biodiversity,
- Development of the hydrocarbons industry must take into consideration existing commercial activity and promote the development of local business capacity,
- The exploitation of finite natural resources will be used to develop lasting benefits to society across the whole of the Falkland Islands,
- Transparency and accountability must be present throughout the hydrocarbon development process from all parties involved, and
- The Falkland Islands will only consider onshore hydrocarbon facilities if they are considered to be in the best interests of the Falkland Islands, and can be proven to satisfy all of the above policy goals.

3.1.6.3 Local Content Code of Practice for Procurement by O&G Companies and their Subcontractors Operating in the Falkland Islands

The Local Content Code of Practice was developed by FIG in 2014 (FIG, 2018b) and sets out a series of principles, strategies and practices aimed at ensuring that local people and companies benefit, to the fullest extent possible, from opportunities generated by O&G exploration and production.

The Code applies to contracts and employment opportunities relating to onshore and offshore, field-related and non-field related projects. However, it should be noted that compliance with the Code is voluntary.

Specifically, this voluntary Code of Practice seeks to:

- Increase the stake of the Falkland Islands' people in the developing O&G industry in a sustainable manner,
- Ensure capacity development and employment of Falkland Islands' people,
- Ensure the use of Falkland Islands' goods and services,
- Ensure the transfer of technology and know-how to secure the localisation of knowledge and ownership, and

- Encourage the integration of the O&G sector with the other sectors of the Falkland Islands' economy to effectively support national growth and development through joint projects / facilities, joint ventures and partnerships.

In line with the Hydrocarbon Policy Statement described above, the Code seeks to create a legacy of long-term benefit and growth to the Islands economy and helps to retain as much local 'value' as possible.

3.1.7 Legislation relevant to O&G development in the Falkland Islands

Detail on activity-specific legislation and the associated compliance requirements is included in each impact / risk assessment chapter (Chapters 10, 11 and 12). Nonetheless, an overview of the relevant international treaties and UK regulations followed by detail on the relevant Falkland Islands national legislation is provided below.

3.1.7.1 International treaties and legislation relevant to the Falkland Islands

A 'treaty' is an agreement under international law which is entered into by sovereign states and international organisations and may also be known as an 'international agreement', 'protocol', 'covenant' or 'convention'.

Treaties can be loosely compared to contracts which provide a means for willing parties to assume obligations among themselves. Any party that fails to live up to its obligations can be held liable under international law.

The UKOTs have no legal treaty-making capacity (EAC, 2014) and ultimately, the UK concludes treaties on the UKOTs' behalf. Indeed, the UK may apply treaties to UKOTs without any consultation and the application of the treaty falls wholly within the responsibility of the UK Government (EAC, 2014). Therefore, the UK remains responsible if a UKOT violates a treaty obligation.

Additionally, in the event that the UK does not extend the treaty agreement to a UKOT, the UKOT may request to be party to the treaty and ratification may be extended under Article 29 of the 1969 Vienna Convention on the Law of Treaties. Ratification is a subsequent and separate process after a treaty is signed. To this end, the chapter on 'Rights' in the 2009 Constitution for the Falkland Islands has been brought up-to-date to bring it in line with international agreements (FIG, 2023c).

International treaties, conventions and agreements relevant to O&G in the Falkland Islands are:

- International Convention for the Prevention of Pollution from Ships (MARPOL) 1973 (as amended by the Protocols of 1978 and 1997 and kept updated by the Marine Environment Protection Committee (MEPC)).
- United Nations Convention on the Law of the Sea 1982, specifically the 'protection and preservation of the marine environment'.
- International Convention for the Safety of Life at Sea (1974, as amended).
- International Regulations for Preventing Collisions at Sea (1972).
- International Convention on Maritime Search and Rescue (1979)[8].
- Kyoto Protocol to the United Nations Framework Convention on Climate Change (Doha amendment, 2020).
- Paris Climate Agreement, United Nations Framework Convention on Climate Change.
- The Climate Change Act 2008 (2050 Target Amendment) Order 2019.

[8] Note that ratification of this Convention has not yet been extended to the Falkland Islands.

- The Global Methane Pledge adopted at the 26th UN Climate Change Conference of the Parties.
- The World Bank Zero Routine Flaring by 2030 initiative.
- Montreal Protocol 1987 on Substances that Deplete the Ozone Layer.
- The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal[9].
- The London Convention on the Prevention of Marine Pollution by Dumping of Wastes and other Matter 1972.
- International Maritime Organisation (IMO) – International Convention for the Control and Management of Ships' Ballast Water and Sediments 2004[10].
- IMO International Convention on the Control of Harmful Anti-fouling Systems on Ships (2001) International[10].
- Convention on Biological Diversity 1993.
- Agreement on the Conservation of Albatrosses and Petrels (ACAP) 2004.
- International Convention on Oil Pollution Preparedness, Response and Co-operation (OPRC Convention).
- The International Convention on Civil Liability for Oil Pollution Damage – CLC Convention.
- Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES).
- Bonn Agreement Oil Appearance Code 2009.
- Ramsar Convention on Wetlands 1971.
- Convention on Migratory Species (CMS) (also known as the Bonn Convention) 1979.
- International Convention on the Establishment of an International Fund for Compensation for Oil Pollution Damage (1996, as amended).

3.1.7.2 UK legislation

It is understood that UK legislation may not be directly transferable to the Falkland Islands and each item of UK legislation that Navitas propose to follow / take cognisance of will be discussed in detail with FIG. This will ensure that it is appropriately and considerately transposed to ensure relevant elements of the legislative requirements are followed, and those that are not appropriate or relevant, are not included. Where the Falklands enact any legislation that supersedes the commitments made by Navitas, the Falkland Islands' legislation will take precedence.

UK legislation that may be of relevance to the Phase 1 & 2 Development is as follows:

- The Offshore Oil and Gas Exploration, Production, Unloading and Storage (Environmental Impact Assessment) Regulations 2020.
- The Offshore Petroleum Activities (Oil Pollution Prevention and Control) Regulations 2005 (as amended).
- The Offshore Chemicals Regulations 2002 (as amended).

[9] Note that the Falkland Islands are not party to the Basel Convention but a bilateral agreement is in place.

[10] Note that ratification of these IMO Conventions has not yet been extended to the Falkland Islands by the UK. However, with regard to ballast water, all vessels which are flagged to a signatory state are required to hold certification confirming compliance with performance standard D-2 and to hold onboard an approved Ballast Water Management Plans. Further, as indicated in Section 10.12 on the risk of introducing marine invasive species, Navitas commit, as part of the industry-standard mitigation, to ensuring all vessels associated with the Development are compliant with the Conventions on ballast water and bio-fouling.

- The REACH Enforcement Regulations 2008.
- Control of Mercury (Enforcement) Regulations 2017.
- Climate Change Act 2008.
- Offshore Combustion Installations (Prevention and Control of Pollution) Regulations 2013 (as amended).
- Offshore Combustion Installations (Pollution Prevention and Control) (Amendment) Regulations 2018.
- The Energy Act 2008.
- The Environmental Protection Act 1990.
- The Ozone Depleting Substances (ODS) Regulations 2015.
- The Fluorinated Greenhouse Gases Regulations 2015.
- The Offshore Petroleum Activities (Conservation of Habitats) Regulations 2001 (as amended).
- Conservation of Offshore Marine Habitats and Species Regulations 2017 (and the Conservation of Habitats and Species (Amendment) (EU Exit) Regulations 2019).
- The Offshore Installations (Emergency Pollution Control) Regulations 2002.
- Dangerous Substances in Harbour Areas Regulations 1987.
- Transfrontier Shipment of Waste (amendment) Regulations 2007 (as amended). Transfrontier waste shipment controls are expected to follow UK norms which are set out in:
  - Retained Waste Shipments Regulation EC No 1013/2006 as amended by The International Waste Shipments (Amendment) (EU Exit) Regulations 2019, and
  - The International Waste Shipments (Amendment of Regulation (EC) No 1013/2006) Regulations 2020.
- The Waste (England and Wales) Regulations 2011 (as amended), and The Waste (Scotland) Regulations 2012.
- The Controlled Waste (England and Wales) Regulations 2012 (as amended) and The Controlled Waste Regulations 1992 (as amended).
- The Special Waste Regulations 1996 (as amended).
- The Merchant Shipping (Standards for Training, Certification, and Watchkeeping) Regulations 2022.
- The Merchant Shipping (Oil Pollution Preparedness, Response and Co-operation Convention) Regulations 1998 (as amended).
- The Merchant Shipping (Prevention of Pollution by Garbage from Ships) Regulations 2020.
- The Merchant Shipping (Prevention of Pollution by Sewage from Ships) Regulations 2020.
- The Merchant Shipping (Prevention of Air Pollution from Ships) (Amendment) Regulations 2023.
- The Merchant Shipping (Prevention of Oil Pollution) Regulations 2019.
- Environmental Damage (Prevention and Remediation) (England) (Amendment) Regulations 2019.
- The Offshore Installations (Offshore Safety Directive) (Safety Case etc.) Regulations 2015.
- Environmental Damage (Prevention and Remediation) Regulations 2015.
- Control of Major Accident Hazards Regulations 2015.

3.1.7.3 Falkland Islands national legislation

Falkland Islands legislation relevant to O&G developments is as follows:

- Offshore Minerals Ordinance 1994 (1997 and 2011 Amendments).
- Offshore Petroleum (Licensing) Regulations 1995.
- Offshore Petroleum (Licensing) Regulations 2000 (2004, 2005 and 2009 Amendments).
- Petroleum Survey Licences (Model Clauses) Regulations 1992.
- Maritime Ordinance 2017.
- Maritime (Amendment) Ordinance 2019.
- Maritime (Oil Pollution Preparedness, Response and Co-operation Convention) Regulations 2019.
- Deposits in the Sea (Exemptions) Order 1995.
- Marine Mammals Ordinance 1992.
- Conservation of Wildlife and Nature Ordinance 1999.
- Fisheries (Conservation and Management) Ordinance 2005.
- Endangered Species Protection Ordinance 2015.
- Planning Ordinance 1991.
- Planning (Environmental Impact Assessment) Regulations 2015.
- Falklands Interim Port And Storage Solution Ordinance 1989.
- Harbours and Ports Ordinance 2017.
- Maritime (Registration of Ships) Regulations 2019.
- Offshore Installations (Safety Case) Order 2008.
- Falkland Islands Environmental Trust Ordinance 2021.
- Maritime (Port State Control) Regulations 2021.

A brief summary of each of the above is provided below.

3.1.7.3.1 Offshore Minerals Ordinance 1994 (as amended) (The Ordinance)

The Offshore Minerals Ordinance (OMO) 1994 (as amended in 1997 and 2011), known as 'The Ordinance, relates to the granting and renewal of production consents for O&G field developments, the drilling of wells and the construction and installation of production facilities and pipelines in the Falkland Islands Designated Area (200 nm from shore).

The Ordinance requires that any operator who wishes to carry out O&G related activities in the Falkland Islands must first conduct an EIA of the activity and then present the conclusions in an EIS. To inform this process, the specific regulations and requirements are clarified within the 'FIG EPD Hydrocarbons Environmental Impact Assessment Guidance Note 2016' (FIG, 2016e).

Schedule 4 of The Ordinance provides further detail on the expected content of the EIS. Detail on how the Phase 1 & 2 EIS (this EIS) meets the Schedule 4 requirements is provided in Appendix 2.

On formal submission of the EIS to DMR and following review by FIG to ensure it meets the Schedule 4 requirements (Appendix 2), the Governor (in Executive Council) will indicate that the EIS is ready to go to formal public consultation (42 days). Operators are required to notify the public of the EIS

submission by advertising its submission in the local press. The Non-Technical Summary (Chapter 1) and the entire EIS must be made available to the public upon request.

Once comments from the consultation have been addressed and included to the satisfaction of DMR (Chapter 0), the EIS shall be further considered at Executive Council where a decision on acceptance will be reached. The EIS is further considered, alongside the Field Development Plan, as part of the application for petroleum consent. Consent may be given or refused, or the consent may be subject to conditions that require modification to the proposed activity to reduce, remedy or offset impacts / risks to the environment. The decision will be published with detail on the review of the EIS.

Consent to begin any activity will not be given until the Governor (in Executive Council) is satisfied with the information provided and that there will be no unacceptable impact on the environment.

FIG is in the process of amending the existing OMO to remove the references to safety and the environment and will develop a new Safety and Environment Ordinance to cover these areas, the OMO will then be updated to cover other licensing areas as required. The OMO will provide for the licensing regime (including model clauses, oil field determination and decommissioning) and the Safety and Environment Ordinance (OMSEO, title TBC) will cover safety and environmental aspects. This will demonstrate separation of functions between licensing and safety regulation. FIG also intends to repeal the Offshore Installations (Safety Case) Order 2008 and replace it with Major Hazard Regulations in order to align with the requirements of the UK Offshore Installations (Offshore Safety Directive) (Safety Case etc.) Regulations 2015.

The proposed OMSEO seeks to modernise the environmental regulatory system governing offshore hydrocarbons by introducing a goal-setting regime. This will include an environmental assurance plan that will be integrated with the existing EIA regime. Performance will be measured against quantifiable standards based on environmental impacts and risks, with associated regular reporting, audit and review procedures. Statutory requirements for Oil Pollution and Emergency Plans (OPEPs) and the introduction of emergency intervention powers and the 'Polluter Pays' principle will also be introduced to align with, or exceed, UK best practice. At the time of writing this process is still ongoing within FIG.

3.1.7.3.2 Offshore Petroleum (Licensing) Regulations 1995 and 2000 (as amended in 2004, 2005 and 2009)

The Offshore Petroleum (Licensing) Regulations 1995 govern licences awarded through a competitive bidding process ('Competitive Round Licences') and stipulate the licensing requirements for O&G exploration and production as well as fees, royalties and working obligations of the licence holder.

They further provide a detailed description on the licensing application process, the required forms, model clauses, fees, and other requirements, such as maintenance, record keeping and reporting.

The Offshore Petroleum (Licensing) Regulations 2000 govern licences awarded through an open process of application for production licences ('Open Door Licences'). These Regulations also stipulate the licensing requirements for O&G exploration and production as well as fees, royalties and working obligations of the licence holder.

3.1.7.3.3 Petroleum Survey Licences (Model Clauses) Regulations 1992

The Petroleum Survey Licenses (Model Clauses) Regulations 1992 describe the framework governing offshore exploration activities including field observations, geological and geophysical investigations, the use of remote sensing techniques and seabed sampling.

These regulations were made under the Falkland Islands (Continental Shelf) Proclamation 1991 and were enforced by the Offshore Minerals Ordinance 1994.

3.1.7.3.4 Maritime Ordinance 2017 (and 2019 amendment)

The Maritime Ordinance covers the registration of ships as well as prevention of pollution from ships and liability for oil pollution in the case of tankers and other ships. It also includes detail on insurance against liability for pollution.

3.1.7.3.5 Maritime (Oil Pollution Preparedness, Response and Co-operation Convention) Regulations 2019

The Maritime (OPPRCC) Regulations relate to oil pollution emergency plans for ships, reporting of pollution events and the duties of ship owners. The regulations also cover the oil pollution emergency plans for harbours, ports and oil handling facilities and how the Governor (in Executive Council) are to respond to reports of pollution. Lastly, the regulations give the power to inspect premises, such as offshore installations, to verify their oil spill preparedness and details the offenses against the regulations.

3.1.7.3.6 Deposits in the Sea (Exemptions) Order 1995

The Deposits in the Sea (Exemptions) Order 1995 exempts 25 specified operations from the licensing requirements.

Deposits of sewage, domestic garbage, wastewater generated from tank cleaning, ballast water and cooling water originating on the vessel are all exempt from licensing requirements. Further, deposits of any substance during firefighting, normal navigation or maintenance, and salvage operations do not require a licence.

Deposition of chemicals, drill cuttings and / or drilling mud are also exempt under this order but are subject to regulation through FIG Petroleum Offshore Notification (PON) 10 (Section 3.1.7.4).

3.1.7.3.7 Marine Mammals Ordinance 1992

The Marine Mammals Ordinance 1992 prohibits:

- The intentional harming, taking or killing of any marine mammal (including whales, porpoises, dolphins, otters, seals, sea lions and elephant seals),
- The use of explosives in such a manner that may cause harm to any marine mammal on land or in inland waters, territorial seas or any fishery waters of the Falkland Islands, and
- The import or export of any marine mammal, or any part of a marine mammal, living or dead, without a licence.

Within this legislation, Falkland Islands' waters correspond to the boundaries of the Falklands Outer Conservation Zone (FOCZ).

3.1.7.3.8 Conservation of Wildlife and Nature Ordinance 1999

This Ordinance repeals the Wild Animals and Birds Protection Ordinance 1964, the Nature Reserves Ordinance 1964 and the Fisheries Ordinance (1986).

Under this Ordinance it is prohibited to deliberately kill, injure, capture, replace, or disturb any protected wild animal, bird or plant without a licence. It also makes provision for the designation of National Nature Reserves (NNRs) on the seabed, on land or on private estates by agreement, with associated regulations for their preservation. Specifically, the Ordinance Schedules list protected bird, animal and plant species which may not be killed at any time but also detail the species that may be killed out with the timing of their closed seasons.

3.1.7.3.9 Fisheries (Conservation and Management) Ordinance 2005

The Fisheries (Conservation and Management) Ordinance 2005 extends the influence of the Conservation of Wildlife and Nature Ordinance 1999 (see above) beyond territorial waters (i.e., >12 nm from shore) to cover the Falklands Interim Conservation Zone (FICZ) and the FOCZ. However, the primary role of the Ordinance is to protect fisheries resources in order to:

- Meet the reasonably foreseeable needs of future generations, and
- Avoid, remedy, or mitigate any adverse effects of fishing on the marine environment so far as is reasonably practicable to do so.

The Ordinance has the following environmental and information principles:

- Associated or dependent species shall be maintained at, or above, a level that ensures their long-term viability,
- Biological diversity of the marine environment shall be maintained,
- Habitats of particular significance for fisheries management shall be protected,
- Decisions shall be based on the best available information,
- Decision-makers shall consider any uncertainty in the information available in any case, and
- Decision-makers shall be cautious when information is uncertain, unreliable, or inadequate.

3.1.7.3.10 Endangered Species Protection Ordinance 2015

The Endangered Species Ordinance 2015 upholds the Convention on the International Trade of Endangered Species (CITES) and controls the import and export of species listed under Appendix I, II and III of CITES.

3.1.7.3.11 Planning Ordinance 1991

The Planning Ordinance 1991 provides the regulatory framework for developments in the Falklands that have the potential to cause a significant impact to the environment or local communities.

3.1.7.3.12 Planning (Environmental Impact Assessment) Regulations 2015

These regulations empower the Planning Officer in the FIG to require applicants to submit an EIS alongside applications for planning permission.

3.1.7.3.13 Falklands Interim Port And Storage Solution (FIPASS) Ordinance 1989

The FIPASS Ordinance 1989 enables the management of FIPASS by the Harbour Master (also acting as the Marine Officer) and FIPASS Manager.

3.1.7.3.14 Harbours and Ports Ordinance 2017

The regulations applying to Falklands Islands harbour and ports was reviewed and updated in 2017. The Harbours and Ports Ordinance 2017 establishes the maritime authority in the Falkland Islands, designates harbours and ports and permissible activity therein.

3.1.7.3.15 Maritime (Registration of Ships) Regulations 2019

The regulations provide for the registration of merchant ships, fishing vessels and small ships.

3.1.7.3.16 Offshore Installations (Safety Case) Order 2008

The Offshore Installations (Safety Case) Order enacts the UK equivalent Safety Case Regulations 2005. Although mainly focused on safety of offshore installations, this order is included here as it covers the prevention of major accident hazards, which can include preventing loss of containment. This order also covers notification of well operations, documentation and verification schemes, which can also apply to environmentally critical equipment.

3.1.7.3.17 Falkland Islands Environmental Trust Ordinance 2021

This Ordinance, which is still to be enacted, establishes the Falkland Islands Environment Trust, responsible for managing payments received from contributors; to provide for applications for funding by persons engaging in an activity that promotes environmental management, and conservation and enhancement of the environment for the benefit of the Falkland Islands; and to provide for connected matters. As an O&G operator, Navitas may be required to contribute to the Environment Trust.

3.1.7.3.18 Maritime (Port State Control) Regulations 2021

The Maritime (Port State Control) Regulations allow the Falklands Maritime Authority to inspect vessels, including confirming the validity of their certificates and assessing the overall condition of the ship.

3.1.7.4 Petroleum Operations Notices (PONs)

The FIG provides numerous Petroleum Operations Notices (PONs) to provide guidance and *pro formas* for reporting. The PONs relevant to the Phase 1 & 2 Development are listed in Table 3.1.

Table 3.1: Summary of PONs relevant to the Phase 1 & 2 Development

PON	Purpose
PON 1	Record keeping and sampling requirements for surveys and wells.
PON 2	Reporting procedure detailing the need for progress meetings, monthly progress reports and daily drilling reports.
PON 3	Notification of Geophysical Surveys
PON 4	Application for the Consent to Drill Exploration, Appraisal, and Development Wells and the Consent to Locate.
PON 5	Application to Abandon or Temporarily Abandon a Well.
PON 6	Application to Complete and/or Workover a Well.
PON 7	Well numbering system.
PON 8	Detailing the: FIG reporting requirements in the event of an accidental oil / chemical release or a visible sheen, and The use of dispersants, and surveying and tracking requirements.
PON 9	Reporting of Injuries, Disease and Dangerous Occurrences (RIDDOR).
PON 10	Application to Use and Discharge Non-Aqueous Drilling Fluids (NADF) and Associated Cuttings.
PON 11	For reporting of the loss or dumping of materials at sea from offshore oil and gas installations.

3.2 Navitas Operating Management System

This section describes the Navitas Operating Management System (OMS) which includes all elements relating to health, safety, security and the environment. This section will demonstrate how the OMS applies to the environmental management of the Sea Lion Field Northern Development Area, Phase 1 & 2 (hereafter referred to as the 'Phase 1 & 2 Development').

3.2.1 Corporate HS&S and E&B policies

Navitas is committed to ensuring that all activities within the life-cycle of a project / operation are carried out in compliance with the relevant international and national legislation, and within the guidance of the Company's OMS to ensure sound health, safety, security, environmental and biodiversity management.

Navitas will conduct the activities associated with the Phase 1 & 2 Development in a manner that is consistent with its Corporate Health Safety and Security (HS&S) (Figure 3-3) and Environment and Biodiversity (E&B) Policies (Figure 3-4).

NAVITAS PETROLEUM

Health, Safety & Security (HSS) Policy

Navitas is committed to protecting the health, safety and security of everyone involved in its activities. Navitas puts the protection of people first and aspires to high standards of practice through a process of continual improvement and the adoption of international codes, standards and procedures. To meet this commitment Navitas has implemented an operational management system (OMS) which strives to:

- Promote, enhance and sustain a strong Health and Safety culture
- Comply with applicable health, safety and security laws and regulations
- Identify, evaluate and manage hazards and risks involved in operational activities to "as low as reasonably practicable" (ALARP)
- Ensure that a high priority is placed on the prevention and control of "major accident hazards" (MAH)
- Regularly monitor and assess the security status and the associated risks of the places where Navitas does business
- Implement controls to ensure that safeguarding of personnel and property is carried out consistently with relevant human rights principles and in a manner that avoids or minimizes risks to the local community
- Provide health, safety and security training to employees and actively promote awareness of health, safety and security issues
- Ensure that those responsible for security are aware of relevant human rights issues
- Ensure that contractors are aware of and comply with Navitas policies and procedures and, where / when necessary, work with contractors to raise their standards to meet Navitas's requirements
- Leverage and influence business partners and stakeholders to promote high standards of health, safety and security
- Ensure that accidents, incidents, near misses and non-compliances with procedures are reported and investigated, and lessons are learned and shared
- Set "key performance indicator" (KPI) objectives and targets for improving health, safety and security performance and monitor and report openly on performance.
- Monitor and evaluate performance, and conduct periodic audits on Navitas's own operations and Contractors' work
- Ensure that a high priority is placed on crisis and emergency response preparedness, contingency and business continuity planning; ensuring that financial and technical capabilities and professional competencies are maintained and any response to an emergency incident can be managed
- Work openly with regulators and industry bodies and promote best practice in protecting health, safety and security
- Consult with, and respond to the concerns of stakeholders on Navitas's health, safety and security performance

Responsibility for compliance with Navitas's HSS Policy is company-wide. It is the responsibility of each individual to be aware of the risks to personal health, safety and security and to take measures commensurate with the environment they are living, working and travelling in.

Figure 3-3: Navitas Health Safety and Security Policy

NAVITAS PETROLEUM

Environment and Biodiversity (EB) Policy

Navitas is committed to protecting the health and sustainability of the environments in which it operates. Navitas aspires to high standards of practice through a process of continual improvement and the adoption of international codes, standards and procedures. To meet this commitment Navitas has implemented an operational management system (OMS) and has focused environmental social governance (ESG) goals which strives to:

- Comply with applicable environmental laws and regulations
- Adopt a precautionary approach to avoid and, where this is not feasible, reduce negative impacts to the environment and biodiversity to "as low as reasonably practicable" (ALARP)
- Conduct environmental impact identification (ENVIID) and risk assessments in the planning stage and put in place site specific Environmental Monitoring and Management Plans (EMMPs) in place prior to commencing operations
- Engage with local of affected stakeholders to utilize their knowledge of the local environment to assist in protecting and conserving biodiversity
- Encourage the development and sharing of environmental knowledge and technologies and seek out the best available techniques to reduce the impact of Navitas operations
- Promote efficiency in the use of energy and water with the aim of conserving natural resources and reducing atmospheric emissions (greenhouse gases [GHG]) thus helping to mitigate the effects of climate change
- Set "key performance indicator" (KPI) objectives and targets for improving environmental and biodiversity performance and monitor and report openly on performance.
- Monitor and evaluate performance, and conduct periodic audits on Navitas's own operations and Contractors' work
- Provide environmental and biodiversity training to employees and actively promote awareness of environmental and biodiversity issues
- Ensure that contractors are aware and comply with Navitas's environmental policy and procedures and, where necessary work with contractors to raise their standards to meet the Navitas's requirements
- Ensure that environmental accidents, incidents , near misses and non-compliances with procedures are reported in a timely manner and investigated with lessons learned and shared
- Prevent pollution and ensure that an appropriate response capability is in place and regularly tested so that environmental incidents can be responded to in a timely and effective manner should they occur
- Work with regulatory and industry bodies in the formulation or improvement of laws, policies, regulations and good practices aimed at protecting the environment and biodiversity
- Consult with, and respond to the concerns of stakeholders on Navitas's environmental and biodiversity performance

Responsibility for compliance with Navitas's EB Policy is company-wide.

Figure 3-4: Navitas Environment & Biodiversity Policy

3.2.1.1 The Navitas OMS Elements

The objectives of the OMS are to:

- Deliver operations which are compliant with the company, industry and regulatory standards,
- Drive operations to meet the company's strategic objectives:

  'No one gets injured, process safety incidents are eliminated and harm to the environment is minimised'

- Ensure a fit for purpose business approach to deliver safe, reliable and cost-effective operations,
- Reinforce values of the company,
- Provide assurance that risks are being managed in a consistent approach and mitigated through routine verification, and
- Secure continuous business improvement.

Figure 3-5 illustrates the inter-connectivity of the Operating Management System's expectations by managing risk and delivering assurance.

There are 14 key elements which sit within the system. Each of the 14 elements provides a set of compulsory expectations, which are summarised in Table 3.2 and described fully in:

- Operating Management System (SEL-REG-OPM-PLN-00001-00)

A series of standards, procedures and guidelines define how each of the 14 elements should be implemented in order to manage HS&S and E&B impacts and risks during the execution of work activities. Where work is to be conducted by third parties, bridging documents are developed to describe the interface between the two companies' management systems prior to the start of activities to ensure that the 14 elements are sufficiently met.

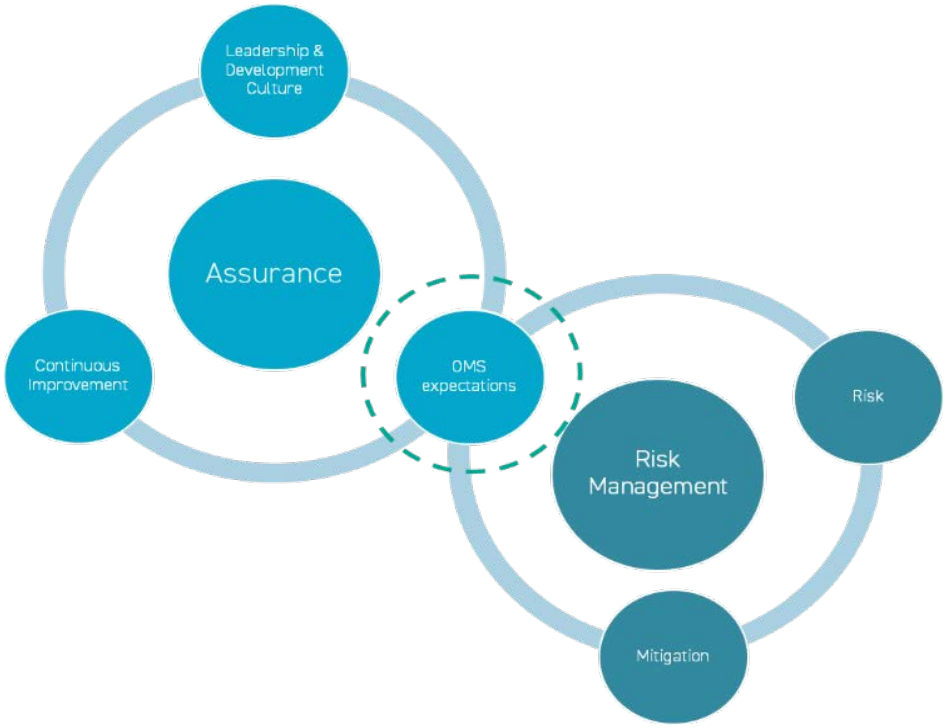

Figure 3-5: Showing the inter-connectivity of the Operating Management System's expectations

Table 3.2: Summary of Navitas OMS Elements

OMS Element		Description
1	Leadership Expectations	Deliver clear and positive safety leadership, visible leadership, commitment, and accountability. Communicate expectations and provide perspective. Set performance targets and provide the structure and resources to support them for all areas of responsibility. Understand high consequence risks, identify safeguards to manage risks and ensure safeguards are working.
2	Health, Safety, Security & Environment	Continually improve Health, Safety and Environmental performance and reduce impacts from our operations whilst protecting people and assets. Ensure work is always controlled. Promote a healthy workforce and mitigate significant workplace health risks. Effective incident investigation, reporting and follow-up in use to achieve performance goals. Emergency response, business continuity and crisis management planning in place to ensure company responds proportionately and effectively to emergencies and reduces impacts and disruptions
3	Performance Management	Business objectives are achieved through a robust long-term planning and scheduling process. Work activities are understood with appropriate resources provided to enable objectives to be met, thus delivering a sustainable and predictable business outcome. Continuous improvement and learnings are routinely incorporated into all aspects of the business and lessons learned are incorporated into future activities. An assurance process in place to ensure that decisions and actions are in line with the group's best interests and that the safeguards expected in the OMS are in place and functioning and meet internal and external requirements. Assurance priorities are established based on risk management assessments and the organisation stops repeated failures and focuses on taking advantage of improvements.
4	Organisation & Capabilities Expectations	People are our most valuable asset, and we develop and enrich our teams of competent professionals to fulfil challenging roles with specific responsibilities defined. The requirements for each role and individual are unique and are considered as such with clear expectations. Our personnel are selected appropriately, trained and their skills and competencies regularly reviewed. Personnel are allocated to a role based on their ability to deliver the requirements and demands of that position.
5	Operations Management	Facilities are operated strictly according to legislation and within established parameters for recognised industry best practice. Facilities are operated within the current design envelope to ensure safe, secure, healthy, and environmentally sound performance.
6	Production Management	Maintain a clear understanding of the entire production value chain from reservoir to export pump, rigorously defining potential, chokes, LMPP, loss management and forecasting. Production is delivered against the IAP and production targets using a clear process to maximise production in a cost-effective manner with a systematic process for managing and optimising the entire value chain from reservoir to export pump. This process includes defining the limit, planning activities, setting targets and forecasting, execution of planned activities, managing losses and seeking opportunities to improve.
7	Maintenance & Inspection management	Facilities are maintained and inspected in accordance with legislation and to prevent injury to people, damage to the environment and to achieve competitive advantage over the lifecycle. Effective maintenance and inspection management delivers the levels of reliability and availability expected to meet business objectives.
8	Management of Change	Change in our organisation is managed to minimise HSE (Health, Safety, Environment) hazards and operational risks. Facilities are designed and constructed to prevent injury, illness, and incidents and to operate reliably and

OMS Element		Description
		efficiently and in an environmentally sound manner. Temporary and permanent changes to our organisation, personnel, systems, procedures, equipment, products, materials, or substances are evaluated and managed to ensure that health, safety, security, and environmental risks arising from these changes remain at an acceptably low level.
9	Management of Contractors & Logistics Management	Third-party contractors are assessed and selected on their ability to perform in a manner that is consistent and compatible with our HSE, process safety, operational, and business requirements. We award contracts that clearly set out the expectations and requirements on each party. The measures applied to control the work are proportionate to the associated risk and based on our ability to manage, influence, or react to the risk. We proactively monitor performance and delivery of, and compliance with, the contract terms. Logistics provide safe, timely and reliable transportation of personnel, materials, and equipment
10	Operational Risk Management	The workforce at all levels of our organisation understands and manages operating risk to prevent accidents and harm to people, to reduce damage to the environment and to achieve competitive performance. Comprehensive risk assessments are used to reduce environmental, Health, safety and security risks and mitigate or eliminate consequences.
11	Responsibility to Stakeholders	Maintain our license to operate through stakeholder confidence in our ability to meet expectations. Communicate and promote a solid understanding of risk awareness, risk management and performance. Key stakeholder groups are identified, and their concerns are addressed to maintain a good relationship and achieve business objectives. Work plans designed to align, involve and empower the whole workforce in the identification and management of hazards.
12	Information Management	Knowledge management process delivers a shared understanding of information required to operate facilities safely and supports the communication of information, knowledge transfer, updating and version control of key documents, maintenance of records and demonstration of compliance.
13	Projects Management	Projects Management are committed to ensure that facilities are designed and delivered strictly according to legislation and within established parameters for recognised industry best practice. Subsea and Topsides facilities design from an integrity and operating envelope is delivered to ensure safe, secure, healthy, and environmentally sound performance.
14	Drilling and Completions Management	Drilling Leadership are committed to deliver safe, reliable, and cost-effective solutions that maximize oil and gas recovery and minimize environmental impact. Commitment to being visible and proactive in our leadership with a clear commitment to continuous improvement, while working to a HSE Management System that shall be established prior to Rig Operations commencing

3.2.2 Project planning and review

The lifecycle of all project planning and review phases within the Phase 1 & 2 Development (from drilling and construction to development and production) are covered within the 14 elements of the OMS.

An example of this is the well engineering project delivery process. This is structured and designed to provide assurance to senior management and joint venture partners with Navitas' operations to ensure / assure that the project team has completed all the necessary work associated with each phase of the project development. To achieve this, Navitas has a 'gated' process for progressing a project through six distinct phases (Figure 3-6).

When following the process, it is necessary for the project team to provide key deliverables before progressing through each 'gate' and on to the next phase of the project. A 'gate-keeper' is assigned

within the project development assurance process to ensure that all deliverables are identified and met.

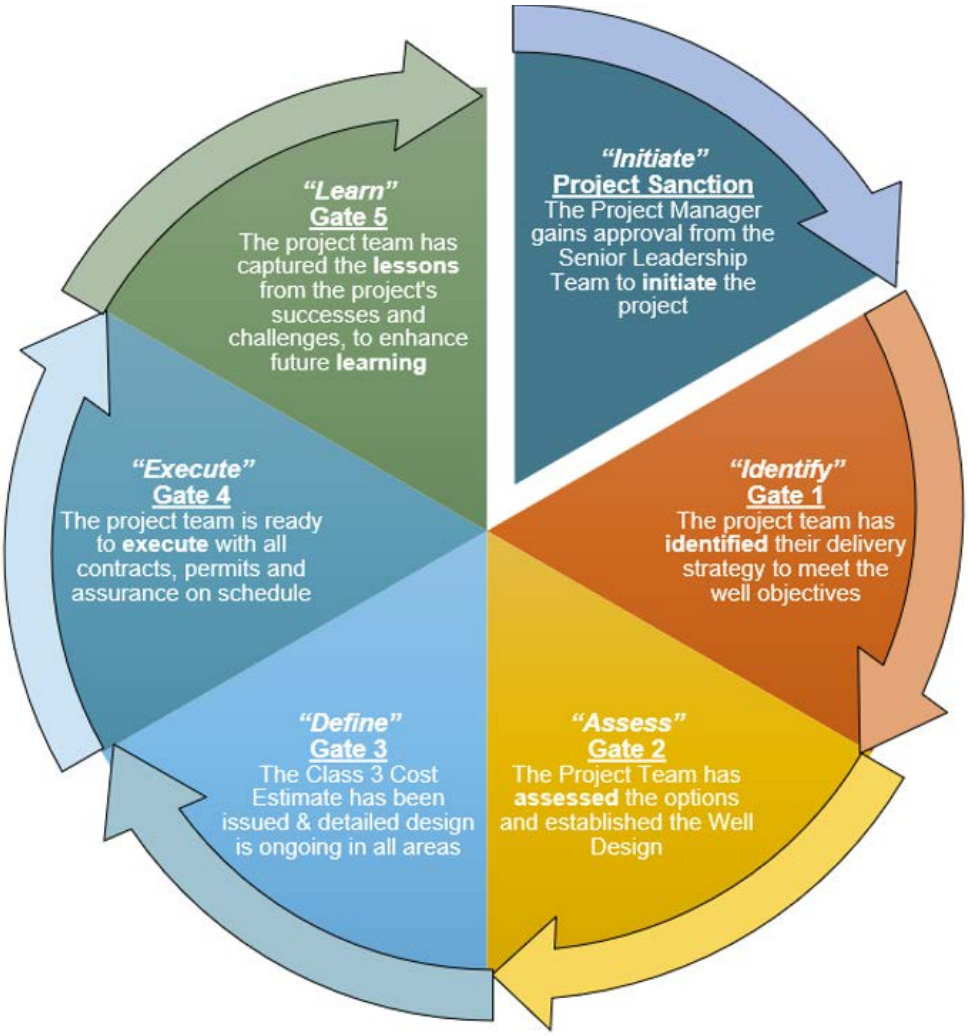

Figure 3-6: Well construction project delivery lifecycle

3.2.3 Environmental baseline data gathering

Element 2 within the OMS is concerned with HS&S and E&B (Table 3.2). The objective of environmental baseline data gathering is to ensure that the existing environmental conditions in areas where Navitas plan to operate are adequately characterised and understood. This informs the Environmental Impact Assessment (EIA) process and enables the identification of trends or changes when conducting monitoring throughout the project lifecycle.

3.2.4 Impact and risk identification and assessment

In line with Element 2 (Table 3.2), the environmental and social aspects, impacts and risks associated with a Development must be identified and assessed. Once the Development activities have been understood, an ENVironmental Impact IDentification (ENVIID) workshop is held to determine the ways the activities will interact with the environment (i.e., noise, emissions, discharges etc.) and what the impacts and risks might be. This can be illustrated by Navitas' ENVIID for the Sea Lion Field Northern Development Area, Phase 1 & 2 as described in Chapter 9.

The impact and risk assessment process and the assessment of mitigation measures ensures that the impacts and risks are reduced to 'As Low As is Reasonably Practicable' (ALARP).

3.2.5 Legal compliance

In line with all OMS Elements (Table 3.2 above), legislative and regulatory compliance shall be adhered to and best practice shall be strived for. These shall be identified at Gate 1 ('Identify Phase') (Figure 3-6) and a Permits, Licences, Approvals, Notifications and Consents (PLANC) register shall be established. This will be updated and verified at all the subsequent Gates.

The PLANC register will define what is required for field development, who is accountable and responsible and when action is required. Therefore, the PLANC register will be used to inform all stages of the Development.

Where no FIG regulation exists for a given activity, or where it awaits enactment, in consultation with FIG, Navitas shall adhere to agreed UK and international standards (Section 3.1.7.2). In accordance with the FIG DMR Guidance Notes on Operations Notices, the FIG PONs will be used / applied for as appropriate (Section 3.1.7.4).

3.2.6 Operational control

OMS Element 10 ('Operational Risk Management') (Table 3.2 above), details that operational control is required in order to ensure that all activities within Navitas' control[11] are carried out in a safe and effective manner. With regard to health, safety and environmental issues, operational controls also serve to prevent and reduce impacts and risks by:

- Preventing an impact from occurring,
- Minimising the impact,
- Remediating the impact,
- Preventing, or reducing the likelihood of, an unplanned event from occurring, and / or
- Minimising the severity of effect in the event of an incident.

Operational controls include:

- Elimination controls e.g., electing not to commence with a specific operation / activity,
- Substitution controls e.g., electing to carry out the activity in a different way, place or time,
- Engineering controls e.g., use of Best Available Technology (BAT) or deployment of additional or alternative equipment, and / or
- Administrative controls e.g., use of standard operating procedures and / or development of project-specific operating procedures / plans where necessary.

Elimination and substitution controls are built-in to the project basis of design such that the project will always endeavour to minimise impacts and risks. During the EIA process, where impacts or risks

[11] Please note that while Navitas OMS Elements 5 (Operations Management) and 6 (Production Management) are relevant to offtake operations between the FPSO and the Conventional Trading Tanker (CTT), the CTT itself is not under Navitas' direct control, and the field operator will not have title or liability for the crude transferred once it is discharged from the offloading flange on the FPSO. Once the Boarding Party, which will include Navitas Mooring Masters, are onboard the CTT, and with the hold back Tug connected, there will be liability across both parties. Navitas' Mooring Master will pilot the CTT entry into the FPSO exclusion zone, during berthing operations, offloading operations, hold back operations and until disconnected with the Boarding Party disembarked from the CTT, there will be some shared responsibilities. Navitas will have in place Terminal Regulations which will govern CTT Operations and within this it will clarify responsibilities through the entire operation. In the event of an incident involving the CTT, the liability would sit with the crude offtaker / tanker owner and would be covered by the tanker P & I Club Cover, and insurance under CLC 1992. Further detail on the Navitas Assurance Process for purchasers' tankers is provided in Section 5.10.

are deemed significant despite the base-case mitigations and industry-standard safeguards, it is necessary to determine what additional, project-specific, controls may be required. All additional project-specific controls intended to prevent or mitigate impacts and risks will be utilised where they are deemed to be 'reasonably practicable'.

The process for identifying the need for project-specific controls and mitigation options is described further under the EIA methodology (Chapter 8).

3.2.7 Safety and Environmentally Critical Elements register

In line with the Element 2 of the OMS (Table 3.2 above), Safety and Environmentally Critical Equipment (SECE) must be identified and performance standards developed that describe and define the equipment's requirements in terms of functionality, availability, reliability, survivability and its interdependence on other systems. The SECE Register will be regularly reviewed and verified prior to commencement of the onshore fabrications / construction stage.

3.2.8 Emergency response

Emergency Response Plans (ERPs) are covered within Element 2 of the OMS (Table 3.2 above). These will be in place for all operations and will be developed for all potential emergency scenarios. Oil Pollution Emergency Plans (OPEP) shall be developed to cover all stages of the Phase 1 & 2 Development and will be reviewed and approved by FIG prior to commencement of the operations.

3.2.9 Incident management

In line with Element 2 of the OMS (Table 3.2), any HS&S and E&B accidents, incidents, near misses and non-compliance will be recorded and investigated in accordance with Navitas' HSS and E&B policies (Figure 3-3 and Figure 3-4). All incidents will be reported in internal performance reports as well as to the statutory authorities in keeping with the required FIG reporting protocols.

3.2.10 Monitoring and measuring

Monitoring and measuring is a fundamental requirement of this EIS. They are noted both in the Navitas HS&S and E&B policies (Figure 3-3 and Figure 3-4) and throughout the OMS. Environmental Monitoring and Measuring will be used throughout the Phase 1 & 2 Development in line with the requirements identified throughout the EIA process, and will be used to:

- Provide assurance of compliance with regulatory requirements standards and FIG policies,
- Determine progress in achieving the objective and targets outlined in the HS&S and E&B Plans,
- Provide an early indication should any of the operational controls fail to achieve acceptable standards,
- Enable Navitas to take remedial action if unexpected problems or unacceptable impacts arise,
- Monitor the performance of the project and the efficacy of project-specific mitigation measures (IEMA, 2008),
- Evaluate any actual environmental impacts,
- Verify the environmental impact predicted in the EIA studies; and
- Provide auditable data.
- Priorities for monitoring will include:
    - Environmental aspects for which significant residual impacts were predicted,
    - Environmental aspects for which successful mitigation is essential to avoid significant impacts, and

- Impacts for which there is a high degree of uncertainty (i.e., a low confidence score) in the impact predictions or in the likely success of the proposed mitigations.

Aspect-specific monitoring and measuring requirements are described in each impact and risk assessment chapter (Chapters 10, 11 and 12) and are listed, with defined responsibilities for implementation, in the outline Environmental Monitoring and Management Plan (Chapter 15).

3.2.11 HSE Plans and environmental objectives and targets

In line with Element 2 of the OMS (Table 3.2 above), Navitas shall develop environmental objectives and targets to ensure continual improvement in environmental management throughout all stages of the Phase 1 & 2 Development.

The objectives and targets, and the programmes by which they are met, will be incorporated into the relevant Phase 1 & 2 Development HSE plans, which will include detail on the responsible person and a means of tracking progress.

The HSE Plan will be drafted at each project's 'Gate 1' (Identify Phase) and will be reviewed and updated each gate thereafter.

3.2.12 Environmental performance

Once the Phase 1 & 2 Development operations commence, data on the Key Performance Indictors (KPIs) (e.g., greenhouse gas emissions, waste volumes, oil in water concentrations etc.) will be gathered on a monthly basis and reported as required. Performance monitoring will be carried out *via*:

- Participation in daily calls during the Development to discuss the project / operations status, any issues that have arisen and proposed solutions (where necessary),
- Receipt of daily, weekly and monthly reports to track HSE performance and provide detail on how any issues were closed out,
- Receipt of daily reports including, where relevant, chemical use,
- Monitoring of all waste streams to ensure waste is properly handled, and
- Presence of an HSE representative on board the Mobile Offshore Drilling Unit (MODU) / FPSO and on shore to ensure effective environmental management.

3.2.13 Audit and review

In accordance with Element 3 the OMS, ('Performance Management') (Table 3.2 above), and the FIG EIA Guidance Note (FIG, 2016e), Navitas will carry out periodic audits to ensure that the Phase 1 & 2 Development is being carried out in compliance with:

- Regulatory requirements,
- Contractual obligations, and
- Commitments in the EMMP and other management plans.

Processes and tools, as detailed within the Navitas OMS, will be used to assign, schedule and track all corrective or preventive actions.

Environmental audits / reviews that will be required prior to, and during, the Phase 1 & 2 Development operations and will include, but not be limited to:

- Internal audits / reviews:
  - Senior Management review,
  - Peer review,
  - Stage gate reviews at the start of each project development phase in line with:

- Operational Controls Reviews,
- Internal reviews to ensure impacts and risks continue to be ALARP, and
- Internal OMS audits.

- Contractor, Joint venture Management System Audits:
  - Pre-Award HSE audits / reviews for selected Tier 1 contractors,
  - Pre-mobilisation HSE audits or readiness reviews for assets such as the MODU, FPSO, helicopters and Offshore Support Vessels (OSVs),
  - On site monitoring and inspection,
  - Supply base HSE audit, and
  - Contractor self-monitoring / inspection / auditing.

3.2.14 Contracting strategy

In line with Element 9 of the OMS ('Management of Contractors & Logistics Management') the service sector requirements of the Phase 1 & 2 Development will be quantified, sourced and contracted in line with the Project Execution Plan (PEP).

The PEP lays out the system of local consultation and capacity evaluation that will be followed within the tender and contracting process.

The strategy complies with the:

- Policy and Procedure for Contracts and Procurement,
- Local Content Policy,
- Hydrocarbons Development Policy Statement 2013 (Section 3.1.6.2), and
- Voluntary Falkland Islands Local Content Code of Practice (Section 3.1.6.3).

The Falkland Islands are at the end of an extended supply chain, and tender evaluation will assess the security of that supply chain, the geographical location of supply and the capacity to supply.

The long-term nature of the Phase 1 & 2 Development encourages market investment and expansion (over and above that achieved during temporary short-term exploration and appraisal campaigns) and contract durations will be assessed and set in order to best achieve capital investment and innovative solutions to service provision.

The contracting strategy will normally incorporate an initial pre-qualification process for local requirements (using the Expression of Interest facility within the Penguin News) and for large, tier 1 contractors providing high value or critical service delivery contracts. This will comprise the first screening in evaluating the capacity and long-term security of supply delivered by the tenderer, prior to full evaluation in the tender bid process.

During this process, tenderers will be asked to provide detail of their proposed incorporation of sustainable design features in their tender submissions. Environmental considerations and sustainable design will form part of the contract evaluation criteria.

It is thus assumed that economic market forces of supply / demand will respond to Phase 1 & 2 Development service needs whether that be through local or external contractors and that the tender process is robust in evaluating market response to ensure local supply is not impacted.

3.2.15 Contractor management

Again in line with Element 9 of the OMS (Table 3.2 above), Navitas will evaluate contractors based on their ability and qualification to appropriately manage HSE risks arising from their work. Bridging documents between the Company and Contractor management systems will be defined and

documented to ensure effective mobilisation, ongoing HSE surveillance and close out of contracted work.

HSE impacts and risks associated with contracts will be identified, assessed and competently managed.

3.2.16 Management of Change

In line with Element 8 in the OMS ('Management of Change') (Table 3.2 above), it is important for the Phase 1 & 2 Development to be able to accommodate changes and respond to a need for further environmental and social impact and risk assessment if it arises throughout the different project stages.

The need for further impact and risk assessment may arise for the following reasons:

- If changes to the project design become necessary at the post-design stage, and / or
- A new environmental sensitivity is identified as a consequence of changing environmental conditions and / or evolving trends that are identified *via* monitoring or additional surveys.

The Offshore Minerals Ordinance (Amendment) 2011 states that environmental impacts that are substantially different, or significantly greater, than those already presented in an EIS will trigger an additional EIS. However, if it can be demonstrated that the impacts are not substantially different then the Governor can waive the need to produce a new EIS.

As explained in the EIS Introduction (Section 2.2.4), there are still specific details that can only be confirmed upon completion of contractual negotiations for the execute / operational stage. This is normal when preparing an EIS for a large project. The approach taken has been to use experience from similar projects to propose conservative analogies to ensure that this EIS assesses the worst credible case so that it should encapsulate all eventualities, preventing the need for an additional EIA/S.

However, if significant post-design changes do occur, the impacts will be reviewed and assessed as part of the gated project delivery process and discussions will be held with FIG to determine the most appropriate way to manage the EIS and EMMP.

3.2.17 Stakeholder management

In line with Element 11 of the OMS ('Responsibility to Stakeholders') (Table 3.2 above), key stakeholders in the Phase 1 & 2 Development have been identified (see Chapter 6 and Table 6.2) and a plan developed to enable identification and recording of stakeholder concerns throughout the lifecycle of the field

The results of the informal pre-submission scoping consultations, (which were carried out to inform this and the previous EIA processes), and a record of the statutory consultations carried out following submission of previous iterations of Sea Lion EIS's are recorded in Chapter 6. Representations from the formal post-submission stakeholder 42-day consultation period, and Navitas' responses to these, will be provided in Chapter 0.

3.2.18 Project-specific environmental management

3.2.18.1 Sea Lion Field Northern Development Area management plans

Management plans are designed to identify and communicate environmental management requirements and commitments to all key personnel and to ensure the implementation of controls.

Management plans will be required in compliance with:

- The terms and conditions of the Drilling and Production Licenses,
- The FIG EIA Guidance Notes 2015 (FIG, 2016e),

- The FIG Guidance Note on Approvals Required for Offshore Operations in the Falkland Islands (02/13) (FIG, 2013b), and
- The outcomes of the EIA (that are reported in this EIS).

Project-specific management plans that will be in place for the Phase 1 & 2 Development include (but will not be limited to):

- Environmental Monitoring and Management Plan (EMMP) (Chapter 15 below),
- Preliminary Oil Spill Emergency Plans, which inform development of the operational Oil Pollution Emergency Plan(s) (OPEPs). The OPEP's will:
  - Provide detail on the actions to be taken in the event of an unplanned release of hydrocarbon and must align with the Falklands National Oil Spill Contingency Plan (NOSCP). Specifically, the OPEP will:
    - Assess the potential consequences of an oil spill from drilling or production operations,
    - Define the roles and responsibilities of all emergency response parties,
    - Detail the action plan in the event of a spill,
    - Detail the available oil spill response resources available,
    - Outline and reference the proposed response procedures, and
    - Detail the regulatory spill reporting requirements (e.g., FIG PON 8).
  - Oil spill response planning is based on oil spill trajectory modelling and findings from the EIA. The OPEP must incorporate any learnings and best practice throughout the industry and it must include an assessment of the worst-case oil spill scenario for each operational area along with a detailed analysis of the availability and mobilisation timetable for oil spill response.
- Wildlife Response Plan (WRP):
  - Detailing the oiled wildlife response strategy to be implemented in the event of an unplanned release of hydrocarbons. Navitas will work with wildlife response providers and FIG to ensure the plan defines relevant details including:
    - Initial response requirements,
    - Management / coordination structures, and
    - Appropriate local responder organisation / involvement.
- Waste Management Plan (WMP):
  - The project-specific WMP will be developed in line with Navitas' Waste Management Procedure and will be tailored to each operation in line with the current Islands' infrastructure and in line with relevant FIG / UK legislation. The WMP ensures that:
    - The hierarchy of waste management is applied,
    - Waste is minimised, handled, stored and transported appropriately,
    - Waste is reported on correctly, and
    - The risks of cross-contamination at source and loss of containment are minimised.
- Iceberg Management Plan (IMP):
  - Describes all response actions required in the event of iceberg presence.
- Biosecurity Management Plan (BMP):

  - Provides a framework for the processes intended to reduce the likelihood of introducing terrestrial or marine non-native species, which may then become invasive to the ecosystem of the Falkland Islands.
- Bird Strike Management Plan (BSMP):
  - Detailing measures to ensure the monitoring, recording and reporting of bird-strikes as a result of artificial light as well as detail on how to manage / handle birds in the event of strikes.
- Harbour Management Plan (HMP):
  - Informed by a project-specific navigational risk assessment, the HMP includes:
    - Pre-notification protocols associated with the entry of vessels into Stanley Harbour,
    - Pre-defined passage routes within Stanley Harbour,
    - Procedures associated with vessel collision, and
    - Emergency response.

3.2.18.2 Environmental Monitoring and Management Plan

The EMMP captures all commitments relevant to environmental monitoring and management and will list these in one place alongside detail on the responsible person and the frequency of the requirement to enable tracking of actions throughout the life of the Phase 1 & 2 Development. Specifically, the EMMP will list:

- Legislative and corporate monitoring requirements,
- Baseline data and survey work proposed,
- Environmental research and studies relating to uncertainties in the EIS,
- Conditions associated with drilling and production license approvals, and
- Any actions falling out of the stakeholder consultation process.

It is anticipated that initially the EMMP will be overseen by a group of key stakeholders who will discuss and steer the issues and actions.

Throughout the Phase 1 & 2 Development lifecycle, information arising from the EMMP process will be reported to the EMMP Steering Group on a regular basis, relevant actions discussed and the programme of work updated as necessary. Meetings of the Steering Group will be open to FIG and invited statutory stakeholders with outputs reported publicly.

The basis of the EMMP, which is specifically informed by this assessment, is provided in Chapter 15 and will be translated into a live commitments and compliance register for use during the ‘Execute’ phase (Section 3.2.2).

4.5.10 Oil spill offshore 131

4.1 Introduction

The basis of design for the production of the Sea Lion field has been under development since 2011. Between 2012 and 2020, the relevant licences were owned by Premier Oil Exploration and Production Limited (here after referred to as POEPL) with their Joint Venture partner Rockhopper Exploration (Section 2.1.1). An EIS for POEPL's proposal for the Sea Lion Development was submitted and formally accepted in 2020 (Premier, 2020). However, in 2020 the parent company of POEPL (Premier Oil) and Chrysaor merged to form Harbour Energy Plc. Harbour Energy Plc. then sold POEPL to Navitas Petroleum in September 2022. At this time, POEPL was renamed Navitas Petroleum Development and Production Limited (hereafter referred to as Navitas). Navitas now operates the licences and has further optimised the proposed basis of design.

All intellectual property previously owned by POEPL in relation to the Sea Lion Project is now owned by Navitas and for the sake of context and completeness, the following chapter describes the historical review of alternatives carried out by POEPL (now Navitas) as well as the most recent consideration of alternatives carried out by Navitas since 2022.

4.2 Project development process

During its development, the Sea Lion basis of design must go through the following concept phases:

- Appraise (evaluation of project feasibility, identification of options),
- Select (detailed evaluation of options),
- Define (definition of selected option and Front End Engineering Design (FEED)),
- Execute (detailed engineering and construction), and
- Operate (start-up and ongoing operation).

When evaluating the options during the 'Appraise' and 'Select' project phases, balanced consideration of the following is required:

- Health and safety,
- Environment,
- Technical feasibility,
- Financial, and
- Strategic implications.

During the Appraise and Select phases, assessment of the proposed options is carried out by multi-disciplinary teams, including environmental and technical specialists, as well as stakeholder liaison personnel. Further, a number of technical and environmental supporting studies are undertaken to inform the EIA and final concept selection.

4.3 Historical consideration of alternatives

Between 2012 and 2020, numerous options for producing the Sea Lion Field were considered by POEPL (now Navitas), all of which required an appreciation of the potential challenges inherent within the project. The following sections provide an overview of the identification of key challenges, and consideration of alternative development strategies as carried out under POEPL. Of note, some options were ruled out on technical grounds rather than environmental grounds, however, where environmental criteria were considered key to the selection process, this is indicated in the narrative below.

4.3.1 Identification of key challenges

The identification of challenges inherent in the development of the Sea Lion Field, was informed by assessment of the:

- Potential obstacles to production of the field, and
- Concepts available to overcome the challenges.

Further, it is necessary to consider the above as they apply specifically to the processes of:

- Oil production - which refers to the process of producing the Oil and Gas (O&G) resources from the subsurface reservoirs to the processing installation in order to ready them for use on the installation, or export to market, and
- Oil export - which requires the offload of the product (the oil) from the producing installation and delivery to market in quantities which are cost efficient.

Screening studies commenced in 2011. The identified challenges are outlined in Table 4.1 below and indicated that the options for the Development were limited.

Table 4.1: Summary of the challenges associated with production and export of oil from the Sea Lion Field

Challenges		Consequences and potential solutions	
		Production	Oil Export
Reservoir fluid properties:	High pour point i.e., produced fluid temperatures need to be above 25°C in order to flow. The separated oil (the product) needs to be kept higher than 36°C. High wax appearance temperature (i.e., the oil will become less viscous at < 66°C) such that the live fluid will have potential gelling issues.	Water injection (required to maintain reservoir pressures and oil sweep) will need to be heated, Artificial gas lift will be required for oil wells to increase flow rate as it is produced from the reservoir, Subsea and topside temperatures will need to kept above 60°C in normal operating conditions to minimise the wax deposition / gelling issues, and Temperatures will need to be maintained during turndowns / start-up operations.	The crude will require relatively complex, high upgrading (cracking) refineries to enhance the value of the crude oil, and The crude will require heating in transit (which may limit trading tanker selection) and during storage at the refinery.
Water depth:	Approximately 450 m at the Sea Lion location	Limits the feasible choices for drilling and production installation facilities e.g., bottom founded structures are precluded, Low seabed temperature exacerbates the flow assurance issues described above.	n/a
Weather conditions:	Prevailing metocean conditions result in a significant percentage of time with high winds and moderate sea states, little seasonal variation and few periods of benign conditions.	Limits the choice of installation type, offshore construction and subsequent operations including resupply, personnel movements and oil offloading. The tandem offloading operation from the producing installation to the tanker will be limited by wave and wind conditions.	

Challenges		Consequences and potential solutions	
		Production	Oil Export
Remote and geopolitically isolated location:	Limited infrastructure to support oilfield development, production or crude oil export currently exists within the Falkland Islands, No existing oil market and isolation from regional market, Political isolation may limit third-party participation in supply chain and logistical support.	Extensive planning and innovation for personnel and materials management is required, High redundancy, spares inventory and crew maintenance capabilities for all critical equipment, Limited existing logistics means essentially dedicated additional capacity is required, and Facilities / equipment reliability needs to reflect long response time for support.	The remoteness of the field means that: There are significant travel distances involved in order to access the markets for waxy crude oil, A dedicated oil export arrangement is required noting that consistent delivery of oil to a purchaser is a prerequisite for its sale and generation of revenue, and The frequency of offtake operations is directly dependent on the production rate and operating uptime making it vulnerable to delays in tanker schedules etc.
		The ongoing sovereignty dispute over the Falkland Islands has an impact which extends to other countries in the region. It affects both the potential for local / regional markets and the ability to use existing oil transhipment facilities in South America. Potentially greater challenges in management of oil spills in remote location.	

4.3.2 Identification and consideration of options

4.3.2.1 Production

4.3.2.1.1 Option identification and consideration

During the 'Appraise' process, the following were considered for use during the Sea Lion Development:

- Semi-submersible drilling and / or production installation (Table 4.2),
- Tension Leg Platform (TLP) (Table 4.2), or
- Floating Production, Storage and Offloading (FPSO) vessel (Table 4.2).

A description of the above and a list of the advantages and disadvantages of each is provided in Table 4.2. Ultimately the semi-submersible option was rejected as it offered no advantage over the TLP or FPSO options.

Alongside consideration of the above, it was also necessary to review the options for improving oil recovery from the reservoir. The options included gas lift to reduce the density of the oil and make it flow more easily, the use of Electric Submersible Pumps (ESPs) or of Hydraulic Submersible Pumps (HSPs). Four options were shortlisted:

- TLP with a Floating Storage and Offloading (FSO) vessel and dry trees (i.e., topside wells) with ESPs,
- TLP with an FSO and wet trees (i.e., subsea wells) with HSPs,
- FPSO with artificial lift from downhole HSPs, or
- FPSO with gas lift.

The advantages and disadvantages of the above are also listed in Table 4.2.

Table 4.2: Comparison of the offshore production options identified during the 'Appraise' phase

Production installation	Producing installation options				Well options	
	Description	Advantages	Disadvantages	Outcome	Description	Outcome
Semi-submersible	Floating platform with hull pontoons that can be flooded to submerge the vessel to a pre-determined depth with the columns supporting the deck above the sea surface (Figure 4-1)	Relatively stable platform, and Capable of drilling and production in water depths ranging from 600 - 3,600 m.	Lack of deck storage space, Unable to support topside (dry) wells, and Need for separate FSO vessel	**Rejected:** With wet (subsea) X-mas trees and the need for an FSO, it offered no benefit over the TLP or FPSO options.	n/a	
TLP	Has a similar configuration to a semi-submersible but is moored to the seabed with vertical tethers (Figure 4-1)	Stable platform, Able to support dry trees, and Capable of drilling and production in water depths ranging from 300 - 1,500 m.	Limited weight carrying capacity, and Need for separate FSO vessel	Carried forward for consideration	TLP with FSO and ESPs for dry wells and gas lift to subsea wells.	Carried forward for consideration
					TLP with FSO and subsea wells with HSPs	**Rejected**
FPSO	A ship-shaped floating structure which is either based on a (converted) oil tanker hull, or a new build	Large oil storage capacity within the hull, No need for an FSO, and Substantial open deck space on which process and utility equipment can be placed.	Unable to support topside wells, and Requires a complex mooring system	Carried forward for consideration	FPSO with subsea wells and artificial lift from downhole HSPs	**Rejected**
					FPSO with subsea wells and gas lift	Carried forward for consideration

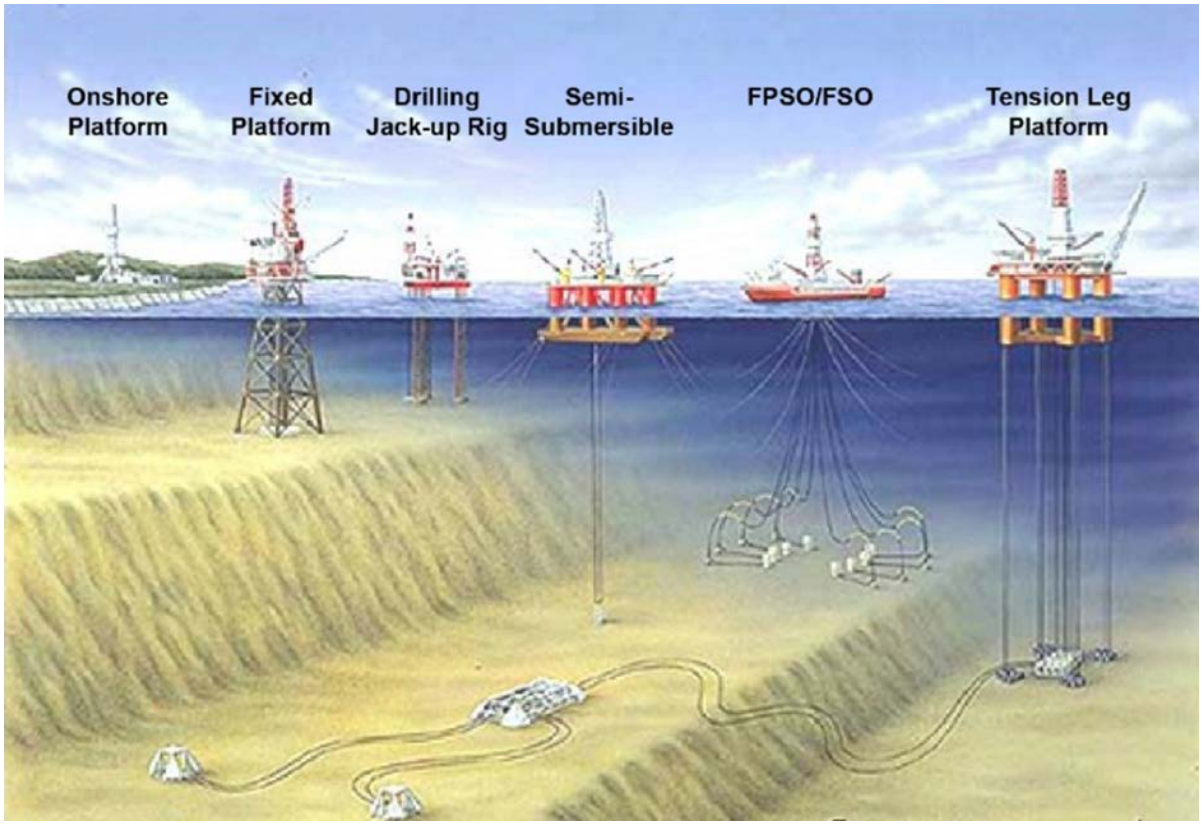

Figure 4-1: Types of offshore exploration and production facilities

4.3.2.1.2 Option selection

The detailed evaluation of the options in Table 4.2 above led to the conclusion that the following two options were the most viable:

- A TLP with artificial lift provided by ESPs (to topside oil production wells) and gas lift (to subsea oil wells), together with an FSO for oil storage, or
- A turret moored FPSO with artificial lift provided by gas lift to subsea (wet) oil production wells.

The Concept Select assessment ranked the proposed options in terms of performance and opportunity to minimise environmental impact against five environmental criteria (Table 4.3). Within each criterion, differentiators were selected to focus attention on those aspects where significant differences between the options might result (Table 4.3).

Both TLP and FPSO options were considered acceptable in terms of environmental criteria. The TLP approach was originally preferred, as it enabled full field development and informal scoping consultations were carried out in 2014 (Chapter 6). However the FPSO provided greater flexibility and enabled a phased development of the field and further scoping was carried out in 2015 (Chapter 6).

The FPSO with a detachable turret and gas lift was ultimately selected by POEPL for the (then) Phase 1 Development because:

- The use of gas lift provides reliability (no rotating equipment in the wells) and acceptable flow performance when compared with the use of ESPs,
- Inclusion of production and storage on an FPSO avoids the need for two infield installations which:

- Minimises the number of crude transfers between the producing, storage and export processes i.e., FPSO direct to oil tanker rather than TLP to FSO to oil tanker, and thus reduces the risk of oil spill, and
- Reduces the potential risk of collision with just a single infield installation and reduced resupply requirement.

- The FPSO can be disconnected from its mooring system and depart from the field should this be necessary (this would be a planned operation rather than an emergency response),
- Use of subsea wells in 450 m is a well-established, proven, and low risk practice with initial drilling undertaken by a dedicated Mobile Offshore Drilling Unit (MODU) which is only in the field during initial well drilling and for any subsequent well intervention if it were to be required, and
- The FPSO was more economic for the operation of (then) up to 30 wells.

Table 4.3: Concept screening differentiators

Environmental criteria	FPSO	TLP
Thermal power of the installation type	<20 MW(th)[1]	>50 MW(th)
Domestic discharges – (number of personnel)	<100	>200
Structural seabed disturbance – (areal extent)	<200,000 m^2	>300,000 m^2
Pipeline seabed disturbance (areal Extent)	<15,000 m^2	>20,000 m^2
Resource usage (steel / material use)	<100,000 te	>125,000 te

[1] Note that MW(th) is an indicator for potential fuel gas usage.

4.3.2.2 Oil export

4.3.2.2.1 Option identification and consideration

Having identified the use of an FPSO with wet wells and the use of gas lift to be the most effective production solution, screening studies identified the oil export system options that could be technically feasible for the Sea Lion Development. These were as follows:

- Offload from the FPSO directly to the export vessel for transport to market using:
  - Conventional Trading Tankers (CTT), or
  - A fleet of suitably equipped vessels.
- Offload from the FPSO to an Offshore Loading Shuttle Tanker (OLST) and Transfer to a CTT:
  - At an offshore / nearshore location,
  - At a sheltered location in another country, or
  - At a sheltered location in the Falkland Islands.

In discussions with FIG and their advisors in the UK (the Health and Safety Executive (HSEx)), it was decided that inshore transfer at a sheltered location in the Falkland Islands should be progressed as the project base-case and that, in parallel, the systems to offload directly to a CTT should be further explored.

Several criteria were considered important in the identification and selection of potential inshore transfer sites and through a desktop operational screening exercise in 2014, three potential inshore sites were identified. A comparative assessment of the environmental sensitivities of all three sites was carried out to enable differentiation, and ranking, of the sites (Premier, 2015c). Berkeley Sound was identified as the most appropriate site and an EIS for the whole development was submitted and underwent statutory consultation in 2018 (Chapter 6). Detail on the representations made, and the POEPL responses are provided in Appendix 3.

However, work to determine the viability of direct offtake (Premier, 2017b) as an option was also underway and a feasibility study was carried out to identify the key differences between offloading from the FPSO to an OLST (for transit to the inshore location for ship-to-ship transfer) and offloading from the FPSO directly to a CTT (for shipment direct to market). Six key differences were identified (Table 4.4). Proposals for ways in which these six areas could be managed to ensure that they were acceptable in terms of operational risk and health and safety are presented in Table 4.4 below.

Further work built on the above report and included:

- Gathering of updated and enhanced metocean datasets (including direct measurements from metocean buoys at the Sea Lion Field location), and
- Further studies to enhance the design of the process for direct offtake from the FPSO to a CTT to maximise availability and reduce risk, thus enhancing the likelihood of Safety Case acceptance by FIG and the HSEx. These were carried out following the commencement of the FEED, and with the support of an experienced FPSO operator.

A summary of the strengths and weaknesses of the direct offtake option is provided in Table 4.5.

Table 4.4: Six key areas that require management to successfully complete direct offtake

Key area	Issue	Proposed solutions
Tanker suitability and crew competency	The CTT (a 'tanker of opportunity') will not be dedicated to this duty and it may be its first time in the Sea Lion Field.	Tanker vetting and verification process implemented to select tankers to ensure they meet a pre-defined specification that includes assessment of suitability of equipment and crew competence, Minimum standard set for tanker crew competency and experience, and A tanker berthing crew will be sent to the CTT consisting of the Mooring Master and Assistant to supplement the CTT crew.
Personnel transfer	Safety of personnel (berthing crew) being transferred to the CTT.	CTT selection will ensure that as a minimum the tanker has winch landing facilities for lowering personnel by helicopter. During the CTT selection process, options for basket transfer and ladder access will also be considered. At the time of each transfer, the prevailing weather conditions will drive the selected transfer method. Safe personnel transfer supported by a detailed procedure. In addition to personnel (berthing crew) a 'mooring and offloading toolbox' will be transferred. The preferred method of transfer of the toolbox is *via* the CTT crane from the Multi-Role Supply Vessel (MRSV) in the field.
Tanker manoeuvring and maintaining appropriate position	The CTT has no Dynamic Positioning (DP) but will be connected to a hold-back tug; and Harsh environmental conditions.	Given the harsh environmental conditions, a controlled and consistent approach of the CTT to the FPSO is essential and should have sufficient uptime probability. The berthing of the CTT has been assessed under various conditions *via* Bridge Simulations involving the CTT and hold-back tug. Conditions including 3 m significant wave height and 30 knot winds were investigated and found feasible, meaning safe berthing is possible in Sea Lion conditions. Manoeuvring only requires a single tug, there was no occasion where a second tug was required at the bow of the CTT during simulations. The governing factor of a safe approach is the ability to safely abort the procedure, so a low speed of approach is required. It is recommended the approach of the CTT and tug is monitored electronically. In addition to speed of approach aids, GPS units may be a useful addition. During offloading, the CTT and its hold-back tug shall assure safe position, heading control and monitoring. An operability study has been undertaken to determine the feasibility and uptime for offtake under prevailing metocean conditions. The study showed a high availability for direct offtake, taking into account the limiting environmental conditions and procedure limits shown above. There are two specific dynamic interactions between the CTT and FPSO that could give particular cause for concern: namely fishtailing (or yaw), and surging.

Key area	Issue	Proposed solutions
		These can potentially lead to high hawser tensions and the need for disconnection if the CTT cannot maintain proper alignment. The studies performed to date have indicated these risks are not significant.
Connection and disconnection	Safety of personnel; and No bow loading system on the CTT; connection will be to a midship manifold	Optimising hawser design to minimise risks during connection and disconnection shall be reviewed during detailed design. Residual risks to be mitigated through development of detailed procedures for safe boatless hawser handling and midship loading hose operations. All operations can be performed without the need for a workboat (i.e., only personnel on the FPSO and CTT are involved). Acceptable environmental operating conditions have been developed for approach and berthing including: Mean 10-min wind speed < 30 knots, Significant wave height <3 m, and Visibility > 1,000 m.
Safety systems	The CTT has no DP but is connected to a hold-back tug; No 'green line system established'[1]	Manual shut down interface and firefighting capabilities shall be in place on both the FPSO and CTT during transfer operations. A tanker position reference system will be provided and shall comply with relevant maritime recommendations, following the 'Tandem Loading Guidelines' (OEUK, 2014). The tanker position reference system will be equipped with a capability to interface with various controls, monitoring systems and communication systems allowing the Berthing Master to initiate manual emergency shutdown. This would cause the FPSO cargo offloading pumps to stop and the offloading valve to close. During offtake, the CTT crew shall monitor the mid-ship manifold and bow mooring. In case of any abnormality the CTT cargo control room and Mooring Master will be informed and action initiated. The MRSV located near to the operation, but outside the exclusion zone, shall have firefighting capabilities.
Emergency disconnection	No bow loading system on the CTT; connection will be to a midship manifold	In case of emergency all effort will be made to stop offload and disconnect the hose in a controlled manner prior to hawser disconnection (and CTT departure) to prevent engaging of the Marine Breakaway Coupling on the floating hose. Controlled emergency disconnection of the CTT from the hawser connect shall be achieved. An emergency disconnection can take place in less than one minute by release of the hawser Quick Release Hook from the FPSO and parting of the Marine Breakaway Coupling on the floating hose. The coupling is designed stop leaks during unplanned disconnection and also protect the hose sections

[1] In the North Sea, DP OLSTs use the term "greenline system" to describe the "permit to pump" telemetry system installed. Sensors are fitted to various systems on the tanker and it is only when all of these sensors are in the correct position that the permit to pump signal is given to the FPSO, which allows the offloading pump to be started.

Table 4.5: Strengths and weaknesses of oil export *via* direct offtake in the Falkland Islands

Strengths	Weaknesses
Avoids bringing crude oil inshore.	Longer transfer hose means a bigger potential transfer spill inventory
Inherently safer as removes three vessels from the field and avoids two oil transfer operations (i.e., FPSO to OLST and then OLST to CTT).	FPSO offloading undertaken by tankers of opportunity so crew competency requires assurance
Best energy efficient option as three vessels are removed.	Fewer associated employment opportunities (local content)
Low fixed costs.	-
No DP operations; reduces underwater noise	-
Large available fleet of CTTs (i.e., no single point failure).	-
Only one support vessel required.	-
No permanent exclusion zones in Berkeley Sound.	-

4.3.2.2.2 Option selection

The above investigations ultimately demonstrated that direct offtake was indeed viable and could commence from the start of operations. POEPL and FIG were satisfied that direct offtake represented the best option. It was considered to be inherently safer and proved to be the best environmental option. As a result, the inshore transfer was removed from the basis of design. The EIS was amended and underwent a second statutory consultation in 2020 (Chapter 6). The EIS describing the Sea Lion Development, with direct offtake as the base-case oil export option, was accepted in 2020.

4.4 Development optimisation by Navitas

Navitas' primary focus has been to accelerate the path to First-Oil and deliver a lean and financeable development plan for the Sea Lion Field, without compromising environmental or safety standards, or potential reservoir performance. Following an internal document review of POEPL's concept selection process, Navitas was aligned with the proposed basis of design with regard to the use of an FPSO with subsea development and direct offtake as the oil export method. Recognising this as the most cost-effective development solution, Navitas further refined the Development concept by considering the following:

- Drilling:
  - Phased drilling schedule,
  - Reduction in well count, and
  - Optimisation of First-Oil and the Phase 1 & 2 well counts.
- The FPSO and considerations of:
  - The source of the vessel (new-build *vs*. redeployment of an existing vessel), and
  - The size of the FPSO and daily production figures.
- The well completion design, and
- Field life.

Of note, some options were ruled out on technical grounds rather than environmental grounds, however, where environmental criteria were considered key to the selection process, this is indicated in the narrative below.

4.4.1 Well count and phased drilling schedule

Two development phases have been considered so far for the Sea Lion Field Northern Development Area, with the potential for a third development phase to be evaluated, post development and during early production. The base-case for the Phase 1 & 2 Development is to complete 23 wells and to conduct the drilling campaign over the two separate phases, resulting in two episodes of simultaneous operations (SIMOPs) separated by a period of steady state production. This is considered optimal in order to:

- Ensure First-Oil can be achieved within approximately three years,
- To enable assessment of the reservoir performance prior to ongoing expenditure on drilling,
- To provide opportunity for learning from the first tranche of wells, and
- To optimise use of the MODU with regard to exploration of less economic (and more remote) targets which may be matured as additional data is acquired.

The phased options considered included:

- Option 1 (23 wells):
  - Phase 1: up to 12 drilled wells, with five completed before First-Oil, and
  - Phase 2: up to 12 drilled wells.
- Option 2 (23 wells):
  - Phase 1: 18 wells, with 11 completed before First-Oil, and
  - Phase 2: 5 wells.

Of importance, the number of wells to be delivered in each phase is a function of the host facility (the FPSO) and expected production performance.

4.4.2 FPSO

4.4.2.1 Sourcing the FPSO

Navitas has performed market surveys and contracted an FPSO broker to assist in assessing the current FPSO market conditions. Upon evaluating newbuild hulls, CTT conversions, and redeployment of an existing FPSO, the most compelling investment opportunity was for the redeployment of an existing FPSO. The benefit of redeployment is the potential for quicker project execution and lower overall capital cost, as well as the opportunity to finance the FPSO *via* Operating Expenditure, through a long-term charter with the owner of the vessel. It also has environment benefits compared to a new-build with regard to the life-cycle footprint.

4.4.2.2 Optimal vessel size

Navitas has assessed numerous vessel sizes, production capacities and hull configurations to find the best solution for Phase 1 & 2 Development.

Options considered included:

- An FPSO with capacity for peak 55,000 bopd using Option 1 for the drilling schedule, i.e:
  - Phase 1: up to 12 drilled wells (seven OP wells drilled & completed prior to First-Oil), and
  - Phase 2: up to 12 drilled wells.
- An initial FPSO with capacity for 45 k bopd, subsequently replaced by a vessel with 80k bopd, again using Option 1 for the drilling schedule, or
- An FPSO with capacity for 80,000 bopd, and Option 2 phased drilling schedule, i.e:
  - Phase 1: 18 wells, with 11 completed before First-Oil, and

- Phase 2: 5 wells.

An economic analysis, comparing the use of a 55,000 bopd capacity FPSO *vs* the larger vessel with capacity for 80,000 bopd is presented in Navitas' Long-term Development Philosophy Document (SLN-SUB-SBS-PLN-00001-06). The study demonstrated only a marginal benefit with the larger vessel in terms of NPV10[12] and recoverable resource. However, the main advantage of the 55,000 bopd capacity FPSO will be reduced capital exposure by leasing a redeployed FPSO, and the ability to subsequently develop other field areas to the south.

The result of this assessment was to select an Aframax (or larger) hull with 55,000 bopd capacity which will ensure more efficient utilisation of the FPSO and therefore a lower emissions intensity per barrel of oil.

4.4.3 The well completion design

The base-case is to run Open Hole Gravel Pack (OHGP) well completions as opposed to the perforation completion proposed by POEPL. The advantages of the OHGP are:

- Less debris in the wellbore thus minimising risk to the FPSO so that the wells can be initially cleaned up to the FPSO rather than the MODU, the latter of which would require flaring;
- Minimises the likelihood of sand within the produced fluids, and
- Removes the requirement for perforation guns and the use of explosives for completion:
  - Note that while this decision was made on technical grounds, it is also considered the best environmental option as it lessens the risk of debris downhole such that well clean-up can be carried out to the FPSO rather than the MODU thus negating the base case need for flaring during clean-up, and requires less use of land onshore in the Falklands for storage of explosives.

4.4.4 Field life

The reduced daily production rate that results from fewer wells producing to the smaller FPSO than that proposed by POEPL means that while the FPSO is more fully utilised, thus increasing overall efficiency per barrel of oil, the overall Field Life is longer. Navitas anticipate a Field Life of up to 30 years.

4.4.5 Selected basis of design

The full basis of design is described in the Development Description (Chapter 5). However, by way of summary, and following all the considerations above, the optimised Sea Lion Development basis of design is as follows:

- A phased drilling campaign,
- Use of a redeployed FPSO with capacity for 55,000 bopd production,
- Up to twelve wells will be drilled overall in Phase 1, with five wells completed prior to First-Oil (Stage 1),
- The remainder of the Phase 1 wells will be drilled alongside the producing FPSO in Stage 2a, which will be a period of SIMOPs (simultaneous operations),
- This will be followed by a duration of steady state production while the reservoir performance is assessed,
- The Phase 2 wells will be drilled during a second stage of SIMOPS, Stage 2b, and
- Oil export *via* the direct offtake method will commence after First-Oil.

[12] NPV10 means Net Present Value in money of the day using a 10 % forward discount rate.

4.5 Mitigations not used

As required by the FIG EIA Guidance, the sections below list the mitigation measures potentially available but not proposed for use in this project, and details why they are not considered appropriate for this development.

4.5.1 Drill Cuttings disposal

During drilling the re-injection of drill cuttings into a dedicated well was rejected as an option because the benefits of disposing of the cuttings was negated by the cost of drilling another well to receive the cuttings (a disposal well). Another option for cuttings disposal was to take them back to shore but as there are no suitable facilities on the Islands for appropriate treatment and/or disposal this option was not progressed further. Similarly, it was not considered viable to send the cuttings back to the UK for treatment and disposal. As noted in Section 5.4.5.3.1, a Thermo-Mechanical Cuttings (TCC) unit is being deployed on the rig, which is able to treat the cuttings offshore and they will be disposed of over the side of the rig, falling to the seafloor – this impact is assessed in Section 10.6.

4.5.2 Drilling mud

There was an option to use Water-based Mud (WBM) in the reservoir sections but WBM cannot be used for lower sections of the Sea Lion wells as only Non-Aqueous Drilling Fluid (NADF) (see Section 10.6.4.1.3.1) gives confidence around hole stability through highly deviated sections. NADF will be used for the lower sections of the wells and the use of this is considered in Section 10.6 and Section 10.7.

4.5.3 Hydrotest water

It is currently planned that hydrotest water will not be routed back to the FPSO during commissioning so will be disposed of overboard. The impact of this discharge is assessed in Section 10.7. Navitas will investigate routing of hydrotest water in detailed design to determine whether any can be returned to the FPSO before being injected downhole.

4.5.4 Atmospheric emissions

Electrification (power from shore) is not a viable option as there is not sufficient power available from the shore in this region, nor is there a realistic prospect of this being available in the future.

It was considered whether the vent gases from the CTT would be recovered as opposed to vented but CTT vent gas recovery capability is not sufficiently widespread in the fleet.

An ‘on demand’ HP flare ignition to remove the need for a pilot flame will be investigated during the FEED process but is not yet included as a project-specific mitigation in the impact assessment.

The impact of the atmospheric emissions from the Sea Lion Development is assessed in Section 10.9.

4.5.5 Waste

Construction of a Navitas landfill site in the Falklands has been discounted as this is not considered commercially viable. Additionally, it is considered more beneficial for a collaborative approach to be taken in long-term waste plans. Navitas will continue to collaborate with FIG on longer-term waste plans. The waste produced from the Sea Lion Development and the disposal of that waste is assessed in Section 10.10.

4.5.6 Marine invasives

The use of antifouling measures, e.g., slick paints is being investigated to reduce marine growth on the hull of the FPSO. The assessment of marine invasive species (Section 10.12) does not take this mitigation into account at this time, to ensure the worst-case is assessed.

4.5.7 Disturbance to other users of the sea

Over-trawlable subsea infrastructure is not considered necessary here due to the water depth and the lack of fishing activity in the area targeting benthic species. The impact to other users of the sea from the placement of the subsea infrastructure is considered in Section 11.1.

4.5.8 Resource competition – Water

Importing fresh water by vessel was considered and discounted in favour of implementing a freshwater header tank at the TDF, which will alleviate pressure on supply. The assessment of water use by the Development is considered in Section 11.4.

4.5.9 Resource competition – Electricity

Building a local (renewable) power supply for the onshore supply base was considered but Navitas has decided to buy electricity from the existing grid. See Section 11.5 for an assessment of the power usage of the Sea Lion development.

4.5.10 Oil spill offshore

The use of dispersants for responding to an oil spill from the Sea Lion Field were discounted as dispersants are not a viable response option for Sea Lion crude as found during oil tests (CEDRE, 2017) as the oil is too waxy to respond to chemical dispersal.

Similarly, the tests conducted at CEDRE (2017) found that oleophilic and weir skimmers were not viable for use with the very waxy Sea Lion crude.

Of note, other skimmer devices were considered viable for the Sea Lion crude and weir skimmers are viable for use with MGO. The impacts and risks of an oil spill at the Sea Lion Field are considered in Section 12.1.

5 SEA LION FIELD, PHASE 1 & 2 DEVELOPMENT DESCRIPTION

Table of Contents

5.1 Introduction 136
5.1.1 Chapter structure 136
5.2 Project overview 136
5.2.1 Project schedule 143
5.3 Sea Lion reservoir characteristics 145
5.4 Phase 1 & 2 Drilling operations 145
5.4.1 Drilling location 145
5.4.2 Drilling Schedule 146
5.4.3 Mobile Offshore Drilling Unit (MODU) 147
5.4.3.1 MODU moorings 148
5.4.4 Number and type of wells 148
5.4.4.1 Phase 1 - Pre-First-Oil wells (Stage 1) 148
5.4.4.2 Phase 1 - Post-First-Oil wells (Stage 2a) 149
5.4.4.3 Phase 2 wells (Stage 2b) 149
5.4.4.4 Assumptions about the drilling operation 149
5.4.4.5 Re-drill contingency 150
5.4.5 Well design 151
5.4.5.1 Drilling, casing and wellheads 151
5.4.5.2 Drilling sequence (batch or sequential drilling) 153
5.4.5.3 Drilling muds and drill cuttings management 153
5.4.5.3.1 NADF: Lower-hole sections 153

5.14 Phase 1 & 2 base-case mitigation technologies 225
5.15 Estimated quantities of residues and emissions resulting from the project 228

5.1 Introduction

In order to identify and understand the potential environmental impacts and risks, and to enable quantification of the residues and emissions to the environment (as requested in the Falkland Islands Government (FIG) EIA Guidance Note (FIG, 2016e), it is necessary to understand:

- What activities will be carried out during the Sea Lion Field Northern Development Phase 1 & 2 (hereafter referred to as the Phase 1 & 2 Development), and
- What technologies will be built-in to the design of the facilities.

Whilst some of the details can only be finalised upon the final award of contracts to specific vendors, the Phase 1 & 2 activities will be consistent with the description provided here which has been prepared to be conservative and therefore aims to describe the worst-case with regard to the residues and emissions.

Note: the following chapter introduces many technical terms and abbreviations. The abbreviations are explained at the first use in the narrative, and in the tables / figures throughout. However, they are also listed in the Abbreviations table in Chapter 18 and a Glossary is included in Chapter 19 to explain any technical terms. These two sections may be of use when reading the below.

5.1.1 Chapter structure

The following chapter describes:

- An overview of the project (Section 5.2)
- The project schedule (Section 5.2.1),
- The Sea Lion Field reservoir characteristics (Section 5.3),
- The drilling operation (Section 5.4),
- Construction: installation of offshore drilling, production and export facilities (Section 5.5),
- Hook-up and commissioning of the FPSO (Section 5.6),
- Simultaneous drilling and production operations – SIMOPS (Section 5.7),
- The production facilities (Section 5.8),
- Steady state production (Section 5.9),
- Oil export process and facilities (Section 5.10),
- Logistics and infrastructure (Section 5.11),
- Decommissioning (Section 5.12),
- Development resilience to the effects of climate change (Section 5.13),
- The Phase 1 & 2 Development base-case mitigation technologies (Section 5.14), and
- The estimated output quantities of residues and emissions from the Phase 1 & 2 Development (Section 5.15).

Sufficient detail is provided below to enable assessment of the environmental impacts of Stages 1-3 under planned, unplanned and accidental conditions. As described in Section 5.12, full details on the decommissioning operation (Stage 4) will be described in a dedicated decommissioning Environmental Impact Assessment (EIA), which will be developed prior to cessation of production.

5.2 Project overview

The Sea Lion Field lies in water depths of approximately 450 m and is located in Block 14/10 in the hydrocarbon license area PL032, which is approximately 220 km to the north of the Falkland Islands. Hydrocarbons are reservoired in sandstones of early Cretaceous age approximately 2,000 m below the

seabed. A Field Life of up to 30 years has been projected and it is estimated, using the P50 case, that approximately 310.5 million stock tank barrels (MMstb) of oil can be recovered in this timeframe.

The proposed Phase 1 & 2 development wells will be drilled from six Drill Centres (DC) with a contingency for an alternative gas injection DC, by a Mobile Offshore Drilling Unit (MODU).

The Development will therefore involve drilling a maximum of 26 wells and completing a maximum of 23 wells as follows:

- The Sea Lion Field Northern Development Area - Phase 1:
  - Seven Oil Production (OP) Wells,
  - Three Water Injection (WI) Wells,
  - One Gas Injection (GI) well, and
  - One contingent GI well at the 'Casper' gas reservoir (in the event the planned location is unsuitable for gas injection, e.g., oil encountered on the NW flank instead of gas).
- The Sea Lion Field Northern Development Area - Phase 2:
  - Nine OP wells, and
  - Three WI wells.
- Either Phase 1 or Phase 2:
  - Two contingent re-drills (the complete re-drilling of individual wells, or of sections of wells (collectively referred to as 're-drills'), may be required in response to technical problems).

To account for the worst-case (as requested in the EIA Guidance Note (FIG, 2016e)), this EIS assesses the impact of:

- Drilling up to 26 wells, and
- Production operations from 23 completed wells.

Production operations will be carried out using a Floating Production, Storage and Offloading (FPSO) unit located approximately 2 km from the main Production Drill Centre (DC) (NA-P-01), 3.5km from the Water Injection DC (NA-W-01), 5.3 km from the Gas Injection DC (NA-G-01), 3.5 km from the Southern Production DC (NA-P-02), 2.7 km from the East Water Injection DC (NA-W-02) and approximately 4.5 km from the Southern Water Injection DC (NA-W-03). An illustration of the main project elements is shown in Figure 5-1 and Figure 5-2.

In addition to crude oil (which is the target product), there will also be hydrocarbon gas in the Sea Lion reservoir fluids which will be produced from the oil wells. Gas that comes out of the oil wells is referred to as 'associated gas'. This associated gas will be used for fuel on the installation, for 'gas blankets' in cargo / slops tanks and for 'gas lift' to improve the oil recovery. Any surplus gas will be re-injected into the GI well.

Seawater injection will also be used to improve oil recovery and will be distributed to the dedicated WI wells. In addition to this, water which comes out of the reservoir along with the oil and associated gas (referred to as 'produced water') will also be re-injected, both to enhance recovery and as an alternative to discharge. In the case of temporary operational or maintenance issues e.g., downtime in the Produced Water Reinjection (PWRI) system (Section 5.8.5.8), produced water may be discharged overboard whilst being monitored for the specified limits (Section 5.8.5.4.1). The amount of produced water available for re-injection will increase over time as the oil content of the reservoir depletes.

Once the oil has been processed on the FPSO, it will be ready for export to market *via* direct offtake from the FPSO. The direct offtake of oil from the FPSO will:

- Minimise the risk of exposure of environmentally sensitive areas in, and around, the Falkland Islands to hydrocarbon spills from offloading operations, and
- Require additional offshore mitigations to be put in place e.g., a dedicated Offshore Support Vessel (OSV) to attend the Commercial Trading Tanker (CTT) offshore in addition to the presence of the Emergency Response and Rescue Vessel (ERRV).

For the purposes of this EIS, the Development has been divided into four stages to differentiate construction and production operations activities. The activities and processes associated with each stage are explained in more detail later in this chapter. However, by way of introduction, an overview of the stages of the initial Phase 1 & 2 Development is provided in Table 5.1.

Table 5.1: Overview of the activities associated with the four stages of the proposed Sea Lion Phase 1 & 2 Development

Phase 1 (11 wells + 1 contingency GI well))	**Stage 1: 31 Months (5 completed wells + 1 contingency GI well)**	**Stage 1 – Pre-First-Oil (construction only): All activities up to 'First-Oil'- drilling / well construction and installation of production facilities, including:** • Commissioning and operation of the onshore production support and drilling support bases, • Mooring of maximum two Large Transport Vessels (LTVs) at any one time in Berkeley Sound for equipment storage and associated vessel activity (for a non-consecutive total of 13 months over Stages 1, 2a, interim Stage 3, and Stage 2b), • Commissioning and operation of an onshore drilling mud plant, • Use of the existing Temporary Dock Facility (TDF), • Drilling, completion and suspension of the first tranche of Phase 1 wells using a MODU **Note:** up to eight wells will be drilled with only five completed prior to First-Oil), • Installation of the MODU anchor and mooring system, wellheads / conductors, FPSO mooring system and turret buoy, connection of the flowlines and risers to the turret buoy and the offshore subsea production infrastructure (e.g., X-mas trees, subsea manifolds, manifold support pile, umbilicals, risers, flowlines, jumpers, hydraulic and electric flying leads and, potentially mud mats for support), • Pre-commissioning of the Subsea System, • Arrival and installation of the FPSO, • Hook-up and commissioning of the FPSO to the pre-installed turret buoy and subsea production equipment, • Introduction of hydrocarbons to the production facilities and commencement of production operations Production Drill Centre (NA-P-01), Water Injection Drill Centre (NA-W-01) and the Gas Injection Drill Centre (NA-G-01), • Flow-back of the OP and GI wells to the FPSO: o Overall contingency for four well tests to the MODU with flaring. • 'First-Oil' with Production Operations commencing from the first completed Phase 1 wells, • Use of supply vessels and Emergency Response and Rescue Vessel (ERRV) to support operations in the field, and • Use of fixed-wing aircraft, road transport, vessels and helicopters throughout.
	Stage 2a: 7 Months (6 wells)	**Stage 2a – Simultaneous operations (SIMOPS) - concurrent drilling and initial (post First-Oil) production (i.e., having the MODU drilling in-field with early production from the FPSO occurring at the same time):** • Use of the onshore supply base, liquid mud plant and TDF, • Anchoring of maximum LTVs at any one time in Berkeley Sound and associated vessel traffic (for a non-consecutive total of 13 months over Stages 1, 2a, interim Stage 3, and Stage 2b), • Drilling and completion, *via* a MODU, of the remaining Phase 1 wells (six wells including completion of three of the wells drilled in Stage 1), • Installation of the remaining subsea production infrastructure (e.g., X-mas trees, jumpers, hydraulic and electric flying leads), • Flow-back of the OP and GI wells to the FPSO: o Overall contingency for four well tests to the MODU with flaring.

Phase 2 (12 wells)		• Production Operations of all 11 subsea Phase 1 wells controlled from the FPSO, and • Direct offtake (offload) of crude from the FPSO to the purchaser's CTT. • Use of supply vessels and ERRV on standby to support operations both in the field and offshore, construction vessels at the LTV mooring location in Berkeley Sound, and • Use of fixed-wing aircraft, road transport, vessels and helicopters throughout.
	Stage 3 (28 Months)	**Stage 3 – Steady State Production (Production Only):** • Production Operations of up to 11 subsea wells controlled from the FPSO, • Ongoing use of the onshore supply base and TDF, • Direct offtake (crude oil offload) from the FPSO to the purchaser's CTT for export to oil market, • Use of supply vessels and ERRV on standby to support operations in the field, and • Use of fixed-wing aircraft, road transport, vessels and helicopters throughout.
	Stage 2b: 28 Months	**Stage 2b –SIMOPS, Production alongside drilling and construction of up to 12 Phase 2 wells:** • Use of the onshore supply base, liquid mud plant and TDF, • Anchoring of maximum LTVs at any one time in Berkeley Sound and associated vessel traffic to support the Stage 2b Subsea construction campaign (for a non-consecutive total of 13 months over Stages 1, 2a, interim Stage 3, and Stage 2b), • Drilling and completion of 12 Phase 2 wells from a MODU: • Flow-back of the OP and GI wells to the FPSO: o Overall contingency for four well tests to the MODU with flaring. • Installation of the remaining subsea production infrastructure (e.g., X-mas trees, jumpers, hydraulic and electric flying leads), • Production Operations of all subsea wells controlled from the FPSO, • Direct offtake (offload) of crude from the FPSO to the purchaser's CTT, • Use of supply vessels and ERRV on standby to support operations both in the field and offshore, construction vessels at the LTV mooring location in Berkeley Sound, and • Use of fixed-wing aircraft, road transport, vessels and helicopters throughout.
Stage 3 - Ongoing Steady State production for Field life		
N/A	Stage 4	**Stage 4 – Decommissioning (No Production):** • Decommissioning activities once the field is ready for abandonment: o Decommissioning of the wells, subsea production infrastructure, and demobilisation / removal of the FPSO, and o Decommissioning of at-shore (TDF) and onshore infrastructure.

5.2.1 Project schedule

The duration of each of the Stages is presented in Table 5.2. The overall project timescale is provided in Table 5.3 below, however, please note that this may be subject to change depending upon the award of project contracts.

Table 5.2: Duration of Stages within the Sea Lion Field Northern Area Phase 1 & 2 Development

Development stage		Duration				
		Months	Years	Weeks[1]	Days[2]	Fortnights[3]
Stage 1	Pre-First-Oil drilling	31	2.6	133	942	67
Stage 2a	Post-First-Oil SIMOPS	7	0.6	30	213	15
Stage 2b	SIMOPS	28	2.3	120	851	61
Stage 3	Steady state production	325	27.1	1,398	9880	706

[1] Calculated as the number of months multiplied by 4.3.
[2] Calculated as the number of months multiplied by 30.4.
[3] Calculated as the number of days divided by 14.

Note: the stars indicate key milestones.

5.3 Sea Lion reservoir characteristics

Based upon the results of the exploration and appraisal wells previously drilled into the reservoir, Sea Lion crude is known to be a medium density, sweet (low sulphur) crude with a high wax content (23 % using the n-alkane method and 42.3 % using the wax crystallisation method). The crude has a 'live' (i.e., when it still contains gas) pour point of 25 °C and a dead (i.e., once gas has been removed) pour point (the temperature below which stabilised crude does not pour out of an upturned container) of 36 °C. Further, the crude has a Wax Appearance Temperature (WAT, the temperature at which wax starts to crystallise) of 66 °C such that viscosity of the crude increases below 66 °C.

Therefore, flow assurance needs to be factored into the design of the subsea facilities, FPSO and oil export facilities (Section 5.8.4.1). The Sea Lion reservoir properties are summarised in Table 5.4.

Table 5.4: Sea Lion reservoir properties

Reservoir	Eastern Area (or "East Flank") [well 14-10/5]	Western Area (or "West Flank") [well 14-10/6]
Gas Oil Ratio (GOR) standard cubic feet / stock tank barrel (scf/stb)	268 (with a range = 215-284)	418 (with a range = 403-466)
Gas Specific Gravity (SG)	0.712-0.787	0.749-0.761
API (calculated) gravity (SL10 and SL20 sands)	28-29	28.5-29
Reservoir depth Total Vertical Depth (TVD) Mean Sea Level (MSL)	2,415 m	
Initial reservoir pressure	242 bara (3,509 psia)	
Initial reservoir temperature	86°C	
Wax content	23 % (n-alkane method) 42.3 % (wax crystallisation method)	
Asphaltene content	0.05 – 0.7 %	
Wax Appearance Temperature	66°C Topsides, storage & offloading (dead single phase oil) 60°C Subsea (live multiphase oil)	
Pour point crude	36°C Topsides, storage & offloading (dead single phase oil) 25°C Subsea (live multiphase oil)	

5.4 Phase 1 & 2 Drilling operations

This section provides a description of the drilling location and schedule, the MODU and its moorings and detail on the number, type and location of wells to be drilled, the well design, management of drill cuttings and all fluids and chemicals associated with the drilling operation. The description is applicable to all wells drilled during Phases 1 & 2 of the Development.

5.4.1 Drilling location

The planned and contingent drill centre locations are provided in Table 5.5.

Table 5.5: Sea Lion drill centre co-ordinates by Development phase

Drill Centre	Northing / Easting[1]	Latitude / Longitude	Phase 1 Wells	Phase 2 Wells
Production Drill Centre, NA-P-01	566 312.62 E	49 15´ 56.329 S	7 (2 pre-1st oil)	5
	4542 613.14 N	59 05' 18.654 W		
Water Injection Drill Centre, NA-W-01	564 612.6 E	49 16´ 13.178 S	3 (2 pre-1st oil)	-
	4 542 113.00 N	59 06´ 42. 475 W		

Drill Centre	Northing / Easting[1]	Latitude / Longitude	Phase 1 Wells	Phase 2 Wells
Gas Injection Drill Centre, NA-G-01	562 966.63 E	49 17´30.566 S	1 (pre-1st oil)	-
	4 539 742.00 N	59 08´ 02.576 W		
Southern Production Drill Centre (Phase 2), NA-P-02	566 312.79 E	49 18´ 13.933 S	-	4
	4 538 363.26 N	59 05´ 16.108 W		
Southern Water Injection Drill Centre (Phase 2), NA-W-03	567 058.43 E	49 19´04.263 S	-	1
	4 536799.76 N	59 04´38.243 W		
East Water Injection Drill Centre (Phase 2), NA-W-02	568 716.13 E	49 15´ 13.675 S	-	2
	4 543 901.00 N	59 03´20.534 W		
Contingent Casper Gas Injection Drill Centre (Phase 1), NA-G-02[2]	562 327.75 E	49 19´ 30.490 S	1 (contingent)[3]	-
	4 536 045.50 N	59 08´ 32.126 W		

[1] Co-ordinate system: WGS84 Transverse Mercator (TM) 60W and co-ordinates are for the centre point of the Drill Centre. Well locations are notional and may be subject to revision prior to drilling.
[2] There will be only six operational DC's in total as only one of the GI's will be completed.
[3] The requirement for the contingent GI well will become apparent during Stage 1. if required it will be drilled in Stage 1.

5.4.2 Drilling Schedule

The indicative schedule for drilling, completion and suspension of the wells by the MODU, and flow back of the wells to the FPSO, is shown in Table 5.6. First-Oil (Stage 1) is anticipated from the field 18-24 months after the project is sanctioned.

Table 5.6: Indicative drilling by MODU at the Sea Lion Field development

Activity	Development stage	Number of wells	Number of days
MODU in-field preparation	Stage 1	-	5 days mobilisation[1]
Drill eight Phase 1 wells: (5 x OP, 2 x WI and 1 x GI). Complete 5 wells. **Note:** only two of the OP wells will be completed prior to First-Oil[2].	Stage 1	5	52 days per well
FPSO arrives	Stage 1	-	-
FPSO installation, hook up and commissioning	Stage 1	-	-
First-Oil	Stage 1	-	-
Complete the three pre-drilled OP wells. Drill and complete a further three Phase 1 wells (2 x OP and 1 x WI)[3]	Stage 2a	6	52 days per well
MODU moves off	Stage 2a	-	5 days
Steady State Production	Stage 3		
MODU in-field Preparation	Stage 2b		5 days
Drill and complete 12 Phase 2 wells (9 x OP & 3 x WI)	Stage 2b	12	52 days per well
MODU moves off	Stage 2b		5 days

[1]As yet it is unknown where the MODU will mobilise from, this will be resolved during the rig tendering process.
[2] In the event that the contingent GI well is required to be drilled it would be included within Stage 1.

[3] **Note:** The drilling in Stages 1 and 2a will run as a continuous drilling campaign. The distinction between Stage 1 and 2a is that 2a is post-First-Oil and drilling will continue as the FPSO starts production.

5.4.3 Mobile Offshore Drilling Unit (MODU)

Drilling operations for Phase 1 & 2 will be carried out using a semi-submersible drilling rig, an example of which is shown in Figure 5-3. Semi-submersible drilling rigs are one of the more commonly used types of MODU worldwide with the ability to drill in deeper water. The MODU will be de-ballasted during transit and ballasted down while on station and drilling to provide a stable platform and keep the MODU on location. The MODU is secured into position using anchors.

At the time of writing, the contract for the MODU has not yet been awarded for the Phase 1 & 2 Development. However, for the purposes of assessing the environmental impacts of drilling activities, generic details of an anchored MODU have been assumed. Where specific details require confirmation, worst-case assumptions have been made.

While in position, a statutory 500 m exclusion zone will be established around the MODU in accordance with safety legislation. Unauthorised vessels, including fishing vessels, will not be permitted access to the 500 m zone. An ERRV (sometimes referred to as a stand-by vessel) will be present in the field while the MODU is on location.

Figure 5-3: Photograph of a typical anchored semi-submersible drilling rig (the *Ocean Valiant*)

5.4.3.1 MODU moorings

On location, the MODU will be held in place by anchors, or will be attached to pre-installed moorings. Anchor layouts will vary based on final MODU selection. It is anticipated that, as a worst-case, the selected MODU will require ten anchors with different lengths of chain required in order for the rig to maintain position. Approximately 300 m of chain are expected to be in contact with the seabed per anchor.

When all anchors have been deployed in their correct position, the rig will be ballasted down and the anchors bedded in firmly by appropriately tensioning each chain. At each DC location, all wells will be accessible to the MODU without the need to relocate anchors. However, the mooring will be recovered and re-laid when the MODU is required to move from one DC to another. Anchors will also be re-laid if the MODU has to move away from the DCs for any reason. Pre-set anchors may be suction piled or conventional anchors and will be reviewed during the detailed design of the project.

Details on the vessels used to transit, position and anchor the MODU are provided in Section 5.11.2.

5.4.4 Number and type of wells

For the Phase 1 & 2 Development a maximum of 26 wells will be drilled by the MODU, with only 23 of the wells completed and connected ('tied-back') to the FPSO.

The maximum 26 development well configuration comprises:

- 16 x OP wells (also referred to as 'production' wells),
- 6 x WI wells,
- 1 x GI well,
- 1 x contingent GI well, and
- 2 x contingent re-drills / side-tracks.

The production wells will produce oil (the target product), associated gas and produced water. The associated gas from these wells will be used to:

- Provide fuel gas for power generation on the FPSO (Section 5.8.3.3),
- Blanket the oil storage / slops / off-spec tanks (tank blanketing, Section 5.8.4.6), and
- Improve the production of oil from the reservoir *via* 'gas lift', which reduces the density of the oil enabling it to flow at higher production rates (Section 5.8.5.6).

The WI wells will also be used to improve oil recovery as water is injected into the reservoir to replace the extracted oil and maintain the pressure in the reservoir (Section 5.8.5.6). The WI wells will initially inject treated seawater into the reservoir. However, after an initial period, water from the reservoir will be produced onto the FPSO with the oil (produced water). Once the produced water 'breaks-through'[13], the WI wells will then be used to inject a combination of treated produced water and seawater.

The GI well will be used to re-inject produced gas back into the reservoir.

5.4.4.1 Phase 1 - Pre-First-Oil wells (Stage 1)

Of the maximum 26 wells to be drilled, eight wells (potentially nine if it is necessary to drill the contingency GI well) will be drilled and five completed before First-Oil.

[13] Produced water refers to the water that comes out of the well along with the oil. It contains injected water and formation water. Produced water 'break-through' refers to the time when the well begins to produce this water as well as the targeted oil.

The eight wells comprise:

- 2 x OP wells (Production Drill Centre: NA-P-01) drilled and completed,
- 3 x OP wells (Production Drill Centre: NA-P-01) drilled and suspended for completion in Stage 2a),
- 2 x WI wells (Water Injection Drill Centre: NA-W-01) drilled and completed,
- 1 x GI well (Gas Injection Drill Centre: NA-G-01) drilled and potentially completed, and
- 1 x contingency GI well (NA-G-02) potentially drilled and completed (if drilled).

Note: if the contingency GI well becomes necessary, it may be that nine wells are drilled pre-First-Oil but only eight will ultimately be commissioned for use.

For drilling efficiency, the Stage 1 wells will be batch drilled (Section 5.4.5.2) and cleaned up to the FPSO (Section 5.4.8).

5.4.4.2 Phase 1 - Post-First-Oil wells (Stage 2a)

Once production has commenced, the remaining Phase 1 wells will be drilled and completed using the MODU. These wells will comprise:

- Completion of the three suspended OP wells (drilled in Stage 1),
- 2 x OP well (Production Drill Centre: NA-P-01) drilled and completed, and
- 1 x WI well (Water Injection Drill Centre: NA-W-01) drilled and completed.

All wells will be cleaned up to the FPSO.

5.4.4.3 Phase 2 wells (Stage 2b)

To maintain production plateau, 12 further wells will be drilled and completed several years after 1st oil. These wells will comprise:

- 9 x oil wells:
  - Five at the Production Drill Centre: NA-P-01, and
  - Four at the Southern Production Drill Centre: NA-P-02.
- 3 x WI wells:
  - One at the South Water Injection Drill Centre: NA-W-03, and
  - Two at the East Water Injection Drill Centre: NA-W-02.

The exact timing of Phase 2 will be subject to production performance and will be timed to minimise production interruption, where possible. For the purposes of this EIS, approximately three years has been assumed between First-Oil and commencement of Phase 2 drilling.

5.4.4.4 Assumptions about the drilling operation

Development wells designed to produce hydrocarbons (either directly *via* oil producing wells or indirectly *via* injection wells) are fundamentally different from exploration and appraisal wells. Exploration and appraisal wells are most commonly drilled vertically into the reservoir with the sole objective of confirming the presence or absence of hydrocarbons. Development wells however, need to fully exploit the potential for recovery of hydrocarbons from the producing reservoir. In order to achieve this, they are typically designed to ensure maximum contact with the producing horizons of the reservoir sandstone. Therefore, development wells are initially drilled vertically from the seabed, then deviate as the depth increases therefore entering the reservoir at either a high angle, horizontally or even a U-shaped trajectory.

Such deviated wells expose a greater measured length of reservoir and it is often necessary to control wellbore stability using drilling muds (drilling fluids) other than Water-based Mud (WBM), which has been used in all Falkland Islands exploration campaigns to date.

The current assumptions relating to the development wells are:

- Tophole well sections and conductor installation:
  - A conductor will be drilled and cemented into each well prior to drilling through the conductor:
    - The conductors will be installed by drilling with seawater and sweeps (a small volume of viscous drilling fluid designed to sweep or remove any debris) and displacing to an inhibited WBM to keep the hole open at target depth prior to installation of the conductor pipe.
  - The tophole sections of the wells will be drilled using seawater and sweeps and displaced to an inhibited WBM sequentially to keep the hole open at target depth prior to installation of the first casing string, and
  - Tophole cuttings and associated sweeps and displacement WBM will be discharged to seabed (details on the 'sweeps' are provided in Section 10.6.4.1.3.1).
- The production wells will have a horizontal well section through the reservoir,
- The water injection wells will likely have a high angle section into the reservoir of approximately 60 - 70°,
- The GI well(s) will be vertical through the reservoir,
- Lower well sections will be drilled using a Non-Aqueous Drilling Fluid (NADF):
  - Cuttings associated with NADF will be treated to meet FIG regulations / UK guidelines and OSPAR requirements to remove the NADF prior to discharge of the cuttings (Section 5.4.5.3.1).
- Wells drilled from the MODU will be completed with OHGP through the reservoir and then suspended with a dual mechanical barrier (retrievable plugs), and
- All wells will be cleaned up to the FPSO, with a contingency option to clean-up to the MODU, if required.

5.4.4.5 Re-drill contingency

The re-spudding, re-drilling or side-tracking of wells may be required in the event that:

- It is not possible to maintain an angle of <1° in the 36" tophole section for cementing of the 30" conductor. This may require a re-spud.
- A significant stuck pipe incident occurs where it is impossible to retrieve the casing or drill-string. This may require a re-spud, re-drill or sidetrack depending on the scenario.
- Unexpected geology necessitates a side-track from a previous casing shoe.

The reservoir is geologically benign with existing well control providing high confidence in a predictable reservoir pressure regime. All wells drilled to date within the Phase 1 & 2 area were within +/- 2 psi of each other on a depth corrected basis. To mitigate any risk, the drilling strategy will be to target areas of high well control first, creating an expanding halo of certainty as the campaign progresses.

Historically, 15 primary wellbores have been drilled in the Sea Lion field with four of these requiring sidetracks. This resulted in 19 penetrations overall. However, of the four sidetracks carried out, only one (6.7 %) was required for unexpected operational reasons (such as those above), as opposed to

planned sidetracks for appraisal purposes. Applying this statistic to a 23 well campaign results in a requirement for two contingency sidetracks / re-drills.

5.4.5 Well design

5.4.5.1 Drilling, casing and wellheads

The basic well profile for the wells is summarised in Table 5.7. Each well will have a different trajectory and endpoint and well sections will vary in length along with overall volumes of cuttings and mud. These profiles are based on the longest planned well and therefore the assessment that follows is precautionary for the Development as a whole.

It is possible that, in the event that the progress of a well is not satisfactory, it is sealed downhole and a new trajectory is re-drilled. This is not a planned event and is difficult to predict so two contingent re-drills have been accounted for. The time taken to undertake these re-drills is included in the overall forecast of rig time and therefore emissions and discharges are included in the assessment.

The development wells will be drilled in up to five sections, depending on the well type. The diameter of the wellbore will decrease with each subsequent well section (Table 5.7). The lengths and diameters of each section of the well are determined prior to drilling and are dependent on the geological conditions through which the well is to be drilled. Once each section of the well has been drilled, the drillbit and drillpipe (or 'drill string') will be lifted out of the wellbore and a protective steel casing will be lowered into the well and cemented into place.

While all casings are essential to support the wellbore and thus contribute to well control, blow-out prevention and environmental management, each type of casing serves a different purpose. In particular, the conductor casing provides structural strength to support the wellhead and the Blow-Out Preventer (BOP), which is used during drilling, and latterly the subsea X-mas tree which is used during production. Further, the conductor prevents unstable upper formations from caving in and pinning the drill string to the side of the wellbore, or forming large caverns in the wellbore.

The main subsea infrastructure that requires installation prior to, and during, the drilling operation includes the following:

- Well conductor and casings:
  - Conductor will be drilled and cemented into place by the MODU. Subsequent casing sections will be drilled and cemented by the MODU.
- A wellhead for each well:
  - Landed on the conductor by the MODU.
- A BOP for each well:
  - Installed onto the wellhead by the MODU.

The tophole sections of wells will be drilled with the drill string and drill bit left open to the seawater (riserless drilling). Consequently, drilling mud and cuttings are discharged straight to the seabed as there is no means of containing them. The conductor and surface casing are then cemented into position.

All wells will commence with 42 / 36" diameter tophole with a 36" conductor casing cemented in place from the MODU. Where the following 26" and / or a 17.5" sections are drilled with WBM, all cuttings will be discharged at the seabed along with the bentonite sweeps.

Once the conductor and surface casings have been installed, a temporary BOP is installed on the wellhead to maintain well control during drilling (Section 5.4.10).

Prior to drilling the lower-hole sections of each well, a pipe known as a 'marine riser' will be run from the MODU and secured to the wellhead on the seabed. The drill string will subsequently be deployed through the centre of this riser. The marine riser provides a closed system through which the drilling mud can be circulated into the well (through the centre of the drill string) and returned to the rig in the annular space between the drill string and the casings and the riser. On some wells, the 17.5" section may be drilled with NADF (Table 5.7). All cuttings and mud will be returned to the MODU *via* the marine riser and the cuttings will be treated to meet Falkland Islands Government (FIG) regulations / UK guidelines and OSPAR requirements to remove the NADF prior to their discharge (Section 5.4.5.3.1).

Table 5.7: Phase 1 & 2 Development well profiles[1]

Hole section	Casing	Drilling Fluid	Section Length (m)
Oil Production Wells Slim Hole design (x 14)			
42"	36" Conductor	Seawater with viscous sweeps	77
17 ½"	13 $^{3}/_{8}$" intermediate casing	Seawater with viscous sweeps	650
12 ¼"	9 $^{5}/_{8}$" production casing	NADF	2,100
8 ½"	8 ½" OHGP	NADF	1,160
Oil Production Wells Big Bore (x 2)			
42"	36" Conductor	Seawater with viscous sweeps	77
26"	20" surface casing	Seawater with viscous sweeps	552
17 ½"	13 $^{3}/_{8}$" intermediate casing	NADF	655
12 ¼"	9 $^{5}/_{8}$" production casing	NADF	2,475
8 ½"	8 ½" OHGP	NADF	1,200
Contingent Re-drills (x 2)			
42"	36" Conductor	Seawater with viscous sweeps	77
17 ½"	13 $^{3}/_{8}$" intermediate casing	Seawater with viscous sweeps	650
12 ¼"	9 $^{5}/_{8}$" production casing	NADF	2,100
8 ½"	8 ½" OHGP	NADF	1,160
WI Wells (x6)			
42/36"	36" Conductor	Seawater with viscous sweeps	77
17 ½"	13 $^{3}/_{8}$" intermediate casing	Seawater with viscous sweeps	651
12 ¼"	9 $^{5}/_{8}$" production casing	NADF	2,622
8 ½"	8 ½ " OHGP	NADF	50
GI Well (x1 / x1 Contingent)			
42	36" Conductor	Seawater with viscous sweeps	77
17 ½"	13 $^{3}/_{8}$" intermediate casing	Seawater with viscous sweeps	850
12 ¼"	9 $^{5}/_{8}$" production casing	NADF	940
8 ½"	8 ½" OHGP	NADF	50

[1] All well designs will be supported by PON4 applications to drill, including well designs and geological well evaluations which will be reviewed by DMR with support from UK HSEx and BGS.

5.4.5.2 Drilling sequence (batch or sequential drilling)

With the exception of the GI well, the Stage 1 (pre-First-Oil) OP and WI wells will be batch drilled and completed. This is where all the drilling operations for each well are performed first followed by all the completion operations (when production tubing is installed in the well), for those wells. Batch operations are generally more efficient with regard to mud use and time.

The remaining Stage 2a and Stage 2b drilling operations may be further sub-divided into batch drilling all the tophole sections first, and then all the lower-hole sections, however this is yet to be determined.

5.4.5.3 Drilling muds and drill cuttings management

During drilling operations, mud of a specified density (or 'weight') is pumped down the drill string to the drill-bit. Drilling mud performs the following functions:

- Ensures that the hydrostatic pressure in the wellbore is higher than that of the surrounding formation so that the well is 'overbalanced', thus preventing a 'kick' of formation fluid (i.e., the oil) flowing into the wellbore and causing a potential well blow-out,
- Removes the drill cuttings from the bottom of the wellbore and carries them to the surface where they are either:
  - Discharged to sea in riser-less drilling (tophole sections), or
  - Treated on the MODU once the marine riser is in place (bottom-hole sections).
- Suspends the drill cuttings in the wellbore in the event that circulation / drilling is interrupted,
- Lubricates and cools the drill-bit as it penetrates the formation, and
- Deposits an impermeable 'mudcake' on the wall of the well bore, which effectively seals the wellbore and stabilises the formation while it is being drilled and prior to installation of the casings.

Two types of mud[14] will be used in the Phase 1 & 2 Development:

- Tophole sections (42/36" and 26" sections) - Seawater with high-viscosity sweeps with heavier Water-based Mud (WBM) pumped downhole to maintain well stability prior to running the conductor or casing (used in the tophole sections (42/36" and 26", and occasionally in the 17 ½" sections), and
- Lower- hole sections (17 ½", 12 ¼" and 8 ½" sections) Non-Aqueous Drilling Fluid (NADF).

As a worst-case from the perspective of drill cuttings and WBM discharge, the 42/36" and 26" top-hole sections will be drilled with seawater and periodic bentonite viscous sweeps, with mud and cuttings being discharged directly to the seabed (Table 5.8 below). Bentonite viscous sweeps will be circulated to remove debris and residual fluids. Once the tophole sections have been drilled, the wellbore will be filled with a WBM to maintain wellbore stability prior to running the conductors / casings.

5.4.5.3.1 NADF: Lower-hole sections

Following installation of the marine riser, the 17 ½" (where applicable, see previous section), 12 ¼" and 8 ½" sections (where applicable) will be drilled with NADF[15] (Table 5.8). The NADF and cuttings will be circulated within the closed system and returned back to the MODU for treatment.

The discharge of NADF contaminated cuttings will be managed in accordance with FIG Petroleum Operations Notice (PON) 10 to ensure best practice (Section 3.1.7.4). FIG PON 10 reflects the

[14] Please note that WBM and NADF drilling muds do not contain plastics or microplastics.
[15] Details of what Non-Aqueous Drill Fluid is composed of are given in Section 10.6.4.1.3.1.

requirement of OSPAR Decision 2000/3 on the 'Use of Organic-Phase Drilling Fluids (OPF/NADF) and the Discharge of OPF/NADF-Contaminated Cuttings'. The PON 10 therefore prohibits:

- The discharge of whole OPF/NADF,
- The discharge of whole OPF/NADFs when drilling tophole sections, and
- The discharge of cuttings contaminated with oil based fluids at a concentration >1 % by weight on dry cuttings.

A Thermomechanical Cutting Cleaning Unit (TCC) unit will be used on the MODU to process the NADF contaminated cuttings which are returned to the MODU *via* the marine riser. The TCC unit (Figure 5-4) will separate the mud and the cuttings to maximise recovery of the mud for re-use during drilling. Prior to discharge, the cuttings will be heated to evaporate the remaining oil and then powdered. They will then be tested to ensure that the oil concentration of NADF is less than 1 % by dry weight on the cuttings at which point they will be discharged to sea below the waterline. If any cuttings are sampled and the concentration of entrained oil is not <1 % by weight on cuttings, the outlet of the mill can be maneuvered onto a skip and the material can then be returned to the feed hopper for re-processing.

The TCC unit will be spared (i.e., critical spares will be held in Stanley) and maintained to sustain the required reliability. In the event of a major malfunction, initial cuttings would be stored in skips offshore whilst awaiting the TCC unit to be re-instated. Untreated cuttings will not be discharged to sea. If the failure of the TCC unit continues, there are two options:

- The skips containing untreated cuttings may be shipped to shore for interim storage whilst the TCC unit is re-instated or a replacement unit is brought in. The stored cuttings could then either be re-transported out to the rig for treatment or sent for treatment elsewhere in the world, or
- Drilling would cease until the TCC unit is commissioned and ready to accept cuttings.

The batch sequencing of the pre-First-Oil sections means that changes in the mud system (from WBM to NADF and *vice versa*) are kept to a minimum, as are unused or waste volumes of mud. Once the drilling operation is complete, NADF left in the mud pits[16] will be returned to the mud plant at the onshore supply base along with other rig materials. All unused inventories will be disposed of in line with the available outlets and principles in the Waste Management Plan. No discharge of whole NADF to sea will occur.

Table 5.8: Typical mud requirements and cuttings volume per well for Sea Lion wells

Wellbore section	Mud	Volume of Mud used (m^3) Gross[1]	Volume of mud used (m^3) Net[1]	Cuttings volume (m^3)	Fate of mud and cuttings
Oil Production Wells Slim Hole design (x 14)					
42"	Seawater with viscous sweeps	250	250	85	Discharged at seabed
17 ½"	Seawater with viscous sweeps	440	440	122	
12 ¼"	NADF	700	250	200	Cuttings cleaning up *via* TCC Unit and dry cuttings discharged from MODU with oil content on cutting of <1 % dry weight. The reclaimed mud will be re-used.
8 ½"	NADF	416	95	50	
Total		**1,806**	**1,035**	**457**	-

[16] Mudpits are located on the 'tween' deck which is between the main deck and riser bay on the upper deck on the MODU. They are adjacent to the shale shakers and situated directly above the mud pumps on the main deck.

8 ½"	NADF	282	30	2	
Total		**1,552**	**960**	**332**	-

[1] In the above table the Gross mud volume is the total volume of mud that will be handled by the rig for the drilling of the section and the Net volume is the volume used in drilling the section taking into account mud that is recycled/returned for use on other wells.

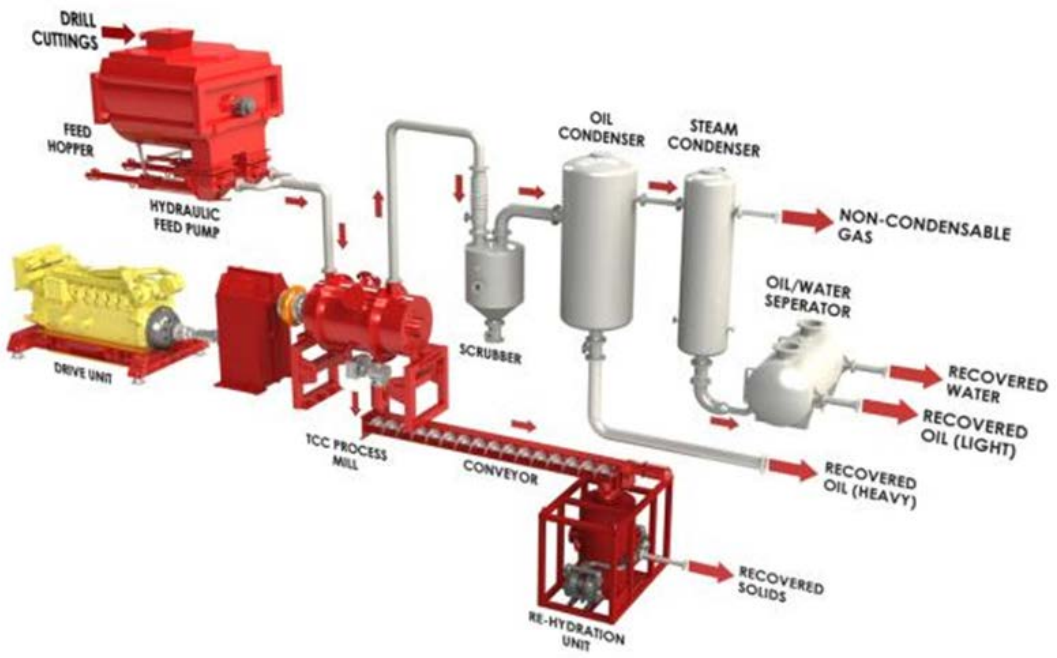

Figure 5-4: Typical Thermomechanical cuttings cleaner used to treat NADF coated drill cuttings

5.4.5.4 Well suspension

Following the batch drilling process for the Stage 1 wells, all wells will be suspended by the MODU using an engineered plug to preserve the integrity of the well bores allowing the BOP to be removed. This is followed by batch completion from the MODU involving reattachment of the BOP, removal of the plug, and installation of the completion and X-mas tree (Section 5.4.10).

Oil production and WI wells will be suspended using two mechanical barriers which are retrievable crown plugs which seal in the top of the X-mas tree. Both the mechanical barriers create dual barriers in the well which allows the BOP to be removed after the completion is installed.

The GI well(s) will be suspended in an underbalanced state (where pressure in the wellbore is less than that in the surrounding formation) to facilitate the initial flow of gas to the FPSO.

All wells will be suspended in accordance with FIG / UK legislation and regulatory requirements, as well as industry-standards e.g., OEUK Offshore Energies UK guidelines.

Further detail on well suspension will be available nearer the time of project execution and presented within the subsequent PON applications submitted to FIG for prior approval (Section 3.1.7.4).

5.4.5.5 Well completion

Well completion refers to the equipment and process of installing the final flow conduit from reservoir to wellhead. This includes the selection of established safety components and materials of construction appropriate for the well fluids and conditions. For Sea Lion, the completion phase shall:

- Install a reservoir (lower) completion which shall be an Open Hole Gravel Pack (OHGP) which enables more robust sand management. The OHGP consists of installing sand screens inside the open hole across the reservoir section and pumping gravel around the screens for an active sand control reservoir completion. The lower completion is installed and the well suspended with the use of two mechanical barriers to allow the removal of the BOP to facilitate batch completion stages. Of note, there are no plastics in the circulation fluids used

for gravel packing. The circulation fluid is water-based and has a gelling agent to increase its viscosity, to improve the ability to transport the proppant[17] into the wellbore. The gelling agent is normally a polysaccharide, such as xantham, which is a common food additive. The proppant is placed in the well during the completion phase of the well, which acts as a filter medium during the production of the well. The proppant is inert ceramic with no plastics.

- Install the X-mas tree (as a contingency the X-mas tree may be installed prior to drilling the bottom hole section or prior to the lower completion).
- Install an upper completion with pressure containing capability consisting of completion tubing, production packer (a device used to isolate the annulus and anchor or secure the bottom of the production tubing string), tubing hanger (a device attached to the topmost tubing joint in the wellhead to support the tubing string) and downhole safety valve (all well types),
- Test the critical pressure retaining equipment items, and
- Enable compliance with the industry principle of ensuring two barriers are in place to prevent uncontrolled flow at all stages of the well completion sequence.

All completion operations will be performed from the MODU. Materials, tubing sizes and other tangibles will vary between well types but the design principles above will be consistent. The detailed design is documented in the Sea Lion Completion Basis of Design (SLN-CMP-WEL-BOD-00001-00).

Further detail on all well completions will be available nearer the time of project execution and presented within the subsequent PON applications submitted to FIG for prior approval (Section 3.1.7.4).

5.4.6 Well chemical use and discharge

Details on the specific well chemicals which will be used during the Phase 1 & 2 Development drilling are not yet known. Importantly however, throughout the Development, all chemicals will be selected to minimise environmental impacts as much as possible, in compliance with legislation. Moreover, all chemical use will be included in PON applications submitted to FIG for approval prior to use (Section 3.1.7.4). Further detail on the legislation regarding chemical use is provided in Sections 10.6.1.1 and 10.7.1.1.

For the purposes of this EIS, analogue chemicals have been used to enable a representative impact assessment, as detailed in the relevant chapters below.

5.4.6.1 Drilling chemicals

It is necessary to add various chemicals to the drilling mud to ensure the correct properties are maintained. Mud additives may be dosed into the mud prior to drilling or may be available as a contingency in the event that they are needed.

Mud additives dosed into the high-viscosity sweeps and displacement WBM will be discharged to sea along with the mud volumes. Mud additives dosed into the whole NADF will not be discharged to sea as the used NADF is recycled and cuttings are treated prior to discharge. Very small quantities may be present on the NADF cuttings, discharges of which will comply with OSPAR 2000/3 (Section 5.4.5.3.1).

Typical primary and contingency mud additives include:

- Potassium chloride (KCl) based fluid for chemical inhibition,
- Weighting agents,

[17] A proppant is a solid material, typically sand, treated sand or man-made ceramic material, designed to keep an induced hydraulic fracture open, during or following a fracturing treatment.

- WBM and NADF Viscosifiers for rheology control,
- WBM and NADF mud filtrate reduction, and filtrate control agents,
- Emulsifiers to control NADF emulsion,
- Bridging materials such as $CaCO_3$ to prevent formation damage,
- Oxygen scavenger for corrosion control,
- Buffers to regulate pH,
- Polymer addition for clay cuttings encapsulation,
- Naturally occurring fibrous, filamentous, granular or flake materials,
- Glycol for hydrate suppression and fluid lubricity, and
- Lime, for NADF alkalinity and for H_2S neutralisation, should it be present (not expected).

5.4.6.2 Cementing chemicals

The cement used to secure the well casings requires several additives to manage its working characteristics, thus ensuring that the casing is safely adhered to the wellbore. For example, the speed at which cement sets can be affected by numerous factors such as depth, temperature and pressure, and may require chemical manipulation to achieve optimal results in each section.

Typical cementing chemicals include:

- Anti-settling agents used to stabilise mixed cement,
- Wetting agents used to alter the 'wettability' of the casing / formation from 'oil wet' to 'water wet' to ensure an improved cement bond,
- Cement slurry dispersants used to reduce the viscosity of the slurry and aid displacement,
- Fluid loss reducers used to control water loss from cement slurries,
- Cement slurry spacer viscosifier used to build weighted fluid spacers to separate cement slurry from drilling muds during slurry displacement,
- Cement slurry retarders for use in well bores where the temperature range is between 50 - 120°C, and
- Cement accelerants used to reduce the time taken for cement to set.

At the time of writing, the detailed cement design has yet to be finalised. However, estimates of cement volume are provided in Table 5.9. Some cement will be discharged at the seabed during installation of the conductor casing as the cement will be pumped until it can be seen at the seabed to ensure the annulus is full. These cement depositions will extend up to 10-15 m away from the well. All cement will be mixed as required and as a result there should be limited operational discharge of any mixed cement or mix-water.

Table 5.9: Typical cement requirements per well

Conductor / Casing	Volume of cement (m^3)
36" conductor	20
20" surface casing	120
13 $^3/_8$" intermediate casing	110
9 $^5/_8$" production casing	40

5.4.6.3 Well suspension, completion, and gravel pack fluids

Full details on the chemicals required during the suspension, completion, and application of the gravel packs for the Phase 1 & 2 wells will be provided in the Completion Programme (SLN-CMP-WEL-BOD-00001-00), post project sanction.

5.4.6.4 Well completion

Completion brines are weighted according to the well type and design and will be dosed with various chemicals as considered necessary. Typically, however, suspension fluids will comprise brine dosed with:

- Weighting agents,
- Corrosion inhibitor,
- Biocide, and
- Oxygen scavenger.

5.4.6.4.1 Completion chemicals

Completion fluids are required to optimise the functionality of the well and to prevent damage to the formation. Completion fluids typically include:

- pH management chemicals,
- Biocides,
- Pipe dope (lubricating grease that prevents thread galling) / asphaltene / oil dissolvers, and
- Brine viscosifier for gravel pack fluids.

5.4.6.5 Other MODU discharges

Liquid storage areas on the MODU, and areas that might be contaminated with drilling muds and additives, are segregated from other deck areas to ensure that any contaminated drainage water can be treated prior to discharge, and that leaks / spills to deck can be contained. Drainage water from these areas, and from machinery spaces, is collected and treated to reduce hydrocarbon concentrations to less than 15 ppm prior to discharge to sea, as is required under the MARPOL Convention 73/78 Annex I.

Black (sewage) and grey (domestic) water is also collected and treated to meet the requirements of the MARPOL Convention 73/78 Annex IV prior to discharge to sea.

During well completion, the NADF fluids are pumped out of the well by circulating a brine mixture so that brine containing residues of NADF is returned to the MODU. In line with UK practice, once returns are visibly oil-free they will be sampled and discharged to sea. Any returns with visible oil would not be discharged and would be treated before discharge either onshore or offshore.

Similar returns of contaminated brine or seawater may occur if the MODU needs to detach the marine riser while drilling with NADF. In this case, the riser is first displaced to brine or seawater before it is detached to prevent a release of NADF. This may be necessary during periods of extreme weather for example. Brine or seawater subsequently returned to the MODU during riser disconnection and reconnection would be treated in the same way as well clean-up fluids.

5.4.7 Use of explosives

Explosives may be required during the drilling operations as a contingency if the drill string gets stuck in the wellbore. If required, the explosives will be deployed at depths greater than 100 m downhole. All explosives will be stored as described in Section 5.11.1.2. A small quantity of explosives will be stored both onshore at the supply base and on the MODU in a jettisonable bunker.

5.4.8 Well clean-up and initial well testing

Following traditional completion of wells using cement and perforation, 'clean-up' operations can be required to ensure the wellbores are clean prior to 'bringing them on', to prevent damage to the subsea

system, turret and FPSO. Damage can result from debris in the wellbore (due to the use of explosives for perforations) or the long-term retention of completion chemicals in the well.

However, as OHGPs will be used for the well completions (Section 5.4.5.5), rather than cement and perforation, Navitas will have more robust sand control and it is anticipated that there will be little solid material debris. This minimises the risk of damage to the subsea and FPSO facilities such that extensive clean-up / flowback operations to the MODU will not be required. As such, the base-case is to leave the OP wells suspended with a suitable completion fluid that can safely be flowed back to the FPSO.

Nonetheless, the contingency will be retained to flow up to four wells (three OP wells and one GI well) back to temporary testing equipment on the MODU. The objectives of these flow backs / well tests will include:

- Confirmation of the integrity of the initial well completions, and
- Establishing well productivity to assess the production potential of up to three OP wells for reservoir management planning and production forecasting.

This process would involve flowing wells to the MODU and flaring off the hydrocarbons, which minimises the risks associated with capturing and handling them. Should this be required, it is estimated that each well would be flowed for approximately one day, at the following rates:

- 1,262 tonnes of reservoir oil and 105 tonnes of gas to be burned from each oil well, and
- 751 tonnes of gas and 76 tonnes of reservoir oil to be burned from the gas well.

Details on the quantities of oil and gas produced and flared are provided in

Table 5.10 and Table 5.11.

Should flaring be carried out, base oil will be used to promote efficient combustion and minimise risk of drop-out from the flare from the well tests. This is common practice whereby the flare is initiated with base oil, which is highly combustible in the atomised form that is emitted from the flare tip, and pumping of base oil continues while crude oil and gas are also sent to the flare. Due to the waxy nature of Sea Lion crude, a higher quantity of base oil will be required to support the combustion of oil wells compared with gas wells.

These operations will be conducted with the highest regards to safety of personnel, infrastructure and duty of care to the environment. Flow period durations and produced volume estimates for each required well test would be established in advance to enable assessment of associated emissions. Any residual oil from the well left in equipment after flaring will be stored, transported to the Islands and then processed in an onshore incinerator, or, if not suitable, would be prepared for transfer to another country for appropriate disposal.

The atmospheric emissions associated with the Sea Lion Development as a whole are presented in Section 10.9. The two outcomes in terms of emissions are:

- Flowback of all wells to the FPSO, i.e., no flow-back / well testing to the MODU and therefore no flaring (base-case), and
- Contingency flow-back / testing of three OP wells and one GI well to the MODU, with associated flaring (
- Table 5.10 and Table 5.11).

Plans for these operations will be undertaken with consultation and the approval of FIG. Emissions accounted for here are a worst-case and Section 10.9 presents the emissions both with and without flaring for these purposes.

Table 5.10: Quantities of oil and gas produced during the contingent flow-back / tests of three oil wells to the MODU

Well clean-up / test flaring quantities					
Oil		**Gas**		**Base oil**	
Well test (stb / day)	10,000	Well test mmscf / day	4.18	Per well test (stb)	400

5.4.9 GI Well commissioning

Two types of gas system require commissioning:

- The first is the gas lift system, which provides lift gas to the production wells and is injected down the anulus of the well and enters the production tubing deep in the well, just above the gravel pack. This is used for increasing the productivity of the OP wells.
- The second is the gas injection system, which includes the GI well, down which excess associated gas can be stored.

Associated gas (liberated from the oil producing wells) will be used for both systems and a certain amount of gas is required in order to meet with the safe minimum operating parameters of the gas compression system on the FPSO. When oil production first commences there will not be enough associated gas to commission the gas lift or injection systems. At start-up there will be a stage where gas is being liberated, causing pressure to build within the flowlines, but not enough gas has yet been generated to initiate the gas compression system for use. As there is nowhere on the FPSO for gas to be stored, the gas must be flared until there is a sufficient amount to initiate start-up.

During commissioning, the initial start-up of the gas compression system takes longer than a normal start-up as control and instrumentation systems need to be calibrated and tuned before handing over to normal operations.

Once gas arrives at the topsides of the FPSO it is possible to build up a sufficient inventory to commission the FPSO compressors. Once the compressors are operational it is possible to start using the gas lift line so production from the oil wells can be increased. Once there is the maximum required gas lift, it is possible to start sending gas down the GI line to be stored in the reservoir *via* the GI well.

Robust pre-commissioning and commissioning efforts will ensure start-up runs as quickly as possible which will reduce flaring. However, in order to achieve these commissioning operations it will be necessary to flare the associated gas for up to 30 days at a conservatively estimated rate of up to 306.2 tonnes of gas per day.

5.4.10 Well control and blow-out prevention during drilling

Well control and blow-out prevention during drilling is managed by:

- Well design based on appreciation of the formation pressures e.g., the use of appropriately weighted drilling muds and additives to overbalance the well so that pressure in the wellbore is greater than the pressure of the surrounding formation, but is less than the formation fracture pressure,
- The use of appropriate well casings and a wellhead, and
- The use of a Blow-out Preventer (BOP) stack.

Details on the drilling mud, additives, casings and wellheads are provided above. In addition to these, a BOP 'stack' will be installed onto each wellhead for the duration of the drilling operation. The function of the BOP is to prevent uncontrolled hydrocarbon flow from the well by positively closing in the wellbore in the event that flow from the wellbore is detected.

The development wells of the Phase 1 & 2 operation are not expected to encounter any zones of abnormal pressure and the BOP will be rated for pressures sufficiently in excess of those predicted. BOP integrity will be tested prior to usage and rated over the range of pressures predicted to occur within the wells. Further tests will be conducted on the BOP approximately every three weeks during drilling operations. Small amounts of water-based hydraulic fluid will typically be discharged every three weeks when valves are actuated during regular operational testing of the BOP.

Pressure testing of the BOP will be undertaken in line with the drilling contractor and Navitas' standards and procedures and in line with FIG / UK legislation and industry-standards.

Use of the BOP is temporary and specific to drilling activities. Following completion of the well the BOP will be removed and replaced with a permanent subsea X-mas tree, which is used during the production phase to ensure well control (Section 5.8.1.1).

5.5 Construction: Installation of drilling, production and export facilities

In order to produce oil from the Phase 1 & 2 Development, and to export the oil to market, it is necessary to install:

- MODU foundation moorings / anchors (see Section 5.4.3.1),
- Subsea well infrastructure e.g., well conductors and casings, wellheads and BOPs,
- Subsea production facilities e.g., manifolds, umbilicals, X-mas trees, flexible flowlines / risers, jumpers, flying leads, and
- The FPSO mooring system, including foundation anchors (see Section 5.5.2).

The installation of the above will be carried out with construction vessels supported by LTVs.

5.5.1 Large Transport Vessel (LTV) support

The offshore installation process will be supported by LTVs. Detailed design of the project is required to size the LTVs and confirm the quantity but it is expected no more than four LTVs will be utilised to support the project, with a maximum of two LTVs present, anchored in Berkeley Sound, at any one time (see below and also Section 5.11.2). These vessels will act as floating logistics and storage bases while installation / construction vessels will transit between the LTVs and the Sea Lion Field picking up equipment for installation.

Each LTV will be spread moored, using anchors, and a 500 m radius exclusion zone will be in place to give a safe clearance. The LTVs will be around 160 m in length and the anchor lines are approximately 100 m horizontally from the bow to the anchor point. The LTVs (and 500m radius exclusion zones around both vessels) will take up *c.* 1.349 % of the area of Berkeley Sound and will be visited by a minimal number of vessels during this time so are not considered to pose a significant impact to other users of the area.

Three indicative mooring locations (Figure 5-5) have been identified for the LTVs in Berkeley Sound (although only two will ultimately be used by the two vessels *in situ*):

- LTV1 Mooring Position: 51.582800 S, 57.886686 W,
- LTV2 Mooring Position: 51.582800 S, 57.872336 W, and
- LTV3 Mooring Position: 51.582800 S, 57.857986 W.

The temporary anchorages will be 1.2 nm (or more) from shore and may be slightly further east or west than shown[18]. Navitas shall work closely with FIMA, and identified relevant stakeholders, throughout the planning and execution stages of the development to ensure that:

- Final locations will be determined with decision criteria covering both environmental and socio-economic (other users of Berkeley Sound) considerations,
- Final positions for the LTV anchorage sites are agreed and well communicated to mariners and other users of the sea,

[18] These indicative locations were initially identified by POEPL in consultation with the FIG Harbour Master as they appeared to offer sufficient sea-room for the mooring and offload of the LTVs, without hindering other Berkeley Sound users, and were not considered to be of particular environmental sensitivity.

- Activity Specific Operating Guidelines (ASOGs) are developed for the vessels operating in the area[19],
- FIMA is advised of all vessels planning to operate in the area, and
- FIMA is advised of the activities and equipment / product transferred between vessels.

The duration of the LTV presence is estimated to be as follows:

- Stage 1 and 2a:
  - Up to two LTVs at any one time, and
  - Present for seven months.
- Stage 2b and 3 (interim between Stages 2a & 2b):
  - Up to two LTVs at any one time, and
  - Present for six months.

Therefore, two LTVs will be present in Berkeley Sound for a non-consecutive total of 13 months.

Detail on all transportation and installation vessels required throughout the Development is provided in Section 5.11.2.

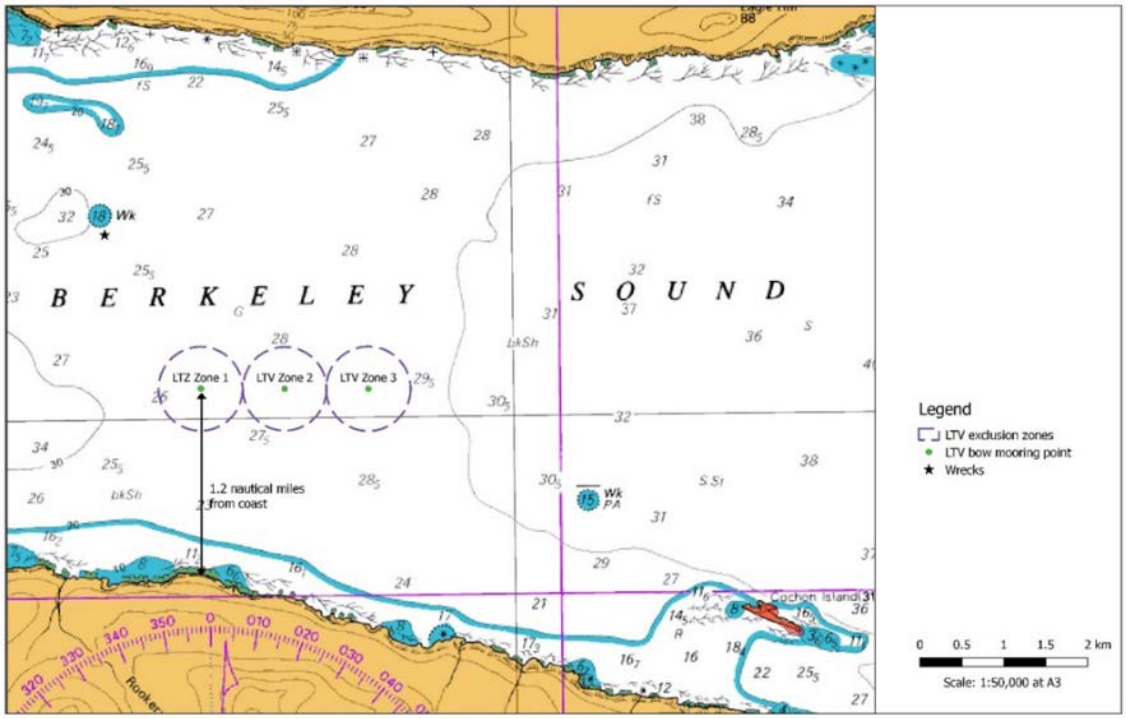

Figure 5-5: Indicative positioning of LTVs (three potential locations shown to accommodate a maximum of two LTVs anchored at any one time) in Berkeley Sound during the installation period

[19] **Post-consultation note (July 2025):** The contents of the ASOGs will be determined in consultation with FIMA and other relevant stakeholders and, as necessary, may include guidance on taking the most northerly possible safe passage into Berkeley Sound to give maximum clearance to Kidney and Cochon Islands as well as consideration of no-transit times e.g., at dusk, between the hours of 1900 – 2300 hours.

5.5.2 FPSO mooring system

The FPSO mooring will comprise 12 anchors connected to the FPSO turret buoy. The anchors are expected to be suction piles approximately six metres in diameter and the installation aids will protrude from the top of the suction anchors by approximately 1-2 metres.

The 12 anchor lines will consist of chain, polyester rope or wire and spring buoys, which will be installed and attached to the FPSO turret buoy. Up to approximately 300-500 m of mooring line is expected to be in contact with the seabed, per anchor.

The turret buoy, which connects directly to the turret mounted in the forward part of the FPSO, will be submerged at a depth of approximately 50 m when the anchors and lines are installed, awaiting arrival and hook-up to the FPSO.

5.5.3 Subsea production facilities

The subsea production facilities consist of:

- A X-mas tree located on each well,
- Subsea manifolds and pipelines:
  - Up to six subsea manifolds for production, GI and WI wells,
  - Subsea Umbilicals, Risers and Flowlines (SURF),
  - Subsea Distribution Units (SDUs),
  - Flexible flowlines between the manifolds and the FPSO,
  - Well jumpers between the manifolds and between wells and manifolds,
  - Hydraulic, optical and electric ‘flying leads’ between the manifolds, wells, SDUs (Subsea Distribution Unit) and SUTA (Subsea Umbilical Termination Assembly), and
  - Control and chemical injection umbilicals.
- Installation supports:
  - Sandbags, grout bags and gravel bags used as markers and construction aids, and
  - Temporary clump weights for installation of equipment and downlines for hydrotesting.

5.5.3.1 Subsea X-mas trees

The X-mas trees will be fully tested on leaving the manufacturer and again upon receipt in the Falkland Islands (site receival tests) for integrity testing prior to installation. The site receival tests of the X-mas trees is expected to be conducted on the LTVs but may be conducted once the trees are loaded onto the installation vessel.

5.5.3.2 Subsea manifolds and pipelines

The flowlines between the manifolds and FPSO will include both a seabed and midwater (riser) section. These flowlines will convey:

- Produced fluids (oil, gas and water) from the wells to the FPSO (production), and
- Water and gas from the FPSO to the wells (injection).

Full detail on the planned Subsea Production System (SPS) and Subsea Umbilicals, Risers and Flowlines (SURF) including function, installation, number and dimensions are provided in Table 5.12.

5.5.3.3 Installation supports

Gravel / sandbags will be used as the primary markers and construction aids during installation of the subsea equipment. Typically, one sandbag with a float would be placed at each corner of significant subsea structures, namely four sandbags per structure. Gravel / sandbags are roughly 330 mm x 675

mm (i.e., 0.22275 m^2 / sandbag). All bag placements will either be within 100 m of the centre of the production DC, the WI DC, water injection splitter manifold or the GI DC, and also within 10 m of the FPSO mooring pile locations.

Including for a contingency allowance, which doubles the estimated number of bags required, it is estimated that the permanent seabed footprint would amount to *c.* 50 m^2. Additional clump weights and tethers may also be required on an 'as needed' basis.

Clump weights may be used as installation aides to temporarily anchor items to the seabed (e.g., to overcome riser buoyancy during connection of riser tethers to the mudmats), to ensure the FPSO mooring buoy is submerged prior to connection to the FPSO turret and riser and umbilical attachments etc., and to enable controlled connection of buoyancy modules to FPSO moorings. The above installation supports will be left on the seabed as permanent deposits until the time of decommissioning.

Further, temporary laydown areas for pre-installation storage may also be used in the event, for example, that the installation sequence changes (Table 5.12). For example, wet storage may be used:

- To park risers and umbilicals on the seabed prior to recovery to the FPSO mooring buoy,
- To park FPSO mooring lines prior to attachment to FPSO mooring buoy,
- For electrical and optical flying lead installation frames which will be landed on the seabed prior to the removal and then installation of the leads, and
- For ROV baskets used for ROV tooling etc.

At the time of writing the EIS, the FEED process had not commenced and while predictions and estimations could be made on the specific number of supports and aides required, these may prove an underestimate in the absence of all the required data. Therefore, as indicated in Table 5.12, a highly conservative and worst-case estimate has been made, assuming an additional 5 % of the overall seabed footprint may be required for temporary and permanent deposits, and a further 5 % of the area estimated for temporary laydown.

It is considered extremely unlikely that the area of seabed temporarily affected will reach the estimated 5 % for each type (i.e., supports, aides and laydown) but this is assessed as a worst-case. Quantification of the potential areal impacts are provided in Section 10.3 on Seabed Disturbance.

Table 5.12: SPS and SURF requirements for Sea Lion Phase 1 & 2 Development

Facility / SURF	Description	Location / Route		Nominal dimensions	Installation and support
		From	To		
Manifolds	Production manifold (3)	Towards middle of each Drill Centre		18m x 8m	Lift installed by installation vessel on seabed with foundation pile or mudmat
	Water Injection manifold (4)			11m x 7m	
	Gas Lift Manifold (2)	In the vicinity of the drill centre		9m x 9m	Lift installed by installation vessel on seabed
	Gas Injection Manifold (1)	In the vicinity of the drill centre		9m x 9m	Lift installed by installation vessel on seabed
Subsea X-mas trees	23 x subsea X-mas trees:	At each individual well		6 m x 6m	Installed by installation vessel onto each wellhead
Umbilicals[1]	1 x Main Drill Centre Dynamic and Static Umbilical #1	FPSO	Main Production manifold	OD 180 mm x 2.7 km	Installed by installation vessel mainly on seabed with riser section to Turret Buoy supported midwater by distributed buoyancy modules
	1 x Static Umbilical #2	Main DC Production manifold	Water Injection Well Site	OD 110 mm x 1.8 km	Laid on seabed from reel on installation vessel
	1 x Static Umbilical #3	Water Injection Well Site	Gas Injection Well Site	OD 110 mm x 3.9 km	Laid on seabed from reel on installation vessel
	1 x Static umbilical #4	Main DC Production manifold	East Water Injection Drill Centre	OD 110 mm x 2.8 km	Laid on seabed from reel on installation vessel
	1 x Dynamic and Static Umbilical #5	FPSO	Southern Production Drill Centre	Outer Diameter (OD) 180 mm x 4.1 km	Installed by installation vessel mainly on seabed with riser section to Turret Buoy supported midwater by distributed buoyancy modules
	1 x Static Umbilical #6	Southern Production Drill Centre	Southern Water Injection Drill Centre	OD 110 mm x 1.9 km	Laid on seabed from reel on installation vessel
Production flowlines / risers	4 x insulated flexible production flowlines / risers	Main Production manifold	FPSO	OD 480 mm x 2.8 km	Installed by installation vessel mainly on seabed with riser section to Turret Buoy supported midwater in pliant wave

Facility / SURF	Description	Location / Route		Nominal dimensions	Installation and support
		From	To		
					configuration by distributed buoyancy modules
		Main production manifold	FPSO	OD 480 mm x 2.8 km	
		FPSO	Southern production manifold	OD 480 mm x 4.1 km	
		FPSO	Southern production manifold	OD 480 mm x 4.1 km	
WI flowline / riser	1 x insulated flexible WI line	FPSO	Water Injection tie in	OD 470 mm x 1.7 km	
	1 x insulated flexible WI line	Water Injection tie in	Water Injection Drill Centre	OD 420 mm x 3.0 km	
	1 x insulated flexible WI line	Water Injection Drill Centre	East Water Injection Drill Centre	OD 420 mm x 5.0 km	
	1 x insulated flexible WI line	Water Injection tie in	Southern Water Injection Drill Centre	OD 420 mm x 4.7 km	
Gas Lift flowline / riser	1 x flexible Gas Lift line	FPSO	Main production manifold	OD 280 mm x 2.7 km	
Gas Lift Jumpers	4 x Gas lift jumpers	Gas Lift Manifold		OD 260 mm x 0.2 km	Laid on seabed and connected by installation vessel
GI flowline / riser	1 x flexible Gas injection line	FPSO	Gas Injection Drill Centre	OD 280 mm x 7.0 km	

Facility / SURF	Description	Location / Route		Nominal dimensions	Installation and support
		From	To		
GI flowline	1 x flexible Gas Production & injection line	Main Production Drill Centre	Southern Drill Centre	OD 260 mm x 4.4 km	
Well Jumpers	16 x production jumpers	Main and Southern production manifold	Production wells	OD 470 mm x typically 50 m	
	6 x WI jumpers	WI Well Sites	WI wells	OD 420 mm x typically 50 m	
	1 x Gas Injection jumper	GI Well Site	GI wells	OD 260 mm x typically 50 m	
Flying Leads	70 x Flying Leads including electrical, hydraulic and chemical injection paths to each well	Drill Centres		OD 120 mm x 150 m (worst-case, longest length)	Laid on seabed and connected by installation vessel
Crossing	7 x GRP Bridge Crossing Structure installed to allow laying over other lines	-	-	13.6 m x 7 m	Laid on the seabed by installation vessel
Permanent sand, gravel bags, additional clump weights and tethers.	Used as markers and construction aids during installation of the subsea equipment	Placed at the corners of key subsea structures		An estimated 5 % of total seabed disturbance area is allowed for in the assessment	Laid on the seabed by installation vessel
Temporary installation aides e.g., clump weights, tethers, ROV basket, flying lead installation frame, concrete mattresses, etc.)	Installation ancillaries which facilitate installation of permanent equipment	At both drill centres and FPSO mooring location			Laid on the seabed by installation vessel

Facility / SURF	Description	Location / Route		Nominal dimensions	Installation and support
		From	To		
Temporary storage and laydown areas	For use pre-installation of equipment (e.g., mooring lines, flexible risers, umbilicals, etc.) whereby permanent works may be wet parked on the seabed for a relatively short duration (less than 12 months)	At both drill centres and FPSO mooring location		An estimated 5 % of total seabed disturbance area is allowed for in the assessment	Laid on the seabed by installation vessel
SDUs	4 x Subsea Distribution Units	Drill Centre		9m x 9m	Lift, installed by installation vessel
Mudmats to support Subsea Umbilical Termination Assembly (SUTA)	9 x mudmats	Drill Centre		3m x 3m	Lift, installed by installation vessel

5.5.4 Arrival and positioning of the FPSO

All practicable pre-commissioning and commissioning activities will be completed prior to the arrival of the FPSO in Falkland Islands waters.

The FPSO (Figure 5-6) will be transported to the Falkland Islands. The route will be selected in consultation with other users of the sea, with the aim of minimising interference to other vessels, the risk of collision, and security risks.

On arrival in Falkland Islands waters, the FPSO is expected to transit directly to the Sea Lion Field where the pre-installed turret buoy will be connected to the turret within the FPSO (Figure 5-7). The connection operation will be undertaken with the assistance of support vessels, which will arrive with the FPSO or will already be in the field supporting the drilling operation (Section 5.11.2).

The location of the FPSO is shown in Table 5.13. Once *in situ*, the FPSO will be surrounded by an exclusion zone of 1,275 m in radius. This is effectively 500 m beyond the installation extremities (including the hose and tanker during crude oil offload) and is considered sufficient to encompass the CTT during the direct offtake operation (Section 5.10).

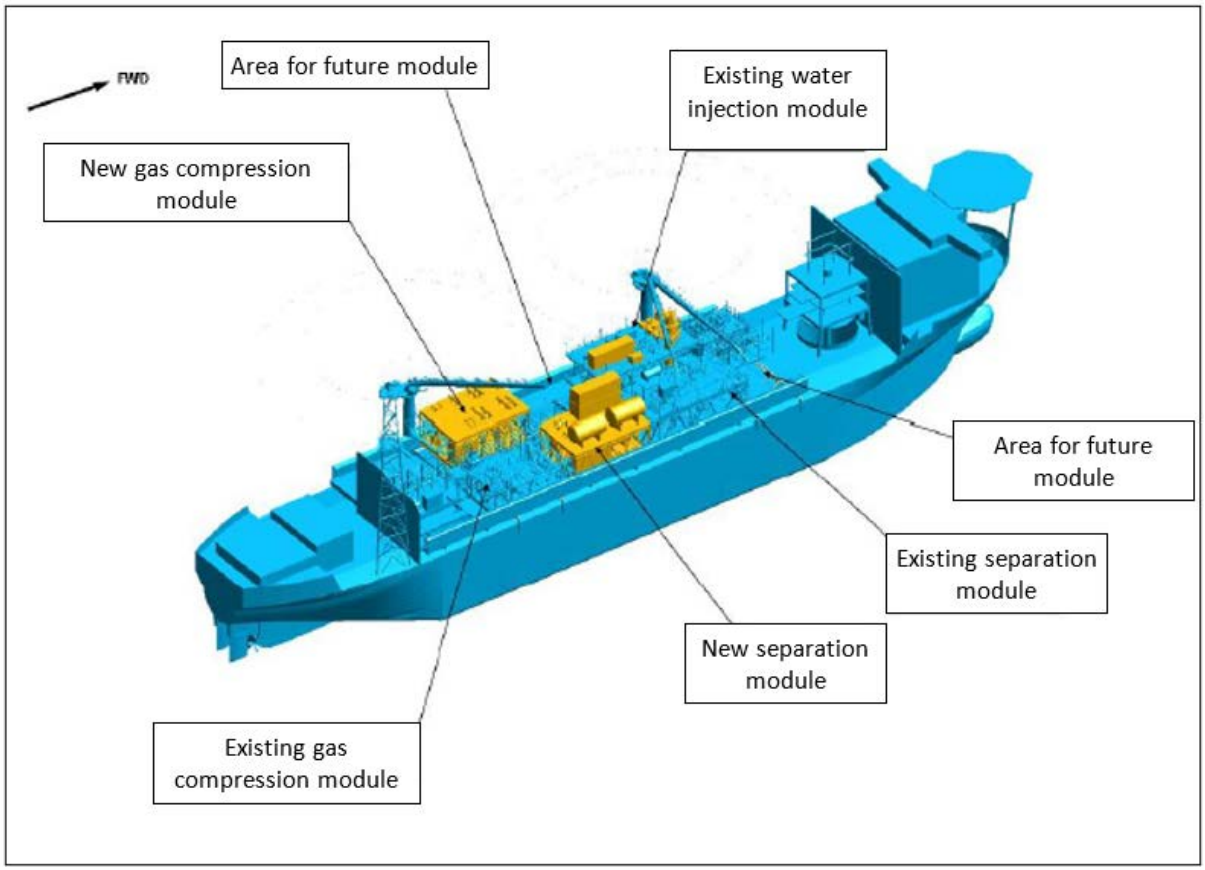

Figure 5-6: An illustration of the Sea Lion FPSO

Table 5.13: Co-ordinates of Production facilities

Parameter	Northing / Easting [1]	Latitude / Longitude
FPSO (centre of turret)	568 024.00 E	49 16’ 36.3” S
	4 541 360.00 N	59 03’ 53.2” W

[1] Co-ordinate system: WGS 1984 Universal Transverse Mercator. Map Zone 21S.

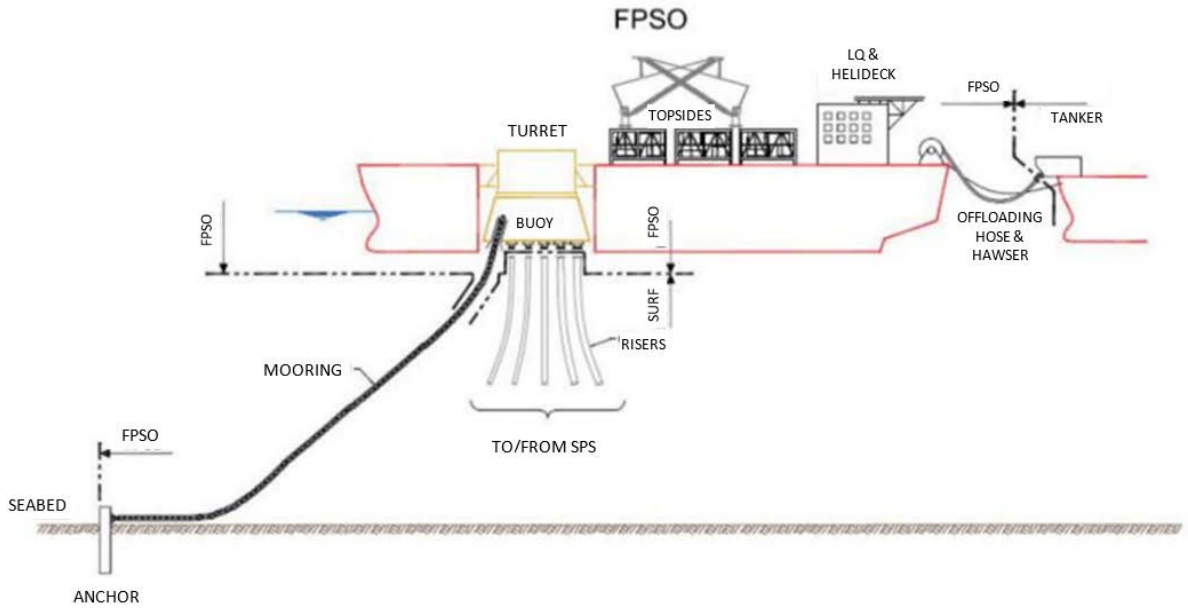

Figure 5-7: FPSO schematic showing the disconnectable turret and offloading tanker

5.6 FPSO Hook-up and commissioning

Once the FPSO is connected to the turret buoy (which will already be carrying the flowlines, risers and umbilicals), the hook-up operation to the SPS and SURF will be completed and commissioning activities will commence. This is collectively referred to as the Hook-up and Commissioning (HUC) process.

The FPSO 'hook-up' refers to making connections between:

- The wells and the FPSO e.g., connecting the flowlines / risers to the FPSO piping within the turret, and
- All utility and control facilities e.g., connecting the subsea umbilicals with the FPSO.

The 'commissioning' process refers to activating the system once it is hooked up. This involves numerous tests to ensure that:

- The system is safe for the introduction of hydrocarbons, and
- All production systems are working appropriately prior to commencement of production.

Leak testing will be carried out on the necessary elements of the systems, including those between the subsea facilities and the FPSO. Any leak testing with water will use seawater containing a biocide, an oxygen scavenger, a corrosion inhibitor and tracer dyes, which will ultimately be discharged to sea. As with all chemical use, chemicals will be selected to minimise environmental impact in line with legislation.

A summary of the transportation and installation vessels used during the Development is provided in Section 5.11.2.

5.7 Simultaneous Operations (SIMOPS): drilling and production

Once the first tranche of Phase 1 wells (nominally five pre-First-Oil in Stage 1) has been drilled and the FPSO has been hooked up and commenced production, there will follow a period of concurrent production and drilling (simultaneous operations). At this time, the MODU will drill the second tranche of Phase 1 wells (six post-First-Oil wells in Stage 2a) while the FPSO produces oil. A period of steady state production will follow before further subsea construction and the drilling of up to 12 planned Phase 2 (in Stage 2b) wells commences alongside simultaneous production from the Phase 1 wells.

With regard to the export of oil during this stage, the separation distance between the FPSO and the MODU will be sufficient to ensure that the CTT, which offloads crude from the FPSO (Section 5.10), remains outside of the MODU 500 m exclusion zone.

Support vessels used during the FPSO and MODU SIMOPS are described in Section 5.11.2.

5.8 Production facilities

5.8.1 Subsea production facilities

This section describes the purpose of the SPS and the SURF and both the subsea and topside facilities required to enable control of the reservoir *via* the FPSO.

5.8.1.1 Subsea Production Systems (SPS)

The production manifolds act as subsea flow routers and are connected to the production wells *via* jumpers. The production manifolds receive the fluid from each production well and co-mingle the produced fluids, which are ultimately carried to the FPSO by the flowlines / risers.

To achieve water injection, the seawater and / or treated produced water is pumped from the FPSO, *via* a WI flowline, to the WI manifold which distributes the water to the WI wells, again *via* jumpers. Manifolds thus reduce the number of flowlines / risers which need to be connected to the FPSO.

The subsea X-mas tree is an assembly of valves, spools, and fittings, which caps the well and controls the flow out of, or into, the well thereby enabling control of the wells during production.

5.8.1.2 Subsea Umbilicals, Risers and Flowlines (SURF)

The SURF (Table 5.12 above) enables:

- The transportation of reservoir fluids from the production wells to the FPSO,
- Communication between the FPSO and the SPS, and
- Injection of fluids (liquid and gas) to the wells from the FPSO.

Risers refer to the length of flowline that runs upwards through the water column between the seabed and the FPSO. Umbilicals are used to provide power, electrical and / or fibre optic and hydraulic control and chemicals to the subsea equipment.

5.8.1.3 Subsea Controls

The SPS and SURF facilities will be controlled by the Master Control System (MCS) and monitored by the Integrated Control and Safety System (ICSS) located in the FPSO Central Control Room.

The ICSS regulates the production process and provides the functionality to:

- Remotely control and monitor all the wells, subsea facilities (manifolds and X-mas trees), and flowlines / risers from the FPSO, and
- Monitor the chemical metering (where provided) and chemical transfer systems to ensure an adequate supply of production chemicals to the relevant injection points within the production system.

5.8.2 FPSO design

Navitas propose to use a 'lease and operate' FPSO with a required service life of 30 years. Subject to production performance, macro-economic factors and asset integrity, the service life may be extended further. The FPSO will utilise a redeployed FPSO that will be moored at the Sea Lion Field upon arrival in the Falkland Islands (Section 5.5.2). The cargo tanks of the vessel will be double-hulled and the redeployment will involve the installation and / or upgrade of the following onto the vessel:

- Processing facilities, marine equipment, utilities and control systems,
- Living quarters, and
- An internal turret mooring system which will be disconnectable (Figure 5-7 above) and will enable the FPSO to weathervane.

The FPSO will operate as a self-sufficient unit with export of produced oil *via* offloading directly to a CTT. The oil export process is further described in Section 5.10.

The hull will comply with FIG / UK legislation, flag state and will be class registered for offshore classification rules. The design, and all topsides pipework, equipment, skids, instrumentation, fittings and installation materials, will be:

- Sufficient to operate in the Sea Lion Field metocean conditions under continuous offshore duty for the service life,
- Rated for the range of ambient and extreme temperatures likely to be experienced, and
- Designed to withstand all forces and movement resulting from the sea state and wind conditions.

5.8.2.1 FPSO Drainage facilities

It is necessary for the FPSO to be designed in such a way that fluids exposed to the deck e.g., operational fluids, spills / leaks to deck and water from heavy rainfall, waves and firewater deluge can be segregated, contained, routed and managed *via* a series of drains.

The FPSO drains system will:

- Be compliant with current FIG / UK regulations and standards,
- Ensure all discharges are compliant with MARPOL 73/78 Annex I,
- Prevent hydrocarbon / chemical spills overboard,
- Prevent hydrocarbon / chemical spills to main deck,
- Prevent hazardous liquids collecting on module floors, due to the risk of pool fires and slip hazards,
- Enable recovery of hydrocarbons / chemicals from fluids prior to disposal *via* the drainage system,
- Prevent the migration of spills, gas and / or fire between process areas or modules *via* the drains system,
- Allow the safe disposal of clean water from rain / firewater, deluge and drains systems effluent, and
- Ensure segregation exists between hazardous and non-hazardous open drains systems.

The FPSO drains system will comprise:

- Open Drains - which will be routed to the marine systems:
  - Hazardous open drains – for collection of liquids from hazardous areas, or directly from hydrocarbon processing equipment, which has been depressurised (in some cases *via* a Process Drain) or operates at atmospheric pressure,
  - Non-hazardous open drains – for collection of liquids from equipment located in non-hazardous areas, or directly from non-hydrocarbon processing equipment, which has been depressurised or operates at atmospheric pressure.
  - **Note:** all open drains water phase will meet MARPOL 73/78 Annex I requirements prior to discharge to sea.

- Deck drains – open drainage for areas where there is no pollution, and
- Closed Drains - the closed drains system will be part of the oil processing system and will be segregated from the open drains systems. The closed drains collect liquid hydrocarbons, produced water or other hazardous substances directly from equipment that normally operate at pressure. Liquid hydrocarbons will be routed to a Closed Drains Vessel from where they are pumped back into the oil processing system.

5.8.2.2 FPSO capacity and production

The FPSO processing capacity will be designed to meet the requirements of Phase 1 & 2 production volumes, with estimated peak production rates (Table 5.14) determining the design capacity of the FPSO topsides. Minor upgrades to topsides equipment or updated operating procedures may be implemented to achieve target rates. The FPSO will be designed to deliver the FDP production profile for both Phase 1 and 2.

Table 5.14: Facility design rates

Service	Phase 1, Maximum design rate	Phase 2, Maximum design rate
Oil production capacity (bbl/d)	45,000	55,000
Total produced liquids (oil, gas and water) capacity (bbl/d)	50,000	110,000
Injection water (produced water + seawater) (bbl/d)	60,000	90,000
Gas handling capacity (mmscfd)	50	90
Seawater Lift ((bbl/d)	60,000	90,000

5.8.2.2.1 Production Profile

Figure 5-8 presents the expected production profile of oil, water and gas (production and gas lift) for the P50 case of 310.5 MMstb and shows the peak in production shortly after the completion of Phase 2 and then the steady decline over Field Life. An average production rate of 28,356 bopd is assumed. The actual production and injection rates will vary according to the performance of the reservoir and the production systems.

Further details on the P10 and P90 production cases are provided in Section 10.9 (see Figure 10-40) which quantifies and assesses the impact of atmospheric emissions associated with the Sea Lion Development.

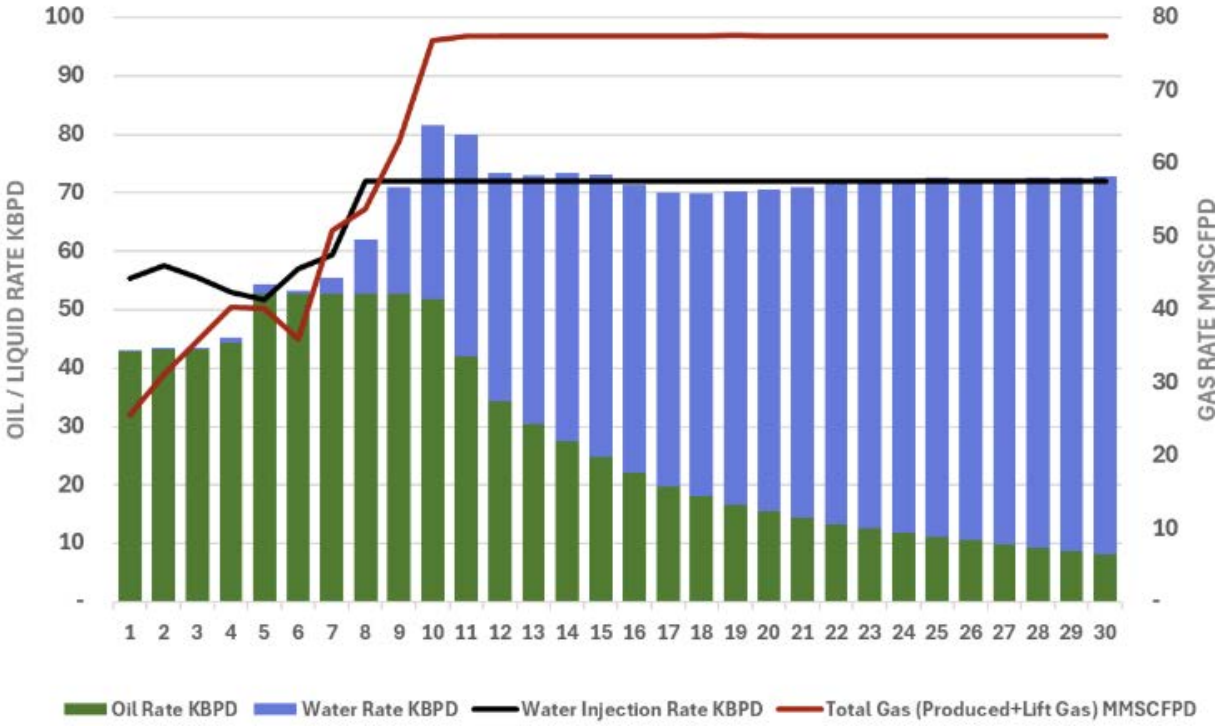

Figure 5-8: P50 Production forecast for the Sea Lion Field Northern Area Phase 1 & 2 Development. Note: kbpd = thousand barrels per day

5.8.2.3 FPSO combustion equipment

While all sources of emissions of Greenhouse Gases are itemised in the emissions impact assessment (Section 10.9), the main combustion equipment on the FPSO is listed in Table 5.15.

Table 5.15. Combustion equipment on the FPSO

Power generating combustion equipment	Fuel system	Typical fuel consumption rate (t/d)	Purpose
3 x Solar Mars 100 Dry Low Emission (DLE) Gas Turbine Generators	Dual fuel	5.5 mmscfd of fuel gas[1] 50 t/day of diesel per GTG (if not operating on fuel gas)	Main source of power generation for all consumer units on the FPSO (See Section 10.9.2).
Gas Fired Boiler (Steam boiler)	Fuel gas	*c.* 2.5 mmscfd of fuel gas	Used to heat injection water during the first year of production.
2 x Auxiliary Steam Boilers	Diesel	15.3 per unit	Operated as back up in the event GTG WHRU and / or Gas Fired Heater out of service. The units would also be routinely operated for *c.* 24 hours each per month.
2 x Essential Diesel Generators	Diesel	22 per unit	Used to provide interim minimum constant power for essential utility and production support systems in the event that all three Gas Turbine Generators malfunction. Weekly test run of 30 minutes each.
1 x Emergency Diesel Generator	Diesel	4.7	Used to ensure living support and to keep safety systems available in the

Power generating combustion equipment	Fuel system	Typical fuel consumption rate (t/d)	Purpose
			event of emergencies. The generator supplies sufficient power for the emergency services and some essential FPSO services. Weekly test run of one hour.
1 x Diesel driven hot oil circulation pump	Diesel	0.9	For use in the hot oil circulation system required to maintain subsea temperatures and flow assurance during emergency shutdowns (Section 5.8.4.1). Weekly test run of one hour.
2 x Diesel driven fire pumps	Diesel	3.8 per unit	For use in the event of fire. Weekly test run of one hour.
4 x Diesel driven Totally Enclosed Motor Propelled Survival Craft (TEMPSC)	Diesel	0.24 per unit	For use in the event of an emergency evacuation. Each engine will be run for 20 minutes per week.

[1] The estimated fuel gas usage includes all GTGs and is for all three turbines. Of note, mmscfd = million standard cubic feet per day.

5.8.3 FPSO vessel utility systems

The following sections describe the utility and safety systems of the FPSO.

5.8.3.1 Anti-fouling

Anti-fouling paint will be applied to the hull of the FPSO prior to its departure for the Falkland Islands to prevent fouling of the steel by marine growth. This prevents additional weight on the hull structure and reduces drag as well as minimising the risk of introducing non-native species upon entry into Falkland Island waters. Paint complying with latest international standards for environmental protection will be used (Section 15.7.2).

5.8.3.2 Heating, ventilation and air conditioning (HVAC)

HVAC systems will be provided for accommodation and enclosed spaces within the hull that are regularly accessed by authorised personnel.

Ozone Depleting Substances (ODS) will not be used in the HVAC systems which will deploy F-Gases instead. During the design process, Navitas aim to use F-Gases which have a comparatively low Global Warming Potential (GWP) wherever possible. No F-gases will be released under normal operations.

5.8.3.3 Power generation and fuel sources

Considerable effort has been invested in ensuring that power generation onboard the FPSO is as efficient as possible. Energy efficiency and the minimisation of atmospheric emissions was evaluated as part of the decision-making process when assessing options for the main power generation system and the main consumer equipment e.g., electric motor driven gas compressors, pumps etc. Fuel use will therefore be minimised throughout design and subsequent operation.

The power generation package will comprise three dual fuel (fuel gas and diesel) Solar Mars 100 Dry Low Emission (DLE) Gas Turbine Generators (GTG) rated at 9.7 MW electrical output (Table 5.16). During normal production, and during production plus offloading operations, all electrical power consumers will be supplied by two of the GTGs in a two out of the three configuration. The concurrent use of all three turbines is not expected even at times of high demand and the third GTG will be a like-for-like unit for sparing and availability requirements. The third GTG unit will be fully maintained on

standby to allow for maximum reliability. This aims to ensure constant GTG availability thus ensuring maximum processing availability, less downtime and less reliance on diesel fuel.

Two types of fuel will be used on the FPSO, namely produced gas (i.e., separated associated gas and from the proven gas cap) and diesel (e.g., Marine Gas Oil (MGO) or Marine Diesel Oil (MDO)). Notwithstanding the implications for resource use and emissions, the use of diesel for the main power generation at Sea Lion is also limited by the available storage on the FPSO and resources in the Falkland Islands. It is therefore anticipated that the oil and gas process will be reliant on associated gas produced from the oil wells which will be the primary fuel source on the FPSO (Section 5.8.4.3).

Therefore, the two GTG units will run continuously through much of the Field Life and will be run on fuel gas except for:

- A duration of up to four weeks after First-Oil while fuel gas is coming online and the equipment is being commissioned, and
- During times of process safety or emergency shutdown when fuel gas will not be available.

The diesel reliant essential power generator (Table 5.16) will be used immediately following First-Oil while commissioning of the systems is proven and steady state is achieved. Further, during commissioning, establishing the GTGs onto fuel gas will take up to *c.* four weeks, so they will use more diesel until production has stabilised. Once into steady state production, with three GTGs available, diesel fuel usage will be low on the GTGs.

With the associated gas and proven gas cap, it is expected that fuel gas will be available for 100 % of the time once the system is fully commissioned. Further, should it be necessary in later Field Life, when less associated gas is being liberated, it will be possible to bring gas back up the GI well riser. Nonetheless, to take a precautionary approach it is estimated that fuel gas may be unavailable for 5 – 7 % of the time owing to process safety and / or emergency shutdowns. During these times, the GTGs will be run on diesel until the fuel gas can be reinstated. This is reflected in the emissions estimates and impact assessment presented in Section 10.9.

Once into steady state operations essential and emergency power usage are nearly always used in an unplanned scenario, when there is a process upset that leads to either a Process Shutdown (PSD) or an Emergency Shutdown (ESD). Therefore, the use of diesel driven emergency power (Table 5.16) will be rare. It may be required on occasion during start-up, but will not be common in steady state operations. Nonetheless, it will be test run every week for at least one hour and such tests are included in the emissions estimate and impact assessment provided in Section 10.9.

Waste heat will be recovered from the exhaust gas of the main power generation system and will be utilised to supplement the heating demand on the FPSO (Section 5.8.4.2) and so reduce overall fuel consumption and associated emissions.

Equipment defined as essential will be provided with an uninterruptable electrical power supply according to DNV GL and SOLAS (International Convention for Safety of Life at Sea) rules. Dedicated emergency power generation will be available on the FPSO.

Details on all power generation systems are provided in Table 5.16.

Table 5.16. Power generation equipment on the FPSO

Power generating combustion equipment	Fuel system	Output (MW)	Purpose
3 x Solar Mars 100 Dry Low Emission (DLE) Gas Turbine Generators (GTGs)	Dual fuel	9.7	Two units will be run continuously as the main source of power generation for the FPSO. The third will be maintained as a standby unit to ensure redundancy and to optimise the availability of power.
2 x Essential Diesel Generators	Diesel[1]	5.6	To provide minimum constant power for essential utility and production support systems in the event that main power is unavailable.
1 x Emergency Diesel Generator	Diesel[1]	1.1	The emergency generator ensures living support and keeps safety systems available in the event of emergencies. The generator supplies sufficient power for the emergency services and some essential FPSO services.

[1] Owing to the limitations on diesel storage and supply described above, the essential power generators may be converted to dual fuel, subject to further design development work conducted through FEED.

5.8.3.4 Bunkering and bulk storage

5.8.3.4.1 Diesel bunkering, storage and treatment system

Diesel will be stored in hull storage tanks. In total, a maximum diesel storage volume of 3,130 m^3 is available for a capacity of approximately 2,524 tonnes of diesel (i.e., MGO) to be stored on board for the following diesel consumers:

- Single-fuel diesel consumers (Section 5.8.3.3), and
- Dual fuel consumers when fuel gas is unavailable.

A minimum of 1,200 m^3 storage will be reserved for the subsea flowline displacement system used for flow assurance (Section 5.8.4.1) in the event of an extended shutdown, which would lead to unacceptable cool down of the flowlines.

Diesel is bunkered from supply vessels to the FPSO diesel storage tanks. Bunding will be arranged at the receiving manifold and hose handling area to contain inadvertent spills during bunkering operations.

The diesel treatment system will be designed to ensure management of any diesel contaminated with water and particulates in order to meet the turbine cleanliness requirements.

5.8.3.4.2 Chemical bunkering and storage

During production, numerous chemicals will be required in order to facilitate the process. The hull of the FPSO will be designed to enable the storage of bulk chemicals following receipt *via* either bulk hose transfer directly into the hull, or tote tanks from the supply vessels. A laydown facility will be provided on the FPSO to enable storage and decanting of chemicals from tote tanks into hull storage when required. The method of chemical receipt (i.e., *via* bulk hose transfer or tote tank) will be dependent on the volumes and frequency of delivery.

Preliminary production and utility chemical groups required during the production of oil and gas are provided in Table 5.17 alongside details on the function of the chemical, the volumes that the hull tanks will be designed to carry and the most likely method of delivery. These volumes are preliminary and will be verified during the detailed design phase of the project development (Section 3.2.2).

Table 5.17: Production chemical functional groups and hull chemical tank storage volumes

Chemical type	Chemical function	Maximum FPSO storage capacity (m^3)
Demulsifiers	Used to break emulsions in the produced fluids i.e., separate the oil and water phases. The type of demulsifier selected depends on the type of emulsion, either oil-in-water or water-in-oil	29 m^3
Deoilers	Used to destabilise the oil in water emulsions	12 m^3
Biocides	Two biocides will be used to kill bacteria in the injection water and produced fluids to prevent or remove biological contamination	5 m^3 / biocide
Solid flocculants	Flocculants are used to aid in the removal of solids from the seawater and produced water by intentionally gathering together small particles and making them larger and thus easier to remove (flocculation)	13 m^3
Oil antifoams	Used to prevent foaming in hydrocarbon based fluids by decreasing surface tension	19 m^3
Water antifoam	Used to prevent foaming in water-based fluids by decreasing surface tension	8 m^3
Oxygen scavengers	Used to remove or decrease the level of oxygen in injected seawater to prevent oxygen induced corrosion	8 m^3
Hydrate Inhibitors	Triethylene glycol (TEG) - used to dehydrate gas and lower the dew point of gas Methanol - used for hydrate inhibition in the production and gas flowback system.	10 m^3 471 m^3
Scale inhibitors	Used to prevent the precipitation of inorganic solids from produced formation water and as formation water and injected seawater commingle. Typical scales are calcium carbonate and barium sulphate. Carbonate scales primarily form when produced water becomes supersaturated with salts due to variation in temperature, pressure or pH. Barium sulphate scale deposition can occur due to mixing of incompatible waters with differing water chemistries A broader range of scales also can be observed, depending on the reservoir conditions and production regime	45 m^3
Wax Treatment chemical	(also known as pour point depressant) Used to minimise wax deposition, oil viscosity and restart pressures after gels have formed	660 m^3
Wax Dissolvers	Used to dissolve wax in the event that it forms	Brought on board as required
Calcium nitrate	Used to prevent the formation of hydrogen sulphide. Calcium nitrate will only be utilised if the Sea Lion reservoir becomes sour (not expected)	126 m^3
Diesel	There will be a separate storage tank for diesel which will be used for flowline displacement (Section 5.8.4.1)	1,200 m^3

5.8.3.5 Freshwater systems

Freshwater is required on the FPSO to provide:

- Drinking (potable) water for personnel,
- Hot and cold water for domestic use,

- Make-up volumes for the cooling and heating water systems,
- Water for the safety showers, general utilities and workshops, and
- Water for slop tanks washing.

Freshwater will be generated on the FPSO from seawater using distillers. Seawater will be pumped onboard *via* seawater lift pumps and the water systems will be designed to produce, bunker, store, sterilise and distribute potable water for domestic consumption and service water for general use on the FPSO.

Based on an estimate of 60 tonnes / day of freshwater required for the marine and topside systems (including personnel water usage), it is estimated that 276 m^3 per day of hypersaline water may be discharged from the FPSO desalination plant. Note that the discharge rate of hypersaline water will be confirmed during detailed design.

5.8.3.6 Vessel and domestic waste treatment systems

Wastewater and food that will be generated on the FPSO includes:

- Food waste from the galley,
- Grey water (from showers, wash basins, kitchen and laundry),
- Black water (domestic wastewater arising from toilets), and
- Bilge water (from machinery spaces, which may contain traces of hydrocarbon, grease etc.).

The following treatment facilities will be in place:

- Food waste:
  - Food waste will be ground to an extent that it can pass through a 25 mm grid before being discharged overboard without further treatment.
- Grey water:
  - Galley drains receiving grey water will be fitted with grease traps, and
  - Laundry drains will be fitted with lint filters.
- Black water:
  - A macerator will be fitted to the inlet of the sewage unit to macerate biodegradable solids prior to discharge.
- Bilge water:
  - Drains from the equipment in the machinery spaces will be pumped into a bilge holding tank for separation,
  - Water from the holding tank will be further treated in an oily water separator to ensure a maximum Oil in Water (OiW) concentration of 15 mg/L is not exceeded prior to discharge, and
  - Separated oil or sludge will be routed to the waste oil drain tank, which will be transferred to tote tanks for onshore recovery or disposal. Alternatively, the separated oil will be recycled *via* the hazardous open drain tank (Section 5.8.2.1) and thus routed back into the oil processing stream.

All treatment and discharge of grey and black water will be in compliance with FIG / UK environmental regulations and classification requirements, and with MARPOL Annex IV. Similarly, the bilge system will comply with FIG / UK environmental regulations and MARPOL 73/78 Annex I.

5.8.4 FPSO oil and gas utility systems

The following sections describe the FPSO utility systems that support the production and processing of oil and gas.

5.8.4.1 Flow assurance facilities

During production, it is necessary to ensure that the produced fluids can flow from the reservoir to the FPSO process equipment, into the storage tanks and on to the point of sale without interruption, deterioration of the crude quality and / or asset damage. Maintaining the ability of the fluids to flow is called 'flow assurance'.

Flow assurance plays a major part in how the Sea Lion system is to be designed owing to:

- The waxy nature of the Sea Lion crude oil, which has a Wax Appearance Temperature of between 60 - 66°C and Oil Pour Points of 25 - 36°C,
- The total fluids propensity to form hydrates which are ice-like solids that form when free water and natural gas (both of which will be present in the produced fluids) combine at high pressure and low temperature, and
- The ambient sea temperature, which ranges from 3 - 9°C.

In addition to the nature of the crude, flow assurance can also be affected by produced fluid chemistry, injection water chemistry and synergistic effects between the production chemicals used. Therefore, maintaining flow assurance is most commonly achieved using a combination of both chemical and technical measures, with effective technical design minimising the need for chemical use as well as the energy requirements associated with active heating of the system.

All subsea and FPSO facilities will be designed to prevent the formation of hydrates, waxes and gels, which may block the system e.g., by insulating the pipework thereby passively maintaining topside arrival temperatures in excess of the live oil wax appearance temperatures (Section 5.3). However, facilities will also be designed to mitigate their effects should blockages occur, and to enable their safe removal.

Table 5.18 gives an overview of the technical flow assurance facilities built-in to the well system and the SPS, SURF and FPSO during the development of the project. These will be developed further after the project is sanctioned. The table lists those methods that will be applied on a continuous and preventative basis as well as those that may be applied on an active, or intervention basis e.g., following a shutdown (Section 5.9.4). Where it is necessary to maintain temperatures to ensure flow assurance, the majority of the measures used will be based on passive heat retention methods, rather than active heating systems in order to minimise the energy demand and associated emissions. Detail on the production chemicals that will be required for flow assurance during steady state production (Stage 3) is provided in Section 5.9.1.1.

Table 5.18: Technical flow assurance strategy for continuous operation & interventions in the Sea Lion Development

Facility	Preventative flow assurance method	Intervention (active) flow assurance method
Downhole production tubing	Passive – Vacuum Insulated Tubing Active – Wax Treatment Chemical / Pour point depressant chemical injection	In the event of wax deposition on the upper section in the tubing, chemical injection will be carried out to reduce the gel strength and reduce the wax deposition.

Facility	Preventative flow assurance method	Intervention (active) flow assurance method
SPS Equipment	Passive – insulation	Two Flow Line Circulation (FLC) pumps will be installed, one electric driven and one diesel driven. This is a new system to be installed on the FPSO as part of the Sea Lion project. Its primary objective is to circulate hot oil and displace flowline fluids in the event of subsea shutdown (and prior to wells re-starting when cooling has occurred), to mitigate against gelling and hydration formation in the flowlines. The hot diesel oil will be circulated through the system and back to the crude oil tanks and comingled as stored product. The electric driven pump will be the primary unit (fed from essential power (Section 5.8.3.3 above)). The diesel driven pump will only be used in the event that there is no essential power, or the electric driven pump[1]. malfunctions.
SURF - production (flexible flowlines / risers)	Passive – insulation	
FPSO and export tankers	System drainage, heat tracing for piping and equipment not in continuous operation, insulation to maintain temperatures. Injection water leaving FPSO is heated so that the flowing bottom hole temperature is >60°C. Crude oil storage tank heating up to 60°C for both the FPSO and export tankers	Flushing - connections for piping, offloading hose, instruments and equipment provided.

[1] Emissions from the potential use of the diesel driven hot oil circulation pump are included within the emissions estimate and impact assessment within Section 10.9.

5.8.4.2 Heating and cooling facilities

During steady state operating conditions, it is anticipated that well fluids will be between 60 – 80 °C depending on the level of reservoir depletion. As the proportion of produced water ('water cut') increases, FPSO arrival temperatures will increase. As described above, it is necessary to manage the temperature of the Sea Lion crude as it flows through the subsea and topside processes to ensure that it is hot enough to remain in a fluid phase. However, it is also important that the crude is not too hot for the storage tanks.

Heating for the water injection system (Section 5.8.5.8 below) during the first year of production will be provided by a gas fired steam boiler (Section 5.8.2.3), the energy demands for which are included in the emissions estimations and impact assessment chapter (Section 10.9).

Both heating and cooling, as necessary, are managed by closed loop systems that will provide efficient and reliable heating / cooling whilst minimising environmental impact:

- The heating medium used in the closed loop will recover waste heat from the main power generator gas turbine exhausts *via* Waste Heat Recovery Units (WHRU), and
- The cooling medium is cooled by cross exchange with seawater and within this system, approximately 70,000 m^3 of seawater will be discharged to sea per day.

5.8.4.3 Gas management system

Produced gas (associated gas from the oil wells) will be required on the FPSO to provide:

- Fuel for the FPSO power generation and seawater heaters,
- Tank blanketing (Section 5.8.4.6),
- Flare purge and pilot, and
- Gas lift for the production wells that require artificial lift (Section 5.8.5.6).

The FPSO has a gas handling / compression capacity of 50 – 90 mmscfd (Section 5.8.2.2).

The daily fuel gas requirement is expected to be, on average, 5.5 mmscfd and the gas requirement for gas lift averages at approximately 15-30 mmscfd, which is recycled. Any gas not required for fuel or lift gas will be re-injected into the GI well. The maximum amount of gas to be reinjected into the gas well is expected to be up to 50 mmscfd.

5.8.4.4 Flaring facilities

The design shall be based, as far as possible, on a 'zero flaring' philosophy during steady-state production with flaring only permitted for significant process upsets, process shutdowns, emergency shutdown or unavoidable maintenance.

On the High Pressure (HP) flare system there are no continuous sources such that no recovery system is required. Both the High Pressure and Low Pressure headers and tips will include a purge and pilot flame to ensure readiness for sudden reliefs from the process. The pilot flames are expected to burn at a rate of approximately 0.5 mmscfd.

With regard to when steady state production commences in the context of zero flaring, the best prediction is that steady state production operations could be achieved as early as within four weeks from startup. However, it could take as long as three months considering modified facilities can sometime be more challenging to start up than a new build.

Measures intended to ensure the best case include:

- Due consideration given to production facility integration and operations in design,
- Robust pre-commissioning in shipyard and during sail over to location,
- Core crew familiarity with new modifications (training and as part of pre-commissioning teams), and
- Robust commissioning plans and procedures in place applied through cross-functional competent teams.

5.8.4.5 Venting and fugitive emissions

The FPSO basis of design is such that the venting of gases will not be carried out during routine operations and good practice will be followed in minimising fugitive emissions including low loss fittings and active leak detection and repair. Use of a Vapour Recovery Package (VRP) is also being studied to minimise fugitive emissions of Volatile Organic Compounds (VOCs).

5.8.4.6 Tank blanketing and venting

Tank blanketing is used in the FPSO oil cargo storage tanks as well as the slops and off-spec tanks to maintain a non-explosive atmosphere in the space above the liquids inside the tanks. The Hydrocarbon (HC) gas blanketing system will use the produced and treated fuel gas on the FPSO. This will ensure that oxygen is eliminated from the tanks forming an atmosphere saturated with hydrocarbon to a level

above the Upper Explosive Limit (UEL), at which combustion cannot be supported (i.e., an atmosphere that cannot burn). Advantages to the HC blanketing system are:

- Use of a gas that is readily available in large volumes, which can continuously protect a number of large tanks, and
- Evaporation in the tanks is minimal.

In the event that fuel gas cannot be used for the blanket or that the gas blanket must be vented (e.g., in the event of VRP malfunction), inert gas from the inert gas generator exhaust will be used as blanket gas. The inert gas will comprise mainly nitrogen and carbon dioxide with restricted oxygen content below permissible levels. In the event of VRP malfunction and the subsequent switch to inert gas, it may be necessary to vent off some of the HC gas blanket. The potential for unplanned emissions such as this is included within the impact assessment for emissions described in Section 10.9.

5.8.4.7 FPSO Off-Spec and Slops tanks

Off-spec oil and water is sent to designated cargo tanks for settling, with a capacity of approximately 13,490 tonnes in a storage volume of 17,038 m^3. Two slop tanks will also be provided on the FPSO with a minimum combined capacity of approximately 7,596 tonnes in a storage volume of 7,751 m^3. The slops tanks and associated systems will be designed to accommodate the:

- Fluids from the open drains system (Section 5.8.2.1),
- Contaminated water resulting from the flushing and cleaning of the cargo loading pipework, discharge pipework and offloading hose,
- Temporary storage of off-spec crude oil and produced water prior to their recycling back through the process for further treatment, and
- Fluids displaced to allow entry into vessels for maintenance purposes.

Prior to being discharged to sea, the slops water will be cleaned to less than 15 ppm OiW content in accordance with MARPOL Annex I regulations. To achieve this, the slops tanks will be arranged in a cascade to enable gravity and time based (two stage) oil / water separation.

Further, inline OiW monitors will be provided in order to isolate the overboard discharge and re-route any off-spec slops water back to the slops tanks for reprocessing if OiW content exceeds the allowable limits.

5.8.5 FPSO oil and gas process facilities

The following sections describe the FPSO facilities that process the produced oil, gas and water.

5.8.5.1 Total fluid separation

The fluid produced from the oil production wells will contain oil, water, gas and possibly solids (predominately sand (Section 5.8.5.5)) and is therefore a multiphase fluid. This multiphase fluid is referred to as ‘total fluids’. The ratio of each of the components will change over time as the reservoir becomes depleted, increasing the reservoir water cut, and also as injection water passes through the reservoir, ‘breaks through’ at the production wells and starts to be produced. Once the multiphase fluid from the wells is produced onto the FPSO, it is necessary for it to be separated into the different components.

The purpose of the separation process is to:

- Remove as much of the water and gas from the oil as possible prior to oil offload and export,
- Remove water from the gas so the gas can be compressed and made ready for use as fuel gas (Section 5.8.4.3) or gas lift (Section 5.8.5.9), or in the event that excess gas needs to be reinjected into the reservoir *via* the GI well(s), and

- Clean the produced water prior to re-injection into the reservoir for Improved Oil Recovery (IOR) (Section 5.8.5.6) or prior to discharge to sea in the event that the Produced Water Reinjection (PWRI) system is unavailable.

The FPSO for the Sea Lion Development will be equipped with a first stage High Pressure (HP) separator used for the initial separation of the total fluids. During normal operations, the reservoir fluids, which have been co-mingled at the subsea manifolds, will arrive at the FPSO and will be routed to the HP separator. The internal design of the separator promotes the separation of the phases owing to the different specific gravities of oil, gas and water.

Following initial separation, each component must then be further treated and stabilised to enable either; its export as the target product (oil), its use elsewhere on the FPSO (gas, produced water), or its discharge to the environment in line with regulatory limits (produced water). To achieve this, the different components are distributed accordingly into the ‘oil process’, the ‘gas process’ and the ‘produced water process’ (Figure 5-9).

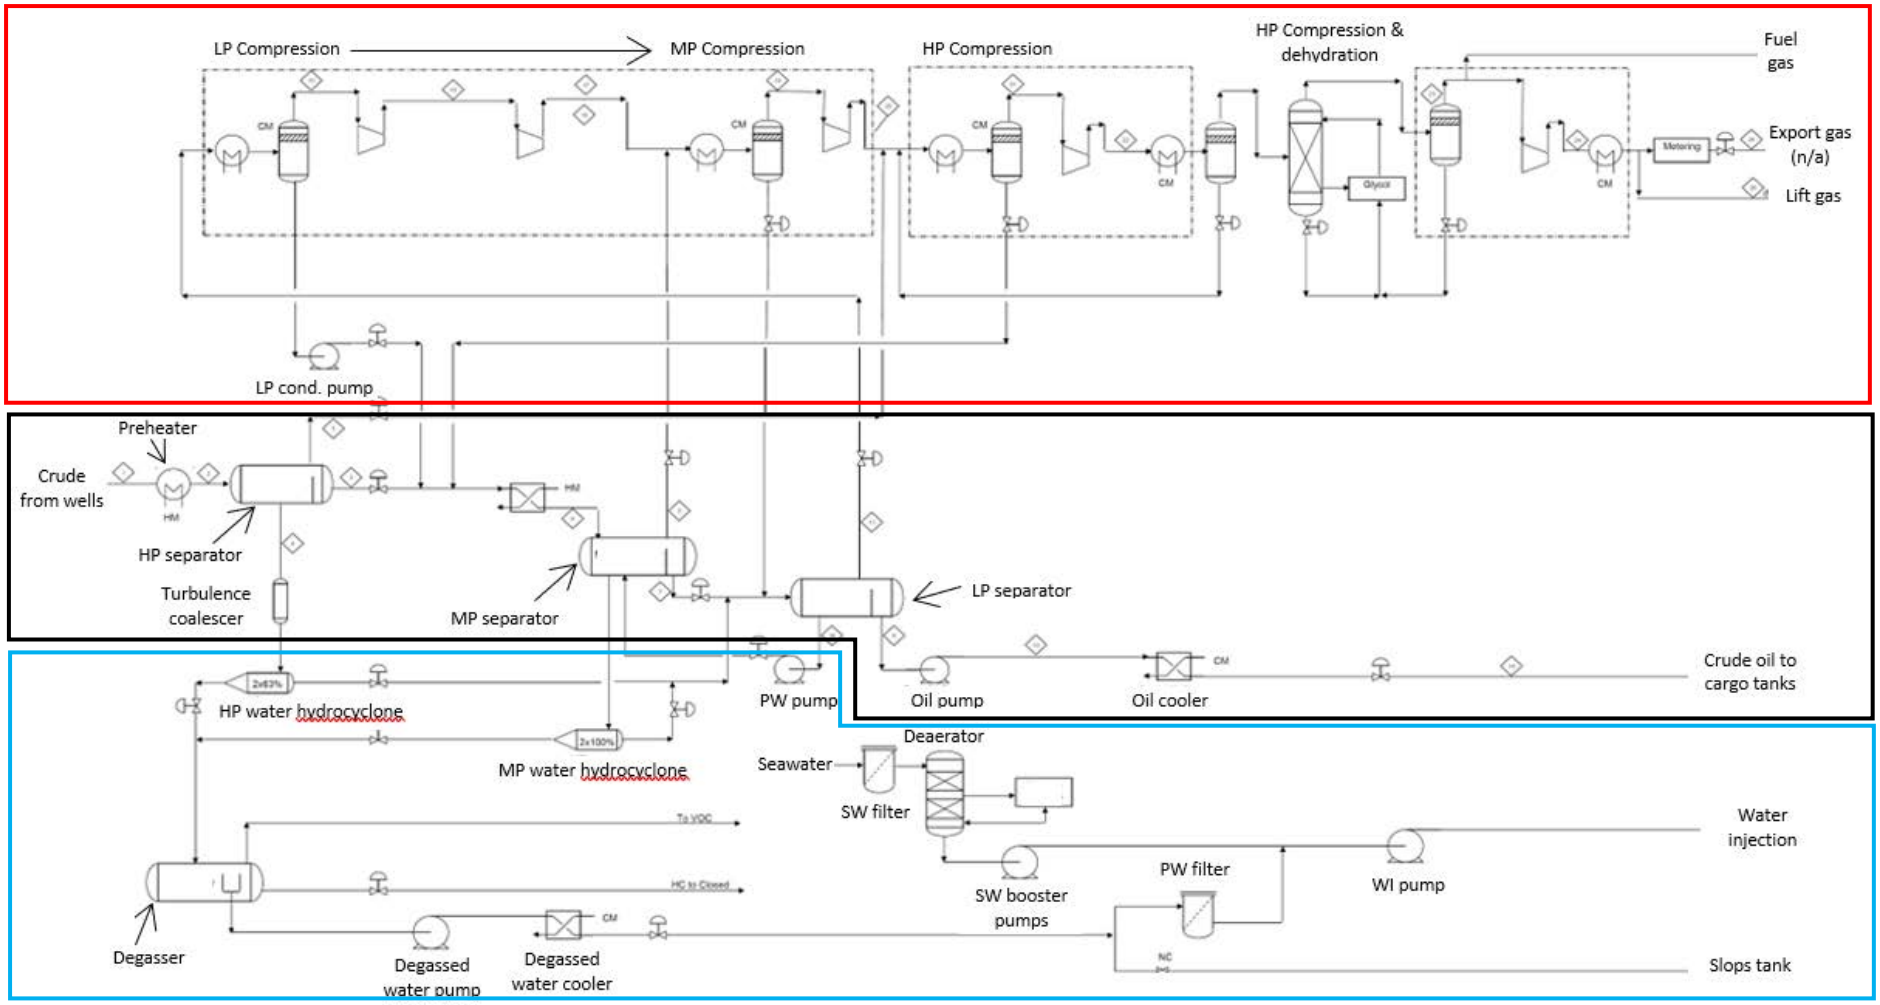

Figure 5-9: Block flow diagram of the FPSO separation and stabilisation processing facilities (before any upgrades/debottlenecking). Black = Oil process, Red = Gas process, Blue = Water process

5.8.5.2 Oil Process

The oil process facilities will receive production fluids at between 60 - 80°C. Following initial separation, oil from the HP separator will be routed to the Medium Pressure (MP) and Low Pressure (LP) separators and possibly an electrostatic coalescer (to be determined) where it is stabilised to meet the export specification. From here, the oil will be treated to achieve the export specifications for salt and water content.

All oil process vessels, piping and instruments with the potential for wax deposition will be trace heated and / or insulated to prevent the crude cooling and solidifying in the lines. The stabilised oil will then be cooled to the appropriate storage temperature to avoid damage to the cargo tanks, while maintaining sufficient heat to prevent the crude oil solidifying, thus maintaining flow assurance to allow offload. The oil export and storage specification is presented below in Table 5.19.

Table 5.19: Stabilised oil specification

Parameter	Specification
Pressure	Atmospheric
CO_2	0.1 mol%
H_2S	3 ppm weight (No H_2S removal facilities shall be provided. H2S management shall be *via* injection of calcium nitrate)
Reid Vapour Pressure (RVP)	8-10 psia max
Basic Sediment & Water (BS&W)	0.5 %
Salt	40 pounds per thousand barrels
Methanol	≤ 25 ppm (export specification)
Crude Oil Temperature	55 °C min (FPSO storage / tanker) 60 °C max (offload)
Export Pressure	Minimum 2 barg delivered to offtake tanker

5.8.5.3 Gas process

Gas in the process will originate from the oil production wells.

Following initial separation, the gas process includes:

- Compression in three stages, depending upon the fate of the gas (fuel gas, gas lift, storage tank blanket gas, or reinjection), and
- Dehydration.

5.8.5.3.1 Gas compression

The aim of the gas compression system is to compress the gas extracted from oil in the separation system, maximising the gas available for re-injection, gas lift and fuel gas. Gas compression occurs in three different stages within the gas processing system. Gas used as fuel gas will be compressed in the 1st stage of the Main Gas Compression Package and dehydrated prior to use. Following the dehydration process, gas required for gas lift and reinjection will be compressed in the 2nd and 3rd stages of the Main Gas Compression package prior to use.

5.8.5.3.2 Gas Dehydration

After first stage of compression the gas stream will be dehydrated. The gas stream is dehydrated to a water concentration of 2 lbs/mmscf maximum to minimise the water content and therefore avoid formations of 'hydrate' in the gas injection or gas lift systems, which could cause blockages.

5.8.5.4 Produced water process

The 'produced water' refers to all the water that is produced with the oil from the oil wells and comprises a mixture of:

- Formation water from the reservoir,
- Seawater which has been injected (or produced water that has been reinjected) into the reservoir and has flowed through the reservoir and 'broken through' at the production wells such that it is produced with the total fluids back to the FPSO, and
- Solids / sand which is suspended within the water (not expected).

Following initial separation in the HP separator, it is necessary to further clean, treat and de-sand (if necessary) the water in the 'produced water process' so that it may be used for Produced Water Re-Injection (PWRI) for improved oil recovery (Section 5.8.5.6). The produced water treatment facilities comprise de-oiling hydro-cyclones, a degasser and a cooler. A flotation unit may also be added, subject to further design work

In order to be suitable for reinjection back into the reservoir, the OiW concentration needs to be <10 mg/l at the point prior to the produced water / seawater mixing point.

Oil removed from the water during the produced water treatment process will be routed back to the 'oil process' and gas will be routed to the 'gas process'. Sand removed from the process will be treated as described in Section 5.8.5.5 below.

5.8.5.4.1 Discharge to Sea

In the event that the PWRI units are unavailable (Section 5.8.5.8) which is estimated to be approximately 7 % of the time, or that the OiW concentration cannot be reduced to <10 mg/l, the treated produced water will be diverted to the off-spec/slop storage tanks which are heated to assist in gravity separation of oil and water before being re-routed back into the separation process. Off-spec PW will not be discharged.

The Sea Lion reservoir has no active aquifer and the Development is therefore critically dependent on water injection for pressure maintenance to support production and deliver reserves. Heated Seawater will initially be injected on Sea Lion to assure crude mobility and, as such, the water injection wells will not thermally fracture, as is the case in other oil fields, but will instead rely on hydraulic fracturing from surface pumps. Produced Water Re-Injection will follow later once injection water breakthrough occurs at production wells.

Over time, and despite adopting Best Available Technologies (BAT) and Best Environmental Practice (BEP), physical and thermal effects and chemical reactions in the receiving reservoir can cause significant losses in produced water injectivity. In the case therefore that produced water reinjection causes a significant reduction in injectivity, Navitas would expect that this would alter the arguments for BAT/BEP such that permission for overboard discharge may be sought, whilst maintaining compliance with OSPAR and the UK OPPC regulations (i.e., achieving the lowest practicable dispersed oil concentrations, with sample concentrations that would amount to a monthly average of <30 mg/l with no single sample exceeding 100 mg/l). The OSPAR Risk-Based Approach to PW would also be applied per UK/OSPAR practices to demonstrate that environmental risks were managed to the lowest practicable levels and to show PW was managed to continue reducing the main elements of risk.

In the event that produced water needs to be discharged, Navitas will sample the produced water twice daily to determine the OiW concentration to ensure compliance. Further, the FPSO will have constant inline OiW measuring devices. If the OiW content is higher than the set limit, the stream will be re-routed back to the tanks for further separation.

In practice, it is anticipated that any produced water discharged to sea will have an OiW concentration in the region of 10 - 15 mg/l.

5.8.5.5 Management of Solids

The production of sand in the multiphase fluid is not anticipated. However, in the event that sand is present, it will most likely fall out of suspension within the HP separator and within the produced water process. Any sand retrieved from the separators and water production process vessels will be tested for Naturally Occurring Radioactive Material (NORM) and to measure its oil content and will be:

- Re-injected, if possible, or
- Transported to shore for clean-up and disposal.

The management of hazardous waste is described in Section 10.10.

5.8.5.6 Improved Oil Recovery (IOR)

IOR will be required for the Sea Lion Field as the reservoir pressure will decline during the Field Life. IOR will be achieved using water injection / reinjection and gas lift, as described below.

5.8.5.7 Field life well testing

Well testing of the oil production wells is periodically carried out to:

- Broaden the knowledge and understanding of hydrocarbon properties and characteristics of the reservoir, and
- To obtain data on the individual well flow rates, water cut and Gas to Oil Ratio (GOR).

Over the life of the field, well testing to the FPSO, to measure individual well flow rates, is carried out *via* multiphase meters which are installed on each well where well metering will be conducted throughout the life of the field as part of day-to-day operations and requires limited, or no, incremental flaring emissions. See also Section 5.8.4.4 on flaring facilities.

5.8.5.8 Water injection / Produced Water Reinjection (PWRI) facilities

Water injection will be used to achieve 'voidage replacement' in order to maintain reservoir pressure whereby oil is extracted and replaced with water. Water will be heated and injected into the reservoir by pumps on the FPSO. During the first year of production it will be necessary to heat the injection water using the gas fired steam boiler (Section 5.8.4.2) to prevent wax formation when the water contacts oil in the reservoir. However, after the first year, it will no longer be necessary to heat the water as there will be sufficient hot water in the reservoir to act as a buffer between the cold water and the oil such that there will be no risk of downhole wax formation. The energy costs associated with the steam boiler use are factored into the FPSO fuel use data provided in Section 10.9.

During the first year of production, when mostly 'dry' oil is being produced with little water, the WI system will use treated and heated seawater. After the injected water starts to be produced with the oil, a combination of unheated seawater and treated produced water will be re-injected. The mixture of seawater and produced water will meet the required reservoir specifications (Table 5.20) prior to re-injection into the reservoir.

Table 5.20: Injection water treatment specifications

Parameter	Specification
Temperature	70 °C for all WI wells will be required for the first year of water injection. Hereafter the injection water will not require heating as there will be a sufficient volume of hot water already in the reservoir to provide a buffer between the cold injected water and the oil to prevent wax formation.
Filtration	98 % removal of particles ≥ 10 microns Total Suspended Solids (TSS) < 2.0 mg/l
De-aeration	<10 ppb O_2
Sterilisation	Sodium hypochlorite in seawater = 3 ppm (achieved by continuous dosing)

Parameter	Specification
	Bacteria and micro-organisms < 500 Bac/l
Produced Water	Free oil in water < 10 mg/l

5.8.5.9 Gas Lift Facility

Gas lift will be used to improve oil production rates of individual wells, particularly when the water-cut increases.

For Phase 1 & 2, at peak approximately 50 mmscfd of produced and treated gas from the associated oil production will be injected into the oil production wells to reduce the density of the produced fluids so they can flow more easily to the surface. The gas within the gas lift system will be circulated through the production system such that it will not be released to atmosphere.

5.8.6 FPSO crude storage tanks

The FPSO crude oil storage capacity will be approximately 605,000 bbls arranged in five pairs of cargo tanks of similar size plus one larger tank. These tanks are situated within the inner hull, being surrounded by either water ballast tanks or void spaces.

5.9 Steady state production

5.9.1 Chemical use

Chemicals used during the operations include:

- Operational Chemicals, and
- Non-operational Chemicals e.g., laboratory chemicals.

5.9.1.1 Operational chemicals

Operational Chemicals include:

- Production chemicals e.g., for enhancing and maintaining flow assurance, maximising separation of the multiphase fluids, minimising the risk of hydrate and wax formation, preventing corrosion, treating water for injection, treating gas for use as fuel, use as the actuating fluid in hydraulic control systems, use in closed systems which require periodic refill, and
- Utility chemicals e.g., detergents and turbine wash chemicals.

Under normal operations, chemicals dosed into the produced fluids to aid flow assurance and separation will not be discharged to sea and will either be exported with the oil or re-injected downhole with the produced water. However, in the event of PWRI downtime, or the unsuitability of the produced water for re-injection[20], the water, and those chemicals that partition to the water phase, may be discharged.

Details on the specific operational chemicals which will be used during the Phase 1 & 2 Development are not yet known. Nonetheless, all operational chemicals used during the Phase 1 & 2 Development will be selected to minimise environmental impacts as much as possible. All chemicals selected will be listed on the Offshore Chemical Notification Scheme (OCNS) List of Notified and Ranked Product generated by CEFAS. Moreover, all chemical use will be included in PON applications submitted to FIG for approval prior to use (Section 3.1.7.4).

[20] Produced water can be unsuitable for reinjection if the specification of water exceeds 10 mg/l of oil in water. However, produced water compatibility tests have been performed to demonstrate that it can be reinjected into the reservoir and process equipment has been designed to ensure the water meets the standards to be reinjected.

For the purposes of this EIS, analogue chemicals have been used to enable a representative impact assessment, as detailed in the relevant chapters below. The functional groups of chemicals which may be required during the steady phase production of Sea Lion crude are listed in Table 5.21.

Table 5.21: Production and utility chemicals which may be required during steady state production

Operational facility	Functional chemical groups anticipated for use [1]
Wells	Wax treatment chemicals / Pour point depressants and methanol
SPS / SURF	Wax treatment chemical / Pour point depressants, methanol, demulsifier, water-based hydraulic control fluids
Topside production process	Demulsifier, scale inhibitor, wax treatment chemical / pour point depressants, oil anti-foam, de-oiler, solids flocculant, and methanol
Topside WI process	Scale inhibitor, sodium hypochlorite, biocides[2], water anti-foam, oxygen scavenger, solids flocculant and calcium nitrate
Topside process utilities	Heating water corrosion inhibitor, heating water, biocide, Triethylene glycol (TEG), TEG pH adjustor, diesel biocide, cooling medium, cooling medium corrosion inhibitor and cooling medium biocide.
FPSO utilities	Detergents and turbine washes

[1] Note that the actual chemicals intended for use are not yet known. Where necessary, analogue chemicals have been used during the current impact assessment as detailed in the relevant chapters below.
[2] Note: by nature, biocides are intended to harm marine life, but efforts will be made to ensure selection of a Cefas Gold product with no Substitution warnings (at the time of writing there are >40 such products on the Ranked listings for production and *c.* 15 for drilling operations).

5.9.1.2 Non-operational chemicals

Non-operational chemicals include:

- Domestic chemicals e.g., potable water additives, detergents, cleaning products,
- Fabrication chemicals e.g., paints and other coatings (including those supplied in aerosol cans),
- Laboratory chemicals e.g., for checking OiW concentration, and
- Other chemicals e.g., fuels, consumables, lubricants, fire-fighting foams and other chemicals in firewater systems, chemicals in 'closed systems' where periodic refill is not needed and hydraulic fluids used in cranes and other machinery.

Non-operational chemicals are not covered under the OCNS or the UK offshore Chemical Regulations (2002). They are however covered and assessed under the UK Control of Substances Hazardous to Health (COSHH) Regulations 2002.

The majority of non-operational chemicals will not be discharged to sea. Where they will, or may be, discharged to sea e.g., in bilge / drainage water contaminated with emulsified oil and grease, diesel, hydraulic oil, lube oil, marine fuel oil and grey water etc., these discharges will comply with the requirements of MARPOL 73/78.

5.9.2 Routine monitoring and maintenance

Routine monitoring and maintenance will be carried out on the FPSO and SPS / SURF to ensure the integrity and efficiency of all equipment. Maintenance will be carried out using a Centralised Maintenance Management System (CMMS) to enable the prioritisation and regular inspection / maintenance of safety and environmental critical equipment.

Environmental criticality is a feature built into the CMMS which allows for prioritisation of environmentally important maintenance and this will be used to schedule maintenance necessary to maintain environmental objectives and to monitor and manage any backlogs.

5.9.3 Well workovers

Wells must be monitored and maintained over the course of the Field Life and, in some cases, it can be necessary to mechanically alter the well in response to changing conditions. The latter is referred to as a well workover. The intention however, is to have a minimum intervention policy and as such, there are no workovers planned.

Should a well workover become necessary, it will only be performed if it is economically viable with regard to the mobilisation / demobilisation of a MODU. In the event that a well workover is considered economically viable, discussion will be held with FIG on the most appropriate way to ensure that an EIA is carried out for the operation.

5.9.4 Process shutdown and start-up

Shutdown of the process and utility facilities may be required in order to carry out maintenance activities (planned) or in the event of abnormal operation or an emergency (unplanned).

With a minimum ambient sea temperature of 3°C, when planned or unplanned shutdowns occur, it is possible that the produced fluids within the subsea and topside infrastructure will begin to cool. Given the characteristics of the Sea Lion crude, cooling could lead to the appearance of wax (at < 60°C), hydrate or gel (at < 25°C) which in turn could lead to blockages within subsea wells, jumpers, manifolds, risers / flowlines and topsides facilities.

Shutdown preservation and start-up procedures will be integral to prevent gelling and wax deposition. During shutdowns, the wax and gel management strategies will ensure that the system will be left in a preserved condition with a fall-back strategy in the event that a restart is required with hydrates or gel plugs in the system.

Flow assurance facilities (Section 5.8.4.1) are in place within the Development design to actively prevent or mitigate against blockages during times of 'no flow' and to enable start-up even if the facilities have cooled. Production chemicals may also be used (Section 5.9.1.1).

The flaring facilities are described in Section 5.8.4.4. While flaring is not anticipated during normal routine operations, it will be required during:

- Significant shutdowns,
- Plant malfunctions that require a depressurisation (blowdown) of part or all of the gas inventory,
- Process emergency shutdowns for unavoidable maintenance reasons, and
- Potentially during depressurisation of flowlines and flexible risers when required.

5.10 Oil export process and facilities

The project oil export route involves the direct offtake of crude oil from the FPSO to a Conventional Trading Tanker (CTT) at the Sea Lion location and from there the crude will be exported to market. To ensure that the offloading operations can be controlled within strict safety limits, direct offtake will require an OSV (i.e., a hold back tug) to attend the CTT offshore, in addition to the presence of the ERRV.

Oil offtakes at peak production rates are expected approximately every 7-10 days. As the rate of oil production reduces over time, it is expected that the oil export operation will occur less frequently and/or smaller parcel offtakes will occur over time.

To ensure safe and efficient offshore loading operations, each CTT shall undergo an in-depth Navitas assurance process, prior to being approved for use on Sea Lion. The Navitas assurance process in respect of the direct offtake operation is described below. Following agreement on the purchase of

the Sea Lion crude 'parcel', the purchaser will nominate a CTT to Navitas. At this time, Navitas will carry out a series of checks and audits to vet the nominated CTT, including verification of:

- Compliance with the requirements of MARPOL 73/78 Annex I on discharges of oil to sea:
  - Oil record book.
- Compliance with the requirements of MARPOL 73/78 Annex IV on discharges of sewage to sea:
  - International Sewage Pollution Prevention Certificate (ISPPC).
- Compliance with the requirements of MARPOL 73/78 Annex V on garbage management at sea,
- Compliance with the requirements of MARPOL 73/83 Annex VI on air pollution by shipping:
  - Air quality and pollution:
    - International Air Pollution Prevention (IAPP) Certificate.
  - NOx emissions reduction:
    - Engine International Air Pollution Prevention (EIAPP) Certificate.
  - SOx emissions and particulate matter reduction:
    - Marine Fuel Sulphur Record Book and compliance with the global sulphur fuel limit of 0.5 %, as required since January 2020.
  - VOC emissions:
    - VOC Management Plan.
  - GHG emissions reduction and energy efficiency:
    - Ship Energy Efficiency Management Plan (SEEMP) as required since 2013, and
    - The CTT's position within the Energy Efficiency Design Index (EEDI) (new vessels only).
- The validity of the Shipboard Oil Pollution Emergency Plan (SOPEP) in line with the International Maritime Organisation (IMO) regulations:
  - Oil spill risks and mitigations, including those relating to whether or not the fuel tanks are double-skinned, will be taken into account in the decision-making process and in determining whether specific operational controls should be put in place to manage risks.
- Compliance with the IMO International Convention for the Control and Management of Ships' Ballast Water and Sediments (ratified in 2017):
  - Verification of compliance with IMO Convention standards D1 and D2 (noting that D2 treatment systems need not be installed until the first vessel survey / docking following enforcement),
  - Inspection of the CTT Ballast Water Management (BWM) Plan and Ballast Water Record Book, and
  - Inspection of the BWM System International certificate (if applicable).
- Inspection of the CTT Biofouling Management Plan and Biofouling Record Book as required by IMO.

Additional requirements that may be necessary for vessel insurance (to be advised), are as follows:

- Oil / Bulk Ore (OBO) vessels will not be accepted,
- All CTTs must be double-hull construction, including the vessel's fuel oil tanks,

- Maximum Length Over All (LOA) of the CTT will be specified (to be advised),
- The CTT must be equipped with eight wire mooring lines on fixed drums forward and aft, complete with rope tails, capable of mooring four head, two breast and two springs both forward and aft,
- The CTT will have aft towing bitts with a minimum 80 tonne SWL (Safe Working Load). These mooring bitts will be used for securing the tug towing wires,
- The CTT will have an amidships crane with minimum SWL of 15 T with a 4.5 m outreach,
- CTT manifolds will be fully compliant with OCIMF recommendations,
- The CTT's main engine will be capable of running astern continuously for an extended period,
- The CTT must be fitted with helicopter landing / winching area,
- The CTT must be capable of slop reception in an emergency pollution incident,
- The CTT must be capable of purging H_2S in cargo tanks, and
- Ballast water exchange will be carried out in open ocean when *en route* to the Falkland Islands, in full compliance with MARPOL. Navitas will prepare Sea Terminal Operations Procedures which will ensure that during the selection process of suitable CTT's, MARPOL Ballast Water Management Convention requirements will be followed and that ballast water is treated by a 'D2' water treatment system before being discharged.

The following sequence will then take place within the FPSO 1,275 m radius exclusion zone:

- The purchaser's CTT will arrive in Falkland Islands waters and will tender its Notice of Readiness,
- When the offload operation is imminent, the berthing crew will be transferred to the CTT either by helicopter transfer, or vessel to vessel transfer (weather dependent) (solution shall be dependent on risk assessment which shall be completed with the FPSO contractor in advance of any operations.),
- The CTT will proceed to rendezvous with the OSV, i.e., a tug with sufficient bollard pull to safely support the manoeuvering of the CTT and an over-the-bow winch so it can stay bow on to the CTT,
- The OSV will connect to the stern of the CTT and remain connected while applying light power to control:
  - Heading through approach,
  - Connection to the FPSO, and
  - Pumping, disconnect and departure.
- There will also be the MRSV (acting as ERRV) on standby duty in the field and equipped with oil spill response equipment,
- The CTT and OSV will approach the stern of the FPSO, and will manoeuvre into position, followed by connection of the hawser. A tight hawser connection will be made,
- Once the hawser is connected, the transfer hose will be unreeled from the FPSO and passed to the tanker using its winches. The hose will connect to the manifolds amidships, on one side of the CTT. No additional vessel is required for this process,
- Once connection has been completed, the oil transfer will commence slowly until proven, and then increased to full rate,
- Once completed:
  - The CTT will disconnect and move away from the FPSO.

  - The OSV will detach from the CTT once at a safe distance from the FPSO, and
  - The Berthing crew will disembark *via* helicopter transfer or support vessel (solution shall be dependent on risk assessment which shall be completed with the FPSO contractor in advance of any operations).
- The CTT will then proceed to deliver the crude to market.

5.11 Logistics and infrastructure

The infrastructure required to support the logistics operation for the Sea Lion Phase 1 & 2 project includes:

- Port facilities and onshore supply base, including the:
  - Temporary Dock Facility (TDF),
  - Onshore laydown yards,
  - Storage areas (including warehousing) and offices, and
  - Liquid mud and cement plant facility.
- Use of OSVs for the movement of materials and equipment, installation and support,
- Use of *ad hoc* freighters to support the drilling and completions international equipment requirement as well as use of freighters for the delivery of the subsea construction equipment,
- Personnel transportation facilities:
  - International fixed-wing flights,
  - Helicopters flights to and from the Sea Lion field, and
  - Land transportation.
- Use of other finite resources in the Stanley area, including:
  - Accommodation (short and long term), and
  - General utilities such as freshwater, electricity, roads and waste management / disposal facilities.

5.11.1 Port facilities and onshore supply base(s)

Although the plan for the Phase 1 & 2 Development is to make use of the existing port and onshore yards where possible, it is anticipated that there may be a need to develop further facilities. Discussion on the EIA requirements for the *construction* of any new facilities will be held with FIG prior to the submission of the relevant planning applications / requests for extension of existing planning permission. However, the *use* of the proposed facilities required to support the Phase 1 & 2 Development is covered in this EIS and therefore, it is necessary to describe what may be required.

5.11.1.1 Port facilities

Marine logistics will be centred around the Temporary Dock Facility (TDF) and the adjacent industrial land areas onshore. These facilities will be used for a variety of operations including, but not limited to:

- The loading, offloading and transfer of goods,
- Vessel crew change,
- Refuelling, and
- Re-supply of bulk products, chemicals and consumables *via* both hard pipe and dedicated tanker trucks.

The TDF and its environs will be the primary area of operation; however, Navitas may, on occasion also utilise the capability provided by either Falklands Interim Port And Storage System (FIPASS), owned by FIG; and / or Mare Harbour which is operated by the Ministry of Defence (MoD).

Both options are very much considered a back-up contingency to Navitas' owned and primary TDF.

5.11.1.1.1 The Temporary Dock Facility (TDF)

The TDF in east Stanley is a floating barge facility with pontoon causeway installed by POEPL and Noble Energy Falklands Limited (NEFL) in 2014-15 for the combined exploration drilling campaign (Figure 5-10). The TDF is the principal port facility that will be used to support the Sea Lion Phase 1 & 2 Development.

All vessels, with the exception of the FPSO, the CTTs, the Offshore Construction Vessels (OCV's) and the LTVs (Section 5.11.2), are expected to use the TDF during Sea Lion Phase 1 & 2 Development and production lifecycle.

An upgrade of the TDF causeway is planned to take place from Q3 2025 – Q3 2026. The final design of the proposed causeway is a 'rock berm structure'. The work programme will be evaluated and appropriate planning approval sought during mid-2025. The upgrade is proposed to include:

- Improvement to the causeway, (two-way traffic, lighting, pedestrian walkways),
- Increased draught for the berthing pocket and entry channel, and
- Installation of bulk fluid and cement lines, fuel and water lines.

Any additional works may require a full EIA to support the planning application, and this would be dependent upon the scale of the upgrade and any potential environmental impacts arising. In the event that any additional upgrade is required, discussions will be held with FIG to determine whether an EIA is necessary.

Figure 5-10: Photograph of the existing Temporary Dock Facility with a PSV alongside

5.11.1.1.2 FIPASS

FIPASS is located 500m to the west of the TDF. Due to the current weakness of the deck plates, FIPASS is not able to support the loading or unloading of heavy items of cargo or equipment, however, it may be used to load fuel and water onto Sea Lion's offshore vessels, and for importing initial onshore construction materials / offshore OCTG (Oil Country Tubular Goods), in the event that this cannot be done at the TDF. FIPASS is also the Falkland Islands primary port facility and therefore Navitas is mindful not to over-use the facility, potentially disrupting other industry and trade requirements, unless absolutely necessary.

5.11.1.1.3 Mare Harbour

Outside of Stanley, the only alternative port facility which currently has the capability of handling and unloading large items of equipment is the military port at Mare Harbour. Mare Harbour has a deep water draught (nine metres), a concrete quayside and a Roll On-Roll Off (RO-RO) ramp.

The use of Mare Harbour does not form part of the Sea Lion development "base-case" but may be considered during the life of the project in consultation with MoD and FIG. If Mare Harbour is to be used in future, this may be subject to planning permission and an associated EIA. However, it is expected that the environmental impacts and risks from Sea Lion activity at the Mare Harbour location would be similar to those presented in Stanley and that the impacts to the local population in Stanley would be reduced.

5.11.1.2 Onshore supply bases

The onshore supply base used during POEPL's 2015 exploration campaign was located in the Gordon Lines area to the east of Stanley and extended to approximately 51,000 m² (Table 5.22). It included:

- Pipe and container laydown areas as well as bulk goods warehousing,
- Spare parts and maintenance areas,
- Storage of containerised Tier 2 Oil Spill Response (OSR) equipment,
- Storage of drilling chemicals, fluids and dangerous goods,
- Facility vehicles such as forklift trucks, cranes, minibuses, 4x4 and heavy equipment transporters,
- Power generation in the form of diesel generators with dedicated fuel storage to enable self-sufficiency, and
- A waste storage and management area

The onshore supply base(s) have not yet been selected for the Phase 1 & 2 development; however they are expected to be located in a similar geographical area and similar in composition to the previous exploration and appraisal campaigns but larger in scale due to the increased volume of equipment required for the Phase 1 & 2 Development campaigns and future production needs. During tendering, tenderers will be asked to provide detail of their proposed incorporation of sustainable design features in their tender submissions. Environmental considerations and sustainable design will form part of the contract evaluation criteria. Detail on the additional supply base facilities required for the Phase 1 & 2 Development is provided in Table 5.22.

Table 5.22: Potential supply base requirements for the Sea Lion Field Northern Area Phase 1 & 2 Development

Facility	Exploration yard space (m^2)	Estimated area Required for Phase 1 & 2 (m^2)	Duration of requirement
Supply Base: Onshore representatives' office, Pipe and container laydown (covered & open), Service Companies' yard, Waste storage and management yard, Oil spill response equipment storage, Onshore storage and testing area for equipment, Waste storage and management area, and Radioactive sources (which will need to be sited appropriately).	51,000	120,000[1]	*c.* 9 years[2]
Quayside NADF mud and bulks facility: Liquid Mud Plant (LMP), Dry bulk plant, Water header tank, and TDF car parking.	-	7,500[1]	*c.* 9 years[2]
FPSO Operations support base: Re-supply base, Production chemical laydown yard: A facility to store 24,000 litre production chemical ISO (International Standards Organisation) tanks from the time when they arrive on the islands to the time they are transported offshore to the FPSO, and A separate isolated laydown area to store up to 400 m^3 methanol which will require its own bespoke fire detection and protection system. Materials, equipment, maintenance & spare parts storage base, Oil spill response equipment storage, NORM contaminated materials, Diesel generators, Explosives which require a bespoke and secure storage facility[3], and Contingency Waste incinerator (Section 5.11.1.2.2) (if required)	-	20,000[4]	FPSO 25 years
Total area required	**51,000**	**147,500**	**-**

[1] These areas are required during Stages 1, 2a & 2b (*c.* 5 years).

[2] The drilling supply base and the LMP will only be in active use for approximately five years during the Phase 1 and Phase 2 Development drilling campaigns. However, due to the scheduling of the programme, it will be in place a short time prior to the commencement of Phase 1, during the break between Phase 1 and Phase 2 and throughout Phase 2. If no further drilling activity is planned, after Phase 2 it shall be dismantled. Therefore, the LMP will be *in situ* for up to nine years but only active for five.

[3] Explosives may be required in the event of stuck-pipe, to release a pipe should it get stuck down-hole. Explosives and dangerous goods will be stored in the specialised bunker containers that they are shipped in from their point of origin in compliance with industry best practice and FIG legislative and policy requirements. If they are not shipped offshore immediately, security measures within the dedicated supply base shall be in place. These will be as follows:

- Use of a dedicated fenced off location which will be secured and surveyed 24/7,
- Limited access / egress with only named / nominated personnel able to access the area,
- Training of the named / nominated personnel,
- Use of signage which will be clearly displayed to advise personnel of the security in place and the risks from the goods stored, and
- Storage of the detonators separate from ignition sources.

[4] This area will be required for Stage 3 (*c.* 27 years) and will likely be part of the area already used during Stages 1-2, rather than additional area.

5.11.1.2.1 Diesel generators

The base-case assumption is that electricity at the supply base(s) will be provided by Stanley power station. However, in order to ensure reliable operations in the event that the municipal power supply is not available, Navitas intends to install up a back-up diesel generator for the liquid mud and cement facility. The generator will only be used in the event of interruptions to the Stanley power supply at critical times or in the event that the planned construction of the new municipal power station or upgrades to the distribution network in East Stanley are delayed. Consequently it is not possible to estimate potential running hours although these are expected to be very low. However, if deployed, the use of fuel for the back-up generator would be offset against the reduced fuel use at the power station such that no additional emissions would result. This assumes that power generation efficiency is roughly equivalent.

At the time of writing, the generator model has not yet been selected but this will be provided through the mud plant service company, and would be selected in line with the contract management process (Section 3.2.15) which would include a pre-selection review of environmental performance.

5.11.1.2.2 Waste incinerator

The Falkland Islands Government is planning to build a new waste management facility to service the needs of the community and industry. The proposed facility is expected to be ready for operation well in advance of the commencement of the Sea Lion development campaign and has the capacity to take the majority of Sea Lion project waste. Navitas plans to enter into an agreement with FIG to secure this as the primary route for project waste which cannot be recycled / repurposed.

The project had previously planned to install a portable incinerator at the onshore supply base as a means of:

- Reducing the volume of waste that requires disposal, thus mitigating against landfill impacts, and
- Reducing the number of shipments of waste back the UK or other overseas jurisdiction.

This option would now only be reinstated should an unlikely change to FIG's waste infrastructure upgrade plans occur resulting in the new facilities not being available to the project. The exact model of portable incinerator that could be used has not yet been decided and will be subject to Navitas' tender process. However, if utilised, the model shall comply to all UK standards enabling incineration of all combustible materials, including plastics and rubbers.

The resultant ash from the incineration process would be returned to another country under the auspices of the UN Environment Programme's Basel Convention for disposal if a suitable disposal route cannot be established on the Falkland Islands itself.

The final location of the incinerator would be developed in discussion with FIG and with stakeholder input through the planning process.

5.11.1.2.3 Oil spill response equipment

In the unlikely event of an uncontrolled spill, the local storage of oil spill response (OSR) equipment is necessary to efficiently mitigate the consequences of spill incidents occurring either offshore (crude or MGO) or at-shore (MGO). While offshore OSR equipment will be stored on various vessels (Section 5.11.2), equipment will also be stored onshore at:

- The TDF for Tier 1 MGO spills, and
- The operations support base for Tier 2 MGO and / or Sea Lion crude spills.

5.11.1.2.3.1 Tier 1 OSR equipment at the TDF for MGO release

The OSR equipment at the TDF will be used to minimise the consequences of any MGO fuel spills at the TDF. The proposed OSR equipment at the TDF is as follows:

- Absorbent boom in bales,
- High fence boom,
- Weir / delta head / dragonfly skimmer,
- Portable transfer pump,
- Intermediate Bulk Containers (IBC) for use as storage tanks,
- Coils of rope,
- Metal anchor stakes, and
- Personal Protection Equipment (PPE) for up to 20 persons.

The main response would be to use the absorbent materials to contain and collect any spilled MGO. Some provision will be made to 'wring out' and temporarily store the recovered sorbents after use prior to incineration. Conventional oily waste skips will be used for this purpose.

The fence boom would be used to protect the dock area and the entrance to the Canache or can be deployed in the harbour to 'corral' any spills. In addition, a simple weir / delta head skimmer and pump system will be used to recover / transfer spilled MGO products. The recovered oil will be stored in the IBCs prior to final disposal.

5.11.1.2.3.2 Tier 2 OSR equipment available for MGO / Sea Lion crude release

Proposed equipment is listed in Table 5.23. The supply base will be equipped with a workshop to undertake a planned maintenance programme and will carry critical spares for both the shore-based and the vessel-based OSR kit to ensure the key equipment will be reliable and effective should it be required.

Table 5.23: Indicative Tier 2 oil spill equipment / action set out according to the Development Stages

OSR Resource	No. of Items	Description	Stage		
			1	2a & b	3
Surveillance equipment					
Helicopter Surveillance	2	Crew change helicopters will be utilised to conduct aerial surveillance. Personnel will be trained in aerial surveillance.	✓	✓	✓
Tracking Buoy	1	A tracking buoy will be stored in the warehouse and transported to the field if required. The tracking buoy will accurately track a surface oil spill dependent on prevailing Metocean conditions.	✓	✓	✓
Modelling capability	N/A	The ability to model the fate and effects of a spill event is incremental to prioritising response efforts and predicting the potential impact of the incident. Navitas shall have access to such modelling capability with an internationally recognised third party.	✓	✓	✓
Long wave Infrared Surveillance Equipment	1	Test results from CEDRE experiments suggest that infrared remote sensing tools will enhance the company's capability to detect the location and movement of Sea Lion Crude Oil on the water's surface. Navitas shall have access to such equipment.	✓	✓	✓
Satellite	1	Navitas shall have access to satellite surveillance.	✓	✓	✓
Vessels and equipment					
2 x Anchor Handling Tug Supply vessels (AHTS) *for Stages 1 & 2 and shall be replaced with and OSR equipment transferred by:* 2 x Multi-Role Support Vessels (MRSV)	1 per vessel	**300m (1,500 mm overall height) of heavy-duty oil containment boom**, constructed of robust material for example moulded rubber, neoprene or similar material, and formed of individual floatation chambers to provide additional resilience. (The size of 1,500 mm was chosen due to the ease of handling and to ensure the FRCs can tow the boom using the guiding principles in the IMO, Section IV, Combating Oil Spills 2nd edition, 2005. Can operate in conditions up to Beaufort scale force 4).	✓	✓	✓
	1 per vessel	**Single vessel recovery system bellowed with boom vane (1,500mm overall height)**, constructed of robust material for example moulded rubber, neoprene or similar material. Can be deployed from one vessel utilising a boom vane. To enhance the recovery capability of the available vessels and provide resilience and alternative response options based of the response priorities.	✓	✓	✓

OSR Resource	No. of Items	Description	Stage		
			1	2a & b	3
	1 per vessel	**Large belt skimming system** Selected due to the ability to recover the highly viscous crude oil. Belt systems when operated correctly are proven to reduce water intake. The skimmer will have the ability provide steam and water injection to aid pumping. The skimming system will be accompanied with a heavy-duty multipurpose Archimedes screw pump with a minimum proven transfer rate of 30m^3 per hour for highly viscous oils and with water injection to aid oil transfer. Both the skimmer and pump will be powered by a compatible, diesel driven, intrinsically safe, hydraulic power pack. Can operate in conditions up to Beaufort scale force 4.	✓	✓	✓
	1 per vessel	**Large diameter free floating weir skimmer** Selected to respond to MGO spills in the field. The weir skimming device is to be self-levelling with the ability to recover oil from the surface of the water. The pump attached to system will be an Archimedes screw pump with a minimum proven transfer rate of 30m^3 per hour with water injection to aid pumping. This allows the pumps to be interchangeable between skimmers to increase the resilience of equipment during a response. Both the skimmer and pump will be powered by a compatible, diesel driven, intrinsically safe, hydraulic power pack which can also power mechanical belt skimmers. Can operate in conditions up to Beaufort scale force 4.	✓	✓	✓
	2 per vessel	**100 tonne capacity free floating waste storage bladders** The floating bladder is towable, and collapsible being stored in a small container on the deck of the vessel and when deployed can be towed at a maximum speed of five knots. The bladder is equipped with an integrated pump to assist in the transfer of recovered product.	✓	✓	✓
1 x Emergency Response and Rescue Vessel (ERRV)	n/a	Would act as a boom towing vessel, command control centre and / or runner to and from the operations area to the Stanley facility.	✓	✓	✓
1 x Platform Supply Vessel (PSV)	n/a	Would act as a boom towing vessel, command control centre and / or runner to and from the operations area to the Stanley facility.	✓	✓	

OSR Resource	No. of Items	Description	Stage		
			1	2a & b	3
Vessels of opportunity	n/a	Dependent on the tiered size of the spill, Navitas would charter vessels to respond to a spill in accordance with the emergency response procedure and the incident's requirements.	✓	✓	✓
MODU	n/a	If available and suitable, can: Provide a remotely operated underwater vehicle (ROV), Act as an incident command centre, Provide a helipad and Heli-refuelling station, and Provide a welfare area.	✓	✓	
FPSO	n/a	If available and suitable, can: Act as an incident command centre, Provide a helipad and Heli-refuelling station, and Provide a welfare area.		✓	✓
TDF and Supply Base (Stanley Area)					
TDF Response Equipment	1	Standard quayside Shipboard Oil Pollution Emergency Equipment (as per the IMO Shipboard Marine Pollution Emergency Plan SMPEP) and, in addition, oil spill response fish totes, chemical response totes, two trailers and hand tools	✓	✓	✓
Supply Base / Warehouse / pre-prepared offshore containers	n/a	Tier 2 Shoreline Response Kit: Inshore solid floatation boom, Shore sealing boom, 200m air inflatable boom, Oleophilic skimmer and small weir skimmer (MGO only), Flexible and rigid IBCs, Floating bladders, Waste storage tank, Hazardous waste sacks, A pressure washing system, Oil snares, oil snares on rope, Steam generator, Range of hand tools for shoreline recovery (rakes, shovels, spades) Sufficient PPE for 5 days of offshore and shoreline response, signage to prevent unauthorised access	✓	✓	✓

OSR Resource	No. of Items	Description	Stage		
			1	2a & b	3
		Tier 2 Offshore Response Kit (back up to equipment already on board the vessels): Heavy duty oil containment boom Single vessel recovery system bellowed with boom vane Large belt skimmer Large diameter free floating weir skimmer (MGO only) Floating storage bladder	✓	✓	✓
Oiled Wildlife Response Facility	1	Access to a sufficient warehouse ready to stabilise, clean and recondition up to 200 birds with: Unlimited quantities of soft, warm water (39 – 41°C) of good pressure (60 – 80 psi) Good ventilation to prevent excessive oil fumes and humidity, and to help prevent diseases Temperature control to maintain a draught free, warm environment (24–29 °C) Electrical capability, min. 200 amps, 120/240 volts Adjacent outdoor area for pools, physical reconditioning and response expansion Means to dispose solid and liquid contaminated waste	✓	✓	✓

5.11.2 Use of vessels

Vessels are required throughout the Phase 1 & 2 Development and production project to serve the following purposes:

- To tow and position the MODU and its associated anchors,
- To provide general operational supply and support as well as provide emergency response (if required),
- To support the internal supply chain providing a linkage between the project to its global contractors and key international hubs,
- To transport and install the subsea drilling, SPS and SURF infrastructure,
- To provide floating logistics / lay-down barges in Berkeley Sound for storage of equipment awaiting installation subsea,
- To support and assist the FPSO Hook Up Connection (HUC) process, and
- To support the direct offtake oil offloading and export operations.

A detailed summary of all the vessels that may be used is provided in Table 5.24, which aims to:

- List the worst-case number of vessels anticipated for use in each stage of the Development and production life cycle,
- Describe the purpose of the vessels, and
- Provide a credible worst-case estimate of vessel use with regards to:
  - The origin of the vessel,
  - The time in transit (i.e., to and from the Falkland Islands), and
  - The time in-field (i.e., on location in the Sea Lion Field or in Berkeley Sound).

Note: where the vessel is frequently in transit between the Sea Lion Field and the Islands themselves, the time is averaged out.

At the time of writing, there is a degree of uncertainty over the number and type of vessels that will be used and whether or not synergies will be possible to minimise vessel use. It is known that synergies will exist between the standard Platform Supply Vessels (PSVs) / Anchor Handling Tug Supply (AHTS) vessels and other offshore support vessels. However, it may also be possible for the supply vessels (the PSVs), to be used for the installation of moorings instead of using dedicated AHTSs.

The specifics on the vessel type and use, and any synergies, will not be known until charter parties are awarded following project sanction. Therefore, the data in Table 5.24 assumes the maximum number of vessels to provide the worst-case for all impact and risk assessments relating to the use of vessels e.g., emissions, underwater noise, disturbance to other users of the sea, introduction of non-native species and collision risks etc. Specific detail on the behaviour of the vessels as it pertains directly to the impact and risk assessments are provided, as necessary, in the specific EIA chapters below (Chapters 10, 11 and 12).

Table 5.24: Summary of the worst-case vessel activity anticipated during the Phase 1 & 2 Development[1]

Vessel		Vessel purpose	Expected shipping from	Number of vessels[2]	Duration of use (days)[3]
Stage 1: Pre-First-Oil (approx. 31 months, 942 days)					
Project Support	*Ad hoc* Freighters	Delivery of drilling, development and production equipment and general re-supply.	Europe / USA	5	35
Drilling	Anchor Handling Tug Supply (AHTS) vessel	Towing and positioning of MODU at the Sea Lion Location(s)[4].	Europe	2	15
		Support of MODU throughout pre-First-Oil development drilling.	n/a		684
	Emergency Rescue and Response Vessel (ERRV)	Stand-by support of MODU and other Sea Lion field vessels.	Europe	1	638
	Mobile Offshore Drilling Unit (MODU)	Drilling of development /production wells.	Europe	1	638

	CTT	Purchaser's vessel used for receipt of Sea Lion crude and export to market.	Unknown	n/a	n/a

[1] Note that these data are subject to change following contract award and are estimated here for the purposes of enabling the EIA. It is anticipated that the above vessel list describes the worst-case to ensure that the EIS remains representative.

[2] This refers to the number of vessels or the number of uses of the same vessel e.g., in Stage 1, *ad hoc* freighters will be used 5 times although it may be a different actual vessel.

[3] Note that for the purposes of emissions calculations (Section 10.9) the duration of use for vessels also includes mobilisation and demobilisation (mob / demob) days to ensure the worst-case emissions are estimated. The durations provided above do not include the mob / demob days as these do not affect the majority of the impact assessments related to vessel use.

[4] To minimise the need for vessels, it is anticipated that the MODU supply vessels may also be used as AHTs to position the MODU. This assumption ensures that the worst-case is assessed.

[5] Impacts associated with the CTT outside of the 500m zone are out with the scope of this EIS as the vessel will be owned and operated by the purchaser of the crude.

5.11.3 Personnel transportation and search and rescue (SAR) operations

5.11.3.1 Transportation of personnel

At the time of writing, there is a degree of uncertainty over the exact frequency with which each personnel transportation method will be used. Details will be confirmed upon contract award. However, while subject to change, the below describes the transportation methods and the worst-case frequency of use that is anticipated. A summary of all the personnel transportation requirements and helicopter usage is provided in Table 5.25 below.

Note: the data in Table 5.25 are used as the basis for all impact assessments relating to the use of helicopter and fixed-wing flights e.g., emissions, onshore noise and disturbance and resource use etc. These data will be summarised, as appropriate, within each relevant impact / risk assessment chapter (Chapters 10, 11 and 12).

5.11.3.1.1 Transportation to the Falkland Islands

During Stages 1 and 2 of the Development, which will involve the highest levels of activity, personnel will be transported to the Falkland Islands *via* dedicated charter flights. All fixed-wing flights will land and depart from Mount Pleasant International Airport (MPN), which is the only airfield in the Falkland Islands which is able to receive international / long-range, wide-bodied aircraft. Charter flights will operate once per fortnight for the 3 months prior to drilling and weekly during the drilling campaign. The start / end point of the charter flight has not yet been finalised but is expected to be one of: Santiago, Chile; Sao Paulo, Brazil; or London, U.K. Should the flight be from London, a re-fuelling stop in the mid-Atlantic i.e., Cape Verde, will be required. For the purposes of this document, the 'worst-case scenario' will be considered which is a chartered flight from London – Cape Verde – Mount Pleasant.

During steady state production of the Sea Lion field, once the drilling unit and construction vessels have departed the operation, reliance on charter flights may diminish in favour of weekly commercial flights. However, the varying options will be further informed by the Navitas project design process and the FIG / public consultation processes. Details on the fixed-wing transportation requirements during each Stage of the Development are provided in Table 5.25. For the basis of this document and "worst-case scenario" planning, Navitas shall base the environmental impact on retaining the proposed fortnightly charter flight from the UK to the Falklands for the duration of all three stages: Stage 1 (pre-First-Oil), Stage 2a & b (SIMOPs) and Stage 3 (steady state production.)

5.11.3.1.2 Transportation to the Sea Lion Field

Two helicopters will be used throughout the Development project. The helicopters will be used to transport personnel offshore for routine maintenance and crew change / CTT pilot transfers. Based on the 2015 exploration drilling campaign, each crew change to the MODU / FPSO is estimated to require up to five helicopter round trips (i.e., Stanley – MODU – Stanley). Details on estimated helicopter flights are provided in Table 5.25.

5.11.3.1.3 Transportation between Mount Pleasant Complex (MPC) and Stanley Airport

The project's helicopters will be based at Stanley Airport for both operations and engineering maintenance. On crew change-out days, it is anticipated that personnel will be transported by road between the MPC and Stanley Airport, where they will be briefed prior to boarding the helicopters to fly offshore. However, there is the potential that arriving crew may be picked up directly from MPC by helicopter although this will be subject to approval from FIG/MoD.

5.11.3.1.4 Transportation to the CTT

As described in Section 5.10, oil shall be exported *via* direct offtake which may require the use of helicopters to transfer berthing personnel to the CTT. In this scenario, the berthing crew will be boarded on to the CTT at a safe distance from the FPSO.

Details on estimated helicopter flights are provided in Table 5.25.

5.11.3.2 Search and Rescue (SAR) exercises

The Phase 1 & 2 Development will require SAR helicopter cover. Confirmation is still required with regard to the provision of SAR helicopter(s) and the number of SAR training flights that will be required. However, for the purposes of this EIS it is estimated that 20 hours of SAR training flights will be carried out per month as occurred during the 2015 exploration campaign (Table 5.25).

Table 5.25: Sea Lion Development transportation of personnel and SARs

Activity		Frequency	Stage Duration	Number of trips	Duration per trip (hrs)	Total (hrs)
Stage 1: Pre-First-Oil (approximately 31 months (942 days[1]))						
Charter flights	Delivery of personnel from UK to MPC	Fortnightly	31 months	67	36	2,412
Helicopter transfers of personnel to FPSO, MODU, OCVs and LTVs	MODU & OCVs Crew change	Ten flights per fortnight		670	3	2,010
	LTV crew change	By boat		n/a	n/a	n/a
SAR	SAR exercises and test flights	20 hours per month		-	3	620
Road transport[2]	MPC to Stanley airport (return)	11 buses / vans /Fortnight		737	2	1,474
Stages 2a & 2b: SIMOPs - Concurrent drilling, production and export (approximately 7 months (213[1] days) in Stage 2a and 28 months (851[1] days) in Stage 2b (*c.* total 1,064 days[1]))						
Charter flights	Delivery of personnel from UK to MPC	Fortnightly	35 months	75	36	2,700
Helicopter transfers of personnel to FPSO, MODU and OCVs	FPSO, MODU and OCVs crew change	Ten flights per fortnight		750	3	2,250
LTVs	LTV crew change	By boat		n/a	n/a	n/a
Helicopter transfers to FPSO / CTT	Transfer of Berthing crew to FPSO / CTT in the Sea Lion Field	Per direct offtake (average every 10 days over duration)		106	3	318
SAR	SAR exercises and test flights	20 hours per month		-	3	700
Road transport[2]	MPC to Stanley airport (return)	11 buses/vans /Fortnight		825	2	1,650

Activity		Frequency	Stage Duration	Number of trips	Duration per trip (hrs)	Total (hrs)
Stage 3: Steady state production and export (27 years)						
Charter flights	Delivery of personnel from UK to MPC	Fortnightly	27 years	699	36	25,164
Helicopter transfers to FPSO and CTT	FPSO crew changes	2 flights per week		2,795	3	8,385
	Transfer of Berthing crew to FPSO / CTT in the Sea Lion Field	Per direct offtake (average of 36 pa over Field Life)		972	3	2,916
SAR	SAR exercises and test flights	20 hours per month		-	3	6,500
Road transport[2]	MPC to Stanley airport (return)	6 buses/vans / Fortnightly		4,194	2	8,388

[1] Based on an average of 30.4 days per month, and an average of 4.3 weeks per month.

[2] Crews will be transported to MPC either by coach or minibus. Minibuses are assumed here to give a worst-case environmental impact. Stages 1 & 2(a&b) will require approximately eight minibuses and three luggage vans; Stage 3 will require approximately four minibuses and two luggage vans.

5.11.4 Use of finite resources

Local resources that may be required specifically to support the Phase 1 & 2 Development include:

- Existing accommodation,
- Existing supply bases and warehousing in the East Stanley area,
- Plants, trucks, cars, mini-buses and coaches,
- Stanley Airport and the Mount Pleasant Complex,
- Fuel (land, sea and air),
- Local personnel and personnel services and offices,
- Freshwater for potable use, tophole drilling and cementing in the event that the MODU / FPSO desalination plants malfunction,
- Electrical power supply for the onshore supply base,
- Use of existing road network, and
- Waste management facilities (if available).

Detail on the existing resources on the Islands is provided in the Environmental and Social Baseline (Chapter 7). The following estimates of resource use are based on data extrapolated from the POEPL 2015 exploration drilling campaign and the associated End of Well Reports (EOWR) (rationalised where possible given that resource use during steady state production is likely to be less than during drilling and simultaneous operations).

The following estimates of resource requirements are considered to be worst-case.

5.11.4.1 Accommodation requirements

The development drilling (Stage 1) and the simultaneous operations (Stages 2a & 2b) will require the highest total number of onshore and offshore personnel. When steady state production commences and the MODU and construction vessels depart the field the accommodation requirements will decrease.

Accommodation will be required in Stanley for personnel who are:

- employed at the supply base,
- employed on a rotational basis in Navitas' Stanley office,
- Crew and maintenance personnel supporting the helicopters,
- Crew and maintenance personnel supporting the fixed wing charter flight,
- in transit and resting-up overnight prior to flying offshore / returning from offshore,
- being temporarily housed onshore in anticipation of being called offshore, and
- If required, needing shelter following emergency down-manning of any of the offshore assets.

The profile of the accommodation requirements over the life of field is as shown below in Table 5.26.

5.11.4.1.1 Accommodation provided by Navitas

Recognising the current pressure on housing stock and hotel accommodation (Section 7.7.4.5.1), Navitas is committed to increase local housing supply to meet Sea Lion needs and will enter into a contract or contracts for the construction of *c.* 20 management housing units. Navitas is committed to commission provision of hostel type / 'hotel' accommodation that will meet transit requirements and fulfil contingency needs (Table 5.26). Capacity will be fixed to meet the forecast personnel accommodation need within the current design. In terms of management housing requirements, only a small number of personnel (*c.* 26) (Table 5.26) will be required to permanently live in Stanley and these needs will be met by a contracting strategy that will promote and encourage housing built by the private sector. An expression of interest exercise undertaken in Q1 2024 has already determined that there is interest and capability in the Falklands private sector in responding to this demand and engaging in the competitive tender process.

Specifically, Navitas shall commit to providing:

- Hostel-type accommodation,
- Temporary accommodation unit,
- In-transit accommodation unit, and
- Management housing units.

Further detail in provided in Section 11.3.

5.11.4.1.2 Accommodation type

Plans for the hostel-type / hotel accommodation (for transitory / offshore personnel) are not currently finalised and will be determined through the contracting process with tenderers and assessed against a Statement of Requirements as to whether they are fit for purpose by Navitas. It is expected that innovative solutions will be driven by the private sector.

The hostel-type / hotel accommodation will be:

- Based on single room occupancy with double bed in normal conditions but will be equipped with second fold-down bed (or similar) to double accommodation capacity in the unlikely event of an emergency shut-down of one of the offshore assets or a long delay to the fixed wing charter,
- Emergency accommodation with double occupancy suitable for short durations as in extended down-manning it would be likely that crew would be flown out of the Islands and repatriated on a specially chartered flight,
- Available for the whole Field Life of the Sea Lion Development, and
- Within easy access of the By-pass / Airport Road, TDF and supply bases.

This accommodation will be suitable for in-transit accommodation of personnel on crew change days and to accommodate all offshore crews in the event of a down-manning of the offshore assets throughout all stages of the project. During the tendering process, tenderers will be asked to provide detail of their proposed incorporation of sustainable design features in their tender submissions. Environmental considerations and sustainable design will form part of the contract evaluation criteria.

Design and location(s) of the management housing units are not currently finalized. These will be determined through the contracting process with tenderers and will be assessed against a Statement of Requirements as to whether they are fit for purpose by Navitas. Construction of a small number of single flat-type units is currently envisaged. As with the hostel-type / 'hotel' accommodation, during the tendering process, tenderers will be asked to provide detail of their proposed incorporation of sustainable design features in their tender submissions. Environmental considerations and sustainable design will form part of the contract evaluation criteria.

Table 5.26: Estimated maximum accommodation requirement for personnel required during the Sea Lion Phase 1 & 2 Development

Personnel type	Accommodation Requirement[1]	Stage 1		Stage 2a &2b:		Stage 3:		Base-case provision of accommodation by Navitas[2]
		31 months		35 months		27 years		
		Max no. people[2]	% Stanley pop[3]	Max no. people[2]	% Stanley pop[3]	Max no. people[2]	% Stanley pop[3]	
Permanent onshore personnel who live in Stanley (office, supply base, TDF)	The ability to accommodate all the personnel employed onshore will be required four to six months prior to the start of drilling activity and will endure for the duration of the Sea Lion Field life	26	0.91	24	0.84	24	0.84	Housing strategy to encourage private sector provision
Temporary rotational onshore personnel required during high intensity periods or stand-by personnel who live in Stanley for a few weeks to a few months	Routine and surge hostel-type accommodation for personnel employed onshore within support yards and logistics (on a 28 x 28 day rotation), who are on stand-by, and overnighting fixed wing air crew.	74	2.6	70	2.46	13	0.46	Temporary modular accommodation units initially provided by Navitas, supplemented by local hotels. Transferring to in-transit accommodation as soon as available.
Offshore personnel (in transit) prior to going offshore	Overnight hostel-type accommodation for personnel at the beginning and end of offshore rotations	62	2.18	62	2.18	60	2.11	In-transit accommodation unit provided by Navitas.
Personnel down-manned to shore in the event of an emergency	Short term contingency accommodation in the event of an emergency down manning of the drilling rig or the FPSO. Required for Field Life[4]	140	4.92	140	4.92	100	3.51	The above accommodation can be double occupancy for up to three days
Visiting senior personnel	*Ad hoc* hotel accommodation	Anticipated to be similar to levels during the exploration campaign						None
Total requiring accommodation at any time		302	10.6	296	10.39	197	6.92	-

[1] Based on Navitas' Sea Lion Phase 1 & 2 Development projections.
[2] See Development Description (Section 5.11.4.1) for detail.
[3] Stanley population from the last census, 2,848 inhabitants (FIG, 2023l).
[4] Figures provided by Navitas Logistics and Infrastructure Overview.

5.11.4.2 Freshwater requirements

Freshwater, which is a finite resource in the Falkland Islands, will be required offshore, onshore and at-shore for operational, domestic and general use.

Freshwater requirements during the Phase 1 & 2 Development include those associated with:

- The MODU and drilling activities (Section 5.4),
- The FPSO and production (Section 5.8),
- The offshore marine vessels (Section 5.11.2),
- Onshore / shoreline activities including the:
  - TDF (Section 5.11.1.1.1),
  - Onshore laydown yards, storage bases and associated offices (Section 5.11.1.2), and
  - Personnel accommodation (Section 5.11.4.1).

The following sections aim to:

- Quantify the Phase 1 & 2 freshwater requirements,
- Describe the Phase 1 &2 measures for meeting the water demands, and
- To describe activities for which local freshwater resources may be required.

5.11.4.2.1 MODU

The estimation of freshwater use during drilling is based upon the well design and the way drilling is to be managed in Phase 1 & 2 of the Development (as described in Section 5.4).

The forecast water demand (Figure 5-11) is based upon the daily water requirements associated with:

- Drilling,
- Cementing,
- Well suspension, and
- Completion.

In Stage 1, prior to First-Oil, the wells will be batch drilled (Section 5.4.5.2). This will result in peaks and troughs in water demand over time as activities that are more water intensive are undertaken at each well within the batch process, followed by activities that are less water intensive. The average water demand will be 19 m^3 / day, however, over two, one-month periods, water use will peak at 37 m^3 / day.

Following First-Oil, the wells will be drilled and completed in sequence (Section 5.4.5.2). Therefore, water use will decline to a more uniform 21 m^3 / day. Upon the completion of all drilling activities and once the MODU departs there will be no further requirement for offshore drill-water.

The MODU will be equipped with water-makers and is assumed to be self-sufficient for domestic uses. However, it is likely that the water-makers may not meet the need for drill water such that there be a requirement for local water resources.

With the daily water supply in Stanley currently limited to 1,000 m^3/day under standard working conditions, and 918 m^3/day being used in 2023, this shows that there is only 82 m^3/day of excess production capacity. This is shown below in Figure 5-11 as the 'assumed Stanley potable water supply limit'. For more details on Stanley's water capacity and predicted Sea Lion usage, please refer to Section 11.4.

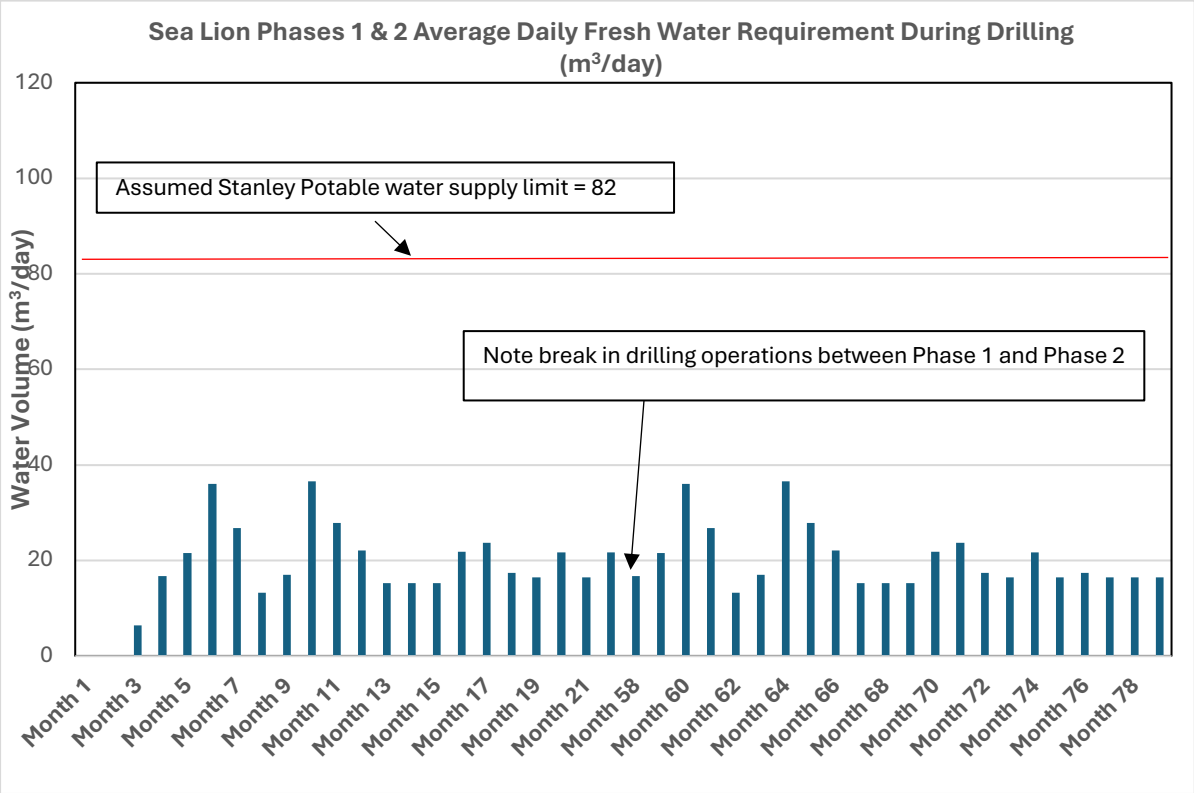

Figure 5-11: Forecast estimates of freshwater demand for Phase 1 & 2 drilling requirements

5.11.4.2.2 FPSO

During production, the FPSO will require water for domestic use and marine and topsides systems.

It is estimated that the FPSO will require 40 m^3 / day. To meet this demand, it will carry a water-maker of sufficient capacity and with redundancy (i.e., a spare unit). It is anticipated that the FPSO will be able to produce enough water to meet its own demand and thus be self-sufficient in water.

5.11.4.2.3 Vessels

The number and types of vessels required varies during the different stages of development depending on the activities being undertaken. Vessels will be equipped with water-makers sufficient for their needs, however a contingency requirement of 10 m^3 / day from local freshwater resources will be assumed for occasional opportunistic top-up of tanks when berthed at the TDF.

The OSVs which support the MODU and the FPSO will carry the water out to the MODU and FPSO.

5.11.4.2.4 Onshore Construction

Where possible, Navitas will utilise existing Stanley-based infrastructure to support Sea Lion operations, acknowledging however that there will be a need to develop further infrastructure to support the project. Additional Infrastructure requiring construction includes:

- Construction Contractors Compound (e.g., laydown area),
- Offshore Transit Hotel Accommodation,
- Wells Infrastructure,
- Liquid Mud Plant (based within property of TDF),
- Chemical Storage facility (Navitas potentially to lease site from FIG in East Stanley),

- Helicopter Hangar and Passenger Exchange (within the curtilage of Stanley Airport),
- Upgrades and refurbishments to the existing TDF and its causeway, and
- Waste Treatment Site.

At the time of writing, it is anticipated that construction of these additional infrastructure requirements will commence in 2025[21].

Water use for welfare of the construction team at work is budgeted at 40 litres per person per day. If everyone was at one location (75 people max) they would consume 3,000 litres per day.

Water requirements for the concrete batch plant and other construction uses is estimated at 3,000 – 4,000 m^3 over the *c.* 15 months of the construction projects. For the batch plant, peak demand will be buffered by up to 40 m^3 of water onsite.

5.11.4.2.5 Laydown yards, storage, and propriety TDF usage

The TDF has minimal use of water (i.e., <1 m^3/day) and water use by the TDF is included within the above estimates of MODU, FPSO and vessel water use.

Water use by the on-shore laydown yard and storage facility has been estimated using the 2015 exploration campaign data and has been scaled according to the anticipated changes in yard area (Section 5.11.1.2).

Water use at the liquid mud-plant, brine and bulk storage facility is included within the offshore drilling use estimates and is not considered separately to avoid double-accounting.

A freshwater tank storage will be provided to service the TDF and bulk plant needs, if required. This will require planning approval. This tank storage will buffer supply to average use levels and prevent water demand spikes during vessel supply or batching.

5.11.4.2.6 Accommodation

As detailed in Section 5.11.4.1, the personnel requirements will vary during the stages within the Phase 1 & 2 Development. Average water use is proportional to the number of personnel based ashore, and therefore peak periods of use relate to the two days fortnightly when crew changes occur. Water use is based upon an average *per capita* use of 300 litres per person per day for domestic usage (UNDP, 2006)

5.11.4.2.7 Total estimated freshwater requirement for Phase 1 & 2

An estimate of the total Phase 1 & 2 water use, based on the above, is presented in Table 5.27.

In addition to direct usage by the MODU, FPSO, vessels etc., data from the previous O&G exploration campaigns indicate that an additional, but unallocated, increase in water use results from:

- The use of sub-contractors and services (e.g., offices, laundry, rental accommodation, etc.), and
- Indirect, but associated, water use by other economic sectors (e.g., hotels, hospitality, retail suppliers, etc.).

It is not possible to accurately separate the direct and indirect water use associated with the O&G industry from that associated with unrelated activities. However, in previous O&G exploration

[21] The predicted timeline for commencement of construction of the TDF causeway did not materialise as anticipated at the initial time of writing the EIS. Timing for replacement of the causeway is dependent on timing of final regulatory approval, but the TDF causeway is required to be operational to support development drilling activities.

campaigns, an additional unallocated usage of *c.* 81 m^3 / day was recorded and this has been included within the estimate in Table 5.27.

Table 5.27: Estimated freshwater use by the Phase 1 & 2 Development

Activity	Assessment	Stage 1 – Pre First-Oil		Stage 2a &b – SIMOPs		Stage 3 – Steady State Production	
		Average (m^3/day)	Peak[1] (m^3/day)	Average (m^3/day)	Peak[1] (m^3/day)	Average (m^3/day)	Peak[1] (m^3/day)
Offshore Demand (supplied *via* TDF)							
MODU Drilling requirements inc. bulks, mud and brines	Drilling Estimates	19	37	20	21	0	0
Vessel requirements	Tank-top up allowance	10	10	10	10	10	10
FPSO	Self-sufficient	0	0	0	0	0	0
Onshore Demands							
Onshore Construction	Construction Estimates	8	44	n/a	n/a	n/a	n/a
Laydown yards and warehousing	Exploration with proportional increase	7	7	7	7	2	2
Bulk, mud & brine storage	Included in offshore drill estimates	0	0	0	0	n/a	n/a
Personnel and accommodation	Per capita rate of 300l/pp/day	70[2]	140	64	126	32	65
Total O&G Demand		114	238	101	164	44	77
Unallocated activity demand[3]	Stanley total usage above allocated exploration use	81	-	81	-	81	-
Total forecast demand		195	-	182	-	125	-

[1] Peak usage relates to the month with the highest daily average usage during drilling and to accommodation during peak in-transit crew exchanges.
[2] This includes offshore personnel as well to account for a worst-case in the event of a 'down man'. Otherwise, water will be mostly made up offshore by watermakers on the MODU/FPSO for personnel use.
[3] Estimates based on the observed additional, but unallocated, increases in water use between 2014 - 2015 during exploration campaigns.

5.11.4.3 Electricity requirements

With regard to electricity requirements, the critical factor is the instantaneous power demand at any one given time, which must be matched by electrical generators within the Stanley supply system.

The following power demand figures are based upon directly recorded or estimated data by FIG Public Works Department during previous oil exploration rounds within the Falkland Islands. Where appropriate, the estimates have been scaled up or down from the observed exploration use according to, for example, the increase in land area used (in the case of the laydown yard) or *per capita* personnel increases (in the case of accommodation usage).

Figures are provided in Table 5.28 for the main infrastructure centres:

- Heliops hangar,
- Accommodation facilities,
- TDF, and
- Drilling and operations bases (including the liquid mud plant, and laydown yards).

In addition to the attributed infrastructure centres listed above, there are a number of directly associated miscellaneous power demands from offices (Navitas and service contractors), separate rental accommodations (for oil personnel) and directly sub-contracted services, such as laundry.

Furthermore, there are associated demands from indirect economic activities such as hotels, entertainment, and retail that will increase due to the presence of oil personnel.

Finally, there may be incidental increases in demand from unassociated economic activity that is wholly separate from the Phase 1 & 2 Development activity, e.g., if fisheries cold-storage practices change. Such changes are out with Navitas' control and will affect the baseline power availability against which the Phase 1 & 2 Development power usage is compared in this EIS.

In POEPL's Sea Lion exploration campaigns, the additional electricity requirements contributed a further 9 % of Stanley's overall energy use although it is not possible to fully separate the proportional increases resulting from the those that are linked to oil activity and those which are not.

Table 5.28: Power demand of Phase 1 & 2 Development infrastructures

Facility	Peak Power (kW) use during exploration	Estimated Stage 1 & 2a & 2b peak power (kW)	Estimated Stage 3 peak power (kW)
Heliops hangar	250 a	250	250
Accommodation facility	120 – 140[1]	264 - 308	120 - 140
TDF (estimate)	25[2]	25	25
Drilling and operations bases (estimate)	75	225	45
Total attributable load	**470 - 490**	**764 – 808**	**440 - 460**

[1] PWD figures (G. Ross, *pers. comm.*).

[2] Estimate assuming that peak power use is 5-times averaged power use over 24-hours.

5.11.4.4 Waste management plan

Wastes will be managed in accordance with the project-specific Waste Management Plan (WMP) which will be developed from the Navitas Falkland Islands Waste Management Procedure, which sits within the company OMS (Section 3.2).

The bulk of waste, including all non-hazardous waste and potentially some hazardous waste, will require a waste handling / treatment facility. It is envisaged that additional municipal disposal facilities will be available in the Falkland Islands that will be sufficient for the Sea Lion Phase 1 & 2 project.

All waste received from the offshore Development will be transported to the onshore supply base by the supply vessels where it will be stored temporarily, in accordance with best practice, in the waste laydown area prior to transportation to FIG's waste reception facility, or export from the Islands for treatment.

Waste streams that are unsuitable for incineration disposal on Island will be sent to another country in accordance with the UN Environment Programme's Basel Convention for treatment / disposal (see Section 10.10).

At all times, and as a responsible operator, Navitas shall ensure that:

- The '5Rs' Waste Hierarchy (Remove, Reduce, Reuse, Recycle / Recover, Residue (Treatment)) is applied,
- Wastes are accurately described / characterised and consigned when they leave the Navitas site where the waste was generated,
- Wastes are securely packed to ensure no loss of containment in transit,
- All parties handling waste on behalf of the company are competent and authorised to do so, and
- Wastes are disposed of in an appropriate way, at a site that is authorised to accept them.

Navitas will provide details of all envisaged waste streams and planned treatment and disposal options from the commencement of field operations within the WMP. A summary of the anticipated waste volumes anticipated throughout the Sea Lion Development can be found in Section 10.10.4.4.

5.11.4.4.1 Oil spill waste management

In the event of an oil spill, clean-up operations intended to restore the site of the spill, will generate large volumes of waste materials which can be contaminated with oil. The management of this waste up to, and including, its final disposal, can cause significant challenges for response coordinators. In order to ensure greater preparation, Navitas has developed Oil Spill Strategies that detail the approach for dealing with such wastes.

In the highly unlikely event that a spill incident should occur, Navitas would be supported by international oil spill response contractors who have significant expertise and resources in the appropriate management of oil spill response waste. These response contractors would be deployed to the Islands in the event of a Tier 2 or 3 oil spill event. There will be oil spill response and interim waste storage capability on the various offshore support vessels, at the TDF (Section 5.11.1.2.3) and at the onshore supply base facility.

The proposed approach will be to develop temporary, lined, storage areas. All solid waste streams will be corralled / contained in the temporary lined storage areas and liquid wastes (i.e., oily water from washing of equipment, for example) will be stored in drums and Intermediate Bulk Containers (IBCs). Final disposal will be agreed with FIG as part of the contingency planning (see Section 10.10.2.2.3). Plans for monitoring of the disposal site and detail of oil spill waste clean-up plans will be detailed in the Phase 1 & 2 Development Waste Management Plan.

5.12 Decommissioning

The Field Life of the Phase 1 & 2 Development is estimated to be 30 years. The date of Cessation of Production (CoP) and the commencement of decommissioning of associated facilities will depend upon field performance and economics. Navitas is required to ensure that all structures are designed to be fully decommissioned in a safe and environmentally responsible manner.

Part V of the Offshore Minerals Ordinance 1994 confers obligations for decommissioning and a decommissioning programme has to be approved by FIG in advance. FIG has powers under the Ordinance to develop additional regulations in relation to field decommissioning. Therefore, decommissioning will be carried out in accordance with the legislation in place at the time. However, at the time of writing, the project defers to the current UK legislation and its sources.

OSPAR Decision 98/3 on the Disposal of Disused Offshore Installations prohibits dumping, and leaving wholly or partly in place, of disused offshore installations within the OSPAR maritime area. While derogation from this prohibition may be sought for qualifying installations, e.g., large steel or concrete footings of fixed platforms, this will not apply to the proposed project which will utilise an FPSO with subsea wellheads and infrastructure. Under OSPAR, all subsea structures must be removed with any

associated piles, well conductors etc. cut to a level below the natural seabed which ensures they remain below the seabed in the face of prevailing conditions.

Of importance, pipelines and other structures which are listed in a UK Pipeline Works Authorisation are excluded from OSPAR Decision 98/3 and in the UK, decommissioning of these is managed in line with the Petroleum Act 1998 (Part IV) and the Pipeline Safety Regulations 1996.

These require a similar assumption of complete removal where reuse of the pipeline and associated structures for further hydrocarbon development is not possible. However, under the UK regulations, there are certain pipelines and/or circumstances in which a pipeline may be wholly or partially left *in situ* e.g., pipelines that are adequately buried or trenched, are not subject to development of spans[22], and are expected to remain so. However, the decision to do so would need to be informed by an EIS which is supported by a formal Comparative Assessment of the options which must include a robust assessment of the environmental impact of removal *vs.* that of leaving wholly or partially *in situ*.

In accordance with the above, the Phase 1 & 2 Development infrastructure has been designed to enable complete removal of all structures. Equally, the flowlines will be surface laid and will not be trenched or buried thus facilitating complete removal (noting that the seabed is very soft, so flowlines may self-bury which could change the methods required for complete removal). Also in line with legislation, all relevant 'As Left' surveys will be carried out to ensure that the seabed is left clear.

Specifically, the Development has been designed to enable:

- Abandonment of wells in accordance with The OEUK Guidelines for the Suspension and Abandonment of Wells,
- Cutting of the well casings to a level below the natural seabed, which ensures they remain below the seabed in the face of prevailing conditions,
- Removal of the 'disused offshore installation':
    - Removal the FPSO and moorings for legitimate use elsewhere - the FPSO will be on a 'lease and operate' contract so may be re-deployed following decommissioning of the Phase 1 & 2 Development,
    - Removal of all subsea infrastructure associated with the installation (i.e., wellheads and X-mas trees) for waste recovery (e.g., reuse or recycling) or final disposal on land. Infrastructure removed will be transported to shore and managed in accordance with the Waste Hierarchy. Any disposal will be justified by demonstrating that recovery and recycling options are not feasible or reasonably practicable, and
    - Any piles will be cut to a level below the natural seabed, which ensures they remain below the seabed in the face of prevailing conditions.
- Removal of the SURF:
    - All subsea umbilicals, risers, flowlines, and associated infrastructure will be removed unless comparative assessment of the safety, environmental, technical, societal and economic impacts indicate that leaving wholly or partially *in situ* is the best practicable option.
- Removal of any debris associated with the production or decommissioning phases.

Note: No part of the Phase 1 & 2 installation will qualify for derogation under the current OSPAR Decision 98/3 on the Disposal of Disused Offshore Installations. As stated, the Phase 1 & 2

[22] A pipeline span is a section of a pipeline that is no longer supported by the seabed due to erosion or scouring. Free spans can develop for a number of reasons, including uneven seabed, tidal currents, scouring, and wave action.

Development will be decommissioned in accordance with legislation and best practice relevant to the time.

Decommissioning will be considered a separate project and will thus follow the standard Navitas planning process and will warrant its own EIA and EIS. However, at this time, the seabed has been extensively surveyed to explore environmental sensitivity. These have not indicated that the structures will cause adverse environmental impact, however, location-specific site surveys will be undertaken immediately prior to installation to ensure there are no localised environmental sensitivities that suggest installation is inadvisable at that location.

5.12.1 Decommissioning programme

The base-case is the complete removal of all structures to approximately two metres below the seabed. However, it is not possible to assess the environmental impacts and risks associated with the decommissioning process at this time due to:

- The varying options for removal,
- Unknowns about the status of the infrastructure at the end of Field Life (e.g., flowlines may self-bury), and
- The potential for technological advances that emerge during the life of the Phase 1 & 2 Development.

Toward the end of Field Life, a detailed Decommissioning Programme outlining the methods for removal and outcomes of the comparative assessment for pipeline decommissioning options will be submitted to FIG for the FPSO, pipelines and subsea infrastructure.

The Decommissioning Programme/s will be supported by:

- An ENVIID which will be carried out to inform the EIA that will accompany the decommissioning programme,
- A comparative assessment for the pipeline decommissioning options,
- An EIS detailing the impacts and risks associated with the selected removal options and waste management strategies, and
- A Stakeholder Engagement Plan.

5.13 Development resilience to the effects of climate change

The impacts of climate change are described in Section 10.9 which estimates the Development's atmospheric emissions and its contribution to this global phenomenon. However, the impacts of climate change, as a global and cumulative concern, have already begun and it is necessary to consider the resilience of the proposed project to such changes.

The key relevant impacts of climate change are:

- The potential for rising sea levels owing to the melting of Arctic, Antarctic and worldwide glacial ice,
- The potential for drifting icebergs which may break away owing to warming temperatures,
- Changing coastlines, and
- More extreme weather.

By design the project is expected to be resilient to such changes. The mitigations e.g., the Iceberg Management Strategy (Section 3.2.18.1), no sea level onshore facilities and the selection of a harsh environment FPSO which is designed to withstand metocean conditions worse than those expected at Sea Lion are built-in to the project design.

5.14 Phase 1 & 2 base-case mitigation technologies

In order to assess the impact and risks it is necessary to quantify, where possible, what the outputs of the Phase 1 & 2 Development may be e.g., how much CO_2 will be emitted, how much light, how much produced water etc. Here it is necessary to understand the project activities and the technologies used to reduce the main outputs. The base-case impact and risk reduction technologies built-in to the design are listed in Table 5.29.

Table 5.29: Summary of the technologies and measures which are built-in to the Sea Lion Field Northern Area Phase 1 & 2 Development basis of design in order to reduce outputs

Project activity	Mitigation technologies built-in to the Sea Lion Field Northern Area Phase 1 & 2 basis of design
General	• All materials, fittings and system contents contained in the FPSO hull will be non-toxic, non-smoke emitting, fire retardant or 'low flame spread'.
Drilling and production	**The following will reduce the amount of atmospheric emissions:** • The main fuel supply for the FPSO will be produced gas, use of which will be facilitated by the availability of three Dual Fuel GTG Turbines, • Use of waste heat recovery to reduce the need for active heat generation and therefore to reduce fuel consumption / CO_2 emissions, • No planned flaring during ongoing well testing throughout Field Life, • No routine flaring during normal production (notwithstanding the flare pilot light), • Use of a Flare Recovery Package during normal operations, • No venting from the FPSO during normal production, • Follow international standards for piping, valves etc. and best practises for integrity management e.g., UK Step Change Hydrocarbon Toolkit • Use of Vapour Recovery Package (VRP) during normal operations, • Use of a vapour balancing system to pass blanket gases from the FPSO cargo tanks to the CTT cargo tanks, when available, during transfer of oil, • The use of passive heat retention systems wherever possible to maintain working temperatures and flow assurance, thereby preventing energy expenditure, and its associated emissions, on active heating systems, • Use of Open Hole Gravel Pack (OHGP) completions which minimise downhole debris and reduce the requirement for well clean-up to the MODU, and thus the likelihood of associated flaring. The base-case is for the wells to be flowed straight back to the FPSO (**Note:** there is a contingency to flow / test four wells to the MODU if considered necessary which would require flaring), • Use of F-Gases with the lowest Global Warming Potential, • Back-up inert gas generator for use as gas blanket in the event that the VRP malfunctions to prevent venting of hydrocarbon gas, and • Use of Marine Gas Oil (MGO) instead of Intermediate Fuel Oil (i.e., a lighter fuel) when operating inshore. **The following will reduce the volumes of drilling discharges:** • Use of seawater sweeps, bentonite and WBM for tophole drilling, and • Batch drilling to optimise drilling mud use. **The following will reduce the volumes of, or negate the need for, discharges of oil and chemicals to sea:** • Produced Water Reinjection (PWRI) as a base-case to alleviate the need to discharge produced water to sea during normal production operations, • Subsea and topside technical flow assurance measures, e.g., insulation and heating, will minimise the use of flow assurance chemicals, • Diversion of produced water to slops / off-spec tanks for retreatment in the event that PWRI is down and produced water is out with discharge specifications, and • Oil in ballast tank detection on the FPSO.

Project activity	Mitigation technologies built-in to the Sea Lion Field Northern Area Phase 1 & 2 basis of design
	The following will reduce the volume of oily waste returned to shore: • Use of a Thermomechanical Cuttings Cleaner (TCC) during drilling which will clean-up drill cuttings on the rig so they may be discharged to sea, reducing the amount of oily waste sent to shore for treatment. **The following will reduce the volume of waste being returned to the UK for disposal:** • Use of municipal waste facilities. **The following will reduce the competition for resources:** • Use of buffer storage water tanks at the TDF, the mud plant and potentially the at-shore bulk supply base to ensure management of peak water use requirements.
Oil spill prevention measures	**Note: many industry-standard preventative mitigation measures must be built-in to the basis of design. Therefore, there are very few 'extra' base case mitigation options available and the standard requirements are summarised below:** **Preventative measures built-in to the FPSO include:** • Cargo and fuel tanks of the vessel will be double skinned, • Bunding of all liquid containing equipment and chemicals, • Open deck drains to catch and collect spills to a dedicated slops tank, • High level tank filling alarm and emergency shutdown of the process, • FPSO offloading hose quick-break connectors to prevent spills on unplanned disconnection, and • Automatic Identification Systems and Marine procedures to prevent collisions. **Preventative measures built-in to the well design include:** • Development of the appropriate, and peer reviewed, well design, • Use of appropriately weighted drilling muds, • The use of appropriate mud additives to ensure over-balanced drilling, and • Use of Blow-Out Preventers and production X-mas trees. **Preventative measures built-in to the CTT nomination and selection include:** • Cargo tanks, and potentially the fuel tanks, of the vessel will be double-skinned, • Vetting and auditing prior to acceptance of the nominated vessel, • Transfer of Falkland Islands' authorised Berthing Master / Pilot and assistant to CTT to manage the offshore direct offtake operation, • Cargo tank hi level and hi-hi level alarms to prevent overfilling, • Bunding of all liquid containing equipment and chemicals, and • Open deck drains to catch and collect spills to a dedicated slops tank.

5.15 Estimated quantities of residues and emissions resulting from the project

In line with Paragraph 1, Schedule 4, sub-paragraph 4c of the Offshore Minerals Ordinance 1994 (and 2011 amendment), the residues and emissions resulting from the Sea Lion Phase 1 & 2 Development are estimated in Table 5.30.

Table 5.30: Estimated quantities of residues and emissions resulting from Stages 1, 2 and 3 of the project

Type of Emission or Residue	Total quantity of emission or residue	EIA chapter / section detailing full characterisation and quantification
Disturbance footprint of temporary MODU anchors installation	0.66 km^2	**Section 10.3**
Disturbance footprint of FPSO anchor installation	0.095 km^2	
Long-term footprint of FPSO anchors	0.0016 km^2	
Disturbance footprint of LTV anchors in Berkeley Sound	0.06 km^2	
Temporary disturbance footprint of SPS / SURF installation and support deposits / wet storage	0.143 km^2	
Long-term footprint of SPS / SURF	0.024 km^2	
Underwater noise offshore – maximum source level during all stages	188 dB re 1 µPa at 1m	**Section 10.4**
Underwater noise inshore from inshore operations – maximum source level	165 dB re 1 µPa at 1m	**Section 10.5**
Water-based Mud (WBM) drill cuttings discharged	18,756 t	**Section 10.6**
Non-Aqueous Drilling Fluid (NADF) drill cuttings (cleaned)	20,905 t	
Oil discharged on cleaned cuttings	106 t	
Potential produced water (PW) discharges (during 7 % PWRI downtime, or 25.5 days in a year) - early Field Life	41,461 m^3 / year	**Section 10.7**
Potential produced water (PW) discharges (during 7 % PWRI downtime, or 25.5 days in a year) - late Field Life	428,294 m^3 / year	
Grey water (over 32.6 years)	330,447 m^3	
Black water (over 32.6 years)	115,656 m^3	
Hypersaline water (for consumption over 32.6 years)	495,670 m^3	
Hypersaline water (for operational use over operational Field Life)	1,519,495 m^3	

Type of Emission or Residue	Total quantity of emission or residue	EIA chapter / section detailing full characterisation and quantification
Currently expected atmospheric emissions (including four contingency well tests) (over 30 years)	5.6 $MtCO_2e$	**Section 10.9**
Worst-case total atmospheric emissions (over 30 years)	7.31 $MtCO_2e$	
Worst-case atmospheric emissions plus contingency of four well flowback / tests)	7.33 M tCO_2e	
Indirect emissions from 100 % combustion of sold product (outwith Navitas's control)	110 - 150 $MtCO_2e$	
Total waste (over Field Life)	28,537 t	**Section 10.10**
Total waste incinerated or going 'waste-to-energy' in the Falkland Islands	24,698 t	
Total waste to recycling (over Field Life)	1,507 t	
Total waste to landfill (over Field Life)	462 t	

6 SCOPING AND STATUTORY CONSULTATIONS

Table of Contents

6.1 Introduction 231
6.1.1 Relevant Guidance 233
6.1.2 Informal scoping Consultation Process 233

6.2.3.1 Consultation format 240
6.2.3.1.1 Commitments resulting from the 2016 scoping 240
6.2.4 Statutory 42-day public consultation in 2018 241
6.2.4.1.1 Commitments resulting from the 2018 formal consultation. 242
6.2.5 Statutory 42-day public consultation in 2020 242
6.3 Navitas informal scoping consultation 2023 242
6.4 Summary of all informal scoping consultation outcomes 242
6.5 Navitas statutory 42-day public consultation 247

6.1 Introduction

As is described in the Falkland Islands Government (FIG) Environmental Impact Assessment (EIA) Guidance (FIG, 2016e), it is considered beneficial for an operator to consult informally with all relevant interested parties on the proposed development plans prior to the execution of the EIA and writing of the associated Environmental Impact Statement (EIS). This 'informal' consultation is intended to focus the EIA and ensure that the environmental assessment underlying the EIS is adequate.

Should the FIG Department of Mineral Resources (DMR) indicate to FIG Executive Council that a valid EIS which is compliant with Schedule 4 of the Minerals Ordinance has been submitted, the statutory 42-day consultation period will follow. This will comprise formal consultation with FIG, its expected consultees and the general public.

As described in Chapter 4, under the previous operator, POEPL, the Sea Lion Field was originally going to be developed *via* an offshore Tension Leg Platform (TLP) and numerous oil export options were under consideration. Direct scoping consultations on development with the TLP concept began in 2014 and included the public, interest groups and other consultees. Also in 2014, additional scoping and statutory consultation was undertaken for the 2015 exploration drilling campaign with FIG departments, key focus groups and members of the public.

Following the decline in the oil price in 2015, the proposed offshore component of the Sea Lion Development was changed and the use of a Floating Production, Storage and Offloading (FPSO) Vessel was proposed instead of the TLP, while the various oil export options remained under consideration (Table 6.1). Further scoping consultations were carried out following each major evolution of the project (Table 6.1), for example, on the oil export options. Statutory consultations were carried out on the submitted EIS, under POEPL in 2018 and 2020.

In 2023, the Sea Lion Development was further optimised, resulting in the basis of design presented in this document, the need for a further informal scoping exercise and the potential for another statutory consultation.

The following chapter describes:

- The historical scoping and statutory consultations carried out between 2014 to 2020 under POEPL (now Navitas Petroleum Development and Production Limited (Section 2.1.1) (hereafter referred to as Navitas), and
- The most recent scoping consultation carried out by Navitas in 2023.

Table 6.1: Comparison between the previous and the current Sea Lion O&G Development proposals

Activity	2014[1]	2015[1]	2016 [1]	2018[2]	2020[3]	2023[4]
Number of completed wells:	33	Reduced to 18 wells	Up to 30	No Change	No Change	23
Well completion	Cement and perforation	Cement and perforation	Cement and perforation	No Change	No Change	Open Hole Gravel Pack (OHGP)
Oil produced and processed by:	TLP with processed oil transferred to a permanently connected Floating, Storage and Offloading (FSO) Vessel	FPSO unit	No Change	No Change	No Change	Smaller FPSO
Gas management:	Gas to be used for fuel gas, gas blanketing and 'gas lift' to enhance oil recovery	No Change	No Change	No Change	No Change	No Change
Produced water management:	Produced water to be reinjected to enhance oil recovery	No Change	No Change	No Change	No Change	No Change
Offloading of oil:	Oil processed on TLP and transferred to FSO, then transferred to a Dynamically Positioned (DP) Offshore Loading Shuttle Tanker (OLST)	Oil processed and stored on FPSO and then transferred to a DP OLST or Conventional Trading Tanker (CTT)	Oil processed and stored on FPSO and then transferred to DP OLST.	No Change	Oil processed and stored on FPSO and then transferred to CTT	No Change
Oil export:	A number of oil export options were under consideration but the preferred route was not defined	Still under consideration. Options were: Inshore Transfer in Berkeley Sound from a DP OLST to a CTT, or direct offtake to CTT from FPSO at the Sea Lion Field	Inshore Transfer in Berkeley Sound from a DP OLST to a CTT	No Change	Direct offtake from FPSO to CTT at Sea Lion Field location	No Change
Field Life:	25 years	20 years	20 years	20 years	20 years	30 years

[1] Informal consultations on the (then) Phase 1 Development as proposed by POEPL.
[2] Statutory and public consultation on the formally submitted EIS (Rev B03) describing the (then) Phase 1 Development as proposed by POEPL.
[3] Statutory and public consultation on the submitted, and revised, EIS (Rev B04) describing the (then) Phase 1 Development as proposed by POEPL.
[4] Informal consultation on the current proposed Phase 1 & 2 Sea Lion Development as optimised under Navitas (previously POEPL).

6.1.1 Relevant Guidance

The informal scoping consultation process is guided by:

- FIG Guidance:
  - The Executive Council (ExCo) 'Falkland Islands Hydrocarbon Development Policy Statement, 158/13', 2013 (Section 3.1.6.2),
  - The FIG Hydrocarbons EIA Guidance Note (2016e), and
  - Schedule 4 of the FIG Offshore Minerals Ordinance 1994 (as amended) which outlines the required contents of an EIS (Section 3.1.7.3.1). See also Appendix 2.

6.1.2 Informal scoping Consultation Process

The informal scoping consultations typically included:

- Development and distribution of a pre-read document,
- A presentation by the operator on the scope of the Development,
- Detail on the key aspects of the project,
- Detail on the oil export activities and the associated oil spill response strategy,
- Detail on the onshore and at-shore activities,
- A summary of the EIA / EIS process, and
- An open Q&A discussion where all comments and queries were recorded anonymously for inclusion in this chapter (see Section 6.4).

6.1.3 Key Stakeholders and interested parties

The relevant interested parties and statutory bodies are identified are listed in Table 6.2.

Table 6.2: Statutory stakeholders and Interested Parties consulted during scoping

Interested party	General purpose	When consulted					
		2014[1]	2015[1]	2016[1]	2018[2]	2020[2]	2023[3]
Department of Mineral Resources (DMR) (FIG)	The regulatory body charged with oversight of the offshore O&G industry and any onshore mining or mineral exploration. Core responsibilities include the role of licensing authority, offshore health and safety enforcement, and offshore environmental approvals (FIG, 2023e).	✓	✓	✓	✓	✓	✓
Public Works Department (PWD) (FIG)	Responsible for Government construction projects in the Falkland Islands, including house building and maintenance as well as larger infrastructure projects such as, road maintenance, power and freshwater.	✓	✓	✓	✓	✓	✓
Policy Unit and Environmental Planning Department[4]	Provides economic, environmental planning and policy advice to Elected Members, the Central Management Team and FIG Departments. It also assists in the development of specific environmental economic and social programmes, working across Government and the community to support the attainment of the goals of the Falkland Islands Plan (FIG, 2023f).	✓	✓	✓	✓	✓	

Interested party	General purpose	When consulted					
		2014[1]	2015[1]	2016[1]	2018[2]	2020[2]	2023[3]
FIG Harbour Master /Falkland Islands Maritime Authority (FIMA)	Marine Officer for the Falkland Islands and Harbour Master for Port Stanley[5]. Responsible for policy development, operational tasks and regulatory functions applicable to Falkland maritime, harbour, port operation and fishery issues.		✓	✓	✓	✓	✓
Ministry of Defence (MoD)[6]	A military presence is based in the Falklands to demonstrate the UK Government's continued commitment to the security of UK Overseas Territories in the South Atlantic. They include air defence assets, maritime patrol capability and infantry forces (UK Gov, 2015).	See note[6]					
Falkland Islands Fisheries Department (FIFD), Department[7] of Natural Resources (DNR) (FIG)	Responsible for the sustainable management of the fisheries within the Falkland Islands conservation zones (FIG, 2023d).	✓	✓	✓	✓	✓	
Members of the Legislative Assembly (MLAs)	Elected members of the legislative assembly, who are empowered to pass legislation for the peace, order and good government of the Falkland Islands. All members are elected as independents (FIG, 2023a).			✓	✓	✓	
Rural Business Association	The Rural Business Association represents Camp-based business interests in discussions with the Government and other stakeholders and provides a focal point for communication with the rural community.	✓		✓	✓	✓	
Falklands Conservation (FC)	A non-governmental organisation working to protect all the wildlife of the Falkland Islands for future generations (FC, 2015).	✓		✓	✓	✓	
RSPB	The Royal Society for the Protection of Birds is a charitable organisation based in the UK, working with BirdLife and FC.			✓	✓	✓	
Wildlife Conservation Society	A US based conservation charity that owns the Jason Islands NW of West Falkland.	✓			✓	✓	
Falkland Islands Civil Aviation Department (FICAD)[6]	Responsible for overseeing aviation activity in the Falkland Islands to ensure compliance with international and British Overseas Territory legislation (FIG, 2023i). The work of FICAD provides assurance that: The aviation industry meets the highest safety standards, and There are improvements in airlines and airports' environmental performance	See note[6]					

Interested party	General purpose	When consulted					
		2014[1]	2015[1]	2016[1]	2018[2]	2020[2]	2023[3]
Agriculture (including Biosecurity Officer) (DoA), Department[7] of Natural Resources (DNR) (FIG)	The department engages in sheep improvement work, support for meat export and support to farmers to run their farms as profitable businesses. It seeks to foster a viable and internationally competitive agricultural industry through integrated applied research, extension, business skill development and regulatory programmes. The Department also provides veterinary, quarantine and agricultural laboratory services, FIG (2023g).	✓			✓	✓	
Falkland Islands Fishing Company Association (FIFCA)	The Association represents the interests of all holders of fisheries quota under the Falklands Individual Transferable Quota System. It works with members to ensure industry views are presented to FIG in areas of interest to the fishing industry, participates in a number of Government and non-Government committees and jointly funds and provides resources for the advancement of knowledge regarding the fishery including its biological, operational, environmental and economic aspects (FIFCA, 2023).	✓		✓	✓	✓	✓
Falkland Islands Tourist Board (FITB)	Constitutionally a 'Company Limited by Guarantee' responsible for the strategic development of the tourism industry in the Falklands and the marketing of the Islands' tourism product (FIG, 2023h).	✓		✓	✓	✓	
Chamber of Commerce	The Chamber of Commerce is the Falkland Islands leading private sector, member focused business organisation. The Chamber is a key player in the Falkland Islands for lobbying, service provision and setting the business and economic agenda (FICoC, 2023).	✓		✓	✓	✓	
South Atlantic Environmental Research Institute (SAERI)	An academic organisation conducting research in the South Atlantic from the tropics down to the ice in Antarctica. SAERI's remit includes the natural and physical sciences. It aims to conduct world class research, teach students, and build capacity within and between the South Atlantic Overseas Territories (SAERI, 2015)	✓		✓	✓	✓	
Shallow Marine Surveys Group (SMSG)	A group of marine scientists, dive enthusiasts, and volunteers conducting research through diving and exploration in the South Atlantic (SMSG, 2016)	✓		✓	✓	✓	

Interested party	General purpose	When consulted					
		2014[1]	2015[1]	2016[1]	2018[2]	2020[2]	2023[3]
Agreement for Conservation of Albatross and Petrels (ACAP) Co-ordinator (Joint Nature Conservation Committee) (JNCC)	Falklands based co-ordinator working to implement the plan for the Agreement on the Conservation of Albatrosses and Petrels	✓		✓	✓	✓	
DESNZ (UK) (previously DBEIS (Department for Business Energy and Industrial Strategy)	UK Department for Energy Security and Net Zero, which manages O&G applications and permits in the North Sea	✓			✓	✓	
HSEx (UK)	UK Health and Safety Executive with responsibility for offshore O&G operations	✓		✓		✓	
Berkeley Sound farm owners	Stakeholders who own or manage land directly adjacent to Berkeley Sound and whose rights and interests may not be represented during statutory consultations			✓		✓	
General public / private companies	Wider stakeholders whose rights and interests may not be represented during statutory consultations.	✓		✓	✓	✓	✓

[2] Statutory consultations carried out on the EIS as submitted by POEPL.
[3] Informal scoping consultation on the current proposed basis of design under Navitas.
[4] Now known as the Policy Department and the Environment Department which both sit within the new Directorate of Policy, Economy and Corporate Services (as at 2023).
[5] Note that when scoping was undertaken the 'Marine Officer/Harbour Master' was a role which is now all included under FIMA.
[6] The MoD and FICAD are important stakeholders and were consulted *via* separate face to face meetings. As MoD and FICAD concerns are generally logistical, as opposed to environmental, they were not consulted as part of the EIA scoping consultations.
[7] Now known as the Directorate of Natural Resources (as at 2023).

6.2 Historical scoping and statutory consultations

Consultations on the (then) Phase 1 Development were carried out under POEPL (now Navitas) as follows[23]:

- Informal scoping consultation in 2014 on the proposed Sea Lion Development with production from 33 wells using a TLP:
  - This initial consultation included the public, interest groups and other consultees (Genesis, 2014).
- Informal scoping consultation in 2015 on the offshore component of the (then) Sea Lion Phase 1 Development with oil production *via* 18 wells using an FPSO:
  - This consultation included the FIG Departments only, as described below.
- Informal scoping consultation in 2016 on the whole (then) Phase 1 Development (including the offshore, onshore, at-shore and the inshore oil export components):

[23] Although not relating to the (then) Phase 1 Development, POEPL (now Navitas) also carried out consultations prior to the 2015 exploration drilling campaign covering the drilling operation and associated activities. The information gathered during this consultation contributed to the overall scoping boundaries for the subsequent (then) Phase 1 Development scoping exercises.

  - This consultation included all interested parties including the general public.
- Statutory public consultation in 2018 on the (then) Phase 1 Development EIS revision B01. **Note:** at this time the selected oil export option was inshore ship-to-ship transfer which was intended to occur in Berkeley Sound. Rev B02 was then issued with detail on the outcomes of the consultation and the operator responses included. Rev B03 was issued in 2019 and provided updated information requested by FIG ExCo as a condition to EIS acceptance, and included an Environmental Monitoring and Management Plan.
- Second statutory public consultation in 2020 on the (then) Phase 1 Development EIS revision B04. **Note:** this second formal consultation was carried out as the basis of design had changed from inshore ship-to-ship transfer oil export option to direct offtake to a CTT at the Sea Lion location offshore and POEPL had made some optimisations to the Field Layout and altered the size of FPSO storage.

6.2.1 Informal scoping consultation in 2014

The informal consultation in 2014 included all interested parties, as listed in Table 6.2 above, and was carried out via:

- Organised meetings with FIG Departments - feedback was received following a presentation describing the TLP Development, and
- Open public meetings and workshops.

A summary of the key outcomes is provided in Section 6.4 below.

6.2.2 Informal scoping consultation in 2015

While representations from the 2014 public consultation on the full field TLP Development remained relevant and were carried forward, it was considered necessary to carry out a secondary informal consultation following the adjustment of the Development to 18 wells and an FPSO (Table 6.2 above).

However, given that the public had already been consulted on the offshore component when the Field was to be produced using 33 wells and a TLP, the second consultation included FIG Departments only. This decision was based on:

- The interests of avoiding stakeholder fatigue given that numerous other consultations had been carried out for the previous exploration campaigns by POEPL (now Navitas) and other operators,
- Recognition that POEPL (now Navitas) had not yet decided upon the oil export process which was likely to be the subject of most interest, and
- The fact that the opportunity to comment on the whole development would be provided in 2016.

The 2015 scoping consultation with FIG Departments was conducted *via* an informal workshop. This aimed to provide an opportunity for stakeholders to raise any issues given the changes to the offshore component of the project.

6.2.2.1 Informal Scoping Workshop

The consultation with the consultees was carried out in a scoping workshop on the 24th November 2015, in the POEPL (now Navitas) Office, Argos House, Stanley, Falkland Islands.

A basic pre-read document describing the revised offshore development was issued to workshop participants and used in the workshop to identify potential environmental impacts associated with the offshore development.

Workshop participants representing FIG were as follows:

- Department of Mineral Resources (DMR),
- Department[24] of Natural Resources (DNR),
- Environmental Planning Department (EPD)[25],
- Policy Unit[26], and
- Public Works Department (PWD).

The main objectives of the workshop were to:

- Provide consultees with an update on the proposed offshore development,
- Inform consultees of the EIS delivery timeline,
- Provide consultees with an indication of the current EIA scope and content in order to determine:
  - Whether this was in keeping with their expectations with regard to Schedule 4 of the Minerals Ordinance (Section 3.1.7.3.1 and Appendix 2), and
  - What could be considered 'in-scope' and 'out-of-scope' in the EIA in order to comply with the Ordinance.
- Identify potential environmental impacts and risks of concern to the consultees to ensure these are included within the EIS, where appropriate.

6.2.2.1.1 Determination of EIA scope

With regard to meeting the requirements of the Ordinance, it was demonstrated that the EIA methodology (Chapter 8) provides for the assessment of the 'sensitivity of', and 'severity of effect on', all the environmental components listed in Clause 4 (2). However, clarity was sought from the consultees on whether or not SAERI's interpretation of 'Human Population' and 'Tangible Property' was appropriate with regard to the inclusion of social impacts and risks.

The FIG Hydrocarbons Environmental Impact Assessment Guidance Note 2016 (FIG, 2016e) lists the following impacts as unlikely to be relevant within the scope of an EIS:

- Tax revenues,
- Wages / cost of living,
- Threats and opportunities for local businesses,
- Land value / rents, and
- Availability of housing and services / facilities (e.g., hospital and school capacity).

Therefore, with regard to the 'Human Population' and 'Tangible Property' components listed in Clause 4 (2) of the Ordinance, SAERI proposed assessment of the following:

- Human Population:
  - Competition for resources including:
    - Accommodation,
    - Fuel,
    - Freshwater,

[24] Now known as the Directorate of Natural Resources (as at 2023).
[25] Now known as the Environment Department which sits within the new Directorate of Policy, Economy and Corporate Services (as at 2023).
[26] Now known as the Policy Department which sits within the new Directorate of Policy, Economy and Corporate Services (as at 2023).

        - Food,
        - Landfill sites,
        - Port facilities (Stanley Harbour, FIPASS, TDF),
        - Electricity,
        - Sewage facilities, and
        - Space on MoD Airbridge flights.
    - Disruption to other users of the sea:
        - Impact from presence of other vessels,
        - Risk of collision between boats, and
        - Risk of snagging by trawlers.
    - Disturbance to the human population from:
        - Light,
        - Noise,
        - Odour,
        - Visual impact, and
        - Changes to air quality.
- Tangible Property:
    - Port facilities,
    - Fishing industry,
    - Road networks,
    - Airports and airlinks,
    - Waste facilities,
    - Tourism facilities, and
    - Protected sites supporting wildlife and managed tourism.

Therefore, in terms of what is considered 'in-scope' and 'out-of-scope', it was agreed that social impacts, such as those listed above were in-scope, and economic issues e.g., impacts upon revenue and house prices etc. were out-of-scope based on interpretation of the Ordinance and the FIG EIA Guidance Note (FIG, 2016e). In light of this agreement, disruption to other users of the community, with regard to impacts on health services, police services, civic amenities etc. was also considered out-of-scope.

Importantly however, while the EIS was not considered to be the appropriate vehicle for assessing and reporting these issues, the need for awareness, assessment, reporting and mitigation of economic impacts and risks was noted by all at the workshop. As described in Section 6.2.2.1.1, an additional and separate socio-economic impact assessment will be developed.

6.2.3 Informal scoping consultation in 2016

By 2016, inshore ship-to-ship transfer had been selected as the oil export option (Table 6.1 above). Scoping consultations for the whole (then) Phase 1 Development were held between the 15th and 26th August 2016 and were carried out via:

- Workshops / meetings with:
    - FIG departments: DMR, EPD[ibid], PWD, DNR, Policy Unit[ibid] and Harbour Master[27],

[27] The Harbour Master function now sits within the Falkland Islands Maritime Authority (FIMA).

- Members of the Legislative Assembly (MLAs),
- Chamber of Commerce members and Tourist Board,
- Fishing Company representatives (FIFCA) and Fisheries Department (FIFD),
- Falklands Conservation,
- Environmental NGOs including: Shallow Marine Surveys Group and ACAP Co-ordinator (JNCC),
- Other Groups: SAERI and the Offshore Hydrocarbon Environmental Forum (OHEF),
- Public in Stanley, and Camp (Hill Cove, Fox Bay, Goose Green and Lorenzo), and
- Berkeley Sound residents and landowners.

A summary of the key outcomes is provided in Section 6.4 below.

6.2.3.1 Consultation format

During the scoping, statutory stakeholders and interested parties were invited to:

- 'By invitation' sessions which included a presentation by POEPL (now Navitas) on the scope of the project identified to date, followed by a Q&A session,
- Open sessions which were held for all stakeholders, including the public at various locations, both in Stanley and in Camp (both East and West Falkland). This again consisted of a presentation followed by open Q&A sessions, and
- Individual consultations which were offered to landowners and managers whose land is directly adjacent to Berkeley Sound.

Additionally, drop-in sessions were offered to all public, statutory stakeholders and NGO's e.g., RSPB. A follow up session was offered to the fisheries groups (FIFD and FIFCA), which was taken up by FIFCA.

A revised project Pre-Read was distributed to the stakeholders, made available at the sessions and emailed or posted to them directly on request. Notice of the 'Sea Lion EIA Scoping Consultation Sessions' were advertised in the Penguin News along with a dedicated consultation contact number and an email address for queries and comments.

6.2.3.1.1 Commitments resulting from the 2016 scoping

As a result of discussions during the scoping consultation, POEPL (now Navitas) committed to:

- Produce a Socio-economic Impact Assessment (SIA) for consideration by FIG (although it was agreed this EIA / EIS was not an appropriate vehicle for this assessment (Section 6.2.2.1.1)). POEPL (now Navitas) will produce an additional and separate socio-economic impact assessment building on and updating the previous work undertaken for FIG and Rockhopper by Regeneris (2013 & 2015) and Plexus Energy (2012),
- Continued discussions with DMR on offsetting,
- Conducting further work on the effect of Sea Lion crude on fur and feathers, weathering and persistence effects and toxicity. This was planned both pre- and post-submission of the EIS,
- Holding an Environmental Monitoring and Management Programme (EMMP) workshop to determine scope, protocols, methodology, reporting and governance (Chapter 15),
- Holding a Wildlife Response Workshop to determine scope, protocols, methodology, reporting and governance which could further inform the Wildlife Response Plan. This was incorporated into a wider 'Oil Spill on Paper' Workshop held in June 2017 (Premier, 2017e), and

- Sharing the outcomes of the ongoing waste assessment with interested parties (e.g., FIG departments).

6.2.4 Statutory 42-day public consultation in 2018

During 2018, the statutory consultation in support of the revised EIS (Rev B03), was held between 10th January and 9th March. At this time the proposed oil export process involved the inshore ship-to-ship transfer. The public consultation process included face to face briefings to FIG departments, NGOs, the general public and other materials including:

- Project flyers,
- Advertisements placed in Penguin News,
- Posters,
- Maps,
- Computer models of reservoir (subsurface),
- Video (drone footage), sound files and animations,
- Samples of crude and drill cuttings, and
- Radio and TV Interviews.

The range of Consultees included:

- Statutory stakeholders: MLAs, DMR, EPD[ibid], PWD, DNR, Policy Unit[ibid],
- Industry Reps: CoC, FIFCA, RBA, Tourist Board, FIDC, Museum / NT,
- NGO's: FC, SMSG, New Island Trust, ACAP (JNCC),
- Others: FIOHEF, SAERI, Berkeley Sound farm owners, and
- The general public.

Following completion of the formal consultation period on the 9th March 2018, the EIS was finalised. On the 10th April 2018, POEPL (now Navitas) submitted responses to *c.* 300 points raised by 11 parties (Appendix 3).

Key points raised during the consultation phase included the following aspects:

- Reinforcement of the importance of progressing the evaluation / decisions on a direct offtake oil export option (as opposed to the proposed inshore transfer),
- Querying the (contingency) well test flaring volumes,
- Requesting an update the underwater noise assessment as new standards had recently been issued,
- Including an air quality assessment for oil spills,
- Management of artificial light and potential for bird strike,
- How the EMMP will operate,
- Coverage of baseline survey data,
- Interpretation of oil spill impact,
- Additional scientific papers to be included, and
- How social impacts will be addressed (via separate studies - the EIS was compliant).

Overall, a total of 270 representations required a detailed and thoughtful response (Appendix 3).

The additional underwater noise assessment continued past the end of the consultation period and was submitted to FIG at the end of May 2018.

The outcomes of the 2018 statutory consultation were reported in the approved EIS (Rev B03) alongside responses from POEPL. For completeness, these are now presented in Appendix 3.

6.2.4.1.1 Commitments resulting from the 2018 formal consultation.

As a result of discussions during the 2018 consultation, POEPL (now Navitas) committed to:

- Update the project Socio-economic Impact Assessment (SIA),
- Respond to matters raised during Bank Due Diligence,
- Hold an EMMP workshop to determine scope, protocols, methodology, reporting and governance (already committed to in 2016),
- Complete seasonal Berkeley Sound Bird Surveys,
- Complete the ongoing Invasive Species Monitoring Programme, and
- Review and update the project PLANC (Permits, Licences, Authorisations, Notifications and Consents) Registers.

6.2.5 Statutory 42-day public consultation in 2020

During 2019, the oil export process was revised and changed from inshore ship-to-ship transfer in Berkeley Sound to direct offtake from the FPSO to a CTT at the Sea Lion location offshore. As this was a material change, the EIS was resubmitted (Rev B04) and underwent a second statutory consultation period, as required under the Ordinance. This consultation period ran from 2nd January 2020 to 25th February 2020 and followed a similar format to the 2018 consultation described above.

The outcomes of the statutory consultation were reported in the approved EIS (Rev B05) alongside responses from POEPL. For completeness, these are now presented in Appendix 3.

6.3 Navitas informal scoping consultation 2023

Following the acquisition and renaming of POEPL by Navitas in 2022 (Section 2.1.1), the Sea Lion Development underwent a process of review and optimisation which led to a number of changes. As such, it is necessary to undertake an impact assessment reflecting the changes to the project and submit a new EIS. While the proposed "Sea Lion Field Northern Development Area, Phase 1 & 2" is largely smaller than the previous POEPL Phase 1 Development (EIS Rev B05 approved in 2020), it was also necessary to conduct a further scoping consultation to inform stakeholders of the changes to the project, the impacts and risks identified and explore any particular concerns.

This informal scoping consultation was carried out between 4th - 8th December 2023. As in the previous consultations, a Pre-Read document was developed and disseminated to FIG and industry bodies prior to meetings, and to other stakeholders on request.

The informal consultation in 2023 included the interested parties as indicated Table 6.2 above, and was carried out via:

- Organised meetings with FIG Departments - feedback was received following a presentation describing the optimised Development, and
- Presentations with Q&A sessions at open public meetings and focus- group workshops.

Details on the key outcomes are summarised in Section 6.4

6.4 Summary of all informal scoping consultation outcomes

Table 6.3 provides a summary of the key themes that were raised by the consultees during the historical and recent informal scoping consultation processes. An indication of the number of times that the theme was raised, and guidance on where in the EIA the comment has been addressed is

provided. For the socio-economic and economic issues that are out-with the scope of the EIA (see above), reference is made to the relevant documentation.

Of note, Table 6.3 does not include the representations of the historical 42-day *statutory* consultations which, by design, included very detailed and technical questions. Full detail on the historical representations, and the operator responses, are provided in Appendix 3.

The number of consultees met during each *informal* consultation is as follows:

- 2014 - Exploration programme: 63 stakeholders met,
- 2014 – TLP proposal: 124 stakeholders met,
- 2015 – Change from TLP to FPSO: with FIG Departments only - 10 stakeholders met,
- 2016 - All components of current EIS: 130 stakeholders met, and
- 2023 - All components of the optimised Sea Lion Development: 38 stakeholders met.

The key themes highlighted by stakeholders over time were:

- Control of vessels and general management in Berkeley Sound,
- Oil spill mitigations and clean-up,
- Onshore infrastructure,
- Offsetting,
- Decommissioning,
- The impact of this particular type of crude,
- Jobs, employment and numbers of people,
- Standards and governance, and
- The use of MMOs on vessels near and on the Sea Lion field prior to the current EIA to update data on marine mammal and seabird distribution.

Table 6.3: Summary of informal scoping consultation outcomes from 2014, 2015, 2016 and 2023 consultations[1]

Consultation	Theme	Concern / comment	2014	2015	2016	2023	Number of mentions[2]	Pos / Neg[3]	Addressed
2014, 2015 & 2016	Social	The carrying capacity of existing onshore infrastructure	✓	✓	✓		11	Neg	**Section 11.3 Section 11.4 Section 11.5 Section 11.6 Section 11.7**
2014, 2015 & 2016	Social / Environmental	Competition for resources e.g., waste facilities, food, water, power supply, health services, schools, aggregates and rental accommodation	✓	✓	✓		10	Neg	
2014, 2015 & 2016	Environmental	Risk of oil spills	✓	✓	✓		10	Neg	**Chapter 12**
2014, 2015 & 2016 & 2023	Socioeconomic	Local content and employment related challenges, including wage inflation, labour shortages and immigration	✓	✓	✓	✓	11	Neg	**SIA (Section 6.2.2.1.1)**
2014, 2015 & 2016	Economic	Inflation e.g., impacts on food prices and availability, and rising costs for housing	✓	✓	✓		10	Neg	**SIA (Section 6.2.2.1.1)**
2014, 2015 & 2016	Environmental	Mitigation measures and offsetting	✓	✓	✓		9	Neg	Base-case, industry standard and project-specific measures are described in **Chapters 10, 11** and **12.** The offsetting strategy is described in **Section 8.11**
2014, 2015 & 2016 & 2023	Social / Environmental	Competition between sea users, in particular management of Berkeley Sound and exclusion zones, and risk of collision	✓	✓	✓	✓	9	Neg	**Section 11.1 Section 11.2**
2014, 2015 & 2016 & 2023	Social / Environmental	Falklands services may improve, e.g., waste management, flight routes, shipping routes and medevac	✓	✓	✓	✓	9	Pos	**Chapters 10** and **11**

Consultation	Theme	Concern / comment	2014	2015	2016	2023	Number of mentions[2]	Pos / Neg[3]	Addressed
2014 & 2016	Environmental	Standards applied by POEPL and extent of liability, particularly in relation to the CTT	✓		✓		7	Neg	**Section 3.2**
2014, 2015 & 2016 &2023	Socioeconomic	Other general community benefits will be made possible by economy of scale as the population grows, increased investment in the Falkland Islands	✓	✓	✓	✓	8	Pos	**SIA (Section 6.2.2.1.1)**
2014, 2015 & 2016	Environmental	Waste generation and management in the Falkland Islands and offshore	✓	✓	✓		6	Neg	**Section 10.10**
2014 & 2016 & 2023	Environmental	Lack of sufficient environmental data in some fields making effective assessment of impacts difficult	✓		✓	✓	7	Neg	**Section 7.2.4**
2015 & 2016	Environmental	Emissions and discharges	✓		✓		6	Neg	**Section 5.15** **Section 10.7** **Section 10.9**
2014, 2015 & 2016	Environmental	Increased light pollution with particular impact on sensitive bird species both inshore and offshore, and risk of bird strike but also as a nuisance to humans	✓	✓	✓		5	Neg	**Section 10.1** **Section 11.8**
2014, 2015 & 2016 and 2023	Socioeconomic	Job opportunities and training	✓	✓	✓	✓	6	Pos	**SIA (Section 6.2.2.1.1)**
2014 & 2016	Environmental	Disturbance to fisheries spawning grounds and migration routes	✓		✓		4	Neg	**Section 7.4.4**
2014 & 2016	Political	FIG decision and policy making perceived as reactive rather than proactive	✓		✓		4	Neg	Out of scope **(Section 6.2.2.1.1)**

Consultation	Theme	Concern / comment	2014	2015	2016	2023	Number of mentions[2]	Pos / Neg[3]	Addressed
2016	Environmental	Vessel Traffic Management System (VTMS) in Berkeley Sound would benefit everyone[4]			✓		3	Pos	N/A[4]
2014 & 2015	Environmental	Introduction of non-native species and biosecurity issues	✓	✓			3	Neg	**Section 10.12 Section 10.13**
2014, 2015 & 2016	Social / Environmental	Noise pollution affecting sensitive receptors including humans	✓	✓	✓		3	Neg	**Section 11.9**
2014 & 2016	Social / Environmental	Conversion of Stanley Common and impacts on aesthetics, visual impact	✓		✓		3	Neg	**SIA (Section 6.2.2.1.1)**
2014, 2015 & 2016	Social	Effects on the 'Falkland Islands way of life' including increased marginalisation of Camp, the potential for increased social disturbance, crime and prostitution	✓	✓	✓		3	Neg	**SIA (Section 6.2.2.1.1)**
2014	Political	Security issues related to the sovereignty dispute with Argentina	✓				1	Neg	Out of scope **(Section 6.2.2.1.1)**

[1] **Note:** the formal outcomes of the statutory consultations carried out in 2018 and 2020 are not included in this table. All representations are provided in Appendix 3.
[2] The 'Number of mentions' refers to the number of times an issue was raised by a group of consultees, as opposed to the number of individuals who raised it.
[3] Denotes whether the majority of comments received on this topic were considered positive or negative.
[4] Note that inshore transfer is no longer included within the basis of design.

6.5 Navitas statutory 42-day public consultation

Following review by FIG DMR, and confirmation by the Executive Council that the EIS complied with the Schedule 4 of the FIG Offshore Minerals Ordinance, the EIS was formally submitted and underwent formal consultation in July - August 2023.

Following the 42-day consultation, all material representations were provided to Navitas by DMR and recorded within this EIS (Chapter 0). This chapter also contains Navitas' responses and, where necessary, indicates what changes have been made to this post-consultation EIA / EIS in response to the representations made.

7 ENVIRONMENTAL AND SOCIAL BASELINE

Table of Contents

7.1 Introduction 256
7.1.1 Falkland Islands location 256
7.1.2 Sea Lion (offshore) licence location 256
7.1.3 Location of Berkeley Sound in the Falkland Islands 258
7.2 Data Sources 259

7.8.1 Key environmental sensitivities 550
7.8.2 Key social sensitivities 553

7.1 Introduction

Having identified the proposed Sea Lion Field Northern Area Phase 1 & 2 Development (hereafter referred to as the Phase 1 & 2 Development) activities (Chapter 5), it is necessary to understand the local environments in which Navitas will be operating and to identify the main environmental and social sensitivities.

Understanding of the environmental baseline was achieved using desktop studies and literature reviews, collation of existing survey data and execution of additional and site-specific surveys where necessary, in line with:

- Navitas Operating Management System (SEL-REG-OPM-PLN-00001-00).

Given that the production and export of oil will be carried out offshore, and that all the Phase 1 & 2 Development activities will require support from the onshore, inshore (Berkeley Sound) and at-shore bases (Chapter 5), the following chapter describes the offshore, inshore and onshore environments. The limits of 'coastal' and 'inshore waters' are not specifically defined; however, in general 'coastal' is used to describe waters within three nautical miles (nm) of the coastline and 'inshore waters' describes a broader zone out to approximately the limit of the Territorial Sea around the Islands (i.e., 12 nm from the coastline). The chapter concludes with an overall summary of the key environmental and social sensitivities identified in the following baseline description.

This EIS is supported by a number of surveys and reports. These supporting documents can be requested from Navitas at sealion.enviro@navitaspet.com.

Note: while some detail on Stanley Harbour is provided below, the full environmental baseline of Stanley Harbour is provided in the EIS previously submitted to support the construction of the Temporary Dock Facility (NEFL, 2013).

7.1.1 Falkland Islands location

The Falkland Islands are an archipelago in the South Atlantic Ocean that sit on the Patagonian Shelf and have a cold, windy and humid maritime climate. The Islands cover an area of 12,000 km^2 and comprise East Falkland, West Falkland and 776 smaller islands. The principal islands are about 500 km east of South America's southern Patagonian coast, and lie between the latitudes of 52 – 53 °S.

7.1.2 Sea Lion (offshore) licence location

The Sea Lion Field is located in the North Falkland Basin (NFB), approximately 220 km north of the Falkland Islands, 770 km north-east of Cape Horn and 480 km from the nearest point on the South American mainland (Figure 7-1).

The Falkland Islands' Exclusive Economic Zone (EEZ) extends up to 200 nautical miles from the Islands and comprises two fisheries conservation and management zones which were designated in 1986 and 1990, respectively (Figure 7-1). These are:

- The Falkland Islands Interim Conservation and Management Zone (FICZ), and
- The Falklands Outer Conservation Zone (FOCZ).

Oil and gas exploration and production licences are granted within the Falkland Islands Designated Exploration Area, the limits of which are based on the EEZ. The Designated Exploration Area is subdivided into quadrants based on one degree of latitude by one degree of longitude (Figure 7-1), each of which is subdivided into thirty blocks. The Sea Lion Field is located in Quadrant 14, within the northern boundary of the FICZ in Licence Blocks PL032 and PL004b (Figure 7-1). The proposed Phase 1 & 2 Development of the Sea Lion Field is located in Licence Block PL032.

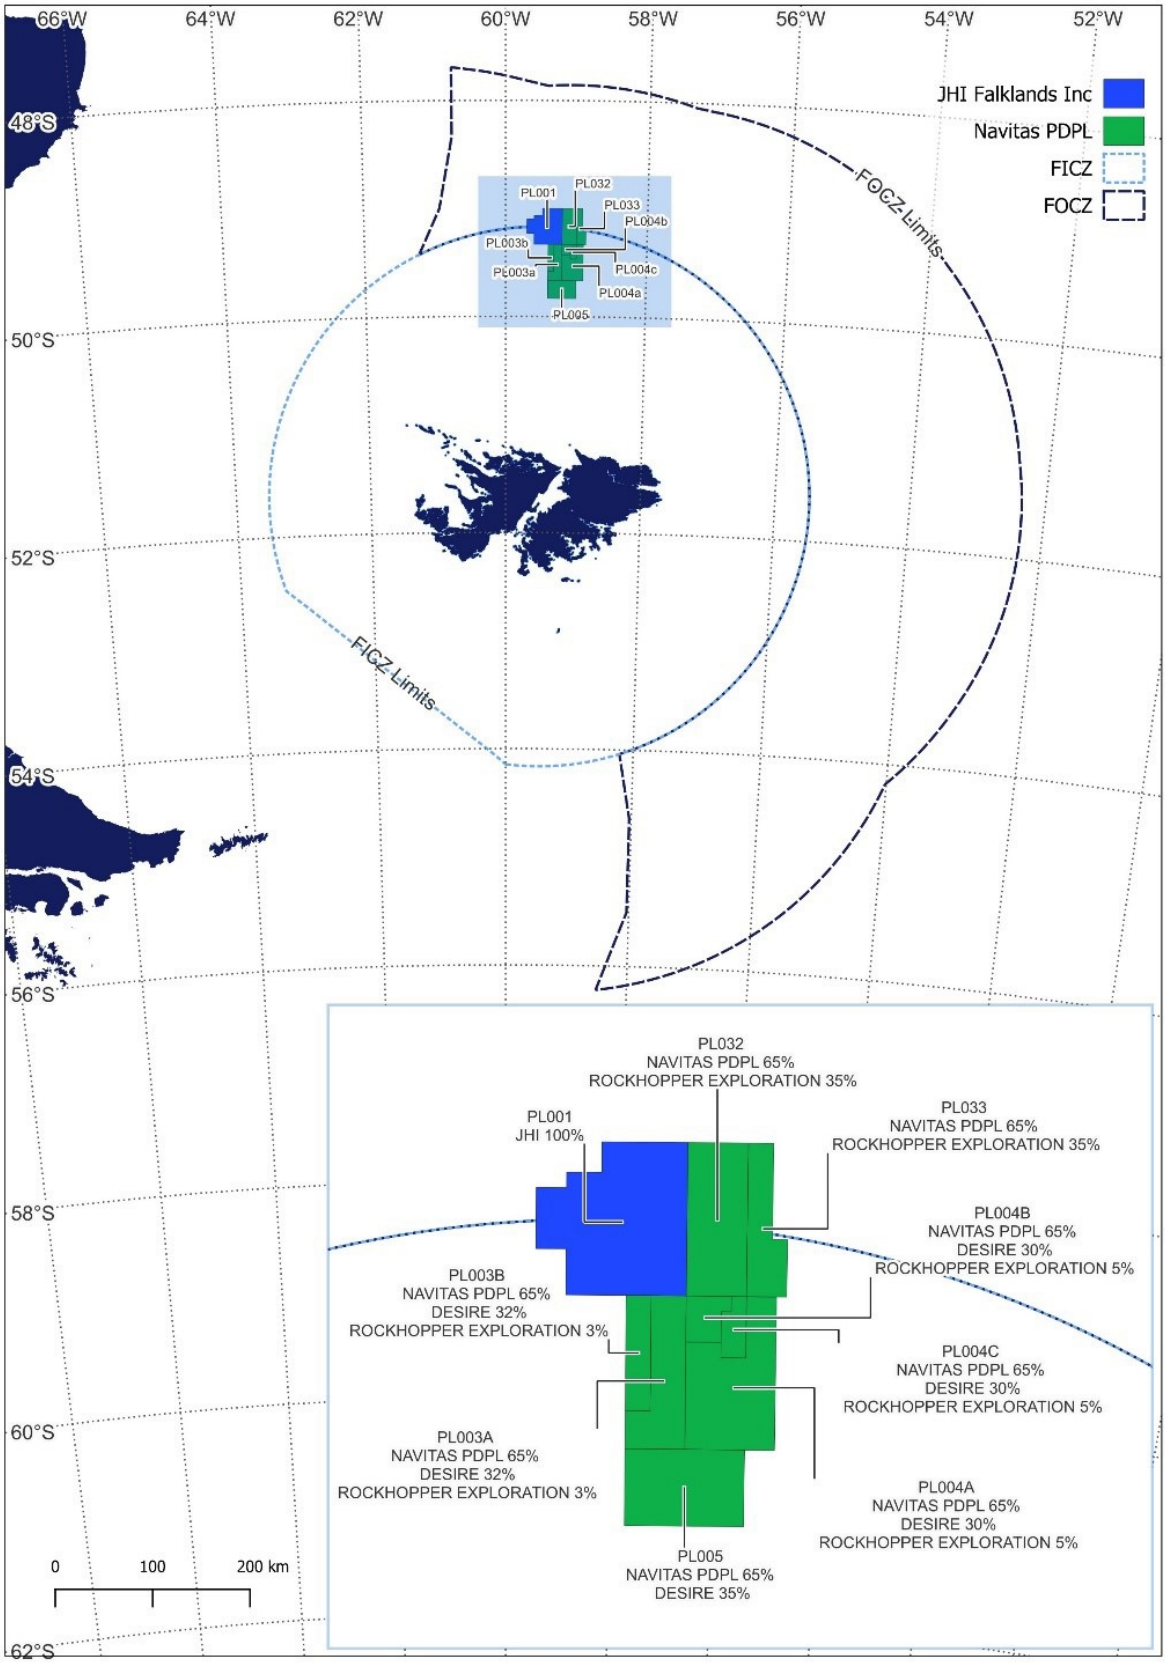

Figure 7-1: Phase 1 & 2 Development drill centre and Licence Block Locations

7.1.3 Location of Berkeley Sound in the Falkland Islands

The sheltered waters of Berkeley Sound have been chosen as the best option for a mobilisation area for the Large Transit Vessels (LTVs) during the construction phase of Phase 1 & 2 Development.

Berkeley Sound is a large east-facing bay in the north-east corner of East Falkland (Figure 7-2) which is approximately 30 km long and 14 km wide at its mouth (Volunteer Point to Mengeary Point; Figure 7-3). The Sound has several smaller bays within it e.g., Port Louis Harbour and Johnson's Harbour, and contains islands such as Cochon and Kidney Islands (National Nature Reserve (NNR)), Hog Island and Long Island. Figure 7-3 provides a map of Berkeley Sound showing all the place names mentioned in this EIS. Due to differences in habitat type and species distribution it is convenient to refer to the 'inner' and 'outer' Sound, with Strike-off Point marking the boundary between the two (Figure 7-3).

Currently, Berkeley Sound's primary use is as a designated locality for the transhipment of fish and bunkering by the Falklands' fishing industry.

7.2 Data Sources

7.2.1 Literature sources

Literature reviews were carried out, where necessary, in order to inform understanding of the local environment. The information and data therefore come from a number of sources including scientific peer reviewed literature, scientific reports, grey literature, data provided directly by a number of organisations, web-distributed data, and data available within the Falkland Islands Data Portal, which collates information from recent surveys and historical sources (http://dataportal.saeri.org/). Where appropriate, personal observations (*pers. obs.*) and personal communications (*pers. comm.*) of learned individuals are referenced throughout the EIS.

In a previous iteration of the Sea Lion project (under POEPL, Section 2.1.1), inshore oil transfer was considered in Berkeley Sound. To aid the decision-making process concerning the choice of the most appropriate inshore transfer site in particular, POEPL commissioned the production of the report 'Environmental Assessment of Potential Inshore Transfer Sites,' (Premier[28], 2015c). This document was one of the primary sources of information used to inform the environmental baseline of Berkeley Sound and surrounding areas described below. Of importance, this inshore transfer concept has been rejected in place of direct offtake at the offshore location, but Berkeley Sound will still be used as an area of mobilisation and support for the construction of Phase 1 & 2. The data gathered is referenced where applicable.

7.2.2 Sea Lion environmental surveys

POEPL and its partner, Rockhopper Exploration, conducted an area-wide environmental baseline survey of the Sea Lion Field in 2012 to determine the physical, chemical and biological characteristics of the environment in support of future development of the area. In addition to the area-wide survey, specific well site surveys comprising six to eight stations each were conducted for five historic well sites drilled in Quadrant 14 of the Sea Lion Field.

Several other environmental surveys have been conducted in the vicinity of the Sea Lion Field and further afield within Falklands waters, which provide background and contextual data for comparison with the Sea Lion area. Table 7.1 provides a summary of all survey and drilling activities conducted in the Falkland Islands waters to date. Figure 7-4 and Figure 7-5 show the location of the 2012 Sea Lion environmental baseline and post-drilling survey locations, and the majority of the other environmental survey sites within Falklands waters. Survey data from the four gridded stations around the project location are shown in Figure 7-6.

Table 7.1: Summary of Falkland Islands drilling and environmental survey activities

Year	Activity - Survey / Drilling	Region	Operator/Reference
1998	Environmental baseline survey – pre-drilling 'Little Blue' 14/09, 'B1' 14/05, Well 14/14, Well 14/23,	NFB	FOSA[1], Gardline, 1998a-h

[28] Please note that while Navitas has acquired POEPL and all intellectual property therein, historical surveys and reports carried out by POEPL are still referenced as 'Premier, XXXX').

Year	Activity - Survey / Drilling	Region	Operator/Reference
	'Braela' 14/24, Well 14/19a, 'Minke' 14/13-B, and 'Galapagos' 14/09.		
1998	Drilling campaign – 6 wells	NFB	FOSA
1998	Post-drilling environmental survey – 1 well site 'Little Blue' (14/09)	NFB	FOSA, Gardline, 1998h
2008	Regional environmental baseline survey – pre-drilling. SFB: Quadrants 61 and 62. Southern NFB: Quadrants 25 and 26.	SFB, southern NFB	Desire Petroleum Plc., Benthic Solutions Ltd. (BSL, 2008a & b)
2009	Environmental baseline survey four proposed well sites – EFB: Endeavour (31/13), Loligo (42/02), Nimrod (41/29), SFB: Toroa (61/05)	EPB, SFB	BHP Billiton, Fugro Survey (Fugro, 2009)
2010-2011	Drilling campaign – 16 wells Drilling – 1 well	NFB FPB	Rockhopper, Desire BHP Billiton
2011	Environmental baseline surveys five proposed well sites – Hero (31/18), Inflexible (60/15), Loligo NW (42/02), Scotia East (31/13), Vinson West (53/16	EPB, SFB	FOGL, Gardline Survey 2012
2012	Drilling campaign 2 wells Drilling campaign 2 wells	SFB EPB	Borders and Southern FOGL
2012	Sea Lion Pre-development area wide survey, Sea Lion Post-drilling environmental survey – 5 historic well sites	NFB	Rockhopper, Gardline, 2013a & b
2014	Coastal sensitivity to oil spill survey	NFB	Premier plc
2015	Drilling campaign 4 wells	NFB	Premier plc, MG3, 2015

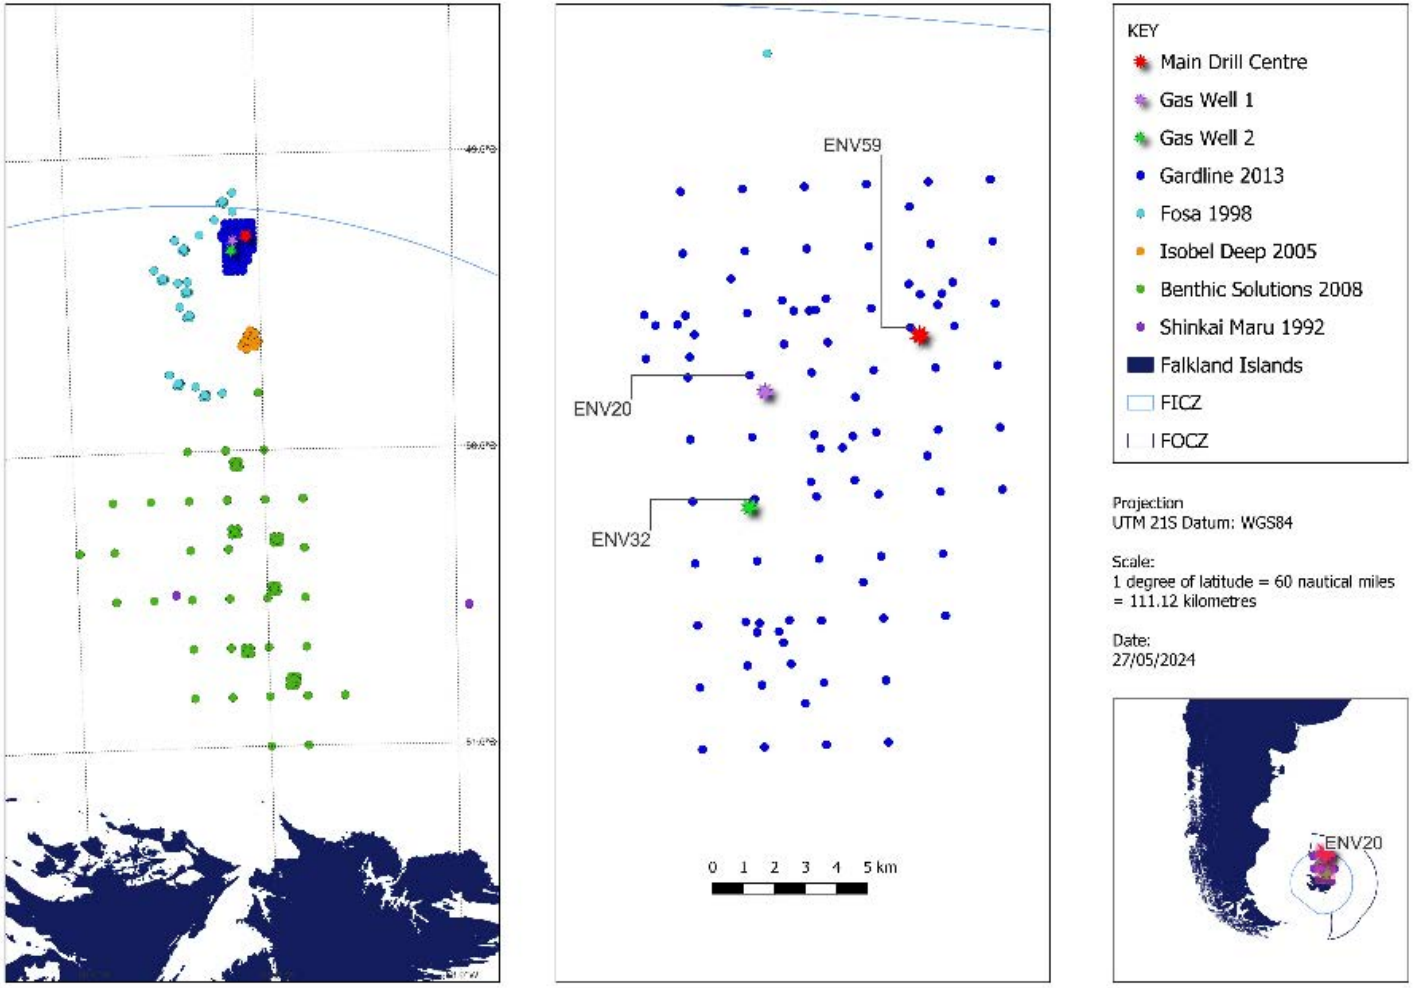

Figure 7-5: Environmental survey locations in the North Falkland Basin and vicinity of the Phase 1 & 2 Development drill centre

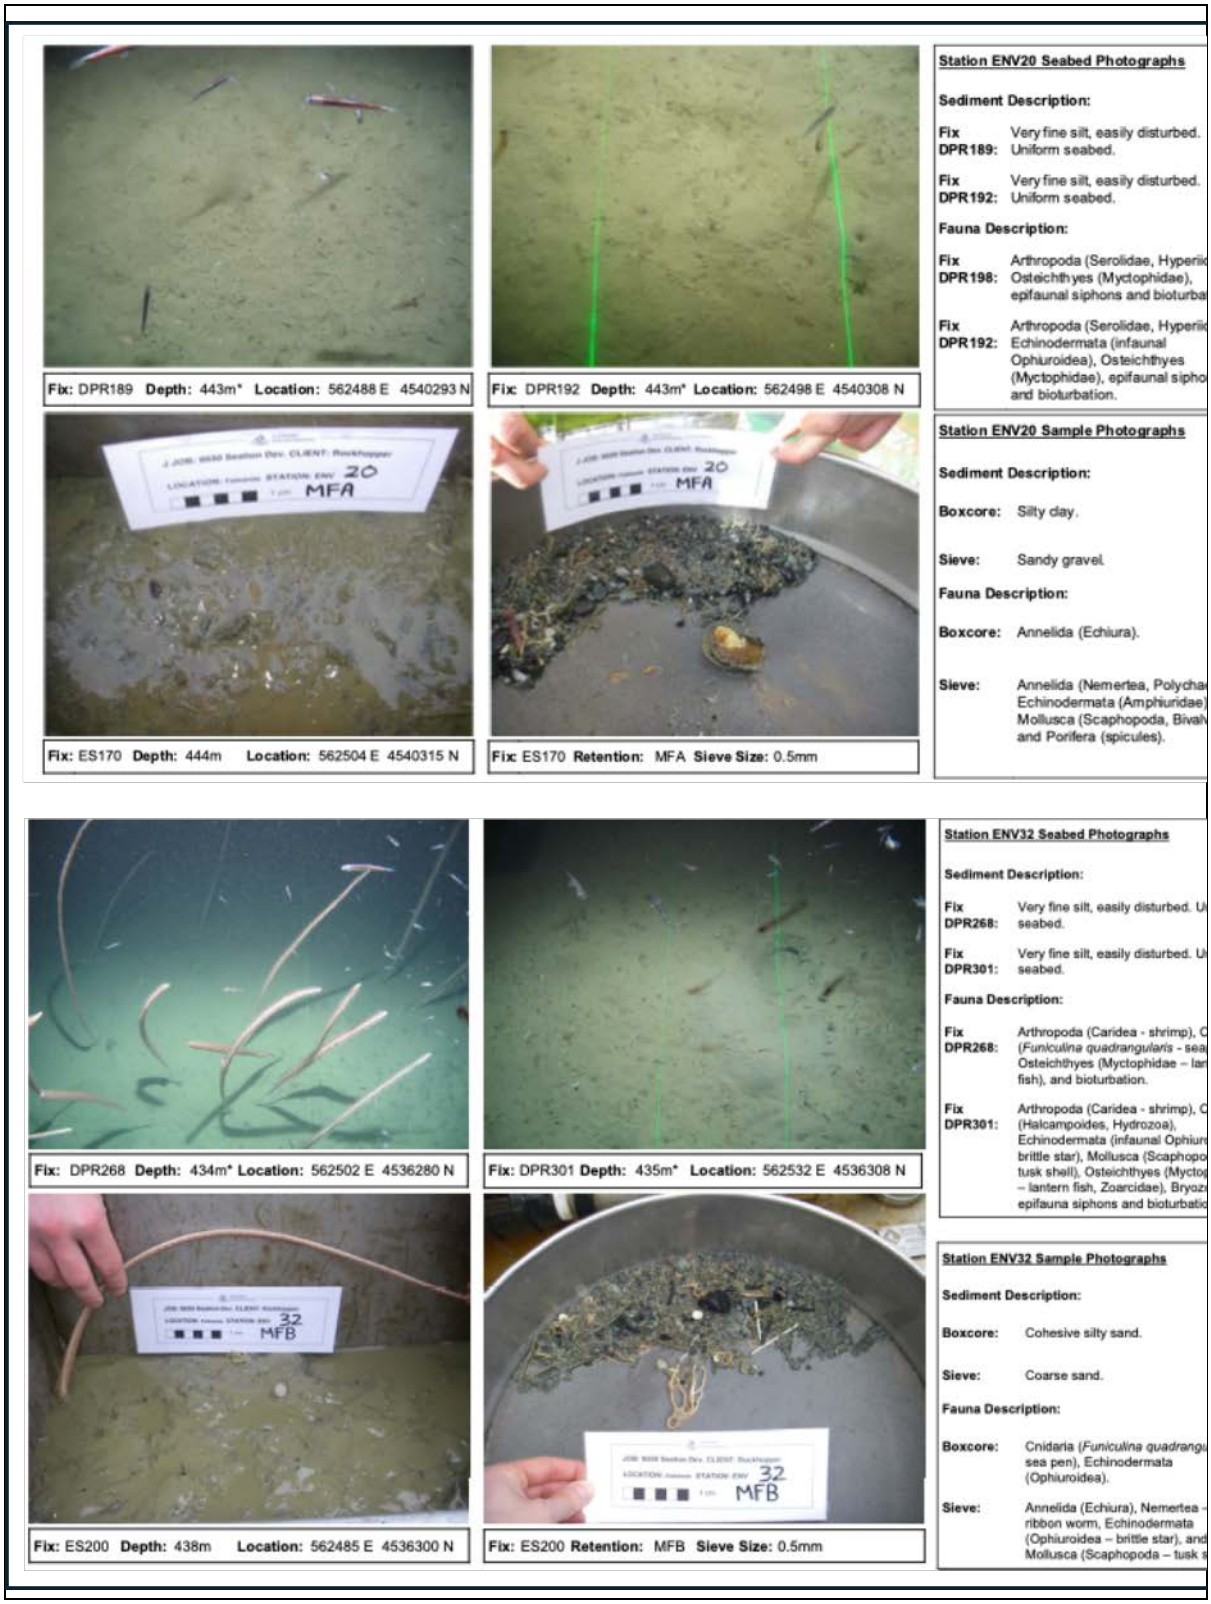

Figure 7-6: Environmental survey information in the vicinity of the Phase 1 & 2 Development drill centre. Note ENV59 is not shown however the area contained anenomes and holothurians on silty brown clay

7.2.3 Berkeley Sound environmental surveys

Several environmental surveys have been conducted in the vicinity of Berkeley Sound (described in this document) which provide background and contextual data for comparison with the Berkeley Sound area. The following provides a summary of the surveys which are referred to throughout the baseline.

7.2.3.1 Shallow Marine Surveys Group (SMSG)

In the mid-1990s, inshore surveys were conducted around the Falkland Islands over a three month period and resulted in the production of 'The first shallow marine survey around the Falkland Islands' (Tingley, *et al.,* 1996). Although the first surveys of their kind in the Falklands, the study lacked a seasonal component and the identification of specimens was not always achieved to species level. In 2006, the Shallow Marine Surveys Group (SMSG) was established in the Falklands. The SMSG conduct regular dive surveys and have greatly advanced the understanding of the sub-tidal shallow water environment of the Islands (Neely, *et al.,* 2010a; Neely, 2010). Combined, this data will go towards improving the classification of marine habitats around the Falkland Islands.

7.2.3.2 Marine Spatial Planning (MSP)

Marine Spatial Planning (MSP) work has been ongoing for a number of years, including the development of a network of Marine Management Areas (MMAs), aligned to international criteria for Marine Protected Areas (MPAs). Following workshops in 2016, and public consultation in 2022, the Falkland Islands Government (FIG) have considered proposals for two offshore MMAs (the Burdwood Bank and Beauchêne Island) and an inshore MMA covering the inshore waters of the Falklands. Following consultation, FIG are now developing a detailed MMA policy for designation and management plans, the main priorities for the MMA Policy in the Falkland Islands are:

- To provide tools and protocols for streamlining the EIA process,
- To help manage shipping and boating,
- To facilitate emergency responses and safety protocols,
- To protect ecologically important areas, and
- To prevent introduction of marine invasive species (biosecurity).

This work is ongoing but has already facilitated the collation of many disparate sources of information, which can be analysed and displayed using Geographic Information System software. This information will be a valuable tool for future management of activities in the marine environment.

7.2.3.3 Operator commissioned environmental surveys

7.2.3.3.1 Habitat assessments of Berkeley Sound

In 2014, POEPL commissioned the South Atlantic Environmental Research Institute (SAERI), along with Environment Systems (EnvSys), to conduct habitat assessments of three potential inshore transfer sites (including Berkeley Sound) on the east coast of East Falkland (Premier, 2015c). This included an assessment of the sensitivity of the coastline, which utilised satellite imagery.

7.2.3.3.2 Geophysical and environmental surveys.

In 2015, POEPL commissioned Benthic Solutions Ltd. (BSL) to conduct an environmental baseline survey of Berkeley Sound. The survey strategy included geophysical and environmental surveys and aimed to determine the geophysical characteristics, sediment chemistry, infaunal communities and macro-faunal assemblages (through sonar, grab and drop down camera surveys) (BSL, 2015a; 2015b & 2015c).

The survey was carried out between June and August 2015 aboard the chartered vessel, *Afon Alaw*. Further details can be found in:

- BSL, 2015a: Geophysical and Environmental Programme Berkeley Sound; 1506 Volume 3: Geophysical survey,
- BSL, 2015b: Geophysical and Environmental Programme Berkeley Sound; 1506 Volume 4: Habitat Assessment Report, and
- BSL, 2015c: Geophysical and Environmental Programme Berkeley Sound; 1506 Volume 5: Environmental Baseline Survey Report.

In 2016, SAERI were commissioned by POEPL to complete the baseline survey programme and worked with the SMSG and EnvSys to map the shallow marine, intertidal and terrestrial habitats found within Berkeley Sound (SAERI and SMSG, 2016).

7.2.3.3.3 Coastal bird survey

POEPL commissioned SAERI to conduct a series of four seasonal coastal bird surveys in and around Berkeley Sound, which were carried out between February 2016 to May 2019. In the course of these surveys, the opportunity was taken to develop an initial shoreline classification index specific to the Falkland Islands for use in oil spill planning.

7.2.3.4 Third-party surveys

Numerous surveys carried out by other parties are used as data sources to inform the assessment of the environmental baseline. These include, for example, those carried out by the Joint Nature Conservation Committee, Falklands Conservation, SMSG, SAERI, SAERI (Falklands) Ltd, and dedicated surveys carried out by other Oil and Gas (O&G) operators or other private or public sector organisations, in support of various proposed coastal and marine operations that required surveys, EIAs, or similar reports. These are described, as necessary, in the relevant sections below.

7.2.4 Data gaps

The Falkland Islands Offshore Hydrocarbons Environmental Forum (FIOHEF) was established in 2011 to facilitate discussion of environmental issues relating to current and future hydrocarbon activities in the Falkland Islands. FIOHEF established a subcommittee, the Gap Analyses Group, to examine the data gaps that needed to be addressed in order to better inform and monitor the potential environmental impacts from offshore hydrocarbon activities operating in the Falkland Islands.

Data gaps were identified and prioritised according to the urgency with which it was perceived that the data was required. Gaps of most relevance to the Development include:

- Offshore benthic ecosystems with regard to collation of data, infauna sampling, sedimentology and chemistry,
- Oceanography in relation to oil spill modelling with regard to hydrographic dynamics, temporal and water column dynamics,
- Seabirds with regard to priority species and temporal movements, and
- Marine mammals (pinnipeds and cetaceans) with regard to populations and breeding activity, spatial and temporal distributions (described further in Section 7.4.6).

Much of these data will take a number of years to collect and assimilate, and this is ongoing through various research projects which are not directly associated with O&G activity. There has however, been significant progress in many areas, e.g., oceanography, offshore benthos and marine mammal distribution. In this EIS, best available data has been used for the assessments including outputs from the GAP Project and parallel studies related to its recommendations.

7.2.4.1 Key data gaps relevant to Sea Lion EIA

The GAP project is complete with most results available (Blockley, *et al.,* 2020), and it is considered necessary to acknowledge the outstanding and project-specific data gaps that have been identified during the Sea Lion EIA process. Note that most of the below were out of the scope of the GAP project.

The remaining key data gaps of relevance to the Sea Lion EIA, and associated actions, are:

- General
  - Predicting the likelihood of introducing invasive species:
    - Settlement plates will be positioned in Berkeley Sound prior to and during the construction phase of the project. Settlement plates will also be positioned at the Temporary Dock Facility / Stanley Harbour for sampling throughout the duration of the project. In the event that a new marine invasive species is discovered, a pathway analysis will be conducted to attempt to determine where / how the species had been brought into the Islands. Marine invasive species will be confirmed using genetic barcoding (see Section 15.6).
  - Auditory sensitivity of penguins and marine mammals:
    - The specific experimental measurement of the auditory sensitivity of penguins and marine mammals is outwith Navitas' responsibility. However, Navitas is committed to the measurement of underwater noise levels *via* hydrophones as a monitoring exercise (see Section 15.6).
  - Quantifying the impact of bird strikes:
    - Navitas is committed to collecting data on bird-strike on all its vessels. Navitas will also investigate the use of alternative spectrum lighting on the FPSO and vessels operating in the field (see Section 15.6).
  - Impact of long-term noise and actual noise outputs from the operations:
    - Navitas is committed to the measurement of underwater noise levels *via* hydrophones as a monitoring exercise (see Section 15.6).
  - Impact of Sea Lion crude on pinniped fur:
    - Investigation of Sea Lion crude impacts on seal fur will be conducted prior to drilling commencing.
- Offshore environment (NFB and Sea Lion Field):
  - Inter-annual distribution and abundance of marine mammals in the NFB,
  - Seabird distribution and abundance,
  - Seasonal abundance of fish and squid in the deeper areas of the Northern Slope (NS), and
  - Benthic habitats and fauna at the Sea Lion drill centre and flowline locations specifically.
- Inshore environment (Berkeley Sound):
  - Location(s) of Loligo (*Doryteuthis gahi*) spawning grounds (this work has been progressed through the GAP project and other projects, but the delineation of the spawning grounds remains a gap in knowledge. However, survey data shows that Loligo do lay their egg clusters on hard surfaced down to approximately 80 m),
  - Inter-annual distribution and abundance of marine mammals, and

- Given the limited operations in Berkeley Sound, the distribution and abundance of Loligo inshore *and* the Inter-annual distribution and abundance of marine mammals will not be specifically investigated by Navitas.

7.2.4.2 Gap Analysis Programme (GAP)

The remit of the Falkland Islands Oil and Hydrocarbons Environmental Forum (FIOHEF) Gap Analyses Group was to examine the data gaps that need to be filled in order to better inform and monitor the potential impacts to the environment from offshore hydrocarbon activities in the Falkland Islands. As a result, the Gap Analyses Programme (GAP) was established by the FIOHEF and led by the Director of SAERI. GAP was supported by two project officers, one of whom co-ordinated the seabird and marine mammal aspects of the work and the other the review, consolidation and curation of oceanic, benthic, inshore and fisheries related data. International researchers were, and continue to be, engaged in this process through workshops and collaborative peer review so the work has international standing and transparency.

7.2.4.2.1 Seabird and marine mammal telemetry

Data gaps were identified for each of the issues of concern and prioritised according to the urgency with which data are required. These data will ultimately be used to inform robust environmental impact and risk assessments for proposed operations associated with the Oil & Gas (O&G) industry. Data collection and analyses are now complete as set out by GAPII objectives. However, it will take further analysis to determine how the results of this work can best be used to quantitatively assess the potential impact of the O&G industry in the Falkland Islands. Examples include quantitative assessments of the overlap of higher predator distribution and oil spill fate modelling for example. So, in the short-term, and until further data analysis is available, existing data will be collated and used to perform assessments through expert-led processes.

At the time of compiling this Environmental Baseline Description, initial analysis of data collected by the GAP project has been published by Baylis, *et al.* (2019a & b; 2021).

7.2.4.2.2 Consolidation and curation of existing data

The hydrocarbons industry and other organisations have collected large amounts of information over the last twenty-five years whilst operating in the Falkland Islands, including data from oceanographic, metocean, seismic, benthic ecology, benthic environmental, multi-beam and Remotely Operated Vehicle (ROV) surveys. Much of these data are held at different locations and the fate / location of some remains unknown. One of the objectives of the GAP project was to create and manage a centralised data repository to hold, manage and curate environmental data collected by the Hydrocarbons Industry and other organisations in the Falkland Islands. Collation of all of the relevant environmental data in the IMS-GIS Data Centre (now called EDS, Environmental Data Service) and the Falkland Islands Data Portal have and will continue to:

- Provide wide spatial and temporal coverage for future EIAs,
- Avoid duplication of work effort,
- Increase the likelihood that these data will be used for future research activities and initiatives that could complement and enhance future EIAs, and
- Increase environmental knowledge of the Falkland Islands continental shelf and slope.

7.3 Physical Environment

The following sections provide data on the physical environment within which the Phase 1 & 2 Development is to be carried out which will be used to inform the impact and risk assessments in Chapters 10, 11 and 12.

7.3.1 Global atmosphere

7.3.1.1 Atmospheric structure

Earth's atmosphere is ultimately very thin when compared to the size of the Earth and is the equivalent in thickness to a piece of paper laid over a beach ball. Nonetheless, atmospheric processes are closely linked to oceanic processes, and together these systems are responsible for keeping Earth habitable for humans where those combined processes are manifested as changing weather (Open University, 2004).

The atmosphere is divided into five main layers, becoming thinner in each consecutive layer until the gases dissipate in space. While there is no distinct boundary between the atmosphere and space, an imaginary line about 110 km from the surface, called the Kármán line, is generally accepted to be the point at which the atmosphere meets outer space (Sharp and Dobrijevic, 2023). Of the five atmospheric layers, (Sharp and Dobrijevic, 2023), the two lowest layers are of relevance to this EIA:

- The troposphere is the layer closest to Earth's surface. It is approximately 8 – 14.5 km in height and contains half of Earth's atmospheric gases (Figure 7-7), and
- The stratosphere starts above the troposphere and ends about 50 km above ground level. Ozone is abundant here and the 'ozone Layer' plays a key role in maintaining atmospheric temperature while also absorbing harmful radiation from the sun (Figure 7-7).

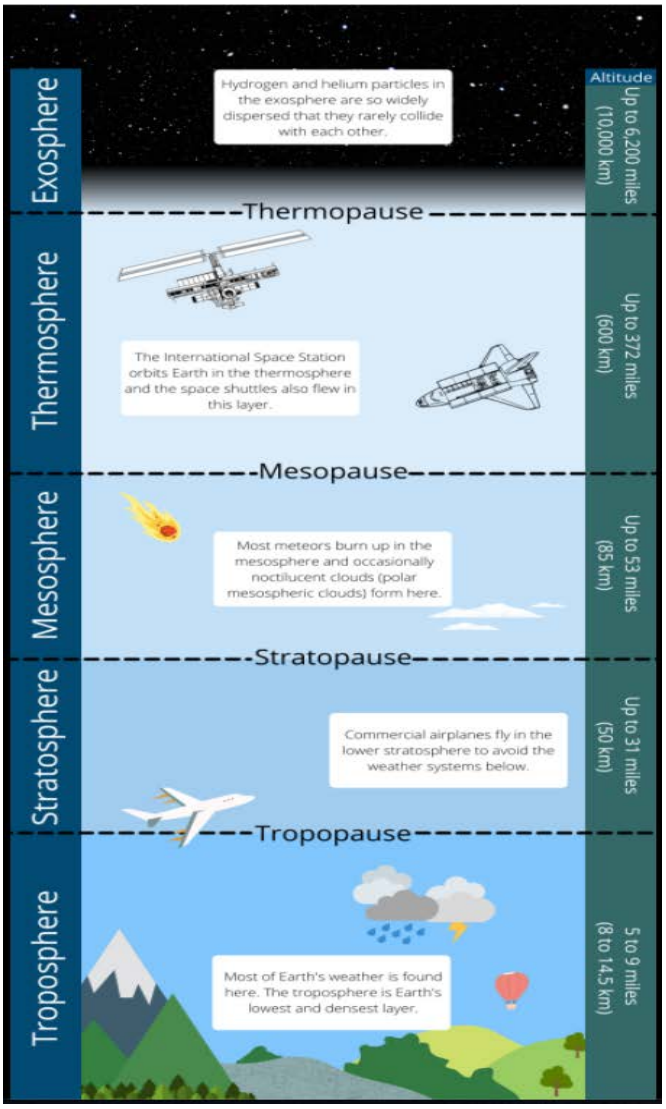

Figure 7-7: Atmospheric structure ***(Source: Tim Sharp, Daisy Dobrijevic last updated July 23, 2023, https://www.space.com/17683-earth-atmosphere.html)***

7.3.1.2 Atmospheric composition

The atmosphere contains many gases, most of which are in small amounts, and water vapour. The permanent gases whose percentage contributions do not change from day to day are nitrogen, oxygen and argon. Nitrogen accounts for 78 % of the atmosphere, oxygen 21 % and argon 0.9 % (Figure 7-8). Trace gases account for about a tenth of one percent of the atmosphere, which includes carbon dioxide, nitrous oxides, methane, and ozone; collectively termed Greenhouse Gases (GHG) and the inert gases neon and helium (Figure 7-8).

GHGs have physical and chemical properties which make them interact with solar radiation and the heat given off from the Earth to affect the energy balance of the globe (Hansen, *et al.,* 2005). The Earth's long-term, globally-averaged equilibrium temperature depends on the balance between the level of incoming solar energy from the sun, and the outgoing radiated heat which has been reflected or emitted from the Earth's atmosphere and the surface of the Earth. Of all the atmospheric gases, the trace GHGs have sufficient thermal absorption to capture energy from the sun and effectively trap heat within the Earth's atmosphere by a natural process known as the 'greenhouse effect'.

The percentage contribution of GHGs varies daily, seasonally, and annually however, and is directly impacted by anthropogenic GHG emissions.

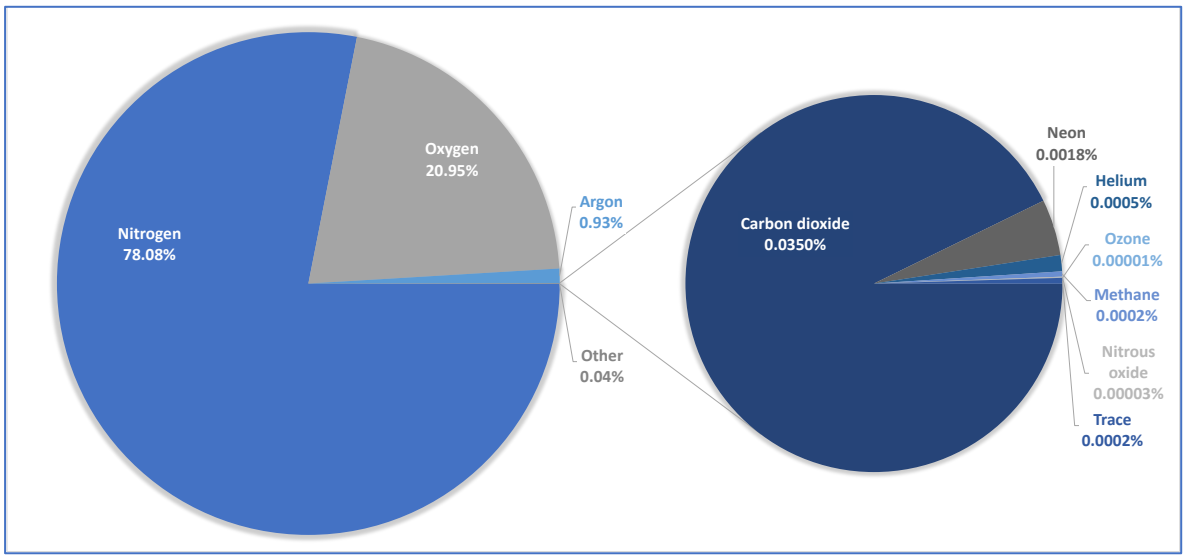

Figure 7-8: Atmospheric composition ***(Source: https://www.noaa.gov/jetstream/atmosphere. Last updated July 28, 2023)***

7.3.2 Meteorology of the Falkland Islands

7.3.2.1 General conditions in the Falkland Islands

7.3.2.1.1 Wind speed

The oceanic climate of the Falkland Islands is temperate, with predominantly west-north-westerly winds (SAERI unpublished weather station data. 14/02/2020 to 16/08/2023). In general, the weather in the NFB is much less extreme than the area south of 50°S, with less frequent storms and squalls (RPS Energy, 2009).

7.3.2.1.2 Temperature

The Falkland Islands have a cold temperate climate with a mean annual temperature of 7.2 °C (max: 23.8 °C, min: -5.1 °C) in Stanley (SAERI unpublished weather station data (14/02/2020 to 16/08/2023)). The range of mean temperatures does not vary substantially over the course of the year, with a summer mean of 10.5 °C and 3.5 °C in the winter, however, variability of the air temperature over the sea is always much less extreme than over land.

7.3.2.1.3 Precipitation

The mean annual rainfall in Stanley is approximately 285.6 mm (SAERI unpublished weather station data, 14/02/2020 to 16/08/2023). Given the rainfall patterns on the Islands, it is expected that the mean annual rainfall within the NFB will be less than this. Snow falls, on average, 11 days of each year, with the highest frequency occurring in August.

7.3.2.1.4 Visibility

Dense fog, reducing visibility to less than 1 km is likely to occur for approximately 3 % of the year in offshore Falkland Islands (Anatec, 2024b).

7.3.2.2 Inshore (east coast) metocean conditions

Understanding the meteorology of the east coast of the Falkland Islands, and Berkeley Sound in particular, is highly important as the weather conditions throughout the year may have an impact on

inshore activities, such as the operation of LTVs and small support vessels. This impact may be from extreme winds or reduced visibility during foggy conditions.

Weather data has been collected elsewhere on East Falkland for a number of years and is summarised below as a proxy for the conditions experienced in Berkeley Sound. The nearest source of weather statistics is Mount Pleasant International Airport (MPN) which is approximately 50 km south-west of Berkeley Sound. Metocean studies for the Sea Lion Field compared measured wind data from MPN, Pebble Island and Stanley Airport. These measured datasets were also compared with output from the regional model covering the Sea Lion location (Climate Forecast System Re-analysis data) and a higher resolution model covering the land and inshore area of the Falkland Islands (Weather Research and Forecasting). Measured wind data available from two MODUs (Borgny Dolphin for 1998 and Eirik Raude for short periods in 2015 and 2016) were also used. Comparisons of the various datasets (measured and modelled) showed good correlation in wind climate and offshore the model is considered to be reasonably representative of offshore conditions. Comparison of the various data sets is described in further detail in the Environmental Modelling Report (Premier, 2017c).

No site-specific measured data is available for Berkeley Sound, although an Automatic Weather Station and Directional Waverider wave buoy were positioned within Berkeley Sound. An analysis of the wave measurements for the period July 2016 to January 2107 indicate that conditions within Berkeley Sound are more benign than the equivalent monthly averages based on modelled data alone, although further data is required to substantiate this.

Two-dimensional gridded atmospheric data, including wind speed and direction, are also available from sources such as the Climate Forecast System Reanalysis project and the European Climate Model.

The following sections describe the wind speed and direction, air temperature and precipitation recorded at MPN over the period 1999 to 2023. This uses data from the Weatherspark data system based on a statistical analysis of historical hourly weather reports from Mount Pleasant Airport and model reconstructions from 1 January 1980 to 31 December 2023.

7.3.2.2.1 Wind speed and direction recorded at MPN

As is shown in Figure 7-9, over the course of the year as recorded at MPN, typical wind speeds vary from 4 m/s to 12 m/s. MPN experiences mild seasonal variation over the course of the year. The windier part of the year lasts for 1.9 months, from July 24 to September 22, with average wind speeds of more than 7.9 m/s. The windiest month of the year is August, with an average hourly wind speed of 8.1 m/s. The calmer time of year lasts for 10 months, from September 22 to July 24. The calmest month of the year is May, with an average hourly wind speed of 7.6 m/s.

As is shown in Figure 7-10 the westerly winds are most common (*c.* 30 % of the time) followed by north winds (*c.* 10 % of the time), north-westerly winds (*c.* 10 % of the time) and then south-westerly winds (*c.* 10 % of the time). South-easterly winds are the least common, occurring only 5 % of the time (Figure 7-10).

Overall, westerly winds are the most likely to occur on the east coast of the Falkland Islands (Figure 7-10).

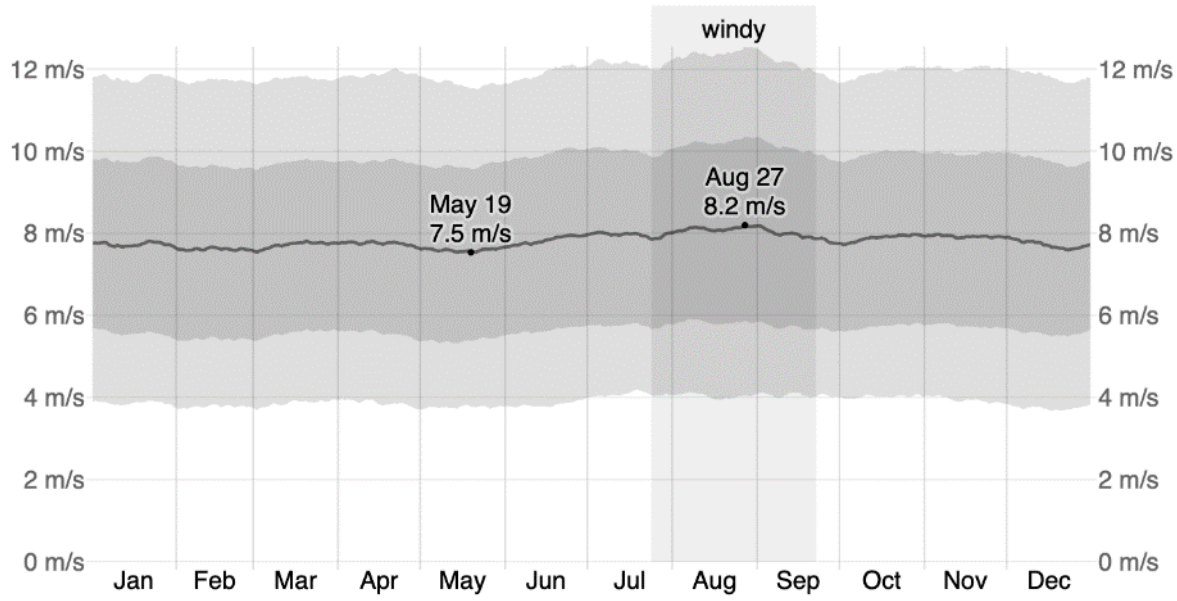

Figure 7-9: The average of mean hourly wind speeds at 10m above ground (dark gray line), with 25th to 75th and 10th to 90th percentile bands ***(Source: Weatherspark, 2023)***

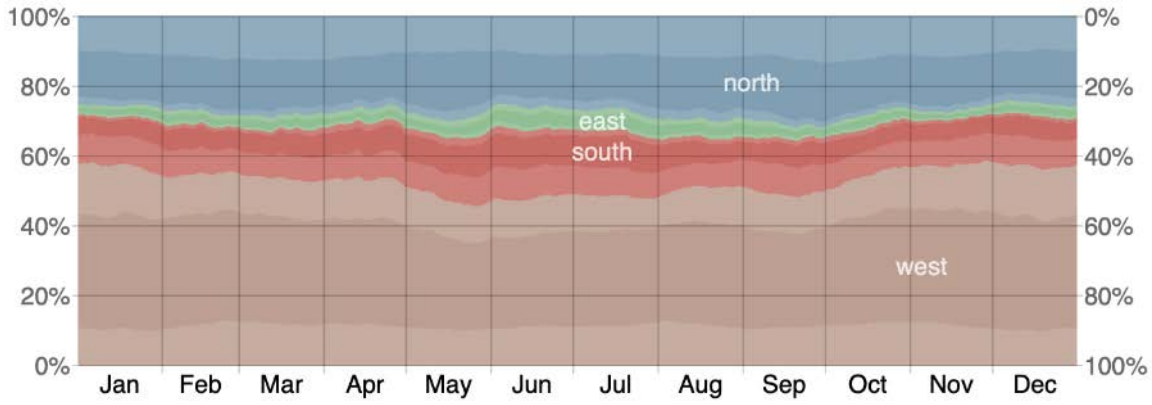

Figure 7-10: The percentage of hours in which the mean wind direction is from each of the four cardinal wind directions, excluding hours in which the mean wind speed is less than 0.4 m/s. The lightly tinted areas at the boundaries are the percentage of hours spent in the implied intermediate directions (north-east, south-east, south-west, and north-west) ***(Source: Weatherspark, 2023)***

7.3.2.2.2 Temperature recorded at MPN

As is shown in Figure 7-11, over the course of a year, the temperature typically varies from 1°C to 15°C and is rarely below -3°C or above 20°C at MPN.

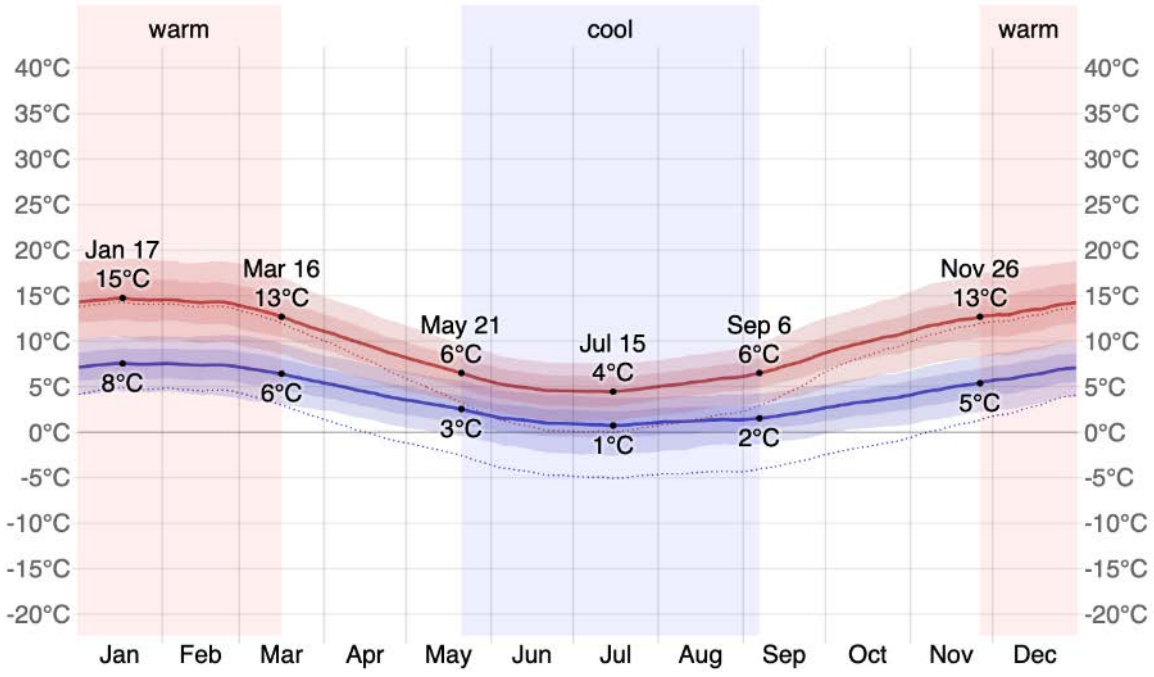

Figure 7-11: The daily average high (red line) and low (blue line) temperature, with 25th to 75th and 10th to 90th percentile bands. The thin dotted lines are the corresponding average perceived temperatures at MPN ***(Source: Weatherspark, 2023)***

7.3.2.2.3 Precipitation recorded at MPN

As is shown in Figure 7-12, rain falls throughout the year at MPN. The month with the most rain at MPN is January, with an average rainfall of 40 millimeters. The month with the least rain at MPN is October, with an average rainfall of 20 millimeters.

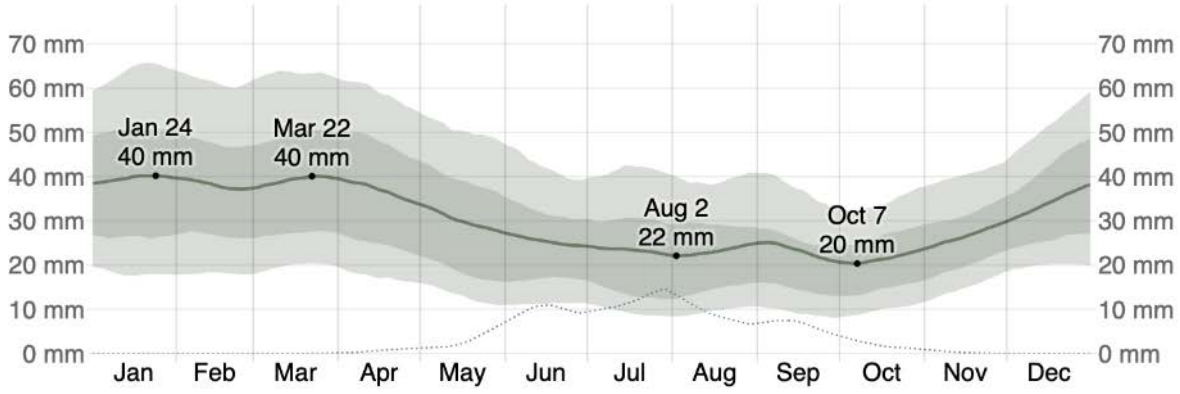

Figure 7-12: The average rainfall (solid line) accumulated over the course of a sliding 31-day period centered on the day in question, with 25th to 75th and 10th to 90th percentile bands. The thin dotted line is the corresponding average snowfall at MPN ***(Source: Weatherspark, 2023)***

7.3.3 Oceanography of the region

It is essential to understand the behaviour of the oceanographic features of the south-west Atlantic owing to their influence on the potential impacts of anthropogenic inputs e.g., how discharges will behave, and also because the biological productivity of the area is a primary factor in the distribution and abundance of all the biological receptors considered hereafter. The following provides a summary

of the key oceanographic features on the Patagonian shelf, which influences the NFB which then influences the Sea Lion Field.

7.3.3.1 Main oceanographic features on the Patagonian Shelf

The Patagonian Shelf is one of the most productive areas in the South Atlantic. Two marine ecosystems, the southern temperate ecosystem and sub-Antarctic ecosystem are separated by a transition zone running from the south-west to the north-east of the Patagonian Shelf through the Falkland Islands archipelago (Boltovskoy, 2000).

The productivity of the Patagonian Shelf is enhanced by the existence of several year-round tidal mixing fronts and seasonal fronts originating from cold freshwater inflows from the Strait of Magellan (Belkin, *et al.,* 2009; Alemany *et al.,* 2009). On the eastern flank, the Patagonian Shelf edge is framed by the Falkland / Malvinas Current Front (FMCF, Belkin, *et al.,* 2009), which runs along the continental slope from 55ºS to 37ºS and comprises multiple smaller fronts running parallel to the shelf break (Franco, *et al.,* 2008). The main oceanographic feature of this front is the cold Falkland Current, which originates from the Antarctic Circumpolar Current (ACC) in the Drake Passage and flows northwards (Peterson and Whitworth, 1989). The ACC reaches the continental slope to the south of the Falklands and splits into two main northward-flowing branches (Figure 7-13), the western branch being the weaker of the two (Bianchi, *et al.,* 1982). The upper 300 m water column in the Falkland Current consists of the Sub-Antarctic Surface Water mass (SASW) with deeper layers occupied by the Antarctic Intermediate Water mass (AIW) (Peterson and Whitworth, 1989).

7.3.3.2 Oceanographic features on the Falkland Islands Shelf

A number of oceanographic fronts exist around the Falkland Islands continental shelf. Primarily these are found in areas to the south and east of the Falkland Islands although, to date, a number of fronts have also been identified on the northern shelf. In particular, four frontal areas have been identified in the southern part of the FMCF (between 54°S and 48°S), all with well-resolved temperature and salinity gradients (Arkhipkin, *et al.,* 2013), interspersed by areas characterised by relatively smooth gradients (non-frontal zones).

As shown in Figure 7-13, the four main fronts are the:

- Southern Front (SF),
- North Eastern Front (NEF),
- Western Offshore Front (WOF), and
- Western Inshore Front (WIF).

The Southern Front is located to the south of the Falkland Islands near Beauchêne Island where the Falkland Current meets the continental slope. It causes a strong upwelling of SASW that mixes with the Shelf water mass forming the Transition Zone (TZ) at depths of between 120-300 m (Zyrjanov and Severov, 1979; Arkhipkin, *et al.,* 2004a). This oceanic front forms one of the most productive areas in Falkland waters and is utilised by squid and fish as a major feeding and spawning ground (Arkhipkin, *et al.,* 2004a; Arkhipkin, *et al.,* 2003; Arkhipkin, *et al.,* 2010). The location of the TZ on the shelf fluctuates both seasonally and inter-annually due to the variation in the intensity and position of the Falkland Current, which in turn influences the distribution of the commercially important loligo squid (*Doryteuthis gahi*), (Arkhipkin, *et al.,* 2004b).

The SF and the NEF appear when the eastern branch of the Falkland Current meanders onto the shelf and mixes with Falkland Shelf waters. However, there is no major counter current in the region, unlike the northern part of FMCF, where the Falkland Current meets with the warmer Brazil Current, creating multiple parallel counter flows along the shelf break (Acha, *et al.,* 2004; Belkin, *et al.,* 2009).

The WOF and the WIF represent the areas of mixing of the western branch of the Falkland Current with Patagonian Shelf waters and Falkland Shelf waters and the TZ respectively.

The northern part of the FMCF (37-38°S) shifts seasonally, offshore in the austral summer and inshore in spring and autumn (Carreto, *et al.,* 1995). Similar shifts of at least two fronts (WOF and NEF) have been observed in the southern part of FMCF (Arkhipkin, *et al.,* 2013). The offshore shifts of these fronts are thought to be a result of seasonal offshore movements of shelf waters. WIF and SF are quasi-stationary throughout the year. The mixing of shelf waters with SASW waters on the western side of the Falkland Current creates a band of increased primary productivity, indicated by higher concentrations of chlorophyll-a (chl-a) especially in spring and summer. This is known as the Patagonia High Chlorophyll Band (PHCB). The distribution of chlorophyll-a in PHCB is patchy and depends on seasonal variability in upwelling intensity along the FMCF (Romero, *et al.,* 2006).

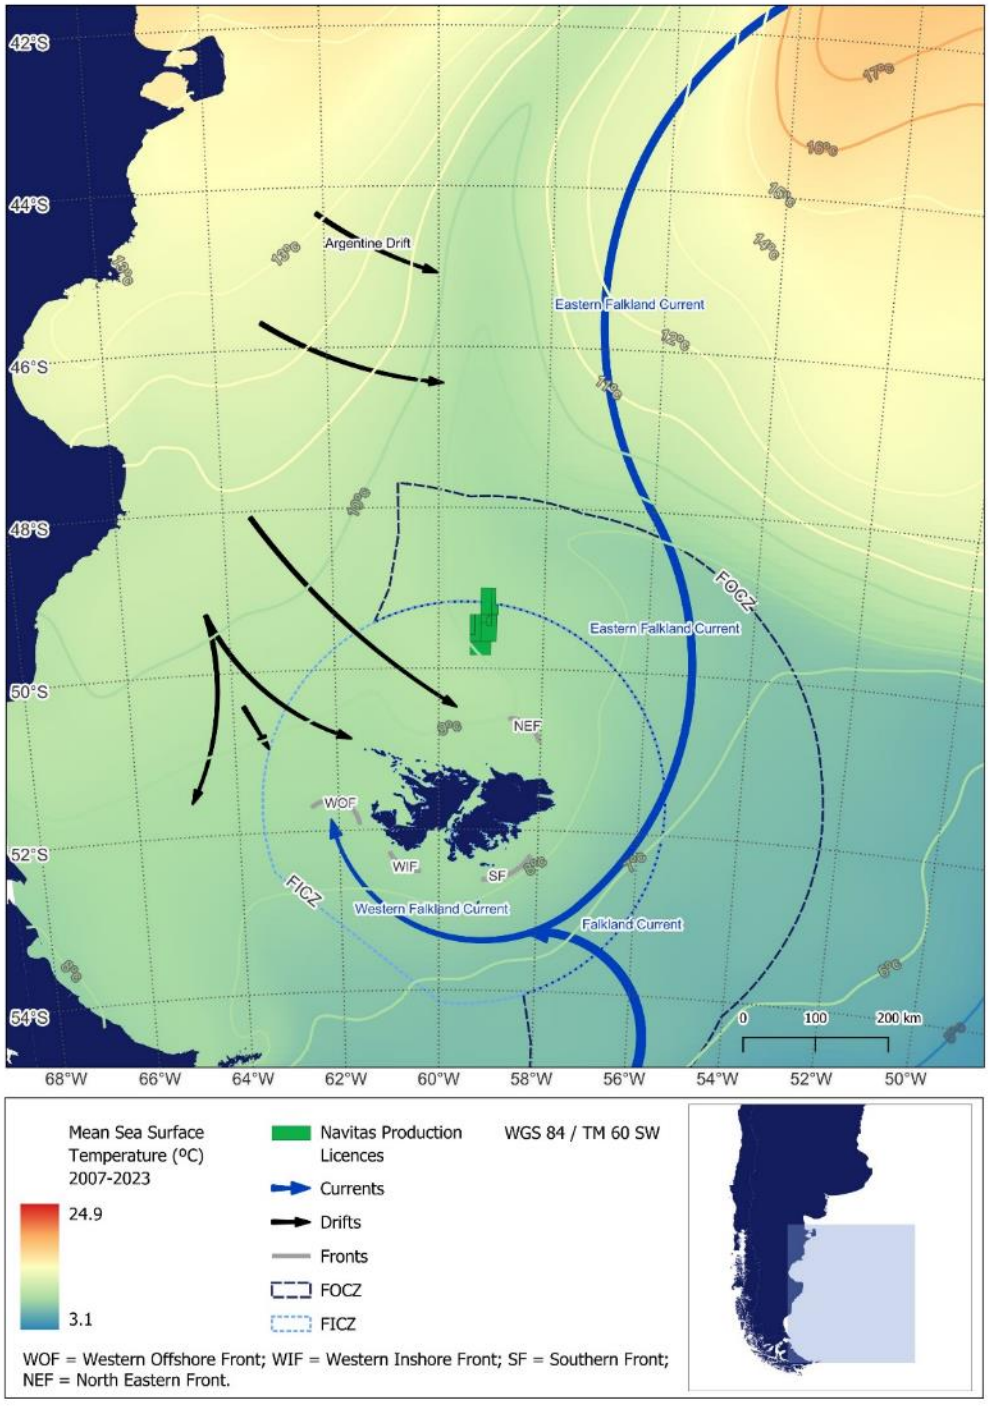

Figure 7-13: Main Patagonian Shelf oceanographic features overlain on Sea Surface Temperature map, March 2008 (WOF = Western Offshore Front; WIF = Western Inshore Front; SF = Southern Front; NEF = North Eastern Front *(adapted from Arkhipkin, et al., 2013)*

7.3.3.3 Oceanographic features in the region of the Sea Lion Field

The Sea Lion Field is located within the near shore area of the Northern Slope (NS) which marks a transition zone between Patagonian Shelf waters and the superficial SASW mass of the Falkland Current.

The currents in the Sea Lion Field predominantly move in northerly and north-westerly directions, with the current speed generally being less than 15 cm/s. At the seabed the currents tend to move in westerly directions with the current speed typically being less than 10 cm/s (BMT Argoss, 2015).

There is only slight seasonal variation in water temperature and salinity. Surface temperatures range from 5-9°C though the year with maximum temperatures observed in April and May. Surface salinity ranges from 34.06–34.11 practical salinity units (psu). The offshore and deeper part of the NS is covered by the SASW mass (Section 7.3.3.1) and shows little variation in near-bottom temperature and salinity which range from 4.1-4.3°C and 34.1–34.2 psu respectively (Arkhipkin, *et al.,* 2012a).

During a one-month environmental baseline survey of the PL032 Licence Block in March and April 2012, water column characteristics were measured using 47 deployments of a CTD (conductivity, temperature, and depth) probe (Gardline, 2013a).

Vertical profiles for temperature, salinity and dissolved oxygen from the 47 CTD deployments were interpolated across horizontal depth horizons at 400 m, 200 m, and 10 m. Temperature and salinity were used to identify the main water masses and their derivatives (Bianchi *et al.,* 1982; Peterson and Whitworth, 1989). Water column dynamics and the dynamics of water masses in the area can fluctuate around seasonal, interannual, and decadal cycles. The following is an illustration of the general water mass pattern in the area.

The CTD data reveal a well-mixed surface layer to a depth of *c.* 40 m. Below 40 m, a distinct thermocline was observed to approximately 80 m, below which temperature decreased gradually to the seabed. Temperature, dissolved oxygen and pH all decreased with depth. Turbidity was slightly higher in the mixed surface layer than the body of water immediately below the thermocline (Gardline, 2013a). Although this survey does not capture seasonal, interannual or decadal variability in water column structure, such variability will likely not be so great that it requires special consideration with respect to the potential impacts or mitigations described in relation to the Sea Lion Development. In other words, the water column characterised at the time will be indicative of the mean field situation. The measurement is therefore believed to be acceptable for this baseline.

7.3.3.4 Oceanography in Berkeley Sound

Eight water quality profiles were completed within the Berkeley Sound survey area using a multi-profiler; four of which were at the beginning of the survey, and a further four in the same locations at the end of the sampling programme, with a temporal separation of approximately two months. The four water quality stations were positioned along an east-west transect along the centre of the Sound, and were spaced approximately 6.5 km apart (see Figure 7-15 and Figure 7-16 below). The multiprofiler, a YSI 6600 V2 model, included sensors to determine temperature, salinity, dissolved oxygen, pH and turbidity.

In addition to the above, an RBRconcerto CTD was deployed affixed to the camera frame at a total of 50 environmental sampling stations to identify the structure of the water column throughout the Sound. A detailed record of a temperature time-series was recorded on a tide gauge (RBR03); this was used to verify temporal changes and observations from the profiling instruments. This device was moored for the duration of the survey in the centre of Berkeley Sound at a depth of approximately 15 m.

Analysis of the water quality profiles taken between the beginning and end of the survey suggest that spatially this body of water is generally well mixed with very little vertical variation with depth. There is a distinct increase of freshwater influence in the west of the Sound however, owing to the proportional increase in surrounding landmass to residual volume of water. A surface temperature of 9 - 10.5°C and a bottom temperature of 7 - 8°C is indicated by two FIG CTD casts. A seabed pressure recorder deployed during the POEPL 2015 survey, between 21st June and 19th August ranged from

3.3°C to 5.2°C. To date the wave buoy has recorded a minimum surface temperature of 4.1°C on 21st August 2016 and a maximum temperature of 12.4°C on 18th February 2017.

Dissolved oxygen showed little variation between the two time periods of CTD sampling, however consistently showed the same trend of decreasing oxygen concentration with depth. The dissolved oxygen concentrations were considered reasonably high, likely owing to the cold water temperature and high energy mixing through wave energy as well as tidal and wind driven systems. During the winter period when the survey was undertaken, phytoplanktonic primary production is expected to be very low, however oxygen may still enter this marine environment through macroalagae such as the *Lessonia* spp. and *Macrocystis pyrifera* kelp forests present within Berkeley Sound.

7.3.4 Bathymetry

7.3.4.1 NFB and the Sea Lion Field bathymetry

The Patagonian continental shelf is one of the largest and flattest continental shelves in the world (Arkhipkin, *et al.,* 2012). For the purposes of the document, Continental Shelf refers to waters less than 200 m in depth, deeper waters are referred to as the Continental Shelf Slope. The Patagonian Shelf varies in width from a few kilometers at 55 °S, south of Staten Island on the tip of Tierra del Fuego, to 850 km at 51 °S (Martos and Piccolo, 1988). The Falklands archipelago is situated on the Patagonian Shelf approximately 500 km north-east of the tip of Tierra del Fuego, between latitudes 52°53' S and 51 °S (Figure 7-1 above).

To the south and east of the Islands the shelf slopes steeply into the Falkland Trough (Platt and Philip, 1995), which is a west-east trench reaching depths greater than 3,000 m and extending 1,300 km from the South American continental shelf to the Malvinas Outer Basin (Cunningham, *et al.,* 2002). South of the Falkland Trough is the Burdwood Bank, which is a large plateau rising to 50 m below the surface and forms part of the regionally dominating Scotia Ridge. There are two major channels crossing the Scotia Ridge that facilitate inflows of the Falkland Current from the ACC. The western channel is 80 km wide and 400 m deep connecting the Scotia Basin with the Falkland Trough between Staten Island and the western Burdwood Bank. The eastern channel connects the Falkland Trough to the Scotia Basin at 55°W east of the Burdwood Bank; the channel is 130 km wide and 1,800 m deep (Guerrero, *et al.,* 1999).

To the west of the Falkland Islands, a north-western extension of the Falkland Trough gradually narrows and reduces in depth as it moves northwards onto the shelf break at the north-west tip of the archipelago. To the north a large area of relatively flat seabed extends to the shelf-break approximately 140 km north of Falkland Sound. Beyond this point, the continental slope represents an increase in the gradient of the seabed and leads into the steep sloping Falkland Escarpment at a depth of approximately 3,000 m. The NFB is the area located between the Falkland Islands and the Escarpment. The NFB is characterised by a gently sloping gradient that increases in water depth from 150 m in the south-west to 1,500 m to the north-east (FIG, 2008a). The Sea Lion Field lies within the central area of the NFB in water depths ranging from 330 m to 463 m (Gardline, 2013a; MG3, 2014).

The seabed in the NFB is characterised by numerous indentations, troughs and trenches. Bathymetric surveys conducted over the NFB indicate the presence of poorly preserved iceberg keel scars, numerous depressions between 4 and 11 m deep, trenches 30 m deep and 500-600 m wide, and furrows or channels commonly up to 1.5 km wide and extending up to 210 km long (Gardline, 1998a-h).

A bathymetric survey of the Sea Lion Field revealed that historic iceberg keel scars and seabed pitting are prevalent throughout the area, and a large trench that runs from the south-west to the east of the survey area (Figure 7-14).

7.3.4.2 Berkeley Sound bathymetry

The bathymetry for the main Berkeley Sound survey area was produced from the results of the concurrent geophysical site survey and is presented in Figure 7-15 and Figure 7-16 (BSL, 2015c). More detailed representations of site-specific bathymetry along with seabed sample photographs and camera tracks are presented in BSL (2015b).

Depths within the area surveyed ranged from approximately 5 m in the west to 55 m in the east. Localised gradients of up to 19° were observed at the pinnacle bedrock features with the highest point elevated 11 m from the surrounding seabed. To the east, the eastward gradient was negligible, ranging from 0.07° to 0.16°; the seabed here was considered to be generally flat, dominated by linear gravel ribbons, except along the northern and southern coasts where bedrock was observed.

7.3.5 Metocean data used in modelling

The impact and risk assessment chapters in the body of the EIA describe only the information required to ensure appreciation and understanding of the modelling results as they are used in the assessment. To avoid repetition, this section is dedicated to describing the metocean data used by SFL and Navitas to model the behaviour of discharges and releases from the Sea Lion Development.

The following metocean data were used in the modelling of:

- Drill cuttings (Section 10.6),
- Produced water (Section 10.7),
- Cooling water (Section 10.7),
- Collision risk modelling around the Sea Lion Field (Section 11.1), and
- Oil spill modelling offshore and inshore (Sections 12.1 and 12.2).

7.3.5.1 Ocean currents data

A hydrodynamic modelling study has been conducted by BMT Argoss, BMT WBM and the UK Met Office to produce high resolution ocean current data sets for the region, which have been utilised as input data for modelling the behaviour of discharges and releases. Details of the hydrodynamic modelling are given in BMT Argoss (2015).

The hydrodynamic modelling consisted of three nested model domains (see Figure 7-17), which have different spatial extents / coverage and spatial resolutions. More specifically, the model system comprised a large scale regional ‘oceanic’ domain that covers the Patagonian Shelf, and two smaller fine resolution coastal domains that cover nearshore areas of complex bathymetry and coastline features around the Falkland Islands.

Ocean currents for the larger regional domain shown in Figure 7-17 were generated by the UK Met Office using the Nucleus for European Modelling of the Ocean (NEMO) PS4 model, whilst currents for the coastal domains were generated by BMT WBM using the TUFLOW FV hydrodynamic model. The current vectors in Figure 7-17 show the average speed and direction of ocean currents over three years of data (2010 to 2012). The strong Falklands Current, which branches of the Antarctic Circumpolar Current, is evident in this graphic and will likely be a dominant transportation mechanism for any oil discharge in the region.

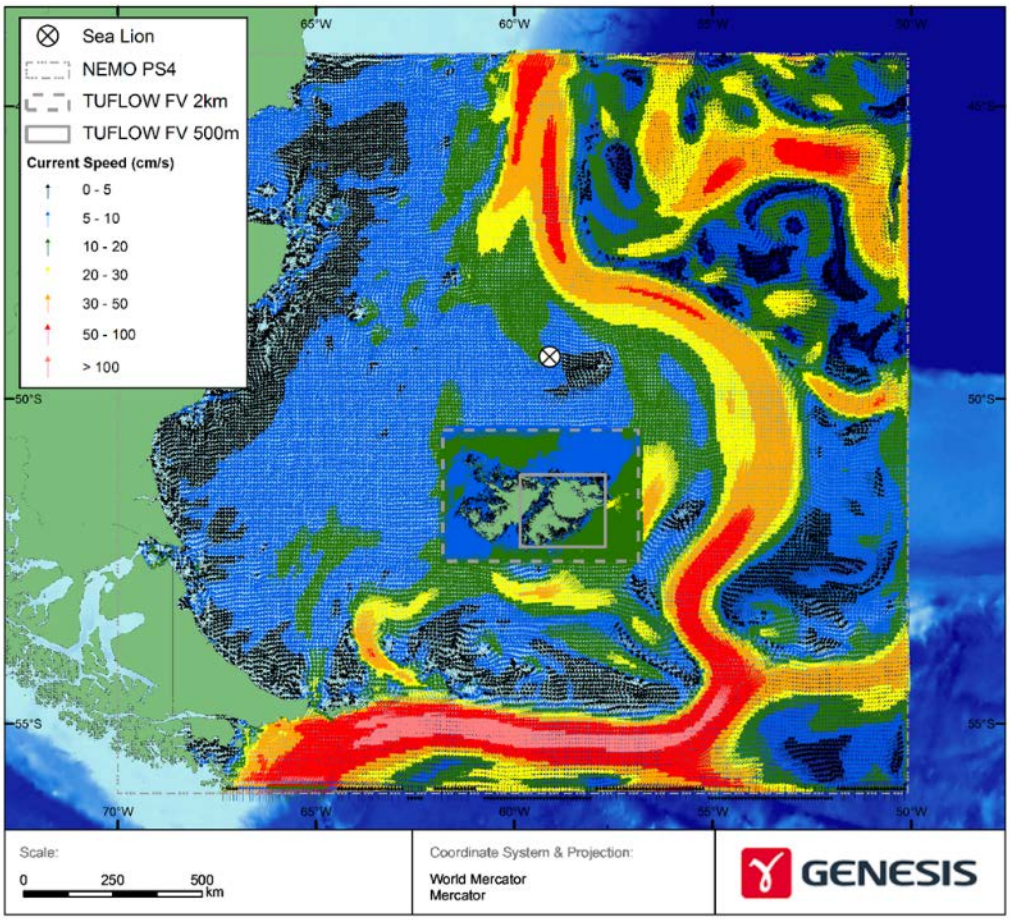

Figure 7-17: Ocean currents field obtained from the hydrodynamic modelling

7.3.5.1.1 NEMO PS4 data set

The NEMO model is a primitive equation model adapted to regional and global ocean circulation problems. NEMO is a flexible tool for studying the ocean and its interactions with the other components of the earth climate system over a wide range of space and time scales. A new NEMO ocean model configuration, named PS4, has been set up by the UK Met Office to cover the Patagonian Shelf and used to provide ocean currents for this area covering the years 2010 to 2012 inclusive.

Ocean currents generated by the NEMO PS4 model were provided on a regular grid that covers the area spanned by longitudes 50° - 70° west and latitudes 44° - 56° south (see Figure 7-17 above). The NEMO PS4 currents data have a longitudinal resolution of 1/12° and latitudinal resolution of 1/16°, which is approximately equivalent to longitudinal and latitudinal resolutions of 6 km and 7 km, respectively.

NEMO PS4 currents were provided in a number of depth layers varying depth resolutions. The depth layering and resolution is such that layers nearer the sea surface (where currents tend to fluctuate significantly with depth) are afforded finer resolutions than deeper layers (where fluctuation with depth is less pronounced). Fine resolution of the surface layers is also important in resolving fluctuations caused by wind driven Ekman currents in these layers. The NEMO PS4 currents were provided in layers consisting of:

- 1 m intervals from sea surface to 10 m depth,
- 5 m intervals from 10 m depths to 50 m depths,

- 10 m intervals from 50 m depths to 500 m depths, and
- 250m intervals from 500 m depths to 7,000 m depths.

The temporal resolution of the data set is 30 minutes i.e., the current speed and direction changes every 30 minutes. The spatial, temporal and depth resolution of this data set are considerably better than any previous available data sets that cover a comparable area.

The NEMO PS4 model has been validated using *in situ* current meter measurements at a number of different locations, and it has been shown that the agreement between modelled and measured currents is very good.

7.3.5.1.2 TUFLOW FV coastal data sets

The coastal currents data sets have been generated by BMT WBM using the TUFLOW FV hydrodynamic model, which is a numerical model that simulates hydrodynamic, sediment transport and water quality processes in coastal waters, estuaries and oceans. Currents generated by TUFLOW FV have been provided on two data grids with spatial resolutions of 2 km and 500 m (see Figure 7-17 above).

The 500 m spatial resolution data set covers the area spanned by longitudes 57.70° - 59.85° west and latitudes 51.22° - 52.35° south, whilst the 2 km spatial resolution data set covers the larger area spanned by 56.87° - 61.80° west and latitudes 50.51° - 52.57° south. Both data sets have a temporal resolution of 30 minutes and are depth layered into 15 bands with varying depth resolution. The depth layering and resolution are such that surface layers (where currents tend to fluctuate significantly with depth) are afforded finer resolutions than deeper layers (where fluctuation with depth is less pronounced). There are approximately five layers representing the top 10 m of the water column, with the remaining ten layers encompassing depths down to approximately 500 m.

Detailed example snapshots of the TUFLOW FV 500 m and 2 km resolution data sets are shown in Figure 7-18 and Figure 7-19, respectively.

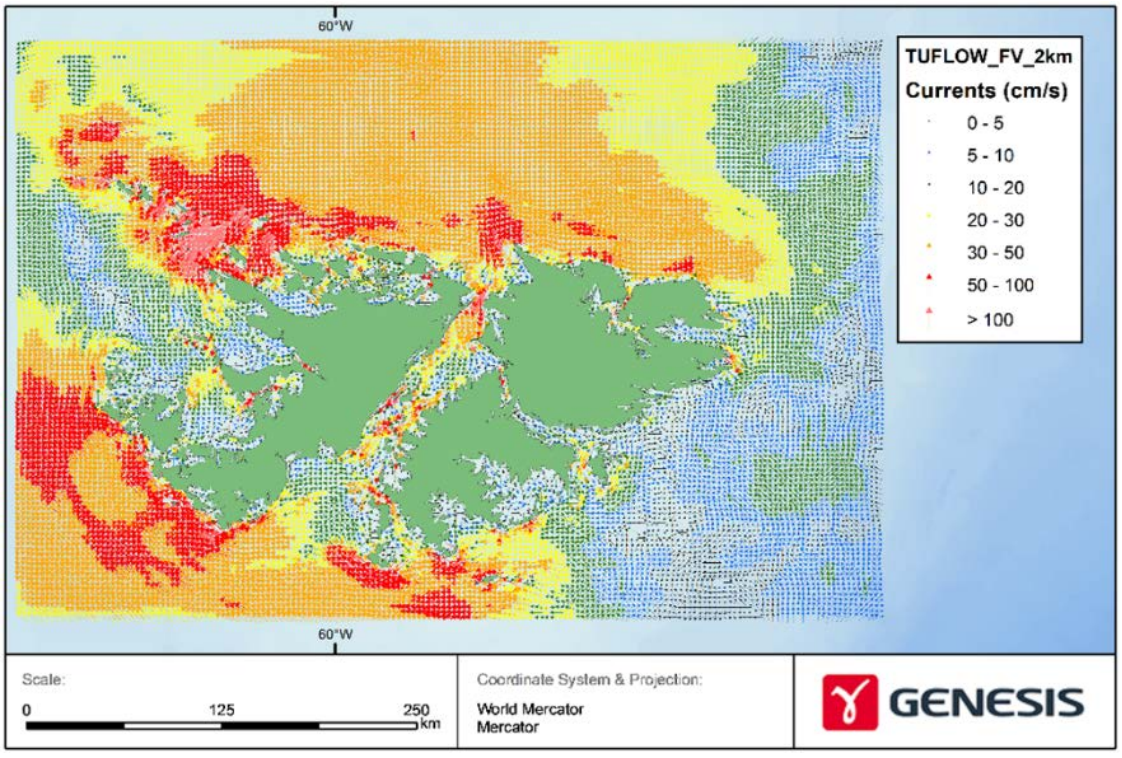

Figure 7-18: Snapshot of TUFLOW FV 2km currents grid

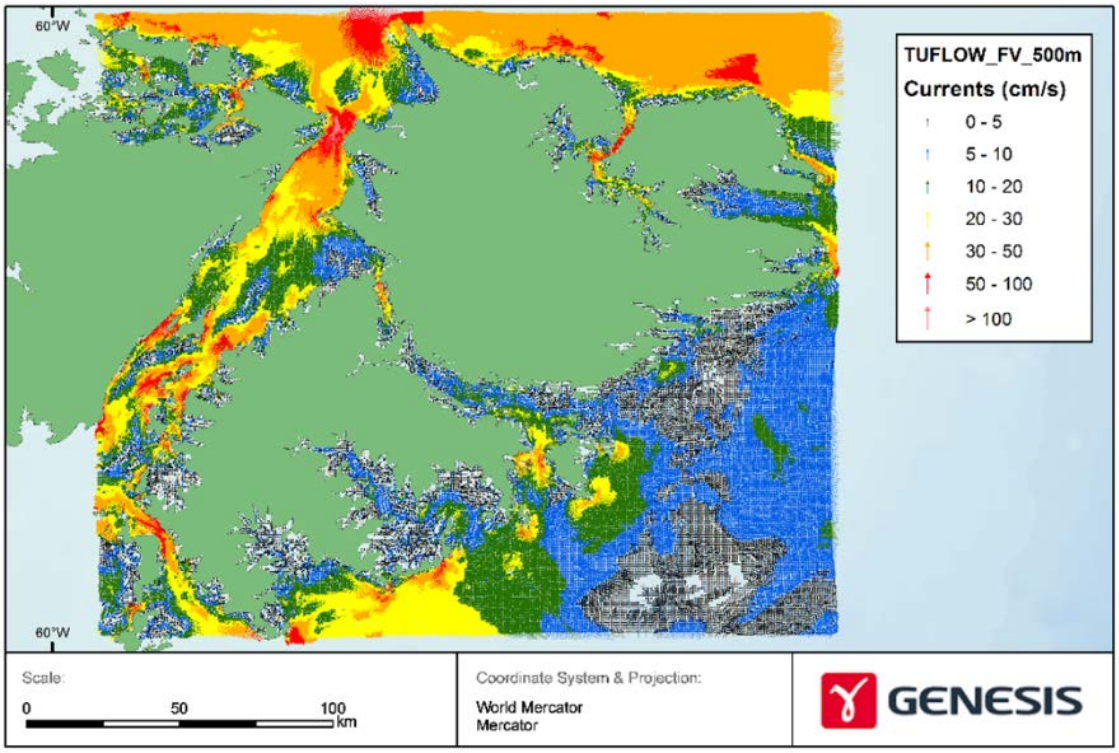

Figure 7-19: Snapshot of TUFLOW FV 500m currents grid

7.3.5.2 Current speed and direction at Sea Lion

The NEMO PS4 currents data set was interrogated at the Sea Lion location to investigate the distribution of currents in terms of speed and direction. The distribution of surface currents at Sea Lion is shown in Figure 7-20, and the distribution of currents nearer the seabed is shown in Figure 7-21. It is observed that the surface currents predominantly move in northerly and north-westerly directions, with the current speed generally being less than 15 cm/s. At the seabed the currents tend to move in westerly directions with the current speed typically being between 5 - 15 cm/s.

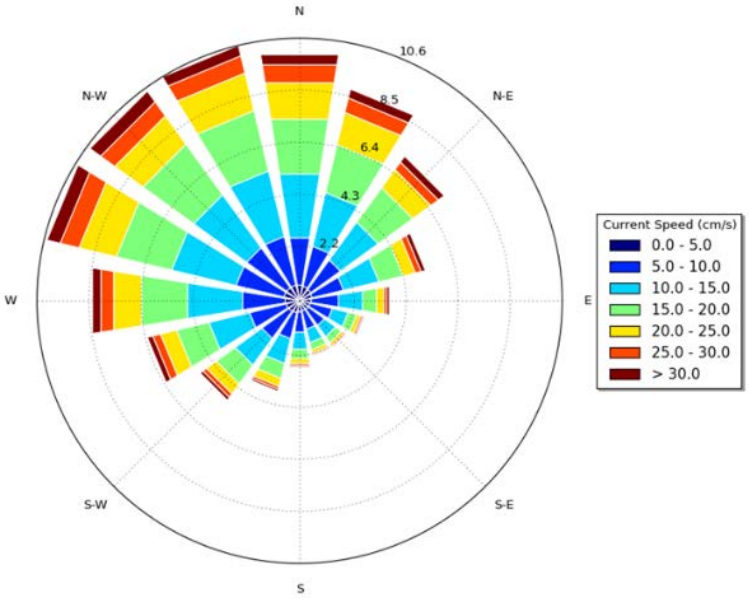

Figure 7-20: Distribution of surface currents at Sea Lion

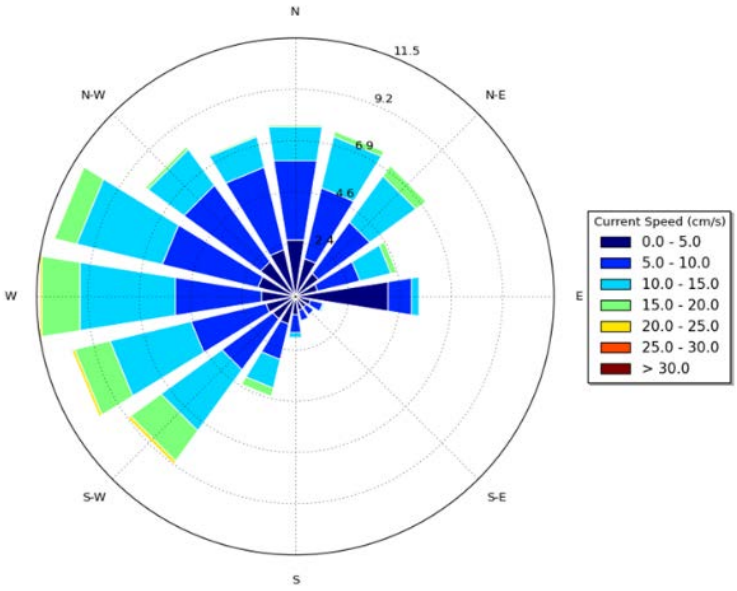

Figure 7-21: Distribution of seabed currents at Sea Lion

7.3.5.3 Wind data

To complement the current data, two different wind data sets have been used in the modelling study. A high-resolution wind data set, which covers the coastal waters around the Falkland Islands, has been produced by BMT Argoss using the Weather Research and Forecasting (WRF) model. Due to the limited coverage of this data set, a second lower resolution data set that covers a larger area has been obtained from the Climate Forecast System Reanalysis (CFSR). Similar to the currents data, the wind data from the WRF and CFSR data sets are combined into a single grid. The combined wind field grid is shown in Figure 7-22, which shows the domains of both the CFSR and WRF models. The vectors displayed in Figure 7-22 show the average wind speed and direction over the full three years (2010 to 2012) of the generated wind data.

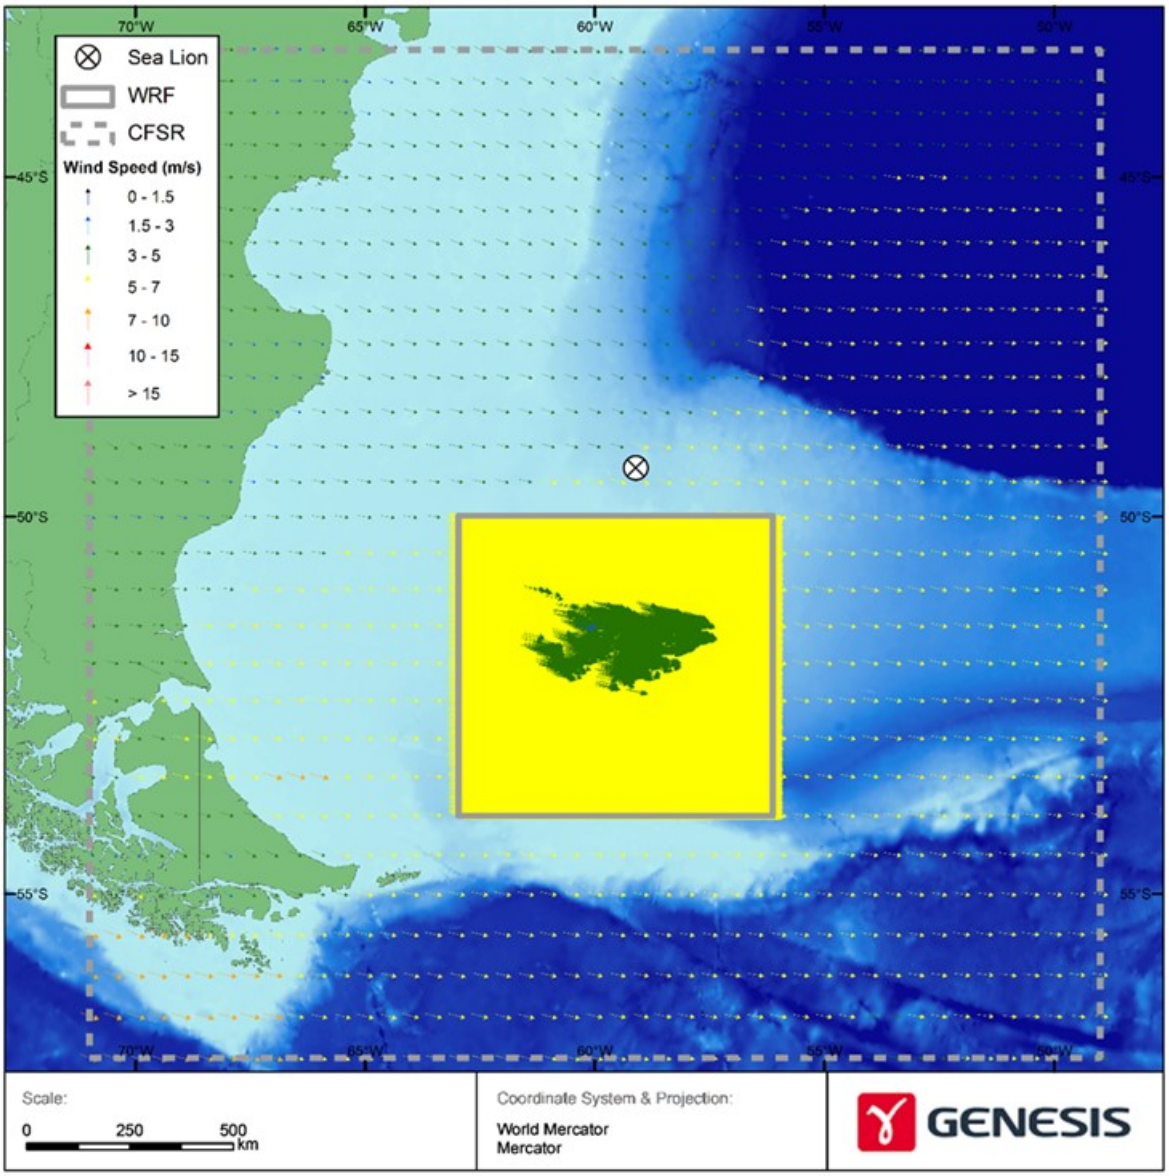

Figure 7-22: Snapshot of combined WRF and CFSR wind field grids

7.3.5.3.1 WRF wind data

The WRF model is a state of the art atmospheric modelling system designed to serve both atmospheric research and operational forecasting applications (Skamarock, *et al.,* 2008). The model has been developed by a number of different agencies including (but not limited to) the National Centres for Atmospheric Research's Meoscale and Microscale Meteorology Division, the National Oceanic and Administration's National Centres for Environmental Prediction and Earth System Research, and the Naval Research Laboratory.

The WRF wind data covers the area spanned by coordinates 50° - 64° west and latitudes 56° - 63° south with a spatial resolution of approximately 3 km and temporal resolution of one hour. In computing wind fields, the model makes use of high-resolution topography data obtained from the Shuttle Radar Topography Mission, and takes into account land / sea effects and local-scale weather variability.

The WRF model parameters and inputs have been optimised by BMT Argoss to produce high accuracy results. The modelled wind speed and direction have been validated against *in situ* measurements made at Mount Pleasant and showed good agreement.

A detailed typical snapshot of the instantaneous wind field generated by the WRF modelling is demonstrated in Figure 7-23, which highlights the spatial resolution of the data set.

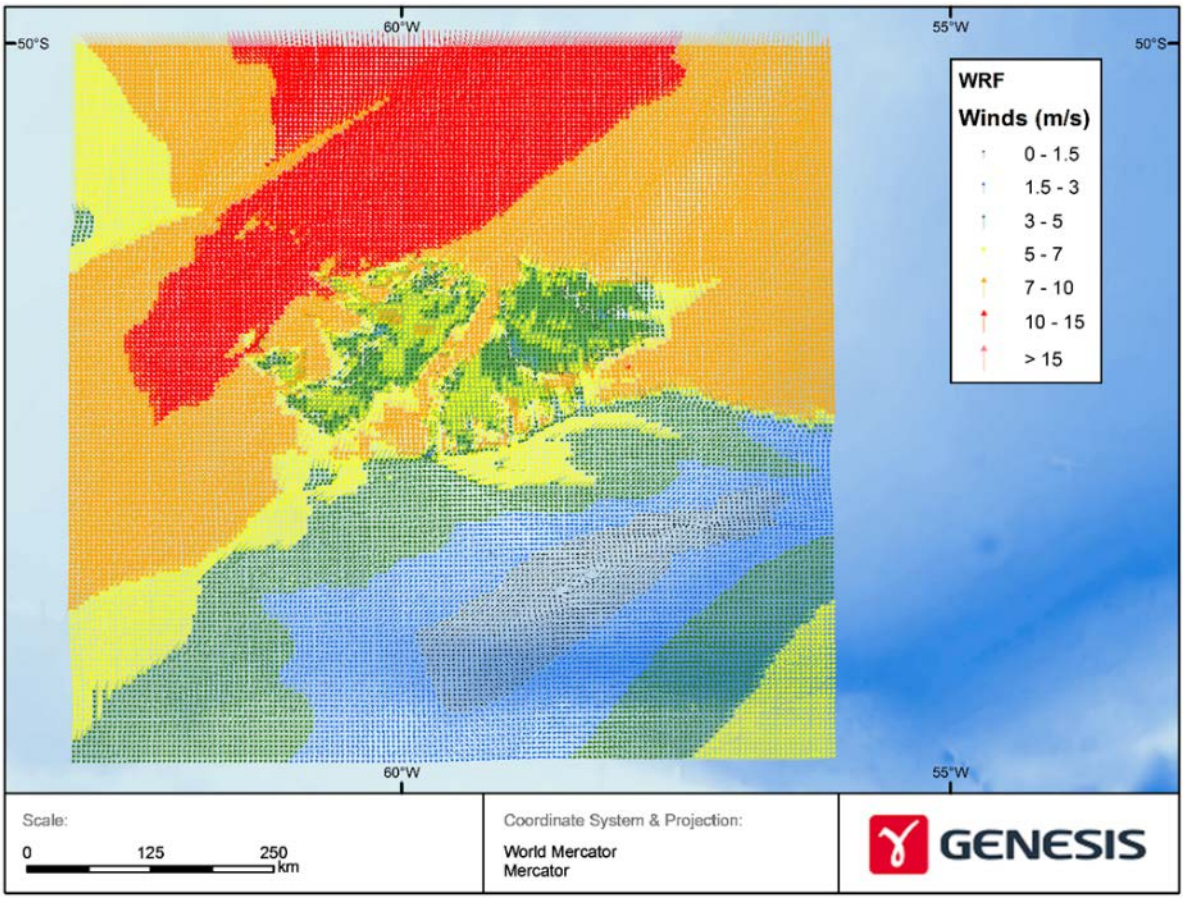

Figure 7-23: Snapshot of wind field produced by the WRF model

7.3.5.3.2 CFSR wind data

A lower resolution wind data set covering a more expansive region than the high resolution WRF data set has also been sourced from the new Climate Forecast System Reanalysis (CFSR) produced by the National Centres for Environmental Prediction (NCEP) (Saha, *et al.,* 2010). CFSR is a third generation global coupled reanalysis product that includes coupled atmosphere, ocean, land surface, and sea ice models, and also assimilates a wide variety of *in situ* and satellite observations.

The CFSR wind data set used in this modelling study contains wind vectors at a height of 10 m above sea level over the same three years as the other metocean data sets (i.e., 2010-2012). The data set covers the area spanned by longitudes 48.8° - 71.2° west and latitudes 42.8° - 56.8° south.

The temporal resolution of the CFSR data set is one hour. The longitudinal and latitudinal resolutions of the data set are 0.5°, which for the area of interest equates to longitudinal and latitudinal resolutions of approximately 36 km and 54 km, respectively. The spatial extent and resolution of the CFSR wind data is highlighted in Figure 7-22 above.

CFSR data is from an internationally recognised source with ongoing calibration and validation. Offshore wind data at the Sea Lion Field has been collected in 1998, 2015 and 2016 and reviewed by

Oceanwise on behalf of POEPL. There is insufficient data to make a statistical annual comparison for the Sea Lion Field, however global hindcast datasets such as CFSR are considered reliable, particularly in marine locations with no land features. In Berkeley Sound, further wind modelling was undertaken to account for local topographical features.

7.3.5.3.3 Wind speed and direction at Sea Lion

The CFSR wind data set was interrogated around the Sea Lion location in order to investigate the distribution of winds in terms of speed and direction. The rose plot in Figure 7-24 shows the distribution of wind at the Sea Lion location.

It is observed from Figure 7-24 that at the Sea Lion location the winds generally blow from westerly directions towards the east, with the wind speed typically being between 6 - 12 m/s.

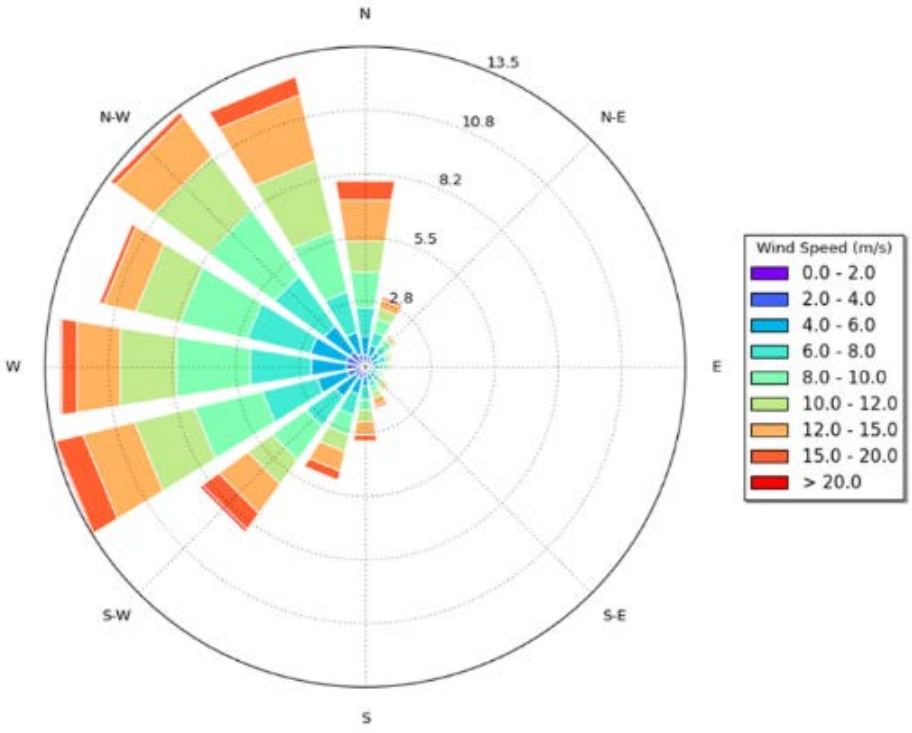

Figure 7-24: Distribution of winds at Sea Lion

7.3.5.4 Bathymetry data

The bathymetry data that has been used in this modelling study has been provided by BMT and was created by combining ETOPO2 (a global relief model of the Earth's surface that integrates land topography and ocean bathymetry) and General Bathymetric Chart of the Oceans (GEBCO) data. For areas in the vicinity of the Falkland Islands, BMT bathymetry was used. Particular attention was given to representation of features on the shelf edge to the north-east of the Falkland Islands, and also to Burdwood Bank to the south. Features were compared with Admiralty chart contours and, in some instances, local modifications were made by BMT.

The bathymetry data supplied by BMT is precisely the same data that was used in the hydrodynamic modelling to produce the ocean currents data sets discussed in Section 7.3.3. This is important since it results in a perfect match between bathymetry and seabed currents data. A mismatch in bathymetry and currents data can result in 'dead zones' near the seabed, which could adversely affect subsea discharge modelling.

The BMT bathymetry data was provided by BMT as irregularly spaced depth samples. This data was interpolated onto a regularly spaced grid in order to be compatible with the OSCAR model. The resulting interpolated bathymetry grid is depicted graphically in Figure 7-25.

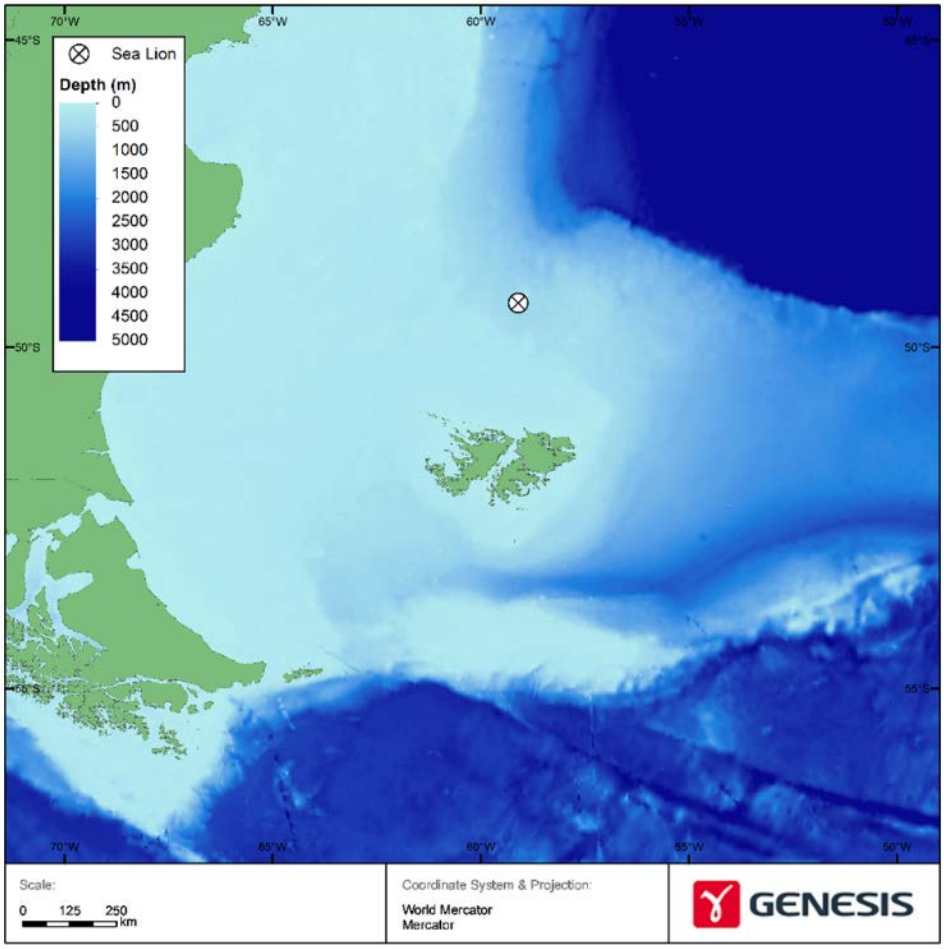

Figure 7-25: Bathymetry data used in the modelling

7.3.6 Geology and subsurface description

7.3.6.1 NFB and Sea Lion Field geology

The NFB is the name given to the set of sedimentary basins that lie to the north of the Falkland Islands (Richards and Fannin, 1997). It consists of two main sub-basins:

- A Northern Rift Basin (NRB) in which the predominant strike of the structural elements is north to south in orientation, and
- A Southern Rift Basin (SRB) in which the predominant strike of the main structural elements is north-west to south-east in orientation.

The main graben of the NRB is about 150 km long and 50 km wide at its northern end.

The Sea Lion Field is located on the north-east margin of the NRB. The Sea Lion Field was discovered in May 2010 by Rockhopper Exploration with well 14/10-2 which encountered oil reservoirs in good quality Lower Cretaceous turbidite sandstones that form a series of deepwater basin floor fans deposited into a stratified anoxic lake (Richards and Hillier, 2000; Holmes, *et al.,* 2015). Following discovery of the Sea Lion Field, the area was appraised by eight wells ikand two sidetracks), which helped delineate the extent of the Sea Lion accumulation and in addition proved the presence of

hydrocarbons in three younger fans (Casper, Casper South and Beverley). The main sediment source for the fans originated from flanking basement highs (primarily to the east), which connect into the main graben depo-centre *via* a series of feeder canyons or channels. Fans are highly sand-prone and were constructed by intrusive density flows. Deposition occurred from both turbidity currents and mass flows (for example, fluidised sediment-gravity flows).

7.3.6.2 Berkeley Sound geology

The geology of the Berkeley Sound area is principally sandstone and mudstone with overlying Quaternary sediments. The Quaternary sediments have been described as 'head deposits', comprising mainly gravels and sands, formed through a process called solifluction (Andersson, 1906; BSL 2015c; Solifluction is 'the gradual movement of wet soil or other material down a slope').

A number of rock outcrops occur within Berkeley Sound; those near the centre of the Sound, near the proposed LTV anchorage location are thought to be composed of sandstone and mudstone, originating from the Fox Bay and Philomel formations (Geological map of the Falkland Islands; British Geological Survey, reproduced in BSL, 2015a). The exposures observed along the northern and southern coasts of the Sound are thought to be formed of quartzite, with origins in the Port Stanley and Port Stephens formations (BSL, 2015a). These quartzite formations are more resistant to weathering and erosion.

7.3.7 Sediment characteristics

7.3.7.1 NFB and Sea Lion Field sediments

It is necessary to have an understanding of the baseline offshore sediment characteristics with regard to sediment types (grain size and organic matter content) and sediment chemistry in order to understand the potential impacts of discharges and disturbances associated with the Phase 1 & 2 Development.

The Falkland Islands are relatively immature in terms of O&G production and whilst 29 exploration wells have been drilled in the NFB to date there is currently no O&G production underway in the region (the Phase 1 & 2 Development is the first proposal for oil extraction). Therefore, typical background sediment types and chemistry datasets for the offshore and Berkeley Sound locations have not been formally characterised.

However, as described in Section 7.2.2 above, 20 offshore benthic surveys have been conducted between 1998 - 2016 within the three main Falklands basins. These surveys cover a range of depths from 140 m to 2,100 m and a range of metocean conditions, predominantly influenced by the East Falklands Current as it flows northwards to the east of the Falkland Islands.

The data provided indicate that Sea Lion sediments are comparable to those within the wider Falkland Islands waters (Gardline, 2013a & b).

7.3.7.1.1 Sediment type

7.3.7.1.1.1 Grain / Particle size

It is important to appreciate the baseline grain sizes of sediments (e.g., fine, medium, course) in the Sea Lion area as grain sizes directly affect the composition of benthic communities.

Sediments across the NFB typically exhibit a south-north gradient of decreasing mean particle size (Gardline, 1998a). The proportion of fine material, defined as material with a diameter <63 µm, generally increases with increasing depths. In the NFB, the sediment types range from 'very fine sand' in shallower waters (225 m depth) in the south-west, to 'coarse silt' in deeper waters (464 m depths) in the north-east (Gardline, 1998a).

During the area-wide 2012 environmental baseline survey in the Sea Lion area mean grain sizes ranging from 18 µm to 39 µm were recorded throughout the field, indicating that sediment types were generally homogenous (Gardline, 2013a). Sediments were predominantly classified as 'medium silt', with the exception of seven stations generally located in the northern part of the survey area that were classified as 'coarse silt'. The percentage of fine material (<63 µm) was high (61.6 – 79.7 %) at all stations across the Sea Lion area. These results were comparable to the sediment types recorded during the 1998 Falklands Offshore Sharing Agreement (FOSA) pre-drilling surveys conducted at 'B1' 14/05 and 'Little Blue' 14/09 wells (approximately 8.5 km and 16 km west of Sea Lion respectively) (Figure 7-5 above).

Post-drilling well site surveys carried out across the Drilling Campaign Areas contained similar proportions of fines, sands and gravels to those recorded in the Sea Lion area-wide survey (Gardline, 2013a & b). Whilst the highest variation was associated with the gravel fraction (>2 mm), which ranged between 0.1 % and 10.3 % contribution, this was attributed to natural variation across the area, and may originate from glacial drop-stones as found in the FOSA area. Analysis of other parameters did not indicate any disturbance from previous drilling activities. In the shallower waters of the southern NFB (140-285 m depths) the sediments were dominated by coarser sand particles, with a mean grain size of 156.5 µm (BSL, 2008b).

7.3.7.1.1.2 Total Organic Matter and Total Organic Carbon

Sources of organic matter in marine sediments include photosynthetic fixation of CO_2 by phytoplankton, decomposition of dead organisms, excretions from marine fauna, terrestrial inputs from rivers etc. and the excretion of extra-cellular products by algae which liberate appreciable proportions of the compounds produced by photosynthesis into the water (Lazar, *et al.,* 2012). Anthropogenic inputs to the marine environment can result in eutrophication which can enhance growth of phytoplankton and thus have the potential to upset the natural balance between organic matter deposition and the capacity of the sediment to 'recycle' the organic matter. The amount of organic matter in marine sediments is generally dominated by fluxes in the deposition of surface derived phytodetritus (decomposing phytoplankton and other plant material) to deeper water sediments.

Given that the level of organic matter in sediments can have a major influence on chemical and biological processes which occur within the sediments, as well as affecting the behaviour of other chemical components such as metals and organic pollutants (Lazar, *et al.,* 2012), it is important to understand the background levels of organic matter in order to determine whether or not anthropogenic activities may have an impact.

Total Organic Matter (TOM) and Total Organic Carbon (TOC) in sediment samples taken from the Sea Lion area were measured as a percentage of total sample weight. Both TOM and TOC levels were generally found to be homogeneous across the Sea Lion area with mean values of 5.6 % (±0.5 SD), and 0.9 % (±0.1 SD) respectively (Gardline, 2013b).

Both TOM and TOC were found to correlate with particle size, with higher proportions of organic matter recorded at stations with a higher percentage of fines ($P<0.001$). This relationship is linked to both the rate of sedimentation (detrital rain) from surface waters, and the hydrodynamic regime. Lower concentrations of organic matter are generally found in sandier sediments where surface sediments indicate some mobility and consequently have a lower percentage fines.

Values for TOM were similar to those recorded during the FOSA 1998 pre-drilling survey for the 'B1' 14/05 well and the 'Little Blue' 14/09 well (mean 5.7 % (±0.5 SD) and 4.3 % (±1.9 SD) respectively) (Gardline, 1998a & b). These samples were the closest to the Sea Lion Field and were located in comparable depths (415-482 m), further indicating the homogeneity of this area of the NFB. In the

southern NFB the level of total organic matter remained consistently low throughout the survey area (1.7 % (±0.4 SD)) perhaps reflecting the reduced proportion of fines and mobile sandy sediments of the shallower waters (BSL, 2008b).

7.3.7.1.2 Sediment chemistry

7.3.7.1.2.1 Sediment hydrocarbons

Total Hydrocarbon Concentrations (THC)

Hydrocarbons in marine surface sediments may have originated from a number of sources, including terrestrial run-off in coastal areas, vessel spills and discharges, plant origin, natural seeps and hydrocarbon extraction.

In the Sea Lion pre-development area-wide survey, the THC ranged from 4.7 - 15.5 $\mu g.g^{-1}$ (mean 9.7 $\mu g.g^{-1}$ (±2.7 SD)) across all stations. Samples collected during the post-drilling survey exhibited THC levels within a similar range as the area wide survey, ranging between 3.5 $\mu g.g^{-1}$ and 17.2 $\mu g.g^{-1}$ with a mean of 8.5 $\mu g.g^{-1}$ (±2.9 SD). Overall, no spatial trends were observed and THC levels were considered to be within natural ranges exhibited by background variation (Gardline, 2013a & b).

Generally, the results from all seven FOSA survey locations show low THC with the exception of the 'Minke' 14/13 well, located approximately 24 km south-west of Sea Lion, which recorded a mean THC 4.6 $\mu g.g^{-1}$ (±4.1 SD) (Gardline, 1998h). Similar levels were also recorded in shallower water depths (140-285 m) during the southern NFB survey in 2008 located >50 km south of Sea Lion (mean 4.3 $\mu g.g^{-1}$ (±1.4 SD)) (BSL, 2008b), although mean THC in both areas were low in comparison to Sea Lion.

Survey results suggest that levels of THC within the Sea Lion area were not above typical background levels for this region.

Hydrocarbon composition

Unresolved Complex Mixture (UCM) is a fraction of hydrocarbons, which are not fully separated during gas chromatography (GC) and appear as a 'hump' on the GC trace. This unresolved fraction consists of a number of individual components, which remain after substantial weathering and biodegradation of petrogenic inputs (Farrington, *et al.,* 1977), and can provide an indication of the origin of contamination or the natural source. At the majority of stations across the Sea Lion Area, UCM accounted for the majority of hydrocarbons within the sediments, which is indicative of well-weathered hydrocarbon sources and suggests that the majority of the material did not originate from fresh hydrocarbon inputs from drilling activities (Gardline, 2013a).

Sea Lion sediments exhibited a mixture of biogenic and petrogenic hydrocarbon inputs, with a predominance of biogenic inputs. These biogenic inputs were likely to be derived from marine organisms associated with the highly productive surface water in this area of the South Atlantic and diffuse terrestrial plant sources (Gardline, 2013a). Petrogenic hydrocarbons may have been derived from various anthropogenic activities, including the historic exploratory drilling activity in the area (Gardline, 2013b).

Polycyclic Aromatic Hydrocarbons (PAH)

Monitoring the aromatic hydrocarbon type and content is particularly important due to the toxic nature (mutagenic/carcinogenic) of several of Polycyclic Aromatic Hydrocarbons (PAHs) even at very low concentrations.

PAHs and their alkyl derivatives have been recorded in a wide range of marine sediments (Laflamme and Hites, 1978) with the majority of compounds produced from what is thought to be pyrogenic sources. These are the combustion of organic material such as forest fires (Youngblood and Blumer, 1975), the burning of fossil fuels and, in the case of offshore oilfields, flare stacks, etc. The resulting

PAHs, are normally transported to the sediments *via* atmospheric fallout or river runoff. Another PAH source is petroleum hydrocarbons, often associated with localised drilling activities. These are rich in the lighter, more volatile 2 and 3 ring PAHs (NPD; naphthalene, phenanthrene and dibenzothiophene).

Mean total PAH concentrations across the Sea Lion area were 0.12 $\mu g.g^{-1}$ (±0.02 SD), whilst mean PAH concentrations at the post-drilling survey stations ranged from 0.10 $\mu g.g^{-1}$ (±0.03 SD) to 0.15 $\mu g.g^{-1}$ (±0.01 SD). Mean total NPD concentrations across the Sea Lion area were 0.05 $\mu g.g^{-1}$ (±0.01 SD), compared to a range of 0.04 $\mu g.g^{-1}$ (±0.01 SD) to 0.065 $\mu g.g^{-1}$ (±0.01 SD) at the post-drilling survey stations.

When compared to the FOSA 1998 pre-drilling baseline survey, the maximum Sea Lion development area and post-drilling PAH and NPD concentrations were marginally higher than the FOSA stations, with the exception of the Minke well location, which exhibited mean PAH of 0.72 $\mu g.g^{-1}$ (±0.01 SD) and NDP of 0.2 $\mu g.g^{-1}$ (±0.01 SD). Comparison on a wider regional basis indicated that PAH and NPD levels from the SFB Burdwood Bank and Toroa surveys were approximately double the mean values recorded from the Sea Lion survey, whilst samples from the EFB were broadly comparable to those from the Sea Lion area.

Analysis of PAH composition in Sea Lion area sediments indicated that they predominantly originate from pyrogenic sources (Gardline, 2013a & b). Whilst there was no evidence of any point source contamination at any of the Sea Lion area stations, the presence of the lighter, more volatile 2-3 ring hydrocarbons is indicative of a minor source of petrogenic hydrocarbon, which may be associated with the relatively recent exploratory drilling activity, or natural diffuse hydrocarbon seeps (Gardline, 2013b).

Heavy metals

Metals occur naturally in the marine environment and are widely distributed in both dissolved and sedimentary forms. Anthropogenic inputs of metals to the marine environment are primarily as components of industrial and municipal wastes and of particular relevance to the offshore oil and gas industry are drilling discharges, which can contain substantial amounts of barium sulphate (barite) as a weighting agent (NRC, 1983). Barite also contains measurable concentrations of heavy metals as impurities, including cadmium, chromium, copper, lead, mercury and zinc (NRC, 1983).

Generally concentrations of heavy metals across the Sea Lion area and from the post-drilling survey were within background levels observed at other locations on the Falklands continental shelf and therefore considered to be within natural variability for this region. Lead (Pb) was the only exception where values from Sea Lion area were higher than those from the FOSA 1998 pre-drilling baseline survey, which were generally found to be below the levels of detectability.

When normalised to 5 % Aluminium (Al), several of the metals (Copper - Cu, Nickel - Ni, Lead - Pb and Zinc - Zn) recorded significant negative correlations with mean particle size and sand, and positive correlations with fines. This suggests the metal concentrations within the survey area were largely associated with natural variation in physical sediment characteristics and therefore should be considered as background in concentration for this area of the Southern Atlantic (Gardline, 2013a).

7.3.7.2 Berkeley Sound sediments

The sediments within Berkeley Sound are very variable, but three general seabed types have been identified: sand with gravel ribbons, mud with fine sands, and bedrock exposures. At the eastern, oceanic end of the Sound the seabed generally comprised sands interspersed with gravel ribbons and varying proportions of fragmented shell material. At the western end of Berkeley Sound and within the shallow bays, sediments were generally finer with muds and fine sands recorded. Bedrock exposures in the form of rocky escarpments were identified in the centre of the survey area, close to the proposed LTV anchorage location, and along the north and south coasts of the Sound. These

exposures consisted of rock faces in a predominantly north-south orientation. Numerous variations to these very general habitats were observed throughout Berkeley Sound; these are discussed in detail in BSL's Habitat Assessment (BSL, 2015b), and are described in Section 7.4.3.3.3.

Black gravels and coarse sands were present at a number of stations, possibly of volcanic origin (i.e., basalt), along with fragmented relic shell material. Other biogenic contributors to the sediments included, intact relic mussel and clam shells. Along with cobbles, these shells were often encrusted with both live and relic barnacles.

7.3.7.2.1 Sediment type

7.3.7.2.1.1 Grain / Particle size

The particle size interpretation of sediments from Berkeley Sound is based upon observations made from the acoustic and seabed photography, and from the analytical results acquired from the surface sediments at 46 locations (Figure 7-26). Material for particle size analysis was recovered from the surface 5 cm and was analysed by BSL upon return of the samples to the UK.

Particle size analysis indicated that the seabed was highly variable throughout Berkeley Sound, with varying levels of fines, sands and gravels (including pebbles). The average sediment composition was as follows:

- Fines (diameter <63 µm): mean 15.44 % ± 19.82 SD (SD = standard deviation),
- Sand (63 µm- 2 mm): mean 70.85 % ± 27.42 SD, and
- Gravel (> 2 mm): mean 13.71 % ± 20.55 SD.

The mean particle size recorded at each station is illustrated in Figure 7-26, and ranged from 40 µm to 15,540 µm (or, 15.54 mm), demonstrating the huge variability in sediment sizes based upon the proportions of silts, clays, sands and gravels recorded around a general sand profile in Berkeley Sound.

The relative proportion of sand, mud and gravel was used to classify the sediment type, using the Folk (1954) classification scheme. The dominant sediment type representing slightly gravelly sand and was recorded at 15 of the 46 stations sampled (Figure 7-27).

The geographical distribution of sandy sediments (>63 µm to 2 mm) is illustrated in Figure 7-28. This figure highlights the widespread distribution throughout the Sound with a general reduction in sands in the lower energy inshore region towards the west. Where sands were prevalent in the western inshore regions (Stations 10 and 25) they also contained a higher proportion of fines (13.49 % and 2.77 % fines, respectively) than the sands found in the east of the Sound.

The geographical distribution of sediment fines (i.e., silts and clays <63 µm), is illustrated below in Figure 7-29. This shows a distribution pattern of an increasing proportion of fines towards the western inshore regions of Berkeley Sound, with stations 02A and 40 showing the highest proportions of fine sediments with 69.2 % and 65.5 %, respectively. In addition to this, fines were also elevated in the trough of the large basin feature around station 34. Again, the percentage of fines here was mostly distributed based upon the hydrodynamic regime, with elevated levels generally located where the water flow is of a lower energy.

The spatial distribution of coarser gravel sediments (granules above 2 mm in size) is presented in Figure 7-30. Coarse sediments were recorded in all but 10 samples spread throughout the survey area; where present, they ranged from less than 0.1 % to 69.9 %, with a survey mean of 13.7 %.

Most of the coarse sediments recorded within Berkeley Sound were generally biogenic in origin, i.e., relating to shell material derived from bivalves and barnacles (including the gravel ribbons). However, at stations in closer proximity to bedrock exposures (e.g., Stations 07, 08, 11, 12, 28, 29, 41, 44), higher proportions of cobbles, pebbles and gravels, from glacial and peri-glacial deposits and from the eroded

rocks themselves, were found. Coarse sediments were often encrusted with biogenic material consisting primarily of molluscs, barnacles and bryozoans.

7.3.7.2.1.2 Total Organic Matter and Total Organic Carbon

Sediments were analysed for Total Organic Carbon (TOC), Total Inorganic Carbon (TIC), Total Organic Matter (TOM) and moisture content.

TOC represents the proportion of biological material and organic detritus within the substrates. In surface sediments, TOC is an important source of food for benthic fauna (Snelgrove and Butman, 1994), although an overabundance may lead to reductions in species richness and abundance due to oxygen depletion.

The TOC levels were variable throughout the survey area, ranging from <0.1 % in the sandy sediments up to 5.92 % at station 34, with a mean of 1.29 % ± 1.46 SD. The distribution generally follows a trend of increased organic enrichment with the percentage of fines. This is illustrated in Figure 7-31, showing an increase in TOC towards the western inshore region of Berkeley Sound, as well as in the large basin feature situated in the area of proposed LTV anchorage (Station 34). These variations are expected to be due to the increased sedimentation in these lower energy environments, compared with the higher energy mobile sands that are considered to be organically poor.

TOC levels could be considered a limiting factor within the substrate, influencing the distribution and abundance of some infaunal species such as deposit feeders. TOC within Berkeley Sound is expected to reflect both autochthonous (originating locally) and allochthonous (originated elsewhere) material. Primary production within Berkeley Sound in both phytoplankton and macroalgae form represent an important component of TOC, especially during summer blooming periods. TOC is expected to be strongly influenced by allochthonous material which includes fluvial transport (limited to small streams) as well as carbon sources entering the Sound from the surrounding sea.

As expected TOM levels followed the same trend as TOC levels which ranged from 0.45 % in sandy sediments (Station 21) to 14.94 % at Station 34, the survey mean was 3.15 % ± 3.73 SD.

TIC is the sum of inorganic carbon compounds such as carbon dioxide, carbonic acid, bicarbonate anions, and carbonate. In contrast to the TOC and TOM, the TIC correlated best with the percentage of gravel. Despite removing shell material from the samples, this correlation is likely due to epifaunal specimens such as bryozoans that contain carbonates in their exoskeletons and have colonised such gravels. Stations predominantly composed of sands and silts exhibited generally low TIC levels. TIC levels were variable and ranged from <0.1 % to 57.40 %, throughout the survey area, with a mean of 11.48 % ± 11.96 SD recorded.

7.3.7.2.2 Sediment chemistry

7.3.7.2.2.1 Sediment hydrocarbons

It should be noted that Berkeley Sound cannot be considered a pristine environment with regards to hydrocarbons, with three significant oil spill events documented in the 20 years preceding this survey (SMSG 2012), along with constant use of the area as an anchorage for large ships and fishing vessels. Understanding of the baseline sediment chemistry is therefore necessary to provide a point of comparison for any future monitoring.

Results for hydrocarbon analyses are summarised and tabulated as total hydrocarbon concentrations, total Polycyclic Aromatic Hydrocarbons (PAH), and total n-alkane and homologue ratios.

Total Hydrocarbon Concentrations

The Total Hydrocarbon Content (THC) of the sediments showed concentrations ranging from 1.03 $\mu g.g^{-1}$ at Station 48 to 159.89 $\mu g.g^{-1}$ at Station 34 (Figure 7-32). The lowest THC values were recorded at the mouth of the Sound in the east, and around Kidney Island in the sandier sediments. Stations located inshore to the west of the Sound showed a general increase in THC, as did the basin feature sampled at station 34 which contained the highest THC (159.89 $\mu g.g^{-1}$), almost four times greater than the next

highest value. This can be compared with a central North Sea average of 9.51 µg.g^{-1} and a 95th percentile of 40.10 µg.g^{-1} (UKOOA 2001).

THC levels generally correlate with the proportions of fines, TOC and TOM. A general exception to this trend were the stations located to the east and north of Cochon Island, which although generally showing low concentrations, were above those expected for this sediment type. In 2005, a reefer grounded on Cochon Island. Although the vessel was refloated and able to anchor within the Sound, this incident resulted in a small oil spill (approximately 130 tonnes of intermediate fuel oil).

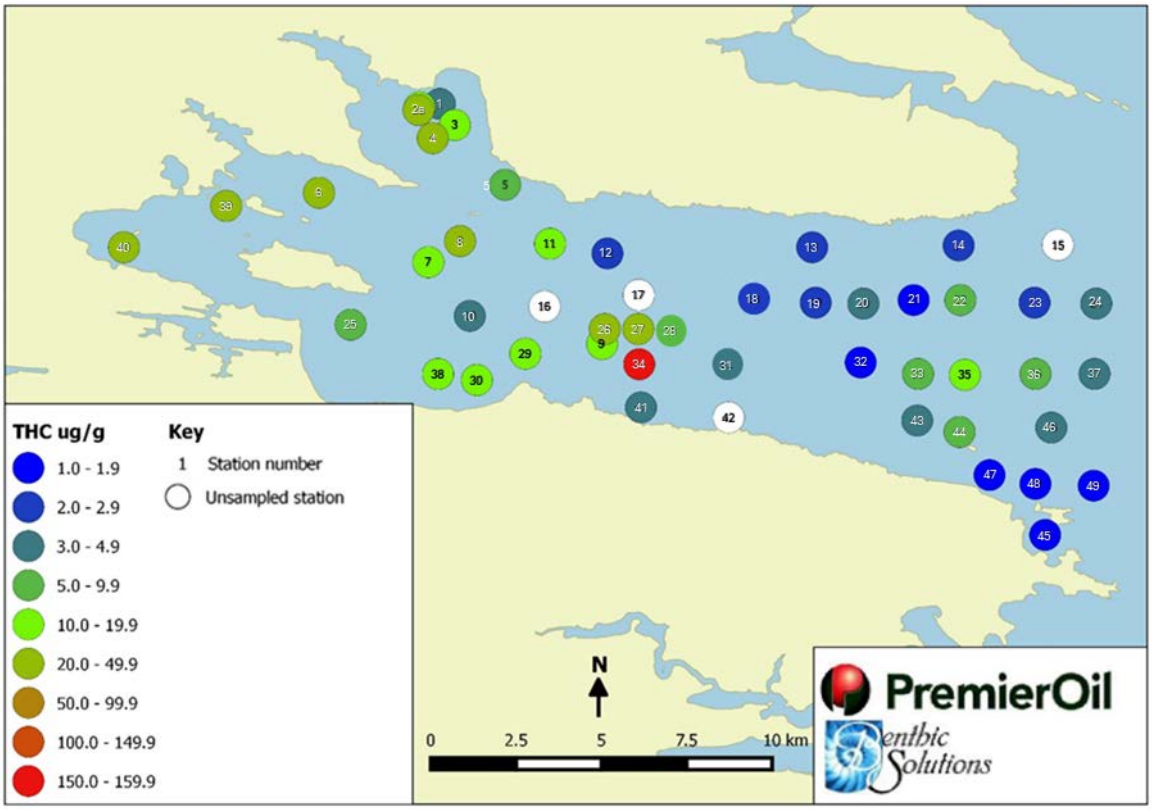

Figure 7-32: Total Hydrocarbon Concentrations (THC) recorded at each of the 46 sites sampled
(Source: BSL, 2015c)

Saturate / Aliphatic Hydrocarbons

All of the sampling stations were analysed for n-alkanes using Gas Chromatography with Flame Ionisation Detection (GC-FID). The total saturate alkane concentrations are illustrated in Figure 7-33.

The total n-alkane concentrations were again highly variable, ranging from 0.03 to 9.99 µg.g^{-1} with a mean of 0.72 ± 1.42 SD. The lowest n-alkane concentrations were found at Station 47 and the highest at Station 34, in line with the THC data. This correlates with the results obtained for fines, TOC and TOM.

The overall concentration of alkanes accounted for <10 % of the total THC recovered at each station (mean 4.22 ± 1.66 SD). This is quite low and is expected for uncontaminated marine sediments where background hydrocarbons are continuously replenished by a low but chronic source of alkanes.

Chromatograms were analysed in detail in order to identify the distribution of alkanes. All samples showed a peak at nC26 which is thought to be trans-squalene, in addition to this all samples except Stations 34, 37-39, 41 and 44-49, showed a peak at around 9.5 minutes which is thought to be Indole. Squalene is likely to have entered the marine environment through terrigenous plant material,

whereas indole occurs due to the breakdown of algal tryptophan by bacteria (Maruyama, *et al.,* 1989). This source is likely attributed to the breakdown of phytoplankton from the preceding summer months.

There were large Unresolved Complex Mixture (UCM) humps at Stations 02-04, 05-09, 26, 27, 29, 34, 35 and 38-40 (mainly western inshore stations). The UCM from nC10-25 is interpreted to relate to weathered diesel (this range is known as the diesel-range organics; DRO; Geosphere, Inc., 2006); whilst the heavier UCM from nC25-37, peaking at around nC33 is likely to represent terrigenous plant materials, which typically comprise the long-chain, odd carbon-number n-alkanes (nC25-33; Eglinton, *et al.,* 1962). Given the location of Berkeley Sound, sources of terrigenous plant matter include mosses and grassland from the surrounding hills.

The chromatogram at Station 40 showed numerous peaks throughout the nC10-37 range, however, a notable hump peaking around nC26 was also observed; this shaped hump was not present at any other station. The station is in close proximity to terrestrial run-off and therefore could be caused by unresolved terrigenous material. Alternatively, this could be resultant from anthropogenic activity at Green Patch Settlement where a livestock farm is located; although the modest TOC and heavy and trace metals concentrations suggests any such influx is not significant.

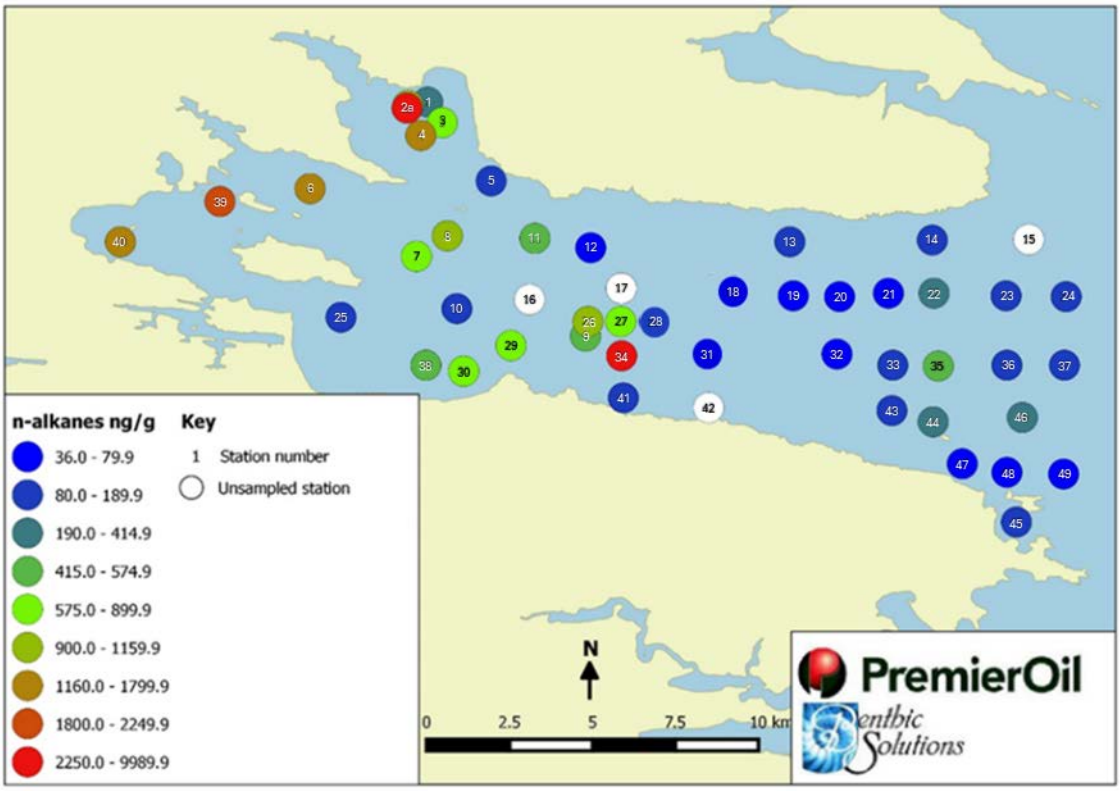

Figure 7-33: Total saturate alkanes recorded at each of the 46 sites sampled ***(Source: BSL, 2015c)***

Polycyclic Aromatic Hydrocarbons (PAH)

Polycyclic Aromatic Hydrocarbons (PAHs) and their alkyl derivatives have been recorded in a wide range of marine sediments (Laflamme and Hites, 1978) with the majority of compounds produced from what is thought to be pyrolytic sources. These include the combustion of organic material such as forest fires (Youngblood and Blumer, 1975), the burning of fossil fuels and, in the case of offshore oil fields, flare stacks. The resulting PAHs, rich in the heavier weight 4-6 ring aromatics, are normally transported to the sediments *via* atmospheric fallout or river runoff. Another PAH source is petroleum

hydrocarbon, often associated with localised drilling activities. These are rich in the lighter, more volatile 2 and 3 ring PAHs (NPD; naphthalene (128), phenanthrene, anthracene (178) and dibenzothiophene (DBT) with their alkyl derivatives.

Total PAH concentrations (2 to 6 ring compounds) were highly variable, ranging from <1 to 938.5 ng.g^{-1} (mean 48.48 ± 153.68 SD; Figure 7-34). Total PAHs showed a general increase in concentration with the percentage of fines; as expected, Station 34 contained the highest PAH level in line with results for THC and alkanes.

The naphthalene (NPD) fraction (2 and 3 ring aromatics) followed a very similar trend to total PAH, ranging from <1 to 372.28 ng.g^{-1} with a mean of 23.18 ± 58.91 SD. A higher proportion of NPD at many stations, ranging from 51.7 % to 100 %, suggest a petrogenic influence.

7.3.7.2.2.2 Heavy and trace metal concentrations

Metals are generally not harmful to organisms at concentrations normally found in marine sediments and some, like zinc, may be essential for normal metabolism, although it can become toxic above a critical threshold. In order to assign a level of context for toxicity, an approach used by Long *et al.* (1995) to characterise contamination in sediments will be used here. These researchers reviewed field and laboratory studies and identified metals that were observed to have ecological or biological effects on organisms. They defined 'Effect Range Low' (ERL) values as the lowest concentration of a metal that produced adverse effects in 10 % of the data reviewed, while 'Effect Range Median' (ERM) values designate the level at which half of the studies reported harmful effects. Consequently, metal concentrations recorded below the ERL value are not expected to elicit adverse effects, while levels above the ERL and ERM values are likely to be toxic to some marine life, though with varying likelihood.

The results of heavy and trace metal analysis, with an indication of whether the mean recorded measurements exceeded the ERL are summarised in Table 7.2. Full results can be found in BSL (2015c).

In Berkeley Sound, cadmium (Cd) levels were variable but generally moderate in concentration (above the ERL) and were highest in areas containing a higher proportion of fine sediments. Results suggest a naturally high background concentration of cadmium in these areas. Nickel (Ni) levels exceeded the ERL at Station 47, and arsenic (As) at Stations 07, 13 and 40. Mercury (Hg) remained at trace concentrations at all stations sampled.

Moderate but variable concentrations of lead (Pb) were recorded, however, the highest value recorded at Station 18 fell below the ERL. As with all metals except copper, lead indicated a significant positive correlation with the percentage of fine sediments.

For this survey, natural barium (Ba) levels recorded were variable, reflecting the sediment changes across the Sound with a general positive correlation with the percentage of fines. The majority of barium is typically insoluble in the form of a non-toxic sulphate (Gerrard, *et al.,* 1999); this metal is rarely of toxicological concern to the marine fauna.

Of the other metals, chromium (Cr), nickel (Ni), copper (Cu), vanadium (V), tin (Sn) and zinc (Zn) all yielded relatively low concentrations. Vanadium is often associated with the oil and gas industry as it is present in relatively high concentrations in most crude oils (Khalaf, *et al.,* 1982). Most vanadium enters seawater in suspension or colloidal form, passing quickly out of the water column and into silt deposition (Cole, *et al.,* 1999). Consequently, as the natural background levels in this region were relatively low, possible impacts from anthropogenic activities are likely to be detected from future surveys.

The slight elevation of arsenic at Station 40 as well as containing the highest concentrations of chromium, vanadium and zinc could be due to its close proximity to a livestock farm located at the nearby Green Patch Settlement. However, as high aluminium levels were also recorded here it is most likely a factor of sediment type, which has incurred enrichment of heavy and trace metals. Further to this, based upon the general low concentrations at which heavy and trace metals are recorded at both this station and throughout the survey area, none are considered to be of ecotoxicological concern.

7.3.8 Summary of physical environment

A summary of the offshore and inshore physical environment is provided in Table 7.3 below.

Table 7.2: Summary of heavy and trace metal concentrations in Berkeley Sound (BSL, 2015c)

Measure	Trace metal concentrations (µg.g^{-1})												
	Arsenic	Cadmium[1]	Chromium	Copper	Lead	Mercury	Nickel[1]	Tin	Vanadium	Zinc	Aluminium	Barium	Iron
Max (St[2])	14.2 (40)	4.12 (34)	52.1 (40)	7.7 (18)	43.7 (18)	0.08 (44)	21.7 (47)	3.0 (31)	72.9 (40)	50.1 (40)	38,600 (40)	424 (30)	15,400 (39)
Mean	3.43	1.24	18.25	4.53	8.59	0.02	6.89	1.08	28.36	18.7	13,783	204.9	5,972

[1] Cd and Ni Levels in Berkeley Sound are above acceptable levels. This is likely due to shipping activity associated with shipping, fishing and bunkering. The only Sea Lion Development activity anticipated in Berkeley Sound is vessel logistics operations and limited MGO bunkering for a duration of 13 non-consecutive months such that ongoing monitoring of Cd and Ni are not warranted from a Navitas point of view.
[2] St = Station number (see Station numbers in Figure 7-34 above).

Table 7.3: Summary of the offshore and inshore physical environment

Subject	Summary
NFB and the Sea Lion Field	
Meteorology	There is little meteorological data available from the location of the Sea Lion Field. A hindcast weather model has been developed, covering 20 years. The model produced wind and wave data for a wide area around the Falklands. The results were calibrated and verified against satellite and measured data, and confirmed previous wind and wave assumptions.
Oceanography and water quality	A detailed metocean model has been constructed to better understand the circulation and hydrodynamics of the Southern Patagonian Shelf. This area has a complex oceanography heavily influenced by the Falkland Current (off shoot of the Antarctic Circumpolar Current), tide and bottom topography. Of note, oceanography was recognised as a gap in the scoping stage but was not adopted as part of the scope for the GAP project (Section 7.2.4.2). For the purposes of the EIA, the oceanographic data available is considered sufficient and valid for the purposes of the modelling. However empirical field data will be required to inform, improve and ground truth modelled data.
Bathymetry	The area of the Sea Lion Field is situated on the Continental Shelf Slope in waters approximately 450 m in depth. The seabed in the NFB is characterised by numerous indentations, troughs and trenches. Bathymetric surveys conducted over the NFB indicated the presence of poorly preserved iceberg keel scars.

Subject	Summary
Sediment types	Sediments across the NFB typically exhibit a south-north gradient of decreasing mean particle size. The proportion of fine material, defined as material with a diameter less than 63 µm, generally increases with increasing depths, and the sediment types ranged from very fine sand in shallower waters (225 m depth) to the south-west, to coarse silt in deeper waters (464 m depths) to the north-east. Sediment types and TOM / TOC levels in the Sea Lion area are generally considered to be homogenous. The sediments are classified as 'medium silt' and, based on post-drilling surveys, appear to be unaffected by previous drilling campaigns.
Sediment chemistry	With regard to sediment chemistry, there was no direct evidence of seabed disturbance or elevated concentrations of hydrocarbons and metals associated with historical drilling activity within the Sea Lion area, although some fractions of hydrocarbon may have been derived from contamination associated with the previous drilling activity. Subtle differences between stations were evident that are thought to be associated with natural spatial variation across the area. Hydrocarbon, TOM, TOC and metal concentrations were considered typical of the medium and coarse silty sediments recorded in the Sea Lion survey area (Gardline, 2013b).
Berkeley Sound	
Meteorology	Over the course of the year, typical wind speeds vary from 2 m/s to 14 m/s (light breeze to strong breeze) and rarely exceed 18 m/s (gale). Westerly winds are the most common. The air temperature typically varies from 0° C to 15°C and precipitation is most likely in June and least likely in October
Oceanography and water quality	Water quality profiles indicate that the water column within Berkeley Sound is generally well mixed with a significant freshwater influence from the surrounding hills, particularly during the winter months. This is especially evident towards the western extent of the Sound, which is interpreted to have a lower energy hydrodynamic regime. The high wind speeds recorded during the survey, along with the influence from the Falkland Current and the gently shoaling bathymetry within Berkeley Sound are likely to be responsible for the well mixed water column.
Bathymetry	Bathymetrically the Sound deepened from the shallow waters in the west to approximately 55 m at the entrance to the Sound in the east. A basin feature dominates the central region of the Sound, around the LTV anchorage location; this depression is approximately 11 m below the level of the surrounding seabed and is expected to act as a sink, with higher deposition rates of finer sediments.
Sediment types	Environmental ground-truthing confirmed the presence of numerous subtle sediment changes throughout Berkeley Sound with differing proportions of coarse material in the form of fragmented shells, gravel, cobbles and boulders. Generally, the majority of sediments were dominated by sands; however the shallow embayments in the west of Berkeley Sound comprised higher proportions of fine materials, reflecting a weaker hydrodynamic regime. Mega-rippled sand and evidence of current turbulence was present at the eastern end of the survey area. Mobile linear gravel ribbons were recorded throughout the sand habitat to the east of the LTV anchorage location, comprising gravels, cobbles and relic bivalve shells (clams and mussels) heavily encrusted with relic and live barnacles and calcareous mats of pink coralline algae (*Corallina spp*.). Bedrock exposures were recorded in the area of the LTV anchorage location and along the north and south coasts of Berkeley Sound, forming large escarpments in some areas with erosional deposits often present around the base.
Sediment chemistry	Physio-chemical parameters generally showed similar trends throughout the survey area relating to sediment characteristics, and in particular to the proportion of sediment fines; this was the case for total organic content and hydrocarbon concentrations. Station 34, located within the basin feature, showed distinct elevations in organics and hydrocarbons including n-alkanes and PAHs. Despite such elevations, the proportions of n-alkanes and PAHs to total hydrocarbons were similar throughout, suggesting that the area does not reflect any significant variation above that dictated by the sediment

Subject	Summary
	type. Consequently, locations that were predominantly sand contained generally low-level hydrocarbon concentrations. Where hydrocarbons are present, these were thought to be largely terrigenous in origin, however, evidence for petrogenic sources was also recorded, with weathered diesel signatures observed in most samples within the central part of the Sound. Heavy and trace metals were variable, with general concentrations positively correlating with the percentage of fine sediments. All metals, with the exception of cadmium, were as expected for this region with Station 40 generally showing marginally higher metal concentrations, potentially attributable to its proximity to the Green Patch Settlement, where a livestock farm is present.

7.4 Biological Environment

The following sections provide data on the abundance and distribution of the key biological receptors identified within Paragraph 4 (2a-k) – Schedule 4 of the FIG Offshore Minerals Ordinance (Section 3.1.7.3.1) and listed in Section 8.4. Each section is separated into a description of the receptors offshore (the NFB and / or Sea Lion Field) and inshore (Berkeley Sound) and ends with a summary of the key life history characteristics. Where necessary, further details on the life history characteristics are provided within the environmental impact and risk assessment Chapters (10 and 12) as is relevant to the impact and / or risks being assessed.

7.4.1 Plankton

7.4.1.1 Introduction

The planktonic community is composed of a range of microscopic plants (phytoplankton) and animals (zooplankton) that drift with the oceanic currents. These organisms form the basis of marine ecosystem food chains and many species of larger animals such as fish, seabirds and cetaceans are dependent upon them. The movements of plankton therefore directly influence the movement and distribution of other marine species such that impacts upon plankton may impact upon other receptors. Therefore, it is important to understand the distribution of these organisms.

In general, it is understood that both the oceanography and topography of the southern Patagonian Shelf (Section 7.3.3) create an area of very high plankton productivity immediately to the north of the Islands.

7.4.1.2 Phytoplankton

The distribution and abundance of phytoplankton itself is heavily influenced by salinity and nutrient gradients, water depth, tidal mixing and thermal stratification within the water column (NSTF, 1993). The majority of phytoplankton occur in the photic zone (the upper tens of metres, which receives enough sunlight for photosynthesis to occur) and are unicellular organisms, such as diatoms and dinoflagellates.

7.4.1.2.1 Offshore phytoplankton

There may be as many as 5,000 species of marine phytoplankton with diatoms, cyanobacteria and dinoflagellates amongst the most prominent groups. Historic samples within the vicinity of the Falkland Islands indicate that there are relatively few phytoplankton species with high diatom abundance south of 44°S, whilst the northern waters were comparatively dominated by dinoflagellates and ciliates (Hendley, 1937; Rodhouse, *et al.,* 1992).

Shelf waters to the north of the Falklands are particularly rich in phytoplankton (Figure 7-35) in part because of the convergence of the Falkland and Brazil Currents (Section 7.3.3). The turbulent interactions of these currents bring nutrient-rich water to the ocean surface, allowing the phytoplankton to take full advantage of the long days and strong sunlight. The area of the shelf-break between the Falkland Islands and the Phase 1 & 2 Development is also an area of high phytoplankton production. It is thought that this is the result of upwelling of nutrient rich waters, created by the Falkland Current and seabed topography at the shelf-break.

Although phytoplankton is present year-round, blooms tend to appear in October and can persist throughout the austral spring and summer.

According to Gonçalves-Araujo *et al.* (2016) the spring phytoplankton community shows elevated biomass and is dominated by diatoms associated with a deeper and more weakly stratified upper mixed layer depth (UMLD) and relatively low nutrient concentrations. In contrast, the phytoplankton

community in summer is represented by lower biomass and is mainly dominated by haptophytes and dinoflagellates, associated with shallower and well-stratified upper mixed layers with higher nutrient concentrations, likely due to lateral advection of nutrient-rich waters from the Falkland Current.

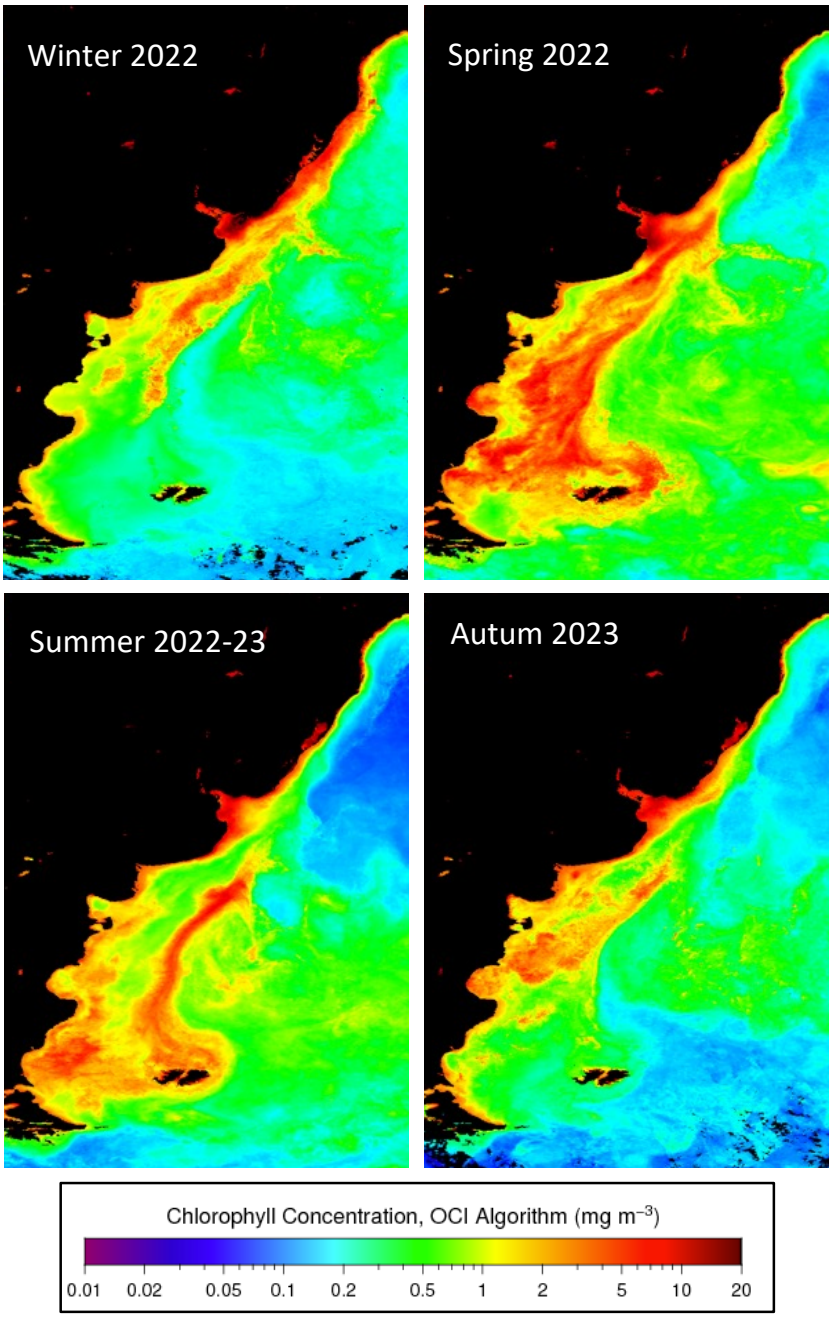

Figure 7-35: Example of Chlorophyll-a concentrations in the south-west Atlantic ***(Source: https://oceancolor.gsfc.nasa.gov)***

7.4.1.2.2 Inshore phytoplankton and Harmful Algal Blooms

Although Harmful Algal Blooms (HAB) of phytoplankton appear to be rare events in the Falklands, they are a common occurrence off the southern coast of Chile. While HABs have not been recorded in Berkeley Sound, in 2002, one occurred in the inshore waters to the west of the Falklands. HAB algae contain toxins that accumulate up the food chain poisoning higher predators or rendering filter-feeding

organisms toxic. The HAB in 2002 resulted in the death of many penguins (Baylis, *et al.,* 2013a & b) and other marine organisms.

7.4.1.3 Zooplankton

7.4.1.3.1 Offshore zooplankton

The high levels of phytoplankton in the NFB supports complex communities of zooplankton (Tarling, *et al.,* 1995; Boltovskoy, 2000), which in turn support complex pelagic and demersal ecosystems (Agnew, 2002).

The Falkland Current, an offshoot of the Antarctic Circumpolar Current, brings oxygen and nutrient rich water to the Falklands. The Islands split the Falkland Current into east and west branches, which sweep around the Islands to re-join to the north. This complex system of currents and bathymetry produces areas of upwelling and eddies, where there is little water movement. In turn, this influences primary production and the distribution of zooplankton. In the Falklands, the peak in total zooplankton abundance occurs between January and March, when an area of very high zooplankton density occurs at the shelf-break to the north of the Islands (Agnew, 2002). An area of high zooplankton density also occurs on the shelf-break to the north-east of the Falklands in winter.

A study by Padovani *et al.* (2012) examining the role of the hyperiid amphipod crustacean *Themisto gaudichaudii* on the Patagonian Shelf concluded that this species contributes greatly, both directly and indirectly, to supporting the fish community in the area. The study proposed that this amphipod plays a key role in the sub-Antarctic region, similar to that of Antarctic krill (*Euphausia superba*) in Antarctic waters, channelling the energy flow and enabling a short and efficient food chain.

Gelatinous zooplankton, such as jellyfish, are also considered an important component of the offshore ecosystem, occurring in the diets of at least seven species of fish. For two species in particular, namely the southern rock cod (*Patagonotothen ramsayi*) and spur dogs (*Squalus acanthias*), comb jellies (ctenophores) comprise more than 10 % of the diet (Arkhipkin and Laptikhovsky, 2013).

Other important components of the zooplankton community include the euphausiids *Thysanoessa gregaria*, *Euphausia vallentini* and *E. lucens* (Tarling, *et al.,* 1995; Boltovskoy, 2000). Together with *T. gaudichaudii*, these comprise important prey items some of the Falkland Islands most abundant finfish species (e.g., hoki (*Macruronus magellanicus*)) as well as Argentine shortfin squid (*Illex argentinus*) (Mouat, *et al.,* 2001; Agnew, 2002; Brickle, *et al.,* 2009). Similarly, lobster krill can be found in dense shoals on the shelf where they constitute important prey for higher predators (Harrison-Matthews, 1932; Arkhipkin, *et al.,* 2001; Arata and Xavier, 2003; Laptikhovsky and Arkhipkin, 2003; Laptikhovsky, 2004; Clausen, *et al.,* 2005; Brickle, *et al.,* 2009; Michalik, *et al.,* 2010; Quillfeldt, *et al.,* 2011 and P. Brickle, *pers. obs.*).

It should be noted that such baseline plankton / zooplankton surveys are not usually undertaken by Oil and Gas operations, so may be regarded as being beyond the reasonable requirement of Navitas to supply for this ES, given that such temporal data collection at such a distant field site would be costly and logistically difficult. Therefore, the baseline here was generated from extant literature.

7.4.1.3.2 Inshore zooplankton

In inshore waters, lobster krill (*Grimothea* spp.) is perhaps the most significant component of the zooplankton community and forms dense shoals inshore but is largely absent from more oceanic waters.

A recent study by Piontek *et al.* (2023) found that copepods, larval lobster krill and euphausiids dominate the local mesozooplankton community by biomass. All species showed seasonal patterns, including ontogenetic behaviour in lobster krill migrating to deeper waters as they develop. While

overall biomass significantly decreased with distance from shore, diversity was found to be highest at 30 km from shore.

There is a PhD studentship (SAERI and the University of Aberdeen) currently working on inshore zooplankton dynamics in Berkeley Sound. However, the results of this study are not expected to be available until mid-2025.

7.4.1.3.2.1 Lobster krill (Grimothea spp.*)*

The near-shore environment is dominated by two morphotypes of lobster krill:

- Gregarious lobster krill ('*gregaria*' type), and
- Short-eyed lobster krill ('*subrugosa*' type).

Once considered two species *G. gregaria* and *G. subrugosa*, however Perez-Barros *et al.* (2008), from analyses of DNA sequence analysis of three mitochondrial mtDNA gene fragments, conclude that they either represent a case of a dimorphic species, or a case of incomplete lineage sorting. Scientists at SAERI and SMSG continue to distinguish the two types until further phylogenetic work can be conducted.

Post-larval stages of these crustaceans (once thought to be a separate species and sometimes known as *Grimothea*) are pelagic and can form dense shoals, turning the water red. The adults are more commonly found on the seabed but also display shoaling behaviour. Shoals are most frequently encountered between November and May, but adult lobster krill can be found throughout the year. These are very abundant species in the Falkland Islands near-shore environment and are critical to this ecosystem (Agnew, 2002). The inshore distribution of this species and its importance as a component of the diets of many higher predators make it an important component of the inshore zooplankton. Evidence from animals examined during the early 20th century whaling, indicate that lobster krill were particularly important prey for sei, humpback and right whales (Harrison-Matthews, 1932). These animals are also important prey for seabirds, (Thompson, 1993; Quillfeldt, *et al.,* 2011; Clausen, *et al.,* 2005; Michalik, *et al.,* 2010; Arata and Xavier, 2003) fish (Arkhipkin, *et al.,* 2001; Laptikhovsky and Arkhipkin, 2003; Laptikhovsky, 2004; Brickle, *et al.,* 2009).

7.4.2 Marine and intertidal vegetation

7.4.2.1 Introduction

Understanding the marine and inshore vegetation of the Falkland Islands is important as algae are one of the major primary producers in the inshore marine environment. It is necessary to determine whether there are any species present that may be at risk from any oil-related activities or pollution.

7.4.2.2 Seaweeds and algae of the inshore environment

There are 253 seaweed taxa recorded from around the Falkland Islands (Brodie and Mrowicki, 2019), primarily in inshore waters. Seaweeds within the Falkland Islands, and elsewhere, fall into one of three categories:

- Brown algae (Phylum: Heterokontophyta),
- Green algae (Phylum: Chlorophyta), and
- Red algae (Phylum: Rhodophyta).

There have been several collections of seaweeds from around the Islands and samples of 400 and 350 specimens were collected by Vallentin (1909-11) and Clayton (2002-03) respectively (described in Wells, 2010). In 2013, two expeditions were conducted to collect further samples (*c.* 500) with the aim of producing the first-ever inventory of the macroalgal species of the Falkland Islands (Mystikou, 2015). Most recently, the Darwin Plus funded project 'Building foundations to monitor and conserve Falklands

marine forest habitats' (DPLUS068, 2017-2019) consolidated specimens from herbariums in Falklands Conservation and the Natural History Museum, London. There appear to be many similarities between the Falkland Islands and southern South America (Wells, 2010), with many new species and new records found recently (Brodie & Mrowicki, 2019). Recent work by Beaton (2020) show that the Falkland Islands has a greater intertidal diversity and taxonomic distinctness than the Straits of Magellan, Beagle Channel, Antarctic Peninsula and South Georgia.

The more conspicuous algal species found in the Falkland Islands are listed in Table 7.4 (Neely and Brickle, 2013).

7.4.2.2.1 Brown algae (Phylum: Phaeophyta)

Of the 58 species of brown algae recorded in the Falklands, the most visually dominant species are the giant kelp (*Macrocystis pyrifera*), the tree kelp (*Lessonia* spp.) and bull kelp (*Durvillaea antarctica*), all of which are classed as brown algae, and are common inshore, between 0.5 m to approximately 40 m depth.

7.4.2.2.1.1 Giant kelp (Macrocystis pyrifera)

The most characteristic seaweed of the Falkland Islands, and most likely to interact with oil and gas activity in Berkeley Sound, is the giant kelp, *Macrocystis pyrifera*. This species is one of the largest (growing up to 60 m in length) and most abundant of the brown algae found around the coast of the Falkland Islands (van Tussenbroek, 1989). Giant kelp forms extensive beds with large floating canopies (known as 'forests') in shallow coastal waters, although relatively sparse within Berkeley Sound when compared with the rest of the east coast of the Islands (Section 7.4.3). Giant kelp is a significant species within the shallow marine environment serving as a primary producer and as the foundation to a much more diverse habitat, which supports many species of invertebrate that in turn support higher predators (seabirds and marine mammals, White, *et al.,* 2002).

Giant kelp is found in more temperate climates, where sea temperatures are less than 20°C. It is found in areas with rocky, or hard, substrate, which the kelp is anchored to *via* a holdfast. The stipe grows out of the holdfast and this leads into the leaf-like fronds, which are buoyed by small gas-filled bladders. Research shows that giant kelp may grow at a rate of 60 cm per day (Neely & Brickle, 2013).

The waters of the Falkland Islands are particularly productive and nutrient rich and giant kelp flourishes in the area. Large kelp fronds may become detached from the seabed, as a result of grazing from benthic herbivores or during storm events, to form large rafts that float freely on the sea surface. The distribution of free-floating kelp patches in Falkland Islands waters was reported from the at-sea surveys carried out between February 1998 and January 2001 (White, *et al.,* 2002). Floating kelp patches were particularly important foraging habitat for grey-backed storm-petrels (*Garrodia nereis*) with an additional 21 seabird species also recorded as associating with free-floating patches of kelp (Gillon, *et al.,* 2001).

Bayley *et al.* (2021) evaluated the ecosystem services provided by kelp in the Falkland Islands. The study incorporated updated knowledge on the potential of kelp to sequester 'blue carbon' and used the extensive kelp forests of the Falkland Islands as a case study to assess the value of kelp forests to society through multiple associated ecosystem services. The analyses showed kelp forests provide a highly valuable range of direct and indirect services, which if managed correctly, will continue to benefit people, both now and in the future. The total estimated value of the Falkland Islands' kelp system was equivalent to *c.* £2.69 billion per year (or £3.24 million km year). However, the true value of the kelp forest surrounding the Falkland Islands is likely to be higher still, given that the estimate does not account for elements such as associated scientific research, tourism, and cultural services, due to the necessary data currently being unavailable. Similarly, the full value of these highly biodiverse ecosystems in supplying habitat and food to a large range of associated species is crucial,

yet extremely difficult to fully quantify. This study illustrates the importance of maintaining kelp ecosystems in a healthy state to ensure they continue to supply valuable ecological processes, functional roles, and ecosystem services, including their overlooked role as significant long-term carbon sinks.

7.4.2.2.1.2 Tree kelp (Lessonia spp.*)*

Tree kelp is often found intertwined with giant kelp. There are four species of tree kelp that have been identified within Falklands waters: *Lessonia flavicans* (Broad-blade tree kelp; the most common of the four), *L. nigrescens*, *L. frutescens* (although this is suspected to be a local form of *L. nigrescens* (Skottsberg, 1921)) and *L. vadosa* (shallow tree kelp). Tree Kelp, distributed at depths >20 - 100 m have an order of magnitude greater biomass than Giant Kelp (*Macrocystis pyrifera*). If confirmed, this will transform our understanding of deeper habitats, and their potential for carbon storage (P. Brickle *pers. comm.*).

Broad blade tree kelp inhabits slightly deeper waters than some of the other tree kelp species, from 2 - 20 m, inhabiting silty sediments and forms dense canopies. Conversely, the shallow tree kelp inhabits depths between 0.5 - 2 m and grows in areas of harder substrate.

Loligo squid, one of the most important marine resources in the Falklands, are known to use kelp beds (primarily *Lessonia* spp.) as spawning sites (Brown, *et al.,* 2010).

7.4.2.2.1.3 Bull kelp (Durvillaea antarctica)

Bull kelp (*Durvillaea antarctica*) has a circum-polar distribution in the Southern Ocean. It is extremely robust and found on exposed shores. Unlike many of the other large brown algae, bull kelp does not have air bladders, instead it floats due to a unique honeycomb structure within the alga's blades, which also helps this species to avoid being damaged by the strong waves.

Table 7.4: Conspicuous algae species found within Falkland Islands Waters[1]

Phylum	Common name[1]	Scientific names[1]
Brown algae (Heterokontophyta)	Giant kelp	*Macrocystis pyrifera*
	Shallow tree kelp	*Lessonia vadosa*
	Broad blade tree kelp	*Lessonia flavicans*
	Bull kelp	*Durvillaea antarctica*
	Creeping ring algae	*Herpodiscus durvillaea*
	Bladder algae	*Adenocystis utricularis*
	Sea potato	*Leathesia marine*
	Rope algae	*Desmarestia chordalis*
	Fur algae	*Desmarestia distans*
Green algae (Chlorophyta)	Cushion algae	*Codium effusum*
	Dead man's fingers	*Codium fragile*
	Sponge weed	*Spongomorpha arcta*
	Sea lettuce	*Ulva lactuca*
	Gutweed	*Ulva intestinalis*
	Ruffled sea lettuce	*Ulva linza*
Red algae (Rhodophyta)	Rock-leaf algae	*Lithophyllum falklandicum*
	Encrusting coralline algae	*Corallina* spp.
	Feathered coralline algae	*Corallina officinalis*
	Blood algae	*Hildenbrandia lecannellieri*
	Coiled algae	*Ahnfeltia plicata*
	Iridescent algae	*Iridaea* spp.
	Red sheet algae	*Gigartina skottsbergii*

[1] Source of data and nomenclature for the Latin names follows Neely and Brickle (2013). **Note:** the full species list provided by Brodie and Mrowicki is in progress and is currently unavailable.

7.4.2.2.2 Green algae (Phylum: Chlorophyta)

Most of the 45 species of green algae in the Falkland Islands are known from shallow waters and include the sea lettuces *Ulva* spp. and cushion algae such as the *Codium* spp. These are anecdotally highly diverse and will be subject to study on how refugia (like the Falkland Islands) in the last glacial maximum contributed to this diversity, at species and population levels, and indeed how they may have recolonised other glaciated areas as the ice retreated (Beaton, 2019).

7.4.2.2.3 Red algae (Phylum: Rhodophyta)

Red algae are the most diverse group of seaweeds, with 150 species recorded in the Falklands. Along with more typical fleshy species, the red algae include coralline, or encrusting, algae that secrete calcium carbonate. Only red algae are able to live and grow at greater depths than other seaweeds because their red pigmentation means they are able to absorb the blue light available at greater depths (maximum depth for most species is less than 100 m but coralline algae may grow in deeper waters).

7.4.2.3 Mapping of kelp beds

Coastal kelp was mapped utilising Land-Sat satellite imagery with a resolution of 30 m (Premier, 2014a). Imagery relates to kelp on the sea surface and may comprise giant kelp, tree kelp or bull kelp. Sub-surface tree-kelp and narrow fringes of bull kelp on rocks may not be visible and it was assumed that the greatest area relates to giant kelp and surface tree kelp. Coastal kelp images were taken in August 2013 (East Falkland) and June 2014 (West Falkland), and as such are representative of winter kelp coverage.

As part of the process of assessing the suitability of Berkeley Sound for LTV anchorage, kelp was mapped for the entire Falkland Islands coastline (Premier, 2014a). The spatial extent present within different sections of the coast was compared to the total island-wide coverage of kelp. The coast between MacBride Head and Cape Pembroke (encompassing Berkeley Sound) contained 19.5 km^2 of kelp, equivalent to about 2 % of all Falklands kelp.

Given the importance of kelp beds as an inshore habitat for a wide range of species assemblages and the unknown importance for kelp as a spawning ground for Loligo, the distribution of kelp is an important consideration regarding the possible impact and response to potential oil spills. Kelp may have the ability to retain oil and prevent effective oil spill response; however, when compared with the East Falkland coastline as a whole, Berkeley Sound has relatively low kelp coverage (Figure 7-36).

In 2016, further analysis of satellite images was conducted to map terrestrial, inter-tidal and shallow marine habitat types (EnvSys, 2016). Under good conditions, it is possible to map the seabed down to a depth of approximately 15 m. With the aid of the results of dive surveys at known locations it was possible to map kelp below the surface and distinguish between some of the most conspicuous species. Figure 7-37 shows the distribution of giant kelp (*Macrocystis pyrifera*) within Berkeley Sound. The most extensive patches of kelp are located in the relatively shallow, sheltered waters of the Inner Sound, around Cochon Island, Kidney Island and in the vicinity of Volunteer Point.

Through SAERI's Darwin Plus (DPLUS065, 2017-2020) project 'Mapping the Falklands & South Georgia coastal margins for spatial planning' broad-scale coast and terrestrial habitat maps have been produced using Sentinel satellite imagery (10 m resolution) imagery. Although finer resolution, this analysis showed similar patterns of kelp distribution at similar spatial scales around the Falklands compared to the POEPL (Premier, 2014a) study.

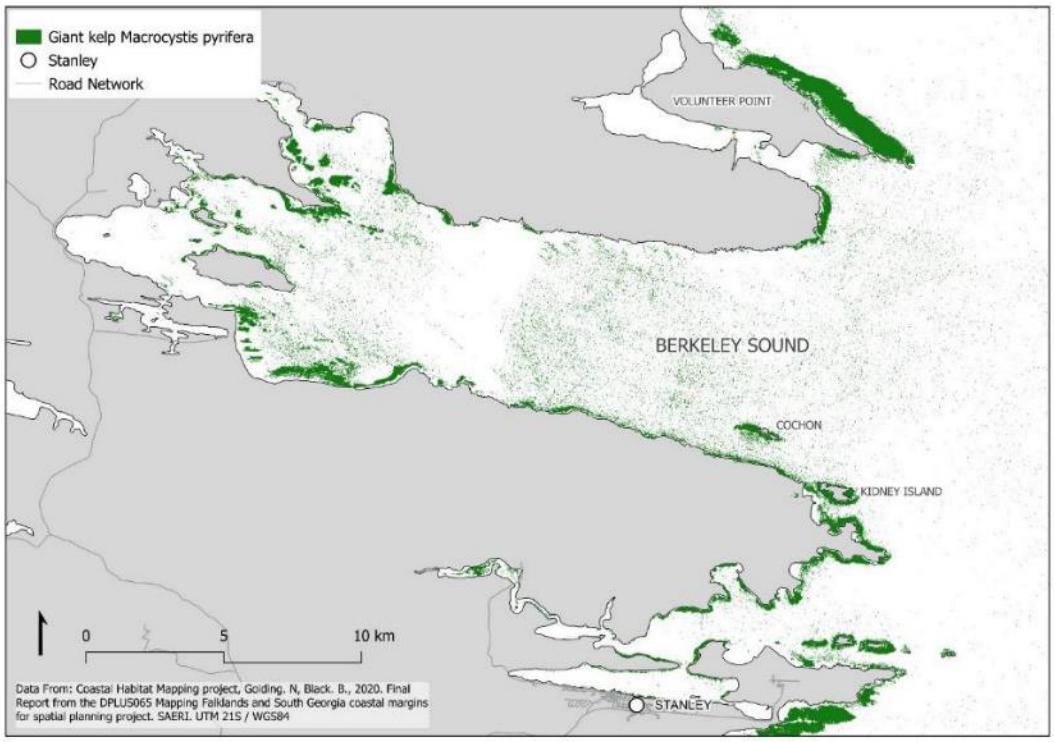

Figure 7-37: Map showing the distribution of giant kelp (*Macrocystis pyrifera*) in Berkeley Sound

7.4.3 Benthic environment

7.4.3.1 Introduction

Benthic organisms (or benthos) are the flora and fauna found on the bottom, or in the bottom sediments, of the sea.

7.4.3.2 NFB and Sea Lion Field benthos

A baseline understanding of the offshore benthic environment is required in order to inform the assessment of:

- Potential environmental impact of disturbance to the seabed from the placement of objects,
- Potential environmental impact of the discharge of drill cuttings and subsea operational discharges, and
- Potential environmental impact of underwater noise offshore and inshore.

Potential impacts of drilling activities would be of particular concern if there are any rare or protected species present within the area likely to be affected by drilling activities.

7.4.3.2.1 Offshore benthic flora and fauna

As described in Section 7.2.2, a number of baseline and post-drilling benthic surveys have been conducted in the Falkland Islands since 1998. Although the results from these surveys are useful in a broad sense, it is important to note that there have in many cases, and especially with the older surveys, been significant inaccuracies and inconsistencies with the survey design, sample processing, and species identification. This is an issue that was addressed by the GAP project (Section 7.2.4.2), which improved taxonomic resolution and quality control, and the design methodologies for future environmental baseline studies.

The pre-development and post-drilling surveys of the Sea Lion area were conducted in March and April 2012 in Licence Blocks PL032 and PL004 (Gardline, 2013a). In total, 90 stations were sampled: 54 in the environmental baseline survey, 28 (four of which were replicated from the Development survey) in areas where drilling had previously taken place, and eight random 'Quality Assurance / Quality Control' stations.

The results and analyses showed that the entire survey area was fairly homogeneous and the benthic community was typical of the sediments in the area (Section 7.3.7.1). The community structure was characterised as undisturbed and unpolluted by anthropogenic activity. In terms of the number of taxa present, polychaetes were the most abundant taxonomic group at most stations, making up 53 % of the taxa found throughout the survey area. Crustaceans were the next most abundant group, making up 23 % of the total taxa. Molluscs, echinoderms and 'other' taxonomic groups made up the remainder.

With respect to individual animals, overall crustaceans were the most abundant, making up 38 % of the total number of individuals; polychaetes made up 37 % of the total. There appeared to be a slight degree of spatial differentiation, with slightly more crustacean species found in the southern part of the survey area. The results of the post-drill survey found that the benthic community was typical of those found in undisturbed / unpolluted medium to coarse silt environments, with no evidence of anthropogenic disturbance as a result of drilling activities. Species diversity and abundance was relatively uniform across the survey area.

Although there are inconsistencies in methodology, analyses, and taxonomic resolution, the surveys generally show that the benthic community throughout the survey area can be characterised as a typical silt / mud benthic environment. The consistency in results between pre and post-drilling surveys, both in 1998 and 2012, suggest that the drill operations to date have had little or no effect on

the benthic community. The surveys have led to the identification of new species being identified within the Falkland Islands, highlighting the incomplete state of our knowledge on the deepwater benthic environment of the Falkland Islands.

7.4.3.2.2 Offshore benthic habitat assessments

At each station, a habitat assessment was conducted in order to identify:

- Sediment characteristics / benthic species which may indicate an area of environmental interest,
- The presence of any potentially sensitive habitats equivalent to those protected under Annex I of the EC Habitats Directive 92/43/EEC (as enacted by the UK's Offshore Marine Conservation (Natural Habitats) Regulations 2010 (as amended)), such as:
  - Biogenic, stony or bedrock reefs or any other habitats, and / or
  - Submarine structures made by leaking gases.
- Threatened and / or declining species or habitats which are on the OSPAR (2008) list in the UK Biodiversity Action Plan (JNCC, 2016).

Following this assessment, it was concluded that none of the above were within the surveyed area (Gardline, 2013a).

7.4.3.2.3 Deep water benthos predictive modeling

The deepwater benthic assemblages between 200 – 3000 m depth within the Falkland Conservation Zones were examined using a predictive modeling approach in a study done in support of the Falkland Islands toothfish fishery MSC certification of sustainability, commissioned by Consolidated Fisheries Ltd. Detailed methods and results of this analysis is found in SAERI (2023) Vulnerable Marine Ecosystems Project: Technical Document. Report prepared for Consolidated Fishing Ltd. July 2023.

Species predictive modeling (sometimes called species distribution modeling) compares a suite of physical variables with actual species observations, then uses the combination of physical variables that relate to the species location to predict the distribution of those species in areas that have not been sampled. In this sense, the analysis produces what is essentially a habitat suitability map for each species, and this is interpreted as the probability of a species distribution in those suitable habitats.

This study was particularly interested in those species considered to be Vulnerable Marine Ecosystem (VME) indicator taxa; that is those species that are particularly vulnerable to impacts, in this case, vulnerable to seabed fishing and bottom contact activities, due to their characteristics of having fragile structure, slow reproduction and growth rates, or rarity, to name a few. In this study, six groups of VME indicator taxa were examined: Porifera (sponges), Pennatulacea (sea pens), Alcyonacea (soft corals), Gorgonacea (bamboo corals, sea fans, bubblegum corals), Scleractinia (stony cup corals), and Stylasteridae (frame building hydrocoral). A seventh species, *Bathelia candida* (reef-forming coral, similar to *Lophelia* spp. reefs in the northern hemisphere) was examined separately from the Scleractinia due to its recognised importance in other deep-sea habitats. Physical factors used for habitat suitability included seabed depth, seabed terrain (slope, aspect, curvature, bathymetric position index, rugosity), sediment type (rock, gravel, sand, mud, carbonates), and oceanographic variables (temperature, salinity, chlorophyll, oxygen, nutrients, seabed current). Species occurrence data were gathered from a variety of locally held data gathered by FIG Fisheries and recorded in previous hydrocarbon exploration campaigns, as well as online data (e.g., OBIS). Physical data were collected from a range of online sources (see SAERI 2023 for details). The prediction algorithms used were an ensemble (average) of two methods; MaxEnt (Maximum Entropy) and RF (Random Forest)

models, which are both suitable for presence-only analysis in deep-sea environments. This analysis is used to provide predicted presence only, not abundance or aggregations.

The total number of VME indicator taxa with at least 50 % probability of being present in the Navitas production area can be seen in Figure 7-38. This indicates that are between 1 and 5 VME indicator taxa with at least 50 % likelihood of being present at any location within the PL032 license area, and 1 - 4 indicator taxa in the production area. The VME indicator groups that are predicted to be found are combinations of Pennatulacea (sea pens), Alcyonacea (soft corals), Scleractinia (stony cup corals), Gorgonacea (bamboo corals, sea fans, bubblegum corals) Stylasteridae (frame building hydrocoral), and Porifera (sponges). No *Bathelia candida* (reef-forming coral) is predicted to be present in the area.

Despite the VME groups predicted to be found in the area, early assessments of surveys by Gardline (2013a) concluded that there were no indications of sensitive habitats equivalent to those protected under Annex I of the EC Habitats Directive 92/43/EEC (as enacted by the UK's Offshore Marine Conservation (Natural Habitats) Regulations 2010 (as amended)) including Biogenic, stony or bedrock reefs or any other habitats, submarine structures made by leaking gases, or threatened and / or declining species or habitats which are on the OSPAR (2008) list in the UK Biodiversity Action Plan (JNCC, 2016). This suggests that of those taxa with a 50 % or greater predicted probability of being present in the area, these taxa are likely to be low density (not in aggregations) and / or rare, given that they went undetected in the Gardline (2013a) survey. The sediment regime in the area was classified as 'mud grading to sand', however glacial dropstones are found infrequently and these are often associated with encrusting VME species, which may result in a patchy distribution and low densities. Finally, it can be seen from the predicted distribution of VME indicator taxa that these species / habitats are widely distributed in the surrounding areas adjacent to PL032 and throughout the Falkland Conservation Zone.

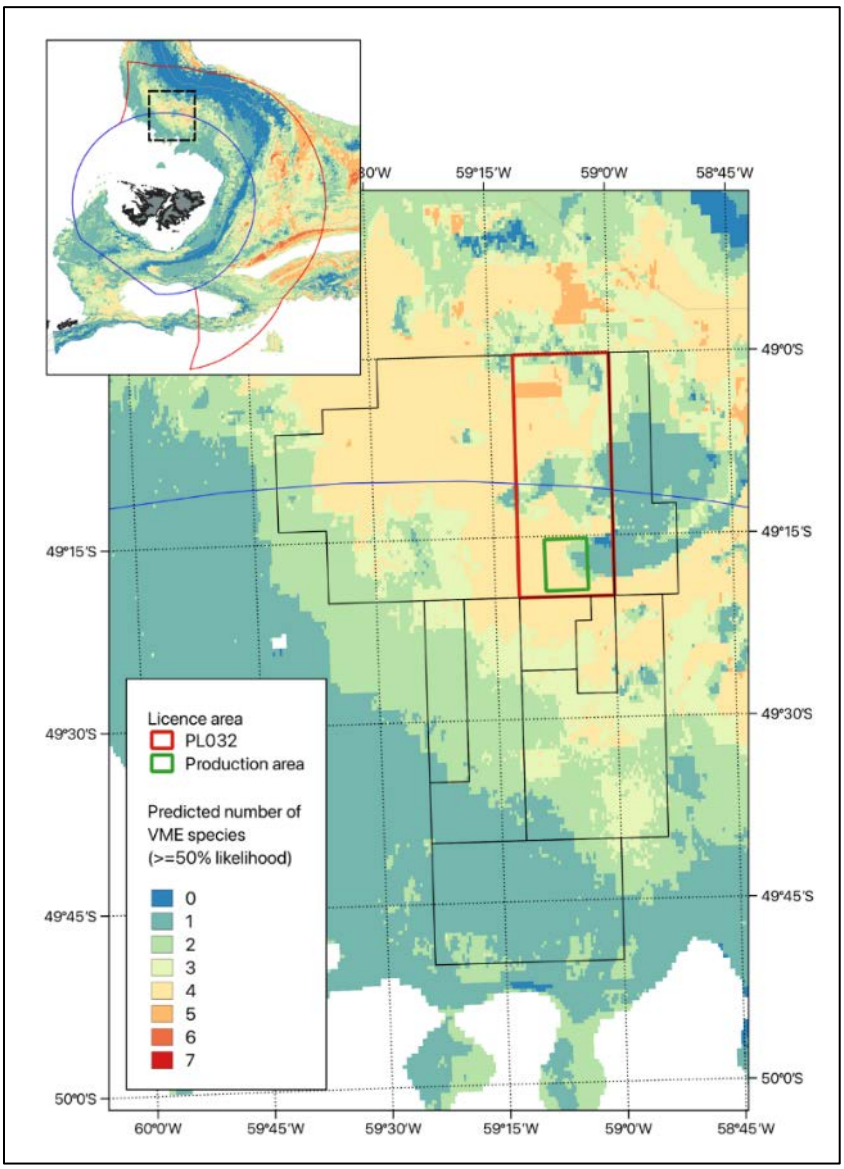

Figure 7-38: Number of VME indicator taxa predicted to be present in the Sea Lion field, licence area, and production area (redrawn from SAERI 2023)

7.4.3.3 Berkeley Sound benthos

A baseline understanding of the inshore benthic environment is important to:

- Inform the assessment of potential impact of disturbances to the seabed from the placement of objects,
- Inform the assessment of risks associated with inshore oil spills,
- Inform the assessment of potential impacts associated with underwater noise inshore, and
- Provide a point of comparison for any benthic monitoring.

The inshore marine environment of the Falkland Islands is poorly studied. Prior to the current ongoing studies by SMSG or those commissioned by POEPL, few surveys of significance have been conducted. Attempts to survey and categorise the inshore environment and marine habitats of the Falkland Islands are therefore relatively recent and are largely limited to studies undertaken by the SMSG.

There have been a number of SMSG expeditions to Berkeley Sound to describe the benthic communities (SMSG, 2009a; Neely, *et al.,* 2010b; SMSG, 2012; Davidson, 2016; EnvSys, 2016), which provide comprehensive coverage of the shallow marine environment, <20 m in depth (see Section 7.4.3.3.1.1). In the winter of 2015, Benthic Solutions, under contract to POEPL, surveyed the deeper waters of the Sound (generally >10 m) using grab samples and underwater photography. Section 7.4.3.3.3 describes the results of these surveys, further details can be found in (BSL, 2015a, b & c; EnvSys, 2016).

7.4.3.3.1 Berkeley Sound benthic flora and fauna

7.4.3.3.1.1 Inter-tidal and shallow marine benthos

Thus far, SMSG surveys have recorded a total of 530 species in the Falkland Islands intertidal and shallow waters (< 20 m water depth). A few species, particularly sponges, are newly identified and are still undergoing scientific description and naming (e.g., Goodwin, *et al.,* 2011; Goodwin, *et al.,* 2016).

In February 2016, SMSG were commissioned by POEPL to survey the shallow marine habitats within Berkeley Sound. In total, 27 stations were surveyed and results are presented in EnvSys (2016) and SAERI and SMSG (2016). Classifications of the subtidal habitats were based upon the habitat classification system created by SMSG in 2010. The survey showed that the main subtidal habitats within the survey area were Macrocystis pyrifera forest, and Sand, both being present at the same number of stations. Other habitats present at varying numbers of sites include: Mixed *Macrocystis* and *Lessonia* forest, Mud, Rock barren, Silty *Lessonia* forest, Fine sand, *Austromegabalanus psittacus* reef, Rock barren and gravel, and Drift algae and Algal litter.

The different habitat types were ranked as follows, according to the number of species found in each (note that the analyses were conducted using quadrat photography and represent epifaunal species only):

- *Macrocystis pyrifera* forest, with 94 species found,
- Rock barren habitat, with 47 different species,
- Mixed *Macrocystis pyrifera* and *Lessonia* forest, with 35 different species being present,
- Silty *Lessonia* forest habitat had 33 species present,
- *Austromegabalanus psittacus* reef habitat had 24 species,
- The Sand habitat had nine species,
- Rock barren and gravel habitat had eight species present,
- Mud had six species,
- Fine sand habitat had five species, and
- Drift Algae and algal litter habitat type had two species present.

A total of 139 species were observed and recorded, from the 27 dives, though not all were identified to species or even genus level. By phyla, Echinodermata: sea star (starfish) was the most prevalent grouping (10.04 %), in terms of relative abundance, followed by Chordata: ascidians (9.06 %), Arthropoda: crab (8.25 %), Porifera: sponges (8.16 %) and Echinodermata: sea urchins (7.62 %). Arthropoda: amphipoda and Mollusca: cephalopods were the least abundant representing 0.09 % of the total. By species, the Chilean red sea urchin (*Loxechinus albus*) had the highest overall relative abundance, followed by the blue-spotted rockcod (*Patagonotothen cornucola*), and giant kelp (*Macrocystis pyrifera*).

All of the subtidal habitats recorded are common within the Falkland Islands, and each has varying degrees of associated biodiversity. Berkeley Sound, itself, has different amounts of exposure and

openness, going from less exposed / more enclosed at the western end of the Sound, to more exposed / less enclosed towards the eastern end. This will have an impact on the habitat types and species present across the area.

7.4.3.3.1.2 Deeper water benthos

Macrofaunal analysis

Benthic Solutions carried out macrofaunal analysis on 138 grab sample replicates obtained at 46 baseline stations within Berkeley Sound (BSL, 2015c).

The analysis identified a total of 28,369 individuals from 350 taxa in all 138 samples analysed (taxa (singularly referred to as taxon) refers to any taxonomic group; species, genus etc.). Nomenclature follows Neely & Brickle (2013).

Of the 350 taxa recorded, 281 were infaunal (including solitary epifauna), consisting of:

- Annelids (segmented worms): 106 taxa (51.4 % of the total individuals),
- Crustaceans (barnacles, shrimps, crabs etc.): 79 taxa (34.6 % of total individuals),
- Molluscs (snails, bivalves and sea slugs): 56 taxa (7.8 % of total individuals),
- Echinoderms (sea urchins, starfish, brittle stars etc.): 16 taxa (1.7 % of total individuals),
- Solitary epifauna: 9 taxa (0.3% of total individuals), and
- Other groups: (Nemertea (ribbon worms), Nematoda (round worms), Sipuncula (Peanut worms), Turbellaria (flatworms), and Brachiopoda (lamp shells), Pycnogonida (sea spiders), Pisces (fish), Enteropneusta (acorn worms)), 15 taxa (4.2 % of individuals).

With the exception of species that were intentionally grouped into higher taxonomic levels (e.g., Nematoda, Nemertea), the majority of adult specimens were identified to genus level or lower. Approximately 60.7 % of specimens collected during this survey were identified to species level with 88.3 % identified to at least genus level.

Infaunal trends

The macrofauna throughout Berkeley Sound was highly variable in terms of abundance, richness and species composition, as would be expected given the highly variable nature of the sediment and the large scale of survey area. A total of 185 taxa were present with an average density of more than one individual per sample (0.1 m^2), while 58 of the 281 infaunal taxa recorded were represented by only a single specimen. Annelids (segmented worms) were found to dominate the infaunal community. This dominance is seen by overall rank, with six annelid polychaetes recorded in the top ten ranked taxa. This dominance was followed by crustacea which were also well represented, with four representatives in the top ten ranked taxa.

The results of further analysis generally indicate a wide variation in infaunal community diversity within Berkeley Sound with higher dominance and lower diversity at stations with impoverished fauna. Of particular note, Stations 02A, 04, 34 and 40 had particularly low species richness and diversity. These stations are all close to sites of human activity and also had elevated levels of pollutants (see Section 7.3.7.2.2; BSL, 2015c for full details). Station 31 is close to the LTV anchorage sites and has been frequently used as an anchoring site by other vessels. This site was made up of slightly gravelly sand, with lower species abundance and richness compared to adjacent areas, particularly with respect to sediment infauna (BSL, 2015b).

Epifaunal and other biological groups

The results show that 44 of the 46 macrofaunal samples recorded the presence of invertebrate species that are generally considered to be epifaunal and are not statistically assessed within the infauna

(discussed above). Analysis of the infaunal and epifaunal communities indicates that generally infauna are numerically dominant, with epifauna making up a small but nevertheless important part of the community. Solitary and colonial epifauna showed a general decrease in richness at stations containing uniform sands. Epifauna were surveyed by a combination of grab and photographic surveys.

Observations on epifauna recovered within the grab samples are as follows.

- Coelenterata (sea anemones, sea pens): The sessile epifauna was characterised by a scarcity of Coelenterata, with only a few small sea anemones, and a few fragmented specimens, mostly of the hydroid *Sertularella* sp.,
- Chordata (sea squirts): Tunicates were mostly represented by large specimens of the stalked solitary species, stalked piure (*Pyura legumen*), a few *Ascidia* sp. specimens and encrusting colonial lace tunicate (*Didemnidae* spp.),
- Bryozoa (bryozoan): The Bryozoa fauna was very rich and diverse within Berkeley Sound. Large numbers were found to inhabit almost any solid surface, including shells, the giant barnacle (*Austromegabalanus psittacus*), and larger species of seaweed. The general knowledge of Cyclopora (e.g., *Tubulipora* spp., *Lichenopora* sp. and *Disporella* sp.) is poor and the latter cannot be identified with certainty as it never been systematically assessed for Antarctic and sub-Antarctic waters. The upright branching genus *Cellaria* are habitat-forming in Northern Atlantic waters offshore but does not reach such importance here. Apart from a few species of what were formerly known as *Anasca* sp. these species are all encrusting, and
- Other: A solitary Entoproct (*Barentsia* sp.) specimen and a few species of Porifera (sponges) compose the rest of the epifauna.

It should be noted that grab sampling often fails to recover coarse material, especially larger pebbles and cobbles colonised by epifauna and samples cannot be taken over bedrock, therefore, it is important to not only assess epifauna through physical samples, but also to analyse photographic footage.

Photographic survey operations were carried out using a combined digital video and stills camera system deployed in a drop-down frame. This survey method is especially useful at stations over exposed bedrock where no samples were recovered, in order to determine what species are present. Seabed imagery indicated a wide variety of epifaunal groups and species throughout Berkeley Sound. Conspicuous species included:

- The fan worm *Perkinsiana antarctica*,
- Schythe-edged serolis *Acanthoserolis scythei*,
- Ornamented hermit crab *Pagurus comptus*,
- Lobster krill *Grimothea gregaria,*
- The spider crabs *Eurypodius* spp.,
- Ribbed mussel *Aulacomya atra*,
- Patagonian scallop *Zygochlamys patagonica*,
- Veined brachipod *Magellania venosa*,
- Snowflake bryozoan *Tubulipora* sp.,
- Beaded sea star *Cosmasterias lurida*,
- Sunstar *Labidiaster radiosus*,
- Chilean sea urchin *Loxechinus albus,* and

- Encrusting sponges:
  - Tedania species *Tedania* sp.,
  - Chalk sponge *Grantia* sp.,
  - Boring sponge *Cliona* sp.,
  - Warty tunicate *Asterocarpa humilis*,
  - Stalked piure *Pyura legumen*, and
  - Bubble tunicate *Styela* spp.

Sponges were extremely prevalent in areas of bedrock exposure, cobbles, boulders and other hard contacts. Urchins, brittlestars, sea cucumbers and hermit crabs were also commonly found in these areas. Starfish and tunicates were fairly common throughout, whereas lobster krill (*Grimothea gregaria*) and isopods dominated sand habitats. Other Crustacea, particularly crabs, were frequently observed at the transition zones between gravel ribbons and sands, and amongst mega-rippled bedforms. Bryozoans and hydroids were often observed attached to and encrusting upon bedrock, hard contacts and algae, and fish such as rockcod (*Patagonotothen* spp.) dominated the free-swimming megafauna. In addition, evidence of cephalopod spawning was recorded at Station 29, where a single egg cluster was found to be attached to a kelp stipe; these are of the commercially important Patagonian long-fin squid (*Doryteuthis gahi*; referred to as 'loligo' hereafter). It should be noted that the survey was conducted between the two main spawning seasons for the main loligo cohorts (Arkhipkin and Middleton, 2002a; 2002b). Nonetheless, this observation confirms that this species spawns within Berkeley Sound, although it is not possible to infer the intensity of the spawning ground.

Seabed photography confirmed the variable nature of the seabed within Berkeley Sound, as indicated by the bathymetric and side scan sonar datasets (see Section 7.3.6.2). Complex gravel ribbons were observed from sites close to the LTV anchorage sites eastwards to the mouth of the Sound, throughout the sand-dominated areas. Sparsely populated epifaunal communities were observed in areas of sand, although the interspersing gravel ribbons (gravels and relic clam shells and barnacles) were colonised by a diverse range of organisms.

7.4.3.3.2 Berkeley Sound inter-tidal and shallow marine habitat mapping and classification

7.4.3.3.2.1 Shallow marine surveys undertaken

Since 2006, SMSG have undertaken surveys at over 300 sites within several broad geographical areas of the Falkland Islands (Figure 7-39), and SAERI/SMSG have more recently collaborated on a number of surveys:

- Beauchêne Island (SMSG, 2009b),
- Jason Islands (SMSG, 2008),
- Adventure Sound (SMSG, 2009c),
- Port William,
- Stanley Harbour,
- Berkeley Sound (SMSG, 2009a; Neely, *et al.,* 2010b; SMSG, 2012),
- New Island,
- Falkland Sound,
- King George Bay,
- Hummock Island (ART/SMSG/SAERI),

- Bird Island (SAERI/SMSG),
- Shag Rock (SAERI/SMSG), and
- Port Stephens Harbour (SMSG/SAERI).

The distribution of these surveys throughout the Falklands archipelago helps to place the significance of the habitats found within Berkeley Sound in context. However, the Falkland Islands have an estimated 7,700 km of coastline and 750 offshore islands and thus large sections of the Falklands shorelines remain unsurveyed.

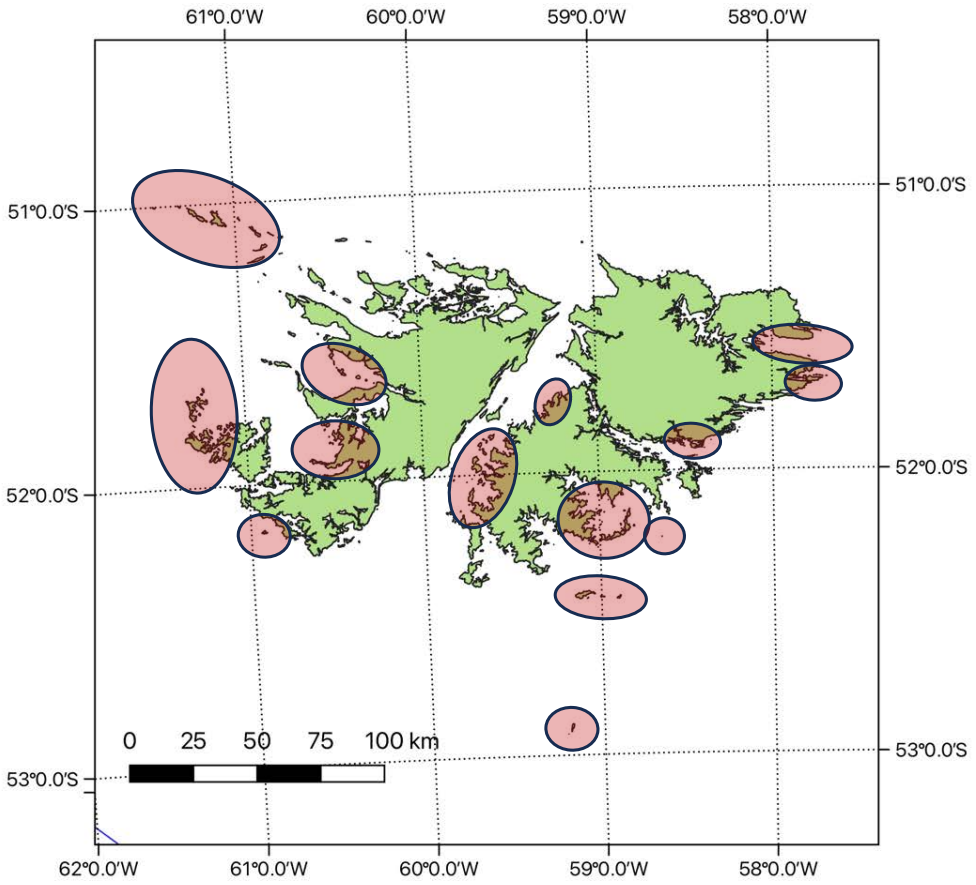

Figure 7-39: Distribution of SMSG dive survey sites across the Falklands archipelago

SMSG dive survey methodology

The survey methodology employed by SMSG consists of three parts:

- Mobile animal surveys,
- Photographic quadrats,
- ROV Surveys, and
- JNCC sublittoral habitat classification.

Full details of the methodology and expeditions can be found in Neely (2010).

Island-wide shallow marine survey coverage

The full spatial extent of each marine habitat type is unknown and has not been fully mapped for the Falkland Islands as a whole. Therefore, it is not yet possible to define spatially limited, rare or 'at risk' marine habitats for the Falkland Islands. While there are some habitats which may be environmentally

sensitive, or equivalent to those listed in Annex I of the EC Habitats Directive 92/43/EEC) (Section 7.4.3.2.2), and these areas have been subject to greater survey effort, thus far these appear to be 'rare' habitat types. Nonetheless, further surveys at other sites may identify additional occurrence of these habitats.

Berkeley Sound exhibits a high diversity of marine habitats, including some spatially limited reef habitats. It is likely that due to the range of coastline types and the projecting position to the north-east of the Falklands with oceanic currents close inshore that the area covering Cape Pembroke, Kidney Island and Berkeley Sound has higher diversity than elsewhere on East Falkland; however, due to unequal survey effort between sites it is not possible to be categorical.

Satellite imagery used for refining the habitat maps

In order to assist in comparative assessment of the Berkeley Sound coast, Environment Systems (EnvSys) was commissioned, in partnership with SAERI, to prepare shallow marine, inter-tidal and terrestrial habitat maps. This work builds on previous projects to map habitat types in the LTV anchorage sites. Background information concerning earlier phases of the mapping project can be found in Pike *et al.* (2014) and Marengo (2014b). The results from the preliminary analysis are presented in 'North Falklands Coastline Environmental Sensitivity for Oil Spill Response' (Premier, 2014a).

Due to the considerable extent of the marine and coastal area that needs to be mapped, a method was developed that combines the use of satellite imagery together with field data, including collection of species presence data, to provide updated detailed habitat maps (EnvSys, 2016).

The satellite imagery used to refine the shallow marine, inter-tidal and terrestrial habitat maps was:

- Three World View images (Figure 7-40) one from November 2011 and two from January 2012 collected in Part 1 of the project. The images were processed for use within a terrestrial and marine environment, as described in EnvSys, (2016), and
- A Sentinel-2 image acquired for this project (Part 2). The Sentinel-2 image used for this study was captured in January 2016. Technical details of this satellite system are described in EnvSys (2016).

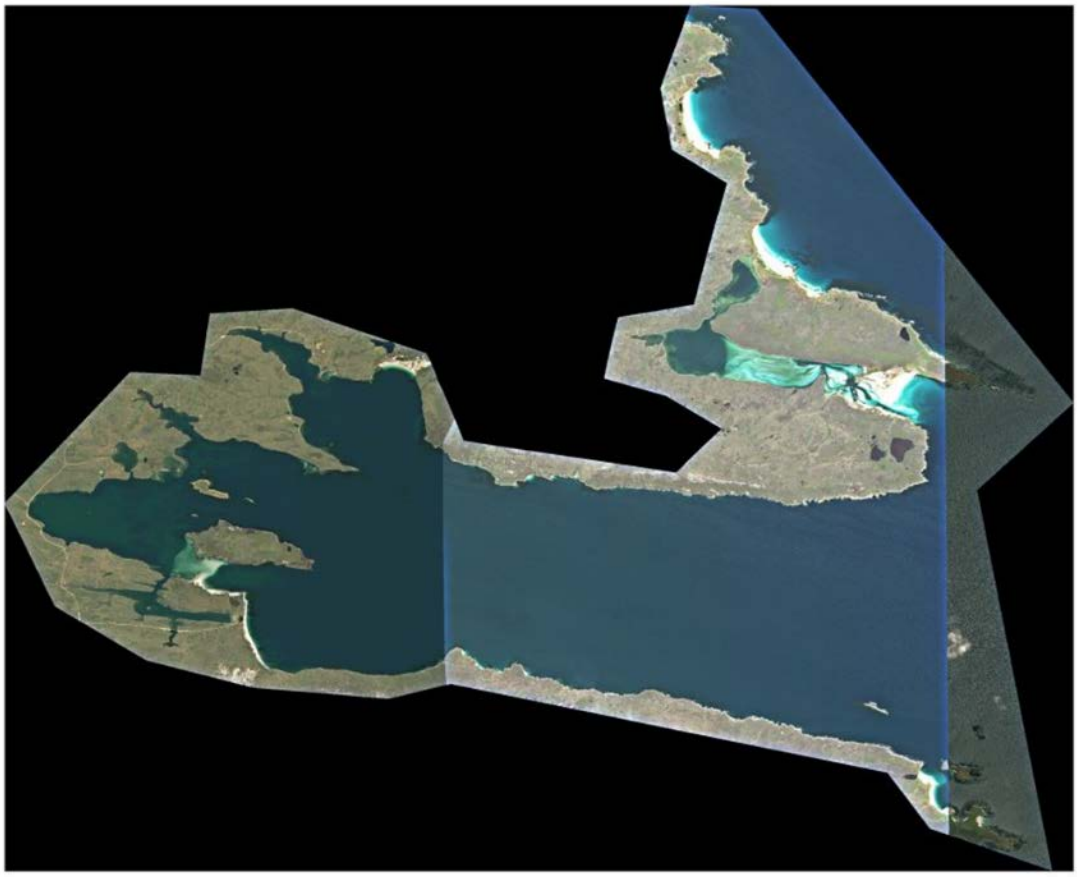

Figure 7-40: Satellite image of Berkeley Sound showing the extent of the three separate images

Using fieldwork to support mapping from satellite data

The fieldwork was undertaken to provide 'ground truth data' to support a detailed understanding of the variability of remote sensing characteristics of particular habitats and to support the selection of an accurate digital elevation model. The species data collected also provided more detailed habitat information on the marine, inter-tidal and terrestrial habitats.

7.4.3.3.2.2 Shallow marine habitat mapping

To date 19 habitats have been identified and full habitat descriptions are provided by Neely *et al.* (2010a) and are described briefly below (Table 7.5). It is likely that further study will identify additional habitat types (especially restricted habitats of limited spatial extent that may be missed with low survey effort) and that some hierarchical subdivision of existing habitat types will occur.

The 18 habitat types currently described are:

- *Macrocystis pyrifera* forest,
- *Macrocystis / Lessonia* mixed forest,
- Deep *Lessonia* forest,
- Silty *Lessonia* forest,
- Shallow *Lessonia* forest,
- Shallow *Lessonia* forest with high algal cover,
- Fleshy algae-covered substrate,
- *Durvillaea* forest,

- Mussel bed,
- *Austromegabalanus psittacus* reef,
- *Crepidula dilatata* reef,
- *Phragmatopoma virgini* reef,
- Rock barren,
- Cobbles,
- Sand,
- Fine sand,
- Mud,
- Sheltered artificial structures (Neely, *et al.,* 2010a), and
- Deep (40-50m) *Microporella* sp. (bryozoan) beds (SFL, 2022a).

WorldView 2 satellite has three bands which can penetrate water to between six and 15 metre depth and these bands were used to map the shallow water marine habitats with the aid of dive survey ground-truthing.

From the information gathered so far, there is some zonation of main cover forming species around the Sound. In particular, the western-most edge, being the most sheltered, tends to have the finest sediments and more *Lessonia* rather than *Macrocystis* kelp species. The proportion of each habitat mapped is shown in Table 7.6 and mapped in Figure 7-41.

Table 7.5: Habitat descriptions for the Falkland Islands shallow marine environment (Neely, *et al.,* 2010a) found in Berkeley Sound

Habitat type	Exposure	Substrate	Depth range	Characteristic species
Macrocystis pyrifera forest	Moderate to heavy	Solid bedrock occ. large boulders	3 – 18 m	Giant kelp, coralline algae, common sea star, pink pencil urchin and beaded brittle star.
Macrocystis / Lessonia mixed forest	Moderate to heavy	Solid bedrock occ. large boulders	2 – 20 m	Tree kelp, giant kelp, coralline algae, ornamented hermit crab, pink pencil urchin and common sea star.
Deep *Lessonia* forest	Moderate to heavy	Solid bedrock occ. large boulders	6 – 20+ m	Tree kelp, coralline algae, sponges, Atlantic purple sea urchin, flower-lobed anemone and common sea star.
Silty *Lessonia* forest	Minimal	Solid bedrock or boulders overlaid with a layer of silt	1 – 20 m	Tree kelp, saffron sea cucumber, Patagonian scallop and pink pencil urchin.
Shallow *Lessonia* forest	Moderate to heavy	Solid bedrock occ. large boulders	4 – 17 m	Tree kelp, coralline algae, sponges, common sea star, bryozoans, flower-lobed anemone and Atlantic purple sea urchin.
Shallow *Lessonia* forest with high algal cover	Moderate	Solid bedrock occ. large boulders with fleshy algae	6 – 8 m	Tree kelp and leafy / digitate algae.
Fleshy algae-covered substrate	Moderate	Solid bedrock occ. large boulders with fleshy algae	2 – 11 m	Leafy / digitate algae.
Durvillaea forest	Heavy, surge and swell	Solid bedrock or immobile boulders	0 – 4 m	Bull kelp, coralline algae and Magellanic copper limpet.

Habitat type	Exposure	Substrate	Depth range	Characteristic species
Mussel bed	Minimal to heavy	Solid bedrock, often abutting sand, mud or silt	0 – 20 m	Giant mussel, ribbed mussel, blue mussel and ornamented hermit crab, coralline algae.
Austromegabalanus psittacus reef	Moderate	Solid bedrock, often vertical faces	3 – 10 m	Giant barnacle, coralline algae, bubble tunicate and giant tunicate.
Crepidula dilatata reef	Moderate	Solid bedrock	1 – 5 m	Broad slipper limpet, coralline algae, digitate red algae and Chilean sea urchin.
Phragmatopoma virgini reef	Moderate	Solid bedrock or immobile boulders	0 – 7 m	Pink feather duster worm, piure and bryozoans.
Rock barren	Moderate	Solid bedrock or immobile boulders	3 – 10 m	Coralline algae, Chilean sea urchin and ornamented hermit crab.
Cobbles	Heavy, often high surge.	Mobile cobbles, 5 – 20 cm in diameter	5 – 20 m	Flaming limpet.
Sand	Moderate	Sand	0 – 20 m	Scythe-edged *Serolis*, purple backed crab and tessellated rock cod.
Fine sand	Minimal	Fine sand	0 – 5 m	Filamentous algae, sea lettuce, striped clam and short-spired volutid.
Mud	Minimal	Mud	0 – 15 m	Gregarious lobster krill.
Sheltered artificial structures	Minimal	Boats, pilings etc.	0 – 4 m	Giant tunicate, vase tunicate and parchment worm.

Table 7.6: The area and percentage cover of each of the habitat types mapped in Berkeley Sound (EnvSys, 2016)

Habitat	Area (ha)	Percentage cover
Open water (area of water outside of the kelp line)	21,613.9	87.24
Sand cobbles and pebbles (detected in the subtidal)	552.4	2.23
Kelp mosaic / other species	525.2	2.12
Sand with rock platforms, boulders and cobbles	491.4	1.98
Sand occasional mud where sheltered	475.5	1.92
Macrocystis kelp forest	442.1	1.78
Cobbles and rocks (with Algae growth)	140.8	0.57
Lessonia kelp forest	121.6	0.49
Sand rocks and mud at different depths – mud where sheltered	115.5	0.47
Boulders and cobbles with some rock ledges and finer sediments	95.2	0.38
Rocks and boulders – with dense algae	70.8	0.29
Mosaic of rocks, boulders and fine sediments (medium diversity) with algae	70.0	0.28
Rock platforms – occasional mussel beds and finer sediment	60.0	0.24
Total	24,774	100

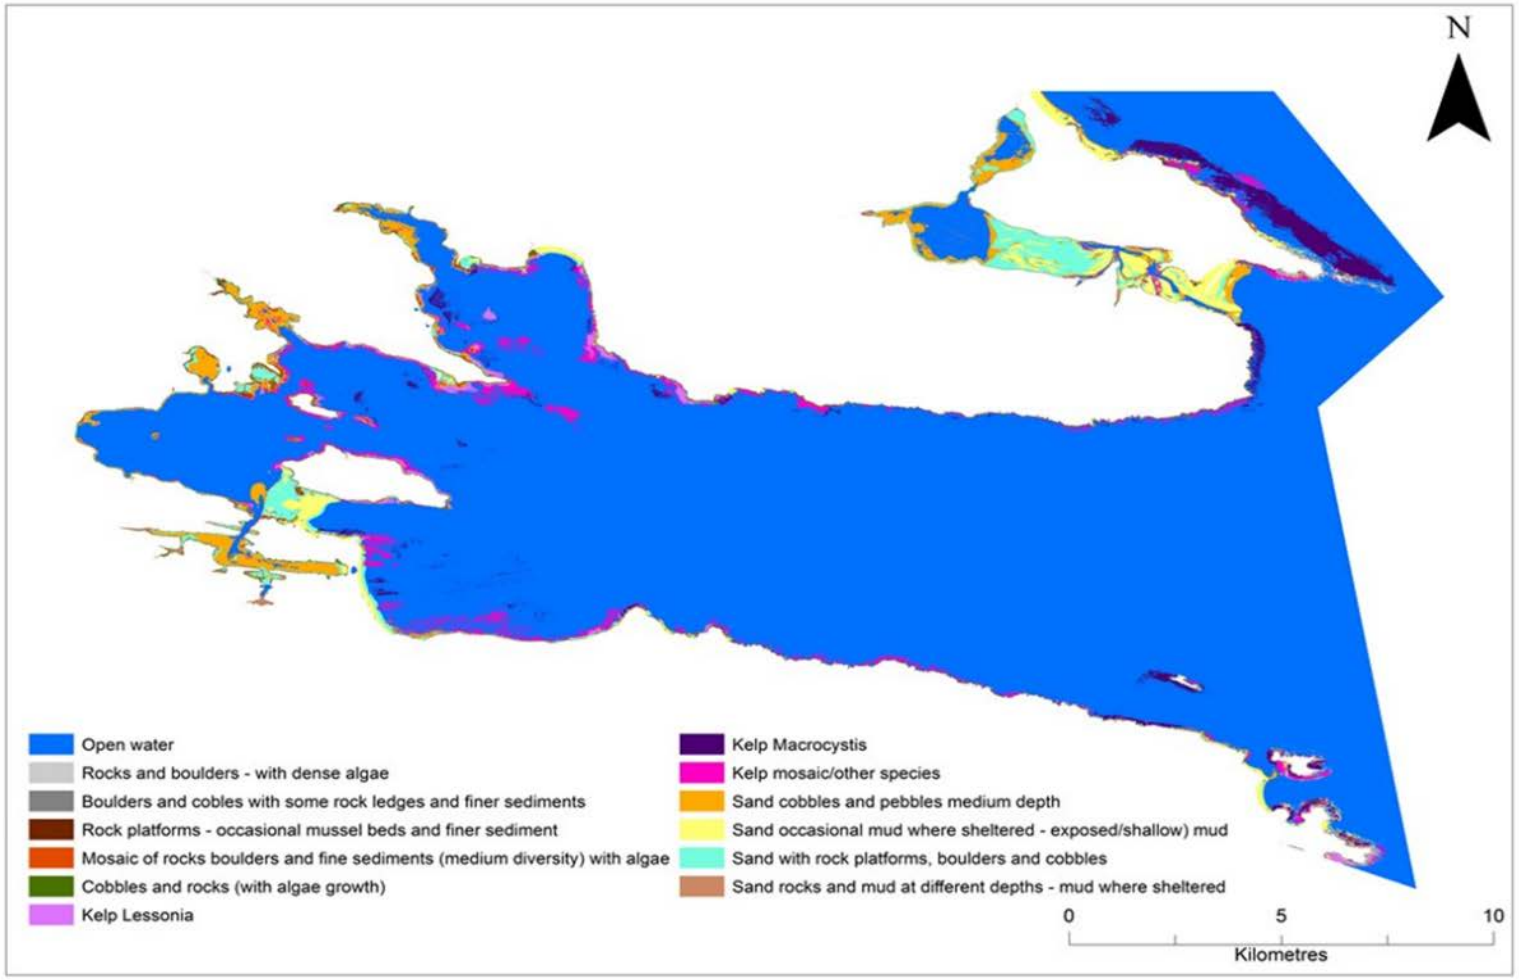

Figure 7-41: Shallow marine and intertidal habitat map for Berkeley Sound (EnvSys, 2016)

7.4.3.3.2.3 Inter-tidal habitat mapping

The inter-tidal zone is a very harsh environment and animals living there are exposed to extremes of temperature and salinity as the tides rise and fall. Intertidal habitats are characterised by vertical zonation with characteristic species present within each zone. Therefore, the same substrate type will support very different species assemblages across a relatively small distance. The species groups that are able to dominate each zone are well known from studies elsewhere in the world and reasonably predictable. However, there is currently no recognised habitat classification specifically for the intertidal habitats found in the Falkland Islands. Preliminary fieldwork to describe the inter-tidal habitats of the Falklands was conducted in February 2016, reported in EnvSys (2016). No formal, detailed habitat classification was obtained, as this would require a much more extensive survey and assessment than was afforded in this project; rather a general, qualitative description of type of substratum, species occurrences and degree of diversity has been generated.

The degree of species diversity was estimated based on the number of species occurring at each point of observation / quadrat and confirmed by visual estimation of the corresponding photos. Classes of species diversity were arbitrarily defined as 'low', 'medium', and 'high'. Anything less than 15 species was classed as 'low' and anything between 15 and 25 was classed as 'medium', while anything above 25 was classed as 'high'.

Following fieldwork, the characteristic of each of the intertidal field sites were examined against the spectral signatures of the imagery, in particular based on the sediment type and any algae or other species cover (e.g., mussel beds). Several other factors were considered in the image classification process including depth, the diversity of the communities and the substrates present. From this analysis, a look-up table (Table 7.7) was created to link the main classes from the field survey with features that could be observed in the remote sensing imagery.

Figure 7-42 and Figure 7-43 illustrate how the data collected during fieldwork was translated into the final habitat map. The map covering intertidal and shallow marine habitats for the whole of Berkeley Sound is shown in Figure 7-41 above. Note that Figure 7-43 shows the inter-tidal and shallow marine habitats combined.

Table 7.7: Look-up table linking fieldwork derived inter-tidal habitat classes and classes discernable in the remote sensing imagery

Fieldwork classes	Classes generated in the final map
Boulders	Boulders
Boulders and cobbles	Boulders and cobbles with some rock ledges and finer sediments
Boulders and pebbles	
Boulders and sand	
Cobbles	Cobbles / sparse vegetation
Cobbles and pebbles	Cobbles and rocks (with algae growth)
Gravel mud	Sand rocks and mud at different depths – mud where sheltered
Mosaic of cobbles, pebbles and gravel	Mosaic of rocks boulders and fine sediments (medium diversity) with algae spp.
Mosaic of platforms boulders and sand	
Mosaic of platforms, boulders and cobbles	
Mosaic of platforms, boulders and rocks	
Mosaic of platforms, boulders, cobbles and gravel	
Mosaic of platforms, cobbles and pebbles	
Mosaic of rocks, boulders and sand	
Mosaic of platforms, rocks, cobbles and sand	Sand with rock platforms, boulders and cobbles
Rock platforms	Rocks and boulders – with dense algae
Rock platforms and boulders	

Fieldwork classes	Classes generated in the final map
Rock platforms and cobbles	Brown rock platforms – occasional mussel beds and fine sediments
Rock platforms and sand	
Rocks	
Sand	Sand occasional mud where sheltered
Sand and boulders	Sand rocks and mud at different depths – mud where sheltered
Sand and cobbles	
Sand and dead shells	
Sand and rock escarpment	
Sand cobbles and pebbles	Sand cobbles and pebbles medium depth

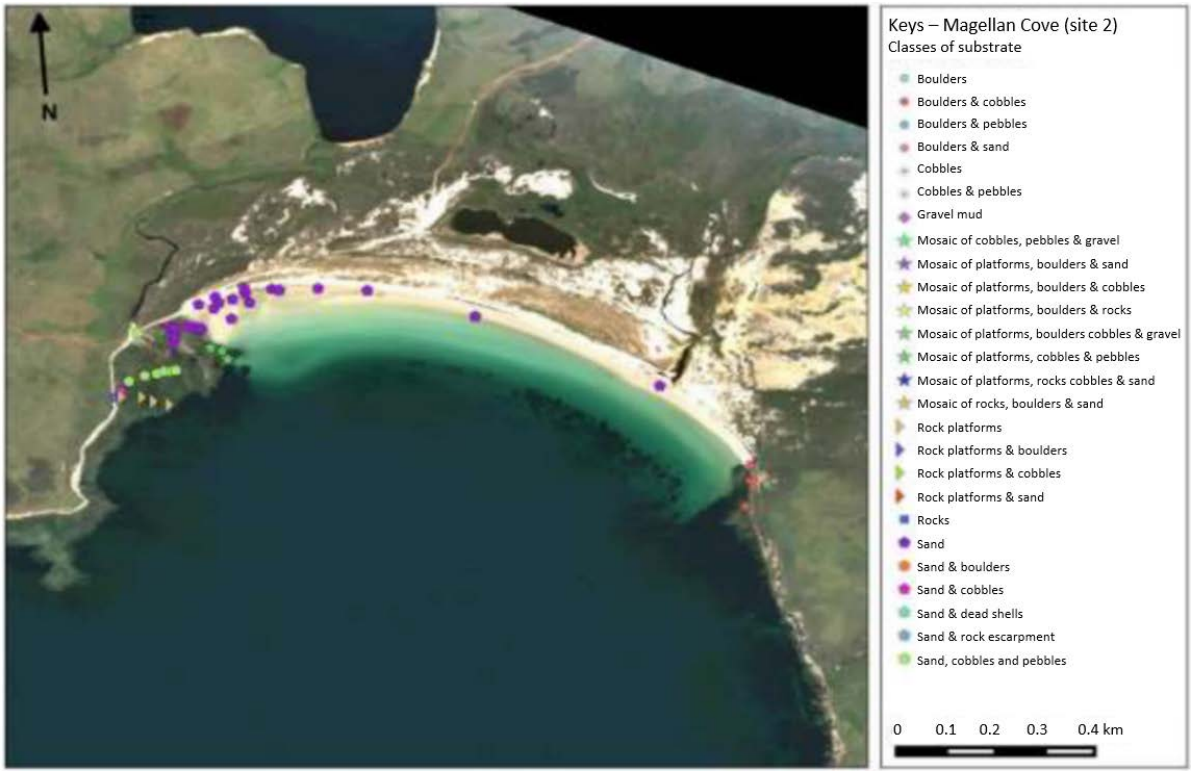

Figure 7-42: Sites and substrate classes recorded at Magellan Cove

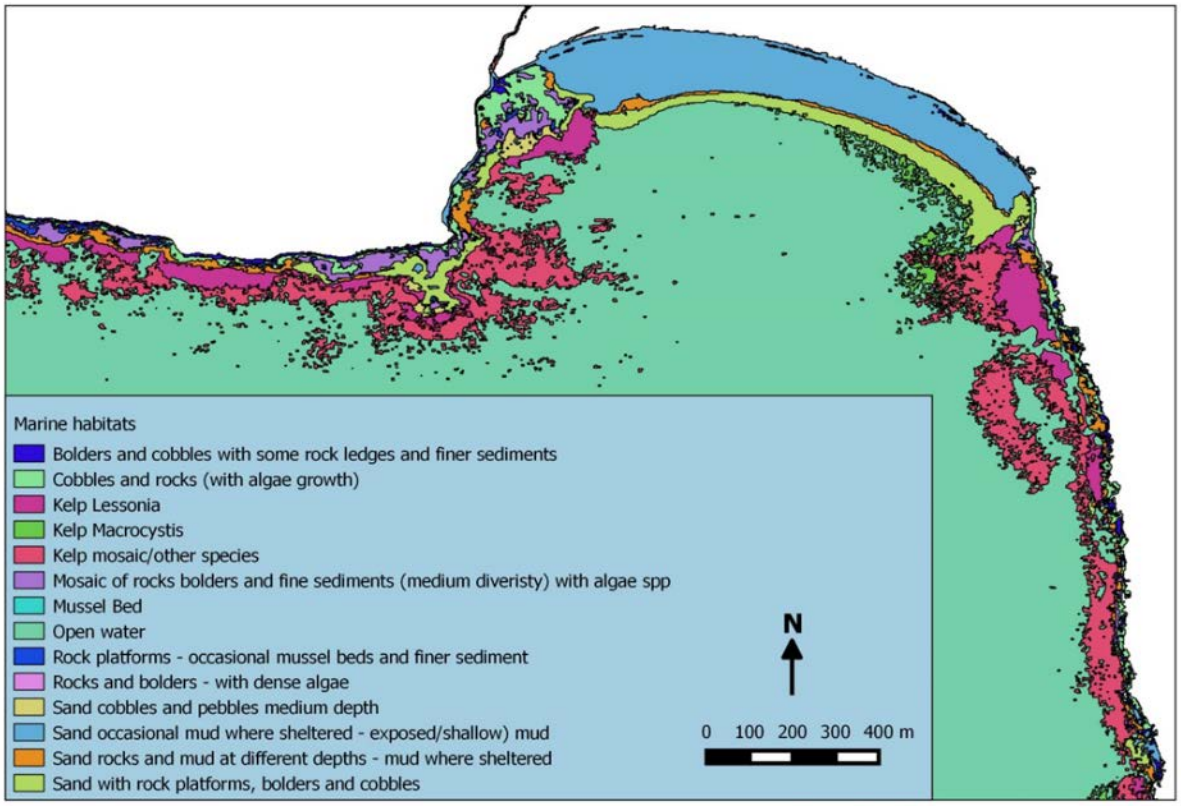

Figure 7-43: Inter-tidal and shallow marine habitats mapped at Magellan Cove

7.4.3.3.3 Berkeley Sound deeper water (>10m) habitat mapping and classification

The surveys carried out by Benthic Solutions recorded numerous subtle sediment changes throughout Berkeley Sound with differing proportions of coarser materials in the form of fragmented shells, gravel, cobbles and boulders. The distribution of habitat types within Berkeley Sound is shown in Figure 7-44 and Figure 7-45.

Due to differences in the depths surveyed, the habitat classification described by SMSG (Neely, *et al.,* 2010a) often only loosely conformed to those encountered by Benthic Solutions.

The six main habitats identified within Berkeley Sound are:

- Rock face and cobbles,
- Mud,
- Sand,
- Kelp forest,
- Mussel beds, and
- Gravels.

The habitat types listed above (and shown in Figure 7-44 and Figure 7-45), and anthropogenic habitats are all discussed in more detail below. Further to the main habitat designations, anthropogenic habitats are also discussed.

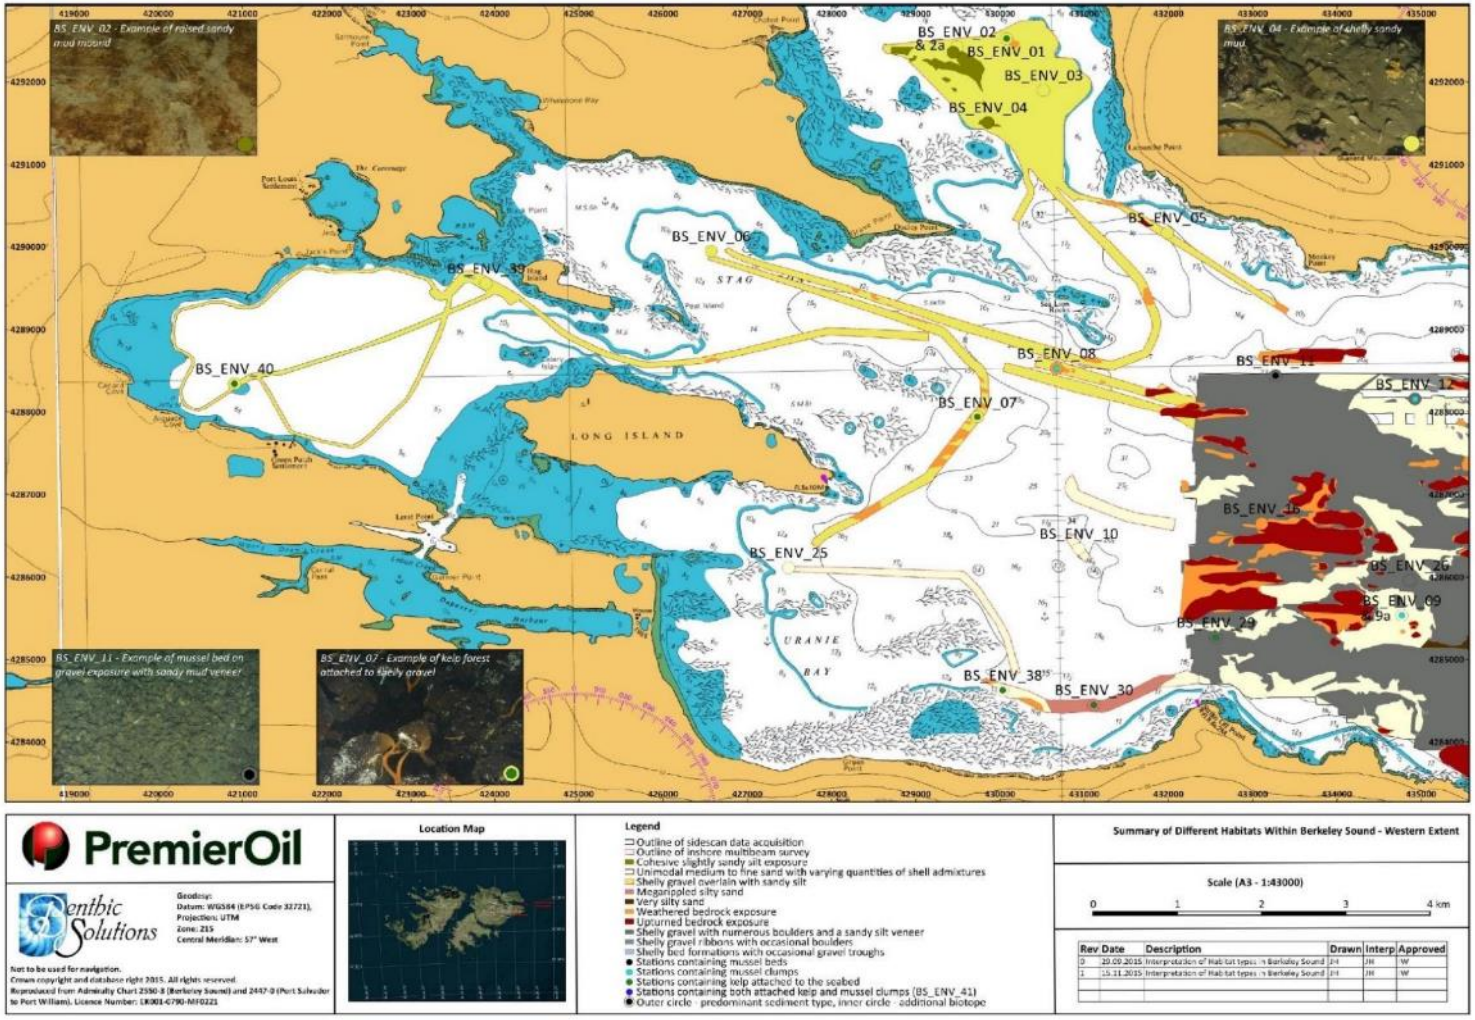

Figure 7-44: Habitats mapped within the inner Berkeley Sound (BSL, 2015b)

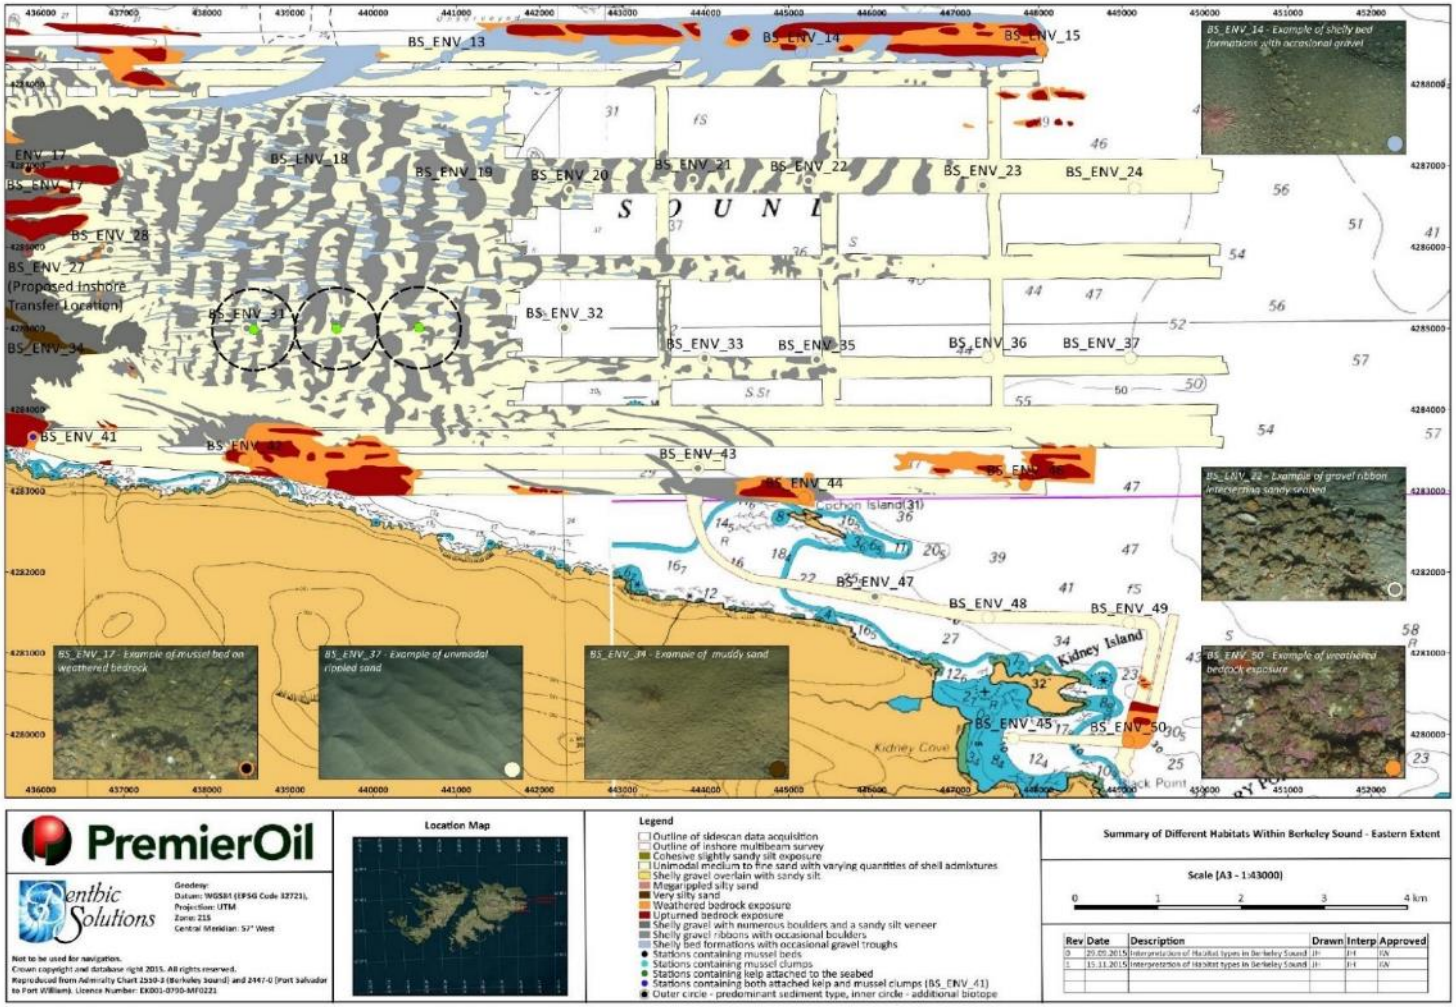

Figure 7-45: Habitats mapped in the outer Berkeley Sound (BSL, 2015b), showing the proposed LTV anchorage and exclusion zones

7.4.3.3.3.1 Rock face and cobbles

Bedrock exposures and escarpments were identified in the area of the LTV anchorage sites, and along the north and south coasts of Berkeley Sound. Around the LTV anchorage sites, the strata generally dipped vertically in a north-south orientation. The size of these exposures varied from localised boulder-sized formations to the most prominent bedrock exposure around site Station 16, which measured over two kilometres across by one kilometre wide. Erosion of these features often resulted in cobble sized deposits at the base and in the gullies of the formations.

Stations observed to conform to the rock face and cobbles habitat included Stations 42, 44 and 46 in the south of the survey area. Only rock face habitats were observed at Stations 16 and 50, and those that displayed further variations of this habitat type include Stations 08, 15, 17 and 41.

Rock features were generally very diverse, characterised by encrusting coralline algae (*Corallina* spp.), numerous sponges (including possibly boring sponge (*Cliona* sp.), lace sponge (*Clathrina* sp.), chalk sponge (*Grantia* sp. and *Tedania* spp.) and bryozoa (branched bryozoa, *Cellaria malvenensis*, *Reteporella* sp.). Further to this, solitary sessile epifauna included (but was not limited to) barnacles, tunicates (bubble tunicate, *Styela magalhaensis*, stalked piure, *Pyura legume*, warty tunicate, *Asterocarpus humilis* (possibly invasive) and flower tunicate, *Sycozoa gaimardi*), anemones (smooth anemone, *Actinostola chilensis*, flower-lobed anemone, *Antholoba achates*) and the invasive parchment worm, *Chaetopterus variopedatus*.

More mobile species were dominated by large numbers of limpets (often encrusted with coralline algae). Other mobile species included chitons, urchins (Chilean sea urchin), starfish (sunstar, *Labidiaster radiosus*, rough armed sea star, *Ganeria falklandica*, badge starfish, *Diplodontias singularis*), brittlestars (rough brittlestar, *Ophiactus asperula*), rock cod (*Patagonotothen* spp.), and various crustaceans (decorator crab, *Eurypodius latreilli*, Chilean snow crab, *Paralomis granulosa*), amongst numerous others. Detailed site-specific conspicuous fauna lists are provided in Appendix III of BSL, 2015b. It is of note that the mottled sea star, *Glabraster antarctica*, which is described as 'a primarily Antarctic and Sub-Antarctic species only rarely seen inshore in the Falklands' by SMSG (Neely and Brickle, 2013), was identified at Station 42 amongst the coralline algae encrusted bedrock exposures.

Bedrock-associated habitats were visually observed to harbour a huge array of encrusting and free-living biota. The biologically diverse nature of these bedrock exposures could be considered to conform to the designation of a geogenic reef, as per the EC Habitats Directive.

7.4.3.3.3.2 Mud

Muddy habitats, with varying levels of fragmented shell material, were encountered in the western part of the area surveyed, particularly within the Johnson's Harbour and Port Louis embayments. Muds also characterised the base of the depression feature around the LTV anchorage sites. Seabed photography recorded bioturbation in the form of burrows and other 'lebensspuren' (animal tracks and furrows) likely to be produced by echinoderms, gastropods, and isopods, including the scythe-edged serolis (*Acanthoserolis schythei*).

This habitat type showed considerable variation in the form of shell material, sand and cobbles. Ribbed mussel beds and silty Lessonia forest were also observed in areas characterised by fines.

Prevalent conspicuous fauna included the scythe-edged serolis isopod, crustaceans (lobster krill, purple backed crab (*Peltarion spinulosum*) and long-nosed spider crab (*Eurypodius longirostris*)), starfish (rough armed sea star, common sea star (*Anasterias antarctica*) and badge starfish), the veined brachiopod (*Magellania venosa*) and gastropods (Gever's trophon (*Trophon geversianus*)) and checkered murex (*Xymenopsis buccineus*)). In most areas, the seabed was generally featureless and absent of current related bedforms, indicating a sedimentary regime with limited hydrodynamic

reworking of the sediments. At the edges of the basin feature close to the LTV anchorage sites and at other locations nearby, patches of rippling were observed on the seabed surface, indicative of some level of current turbulence.

7.4.3.3.3.3 Sand

Sandy sediments were widely recorded within the fairway area to the east of the LTV anchorage sites, and around Kidney Island. Within the fairway the sonar data indicated a variable seabed, with linear patches of course materials separating areas of sand; these have been interpreted as mobile gravel ribbons after review of the seabed imagery and video footage.

Bioturbation and 'lebensspuren' ('life-traces') in the form of crustacean tracks was observed at a number of stations, particularly those with less shell material or fewer cobbles present, with burrows also occasionally recorded.

Sand megaripples with wavelengths of 0.5 m to 1.5 m (crest to crest) were observed at stations closest to the mouth of the Sound, indicative of current turbulence, with the orientation suggesting that the localised currents flow east / west in line with expectations based upon the tides flowing in and out of the Sound. Megarippled shelly bedforms were also identified along the north coast at Stations 13 and 14, and also at Stations 19 and 43 within the fairway and along the south coast, respectively. These were composed of very coarse materials and are indicative of current turbulence with little deposition from fine materials.

Lobster krill (*G. gregaria*) represented the most abundant epifauna inhabiting sandy substrates. Other crustaceans (Chilean snow crab, long-nosed spider crab), starfish (beaded sea star, sunstar, rough armed sea star) and rock cod (*Patagonotothen* spp.) were also noted in these areas, along with numerous relic polychaetae tubes.

7.4.3.3.3.4 Kelp forest

Kelp forests were encountered along the coast, and in shallow areas with exposed or shallow-buried bedrock (Section 7.4.2.2). Two kelp habitats were observed in the seabed video and photography: silty Lessonia forest and mixed *Lessonia* / *Macrocystis pyrifera* forest. In addition, during transits, large areas of giant kelp (*M. pyrifera*) were encountered frequently along the coast of the Sound, and around Cochon and Kidney Islands.

Large clusters of storm-rafted giant kelp were present at the surface throughout much of the Sound, with kelp debris also present on the seabed at a number of stations.

Conspicuous fauna included: Patagonian scallop (*Zygochlamys patagonica*), starfish (rough armed sea star, common sea star), tunicates (piure species., warty tunicate (*Asterocarpa humilis*; possibly invasive), bubble tunicate (*Styela* sp.)), ornamented hermit crab, ribbed mussel, nudibranchs, fur algae (*Desmarestia distans*), urchins and various encrusting sponges. Encrusting pink coralline algae (*Corallina* sp.) was recorded in low quantities at nine stations, and in addition, at Station 41 ribbed mussel densely populated the *Lessonia* holdfasts. It should be noted that this example of a silty Lessonia forest was composed of comparatively less silt than other examples further to the west of the site.

At Station 29, sparse kelp coverage was encountered, with fur algae attached to the shells of bivalves and other hard contacts. One cluster of squid eggs was photographed at this station; these eggs are thought to belong to the commercially exploited loligo squid.

7.4.3.3.3.5 Mussel beds

Mussel beds, mostly thought to comprise the ribbed mussel, were identified at two stations within the environmental survey area (Stations 17 and 11), with smaller patchy aggregations noted at a further four stations. Three species of mussel are known to form the majority of extensive beds in the Falkland

Islands: blue mussel, giant mussel (*Choromytilus chorus*) and ribbed mussel (Neely, *et al.,* 2010a). Blue mussel is thought to inhabit shallower waters, whereas both giant and ribbed mussels tend to be found in deeper areas. The majority of mussel beds were observed at stations characterised by silty sediments, and located on slope faces, and all mussel beds observed were found to be located in the western half of the survey area, where the silt content was visually interpreted to be higher.

Mussel beds provide a complex structure which creates a habitat within which small organisms are able to shelter, and a substrate for encrusting organisms to colonise. Mussel beds are included in the OSPAR List of threatened habitats (specifically horse mussel, *Modiolus modiolus*), and are recognised for creating biogenic reef structures, and are therefore included in the Annex I Reefs list in the EC Habitats Directive. The two large beds identified at Stations 11 and 17 could therefore be construed as biogenic reefs.

Ribbed mussel individuals were often found to be encrusted with calcareous coralline and other algae, barnacles, sponges and small tunicates, such as *Styela magalhaensis*. Starfish, such as rough armed sea star and beaded sea star, were common amongst the mussel beds, along with crustaceans (Chilean snow crab, ornamented hermit crab), veined brachiopods and various gastropods.

7.4.3.3.3.6 Other habitats

Gravel ribbons encompassed differing proportions of sand, silt, shell material, gravels and cobbles, and include the complex gravel ribbons and megarippled shelly bedforms mentioned previously. The presence of ribbed mussel beds and silty *Lessonia* forest were noted at Station 41 along the southern coast of Berkeley Sound.

Gravel ribbons comprised large patches of relic bivalve shells (likely the striped clam, *Eurhomalea exalbida*), gravels and cobbles. These materials were heavily encrusted with both relic and live barnacles and calcareous mats of *Corallina* spp.

Gravel ribbons were also found to support a diverse range of organisms, including numerous crustaceans (ornamented hermit crab, long-nosed spider crab and Chilean snow crab), the naked urchin and the white feather-duster worm (*Perkinsiana antarctica*), along with various sponges, tunicates, hydroids and bryozoans colonising the hard contacts. Relatively few conspicuous fauna were recorded in areas of shelly bedforms, with the mobile sunstar most frequently observed, followed by the long-nosed spider crab and the Chilean snow crab.

7.4.3.3.3.7 Anthropogenic habitat

Examples of anthropogenic structures were prevalent throughout the Berkeley Sound (see Section 7.7.6.2) and were mostly present in the form of localised sonar contacts. The shipwrecks of the Ocean 8 and Blakeney were also identified in the analogue data; however, no seabed photography was acquired at these locations. The introduction of anthropogenic structures such as wrecks into the marine environment can often be seen as a long-term benefit, providing a hard surface that is often an alternative substrate to natural rock. This can therefore benefit epifaunal species that are otherwise only present on rocky reefs (Hiscock, *et al.,* 2010).

While the addition of these vertical and horizontal hard surfaces could be considered to be ecologically beneficial to the region, other anthropogenic activities can have the opposite effect. Anchor scars were identified throughout the survey area. The physical dragging of the anchors disturbs benthic communities, stripping hard surfaces and overturning soft sediments.

Evidence of shipping activities in the region were observed at Station 09; these ranged from uncolonised aluminium cans, to a heavily colonised steel structure, as well as the aforementioned anchor scars. The presence of shipping debris throughout the area relates to Berkeley Sound's long history as an anchorage.

The steel structure at Station 09A was investigated using seabed photography (Figure 7-130 below under Section 7.7.6.2.3) and is thought to be an arm from a jigger. The structure was found to be densely populated, with bivalves (possibly mussels), gastropods (broad slipper limpet, Gever's trophon and checkered murex), decorator crab, giant tunicates (*Paramolgula gregaria*), starfish (common sea star, possibly badge starfish), naked urchin, painted shrimp (*Campylonotus vagans*), and encrusting sponge recorded.

Numerous rock cod (*Patagonotothen* spp.) were also present around the structure, likely belonging to more than one species. Sheltered structures are often used by mobile species as a nursery area; this is supported by the presence of numerous fish in the subsea video.

Seabed imagery indicated the possible presence of the filamentous bacteria *Beggiatoa* sp. within the anchor scars, visible as a white mat on the seabed. This bacteria species is generally only found in areas that interface aerobic and anaerobic conditions and is often found in areas of organic enrichment.

7.4.3.3.4 Berkeley Sound environmentally sensitive habitats

The classification of intertidal habitats is still in development, however, to date it appears that the range of intertidal habitats found are widespread.

However, during the Benthic Solutions' field programme (BSL, 2015b), several potentially environmentally sensitive habitats, or those of conservation significance recognised under the UK's Offshore Marine Conservation Regulations 2010 (which implements the EU Habitats Directive 92/43/EEC) were identified within Berkeley Sound. These include:

- Geogenic Reefs (rock faces and cobbles),
- Biogenic Reefs (mussel beds), and
- Kelp Forests.

7.4.3.3.4.1 Geogenic reefs

Geogenic reefs were interpreted to occur in areas of bedrock exposure. The biological diversity observed at these sites was considered to conform to the EC Habitats Directive designation of geogenic reefs. These areas were found to be colonised by a diverse array of biota, with numerous associated free-living species present too. Bedrock exposure was observed in the form of escarpment outcrops in the centre of the Sound and along the north and south coast.

7.4.3.3.4.2 Biogenic reefs

Biogenic reefs took the form of mussel beds and were predominantly thought to comprise the ribbed mussel (*Aulacomya atra*). Although examples of the small-ridged mussel (*Philobrya blakeana*) were also recorded, this species is not known to form the dense aggregations observed during the survey. Three further species of mussel are known to inhabit the Falkland Islands: purple shore mussel (*Perumytilus purpuratus*), giant mussel (*Choromytilus chorus*) and the blue mussel (*Mytilus chilensis*); the latter two of which are capable of aggregating to form extensive subtidal beds, as observed with *A. atra*. Mussel beds were identified at two stations: 11 and 17, with patchy aggregations observed at four further stations although these are not thought to constitute the dense aggregations that define this habitat type. Mussel beds (specifically horse mussel, *Modiolus modiolus* and intertidal blue mussel beds) are included in the OSPAR List of threatened habitats and are recognised for creating biogenic reef structures; they are also included in the Annex I Reefs list in the EC Habitats Directive. However, blue mussel beds are an extremely common feature in the Falklands coastal waters and it is questionable whether blue mussel beds represent a threatened habitat in the Falkland Islands.

Further biogenic reefs have been previously identified locally by the SMSG (Neely, *et al.,* 2010a) but were not recorded during this programme. The full spatial extent of each habitat type is unknown and has not been fully mapped. Therefore, it is not yet possible to define spatially limited rare or 'at risk'

marine habitats for the Falkland Islands. There are no designated species or habitats equivalent to those of conservation significance recognised under the UK's Offshore Marine Conservation Regulations 2010 (which implements the EC Habitats Directive 92/43/EEC) or listed as a priority habitat within the *Natura 2000* marine network.

The habitat types most likely to meet such criteria that have been recorded in the Falklands shallow marine environment are the following cold water reef forming species:

- Giant barnacle (*Austromegabalanus psittacus*) reef,
- Broad slipper limpet (*Crepipatella dilatata*) reef, and
- Purple-crowned feather duster worm (*Phragmatopoma virgini*) reef.

Giant barnacle reefs and broad-slipper limpet reefs have only been encountered within Berkeley Sound (in the region of Strike-off Point; Neely, *et al.,* 2010a) and a feather duster tubeworm reef has been observed at only one site within Port William, near to Cape Pembroke, these are likely to be rare and spatially limited habitat types. However, Berkeley Sound and Cape Pembroke have also been subject to the greatest survey effort and the identified species / habitat accumulation curve is more advanced. Further survey at other sites may yet identify additional occurrence of these habitats.

7.4.3.3.4.3 Kelp forests

Kelp forests are known to provide shelter for sometimes hundreds of species within their holdfasts (Chile; Ríos, *et al.,* 2007), illustrating their importance within biological communities. The sensitivities of kelp forests have been recognised elsewhere in the world, with an extensive *M. pyrifera* forest in Alaska currently undergoing consideration for red list status (Endangered to Critically Endangered; Keith *et al.,* 2013), however, no legislative protection is currently in place for this habitat type globally.

Marine algae and especially the species of kelp (Giant Kelp - *Macrocystis pyrifera*, Tree Kelp - *Lessonia* spp. and Bull Kelp - *Durvillaea antarctica*) form a significant component within 7 of the 18 coastal habitat types described by SMSG (Neely, *et al.,* 2010a) and dominate much of the coastline of the Falklands. While no index of diversity is available, it is likely that kelp forest forms the most diverse habitat with greatest range of faunal associations of the Falkland Islands marine habitat types. *Macrocystis* and *Lessonia* kelp in particular form a complex stratified 3-dimensional habitat matrix through the water column.

Kelp although relatively resistant to low-level oil accumulations, due to the protecting mucilaginous exudate on foliage, may be impacted by heavier accumulations due to:

- Reduced photosynthetic output,
- Breakage from increased foliar loading, and
- Inhibition of settlement and growth of new young plants due to sedimentation.

Furthermore, indirect impacts may result if faunal assemblages are impacted with a resultant increase in grazing fauna leading to defoliation. Kelp may also limit oil dispersal and retain oil in the near-shore environment.

Understanding the marine and inshore vegetation of the Falkland Islands is important as algae are one of the major primary producers in the marine environment. As with other components of the inshore marine environment the marine algal habitats and floral and faunal associations that exist within Falklands waters are poorly described and understood. See also Section 7.4.2 for detail on the mapping of kelp forest.

7.4.3.3.5 Marine non-native/invasive species

The introduction of invasive marine species has had environmental, and in many cases economic, impact across the globe. The first confirmed vessel landing in the Falklands occurred in 1690 (17th

century) and was likely carrying non-native species and this continues to the present day. The Falklands, like many other parts of the world, are perceived to be relatively pristine but may have already been significantly altered by invasive marine species. One of the major issues regarding the detection of marine invasives is the lack of baseline data regarding the native fauna. The surveys of SMSG are beginning to fill some of these gaps by conducting baseline surveys to record the species and habitat types present in the Islands (see Neely, *et al.,* 2010a; Neely, 2010). These surveys have identified two non-native species that are present; the vase tunicate (*Ciona intestinalis*) and the parchment worm (*Chaetopterus variopedatus*). These species are known to be problematic in other parts of the world, which sparked dedicated surveys to map the distribution of these species in Stanley and Mare Harbours (SMSG, 2011), the primary ports in the Falklands.

Vase tunicates are very competitive and can rapidly cover nearly 100 % of the available substrate, excluding almost all of the native species in that area. The results of surveys thus far indicate that this species is restricted to Stanley and Mare Harbour (i.e., not in Berkeley Sound), hinting at a relatively recent introduction (SMSG, 2011). This also highlights the risk of vessels visiting these Harbours having the potential to translocate this organism to other parts of the Falklands.

The parchment worm is more widespread throughout the Falkland Islands and it is likely that it was introduced some time ago, possibly during the era of wooden sailing vessels (SMSG, 2011).

In addition to the species above, several non-native species have been found recently that are considered to be invasive elsewhere but seem to be having little impact on the native Falklands floral and faunal assemblage at this time. These include:

- The cnidarian *Metridium* sp. (plumose anemone, SMSG, 2013),
- The ascidian *Asterocarpa humilis*,
- Nine species of algae (Brodie and Mrowicki, 2019), and
- The blue mussel *Mytilus edulis* (SFL, 2022b).

The effect of shipping on modern invasive species introductions in Stanley Harbour can be clearly evidenced by the recent discovery of a northern hemisphere clade of the blue mussel (*Mytilus edulis*) on FIPASS (SFL, 2022b). Here, a survey of the blue mussel assemblage in the top 5 m depths of the FIPASS hull showed that at least 12 % of the *Mytilus* sp. assemblage was the introduced *M. edulis*, with the remainder being the endemic species *M. chilensis*. Although it is not clear when this species was introduced, analysis shows that they are present in higher densities in areas frequented by vessels mooring along-side, suggesting they have not had time enough to spread widely. However, multiple cohorts of *M. edulis* were found, suggesting they are recruiting into the same locations.

There is potential for other non-native species to be present but yet to be discovered. The surveys of BSL (2015c) found several species within Berkeley Sound that were previously only known from the North Atlantic. As many of the vessels visiting the Falklands originate in Europe, it is plausible that these arrived in ballast water or as biofouling organisms.

To further address the lack of baseline, POEPL commissioned (in partnership with SMSG, SAERI, University of Aberdeen, and FIG-Biosecurity) a multi-year (2015-2018) monitoring program to test the effectiveness of methods for the monitoring and early detection of marine invasives in the Falklands (Premier, 2019a). Monitoring sites were located in Stanley Harbour at the Temporary Dock Facility, and at York Bay in Port William. Monthly visual inspections of species recruitment onto settlement plates was carried out, and periodic analysis of the whole settlement plate assemblage was done using metagenomic analyses (see Figure 7-46).

The results showed:

1) Natural species recruitment on settlement plates can vary significantly within and between sites, and temporally within and between years,
2) Whilst metagemonic methods can detect the total species present including cryptic and newly settled species, traditional taxonomic analysis of plate assemblages are required to confirm species' identity, and
3) Comparing gene sequences to GenBank showed that of the 51 unique species detected throughout the study, eight were confirmed to 100 % likelihood of a named identity, and 21 were confirmed to *c.* 90 % likelihood of a named identity, suggesting that *c.* 50 % of species found require formal identification and genetic bar-coding for detection in the future.

This study will inform a marine invasives species monitoring program, as recommended at the EMMP workshop. This will likely involve firstly, the establishment of a more comprehensive baseline of a species bar-coding library, as well as deploying settlement plates in Berkeley Sound and Stanley Harbour for monitoring pre-construction phase in advance of the first vessels arriving to the Falklands. Recommendations regarding new, highly portable technology to be potentially used in the Falklands were also made.

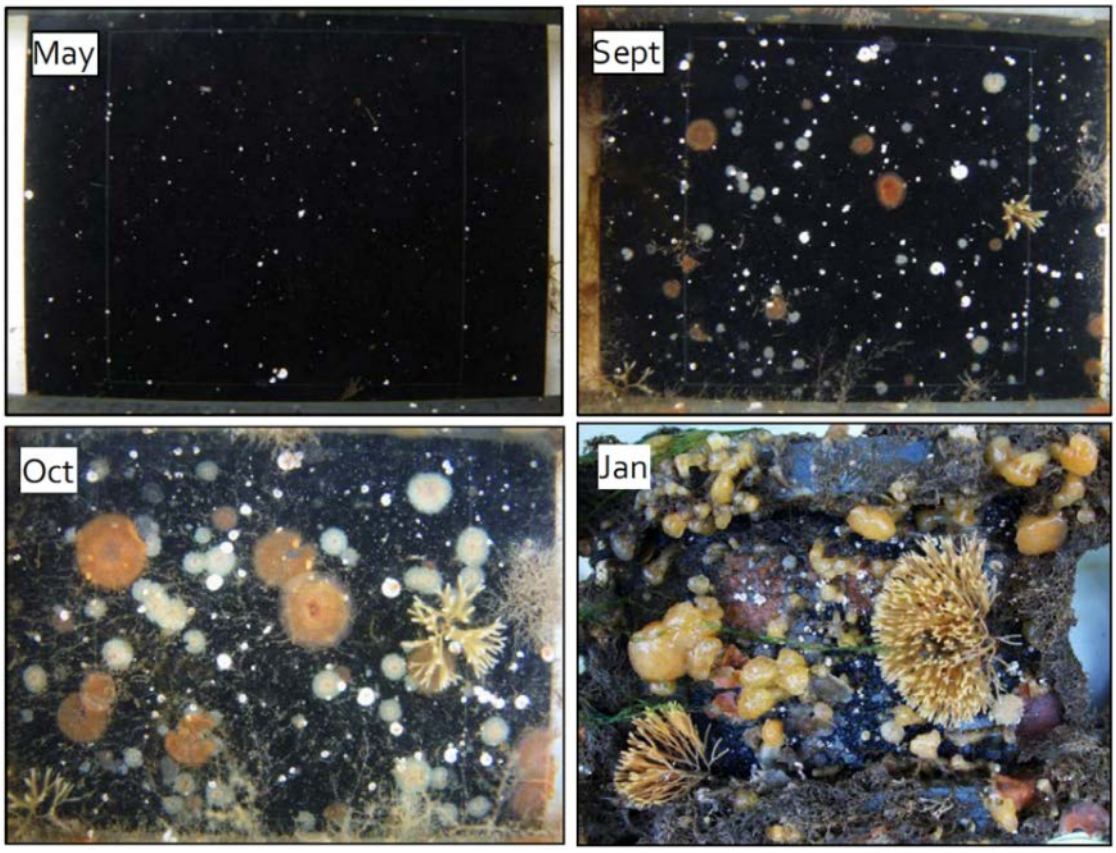

Figure 7-46: Example of progress in colonisation and growth of organisms on settlement plate over time (TDF site, May 2016 – Jan 2017)

7.4.3.4 Marine flora and fauna in Stanley Harbour and surrounding areas

The mud habitats in and around Stanley Harbour have been described as having a relatively high abundance of the saffron sea cucumber (*Cladodactyla crocea*), the tessellated rock cod (*Patagonotothen tessellata*), the invasive sea squirt, vase tunicate (*Ciona intestinalis*), the pencil urchin (*Austrocidaris canaliculata*) and the common starfish (*Anasterias antarctica*). Approximately 30 commonly occurring species were recorded during a broad survey of the wider extent of Stanley

Harbour conducted in 2011 by the Shallow Marine Surveys Group (SMSG; Brickle, *et al.,* 2011). These are all considered to be common and widespread species and are not considered to be restricted in distribution or of great ecological concern.

In 2013, a more detailed benthic grid survey of the immediate development area to the east of The Narrows was carried out by SMSG (SMSG, 2013). Findings of the 2013 survey were broadly similar to the 2011 SMSG study with the most common and widespread species being the saffron sea cucumber. The species assemblages suggested that the area was not rich in biodiversity and showed little variation between sites surveyed. The area in and around Stanley Harbour, and specifically the TDF development, has relatively low biological significance with similar habitats widely represented within the Falkland Islands. Further benthic studies carried out in Stanley Harbour in 2021 (Royal Haskoning unpublished data 2021, EIS document PB7829-RHD-ZZ-ZZ-RP-YE-0005.P01.01) in relation to FIPASS development recorded similar patterns for the epibenthic floral and faunal assemblage. However, this study differed from previous studies by including detailed sediment infaunal analysis. The infaunal assemblage, as defined by species retained on a 500 micron sieve, was highly diverse but also highly patchy in the eastern Stanley Harbour area. The final list species list comprised 233 species.

The most specious group were the Polychaetes with 94 species/putative species found. Of these, the most abundant species was *Aphelochaeta magellanica* (3,101 individuals) and another unidentified species of the same Genus (960 individuals). The Family Capitellidae (*Capitella* sp. 2 and *Mediomastus* sp. 1) were also particularly abundant, as was the Paronidae (*Paradoneis* sp.1). The Amphipoda were the next specious group with 27 species observed, with the Phoxocephalidae showing high abundance (*Proharpinia antipoda*, 422 individuals; *Paradexamine nana*, 389 individuals; *Proharpinia stephenseni*, 185 individuals). A total of 36 species/putative species of Gastropods were observed with relatively low abundances. The Gastropod fauna was dominated by the minute sea snail *Eatoniella* sp (481 individuals), and unidentified Bivalvia (293 individuals). Other dominant species were juvenile Mytildae bivalves (1,751 individuals), and A total of 29 Bryozoan (lace coral) species, however these are not considered infauna *per se*. Species accumulation curves for infaunal sampling did not reach asymptote in Stanley Harbour suggesting that further sampling would be required to understand the full infaunal species inventory, where the Chao2 richness estimator predicted 299 species.

7.4.3.5 Summary of the offshore and inshore benthic environment

Table 7.8 provides a summary of the offshore and inshore benthic environments.

Table 7.8: Provides a summary of the offshore and inshore benthic environments

Subject	Summary
NFB and the Sea Lion Field	
Offshore benthic flora and fauna	The epifaunal community was relatively uniform across the observed area, commonly including Polychaeta (Terebellidae (spaghetti worm)) Arthropoda (the isopod Serolidae, the crustacean Euphausiacea (krill)), Echinodermata (Ophiuroidea (brittle stars)), Sterechinus sp. (urchins), Chordata (Myctophidae (lantern fish)) and Cnidaria (*Primnoella* sp. (sea pen)). Epifaunal siphons were noted at most stations indicating the presence of the spoon worm, Echiura. There were many other less commonly observed fauna across the survey area. There were no species or habitats equivalent to those of conservation significance under the UK's Offshore Marine Conservation (Natural Habitats, & *c*.) (Amendment) Regulations 2010 (which implements the EC Habitats Directive 92/43/EEC observed within the surveyed area.
Offshore habitats	The habitat encountered in the NFB is relatively uniform in character due to the lack in diversity in substrate type. In places, erratic rocks are present a hard substrate for encrusting organisms such as sponges and deepwater corals. However, these features have not been encountered in the area of the Phase 1 & 2 Sea Lion Development.
Berkeley Sound	
Shallow marine and inter-tidal flora and fauna	The results of dive surveys show that the shallow marine environment of Berkeley Sound is numerically dominated by the phyla, Echinodermata: sea star (starfish) (10.04 %), followed by Chordata: ascidians (9.06 %), Arthropoda: crab (8.25 %), Porifera: sponges (8.16 %) and Echinodermata: sea urchins (7.62 %) Arthropoda: amphipoda and Mollusca: cephalopods were the least abundant representing 0.09 % of the total. By species, the Chilean red sea urchin (*Loxechinus albus*) had the highest overall relative abundance, followed by the blue-spotted rockcod (*Patagonotothen cornucola*), and giant kelp (*Macrocystis pyrifera*).
Deeper water flora and fauna	The macrofauna communities were dominated by Polychaeta (bristle worms) and Crustacea (shrimps) and reflected the very diverse habitats recorded throughout Berkeley Sound. A total of 281 infaunal taxa and 69 epifaunal species were identified during the seabed sampling campaign. The results were analysed using multivariate techniques which showed the community forming one main cluster with subtle variations within, generally separating out based on sediment type. Three statistically significant sub-clusters were evident, grouping together stations characterised by mud, gravel and sand sediments. A diverse epifaunal community was recorded throughout the Sound, constituting an important element of the ecosystem in this area. These conspicuous groups were represented by Porifera, Bryozoa, Cnidaria, Crustacea, Echinodermata, Mollusca and Tunicata. Sponges were prevalent in areas of bedrock exposure, mainly in encrusting form but with some solitary specimens also identified.
Shallow marine and inter-tidal habitats	Shallow marine habitats within Berkeley Sound are very diverse. Of note are kelp forests (which support a wide range of benthic organisms and are utilised by foraging higher predators) and biogenic reefs. Surveys near Strike-off Point have found reefs composed of slipper limpets and giant barnacles.
Deeper water habitats	The benthic communities in the deeper waters of Berkeley Sound are closely linked to the sediment type. Of note were, exposed areas of bedrock, which supported large numbers of encrusting epifaunal organisms (such as sponges). These were classified as meet the criteria necessary for geogenic reefs.

7.4.4 Fish and invertebrate ecology

7.4.4.1 Introduction

This section provides a summary of the most abundant fish and squid species within Falkland Islands waters, describes their seasonal abundance in relation to the Sea Lion Field, their seasonal spawning migrations and their principal diet. Note that, to inform the EIA of impacts to other users of the sea, indication is made as to which species are of commercial importance with catch statistics provided in Section 7.7.3.1.1.

7.4.4.2 NFB and Sea Lion Field fish and invertebrate ecology

The wider area of continental shelf and slope in the vicinity of the Sea Lion Field provides important feeding grounds for a number of species throughout all seasons of the year, with a slight decrease in the number of species present during the spring months. Whilst a number of these fish and squid species spawn within the Falkland Islands inner shelf and deep slope waters, none of the commercial species are known to have spawning grounds within the area of the Sea Lion Field and many species migrate outside of Falkland Islands waters to spawn (Arkhipkin, *et al.,* 2012a; Arkhipkin, *et al.,* 2023). A number of skate species are known to spawn in this area based on the evidence from the occurrence of hatchlings and reproductively active females (Pompert, 2011).

7.4.4.2.1 Patagonian Shelf habitats

The Patagonian Shelf and Slope are amongst the two most biologically productive areas in the south-west Atlantic. As the Falkland Current meets the continental slope it results in an area of strong upwelling of Sub-Antarctic Surface Water (SASW) that forms a highly productive frontal zone as it mixes with shelf waters (Section 7.3.3). Due to its high primary productivity, the Patagonian Shelf ecosystem is characterised by abundant pelagic and demersal organisms that support rich squid and fish resources. Many species of fish and squid within the Patagonian ecosystem, such as Argentine shortfin squid, common hake (*Merluccius hubbsi*) and hoki, migrate seasonally to the productive frontal zones to feed, and return to non-frontal zones during spawning periods, resulting in seasonal changes in the fish assemblages across the ecosystem. The convergence of the SASW and Patagonian Shelf waters at the Falkland Islands shelf break forms the transition between the temperate and sub-Antarctic ecosystems (Section 7.3.3), and consequently species belonging to both temperate and sub-Antarctic taxa are found within the area.

7.4.4.2.1.1 Conservation and management zones

The Falkland Islands Conservation and Management Zones (FICZ and FOCZ) delineate the extent of the Falkland Islands EEZ, and six main habitat zones have been identified within this area characterised by a combination of bottom topography, bathymetry, water structure and hydrodynamics. These zones are explained in detail by Arkhipkin *et al.* (2012a). These zones are represented by:

- The Inner Shelf (IS),
- The outer shelf (OS) is subdivided into two habitats:
  - North-Western Outer Shelf (NWOS), and
  - South-Eastern Outer Shelf (SEOS).
- The upper continental slope is partitioned at latitude 51° S into two habitats:
  - Northern Slope (NS),
  - Southern Slope (SS), and
  - Deepwater Slope (DS) at depths between 600 and 1,200 m.
- The Sea Lion Field sits in the Northern Slope area in the FICZ (Figure 7-47).

The NS covers an area of 50,686 km^2, with an average depth of greater than 400 m. This ecoregion was identified by bottom topography (most representative), bathymetry, water structure and hydrodynamics, however, the bottom topography is not homogeneous. The shallow-water area (250–350 m) of NS is mainly flat with sandy or muddy bottom topography and parts are heavily trawled throughout the year for finfish and skates (**note:** the skate specific Individual Transferable Quota (ITQ[29]) has not been used for several years now but they are regularly caught as bycatch). In the NS, in waters of > 350 m there is little to no fisheries activity. The deepwater area to the north-east of the NS has rough bottom topography and is covered with corals to the north and is therefore difficult to work by trawlers Figure 7-47).

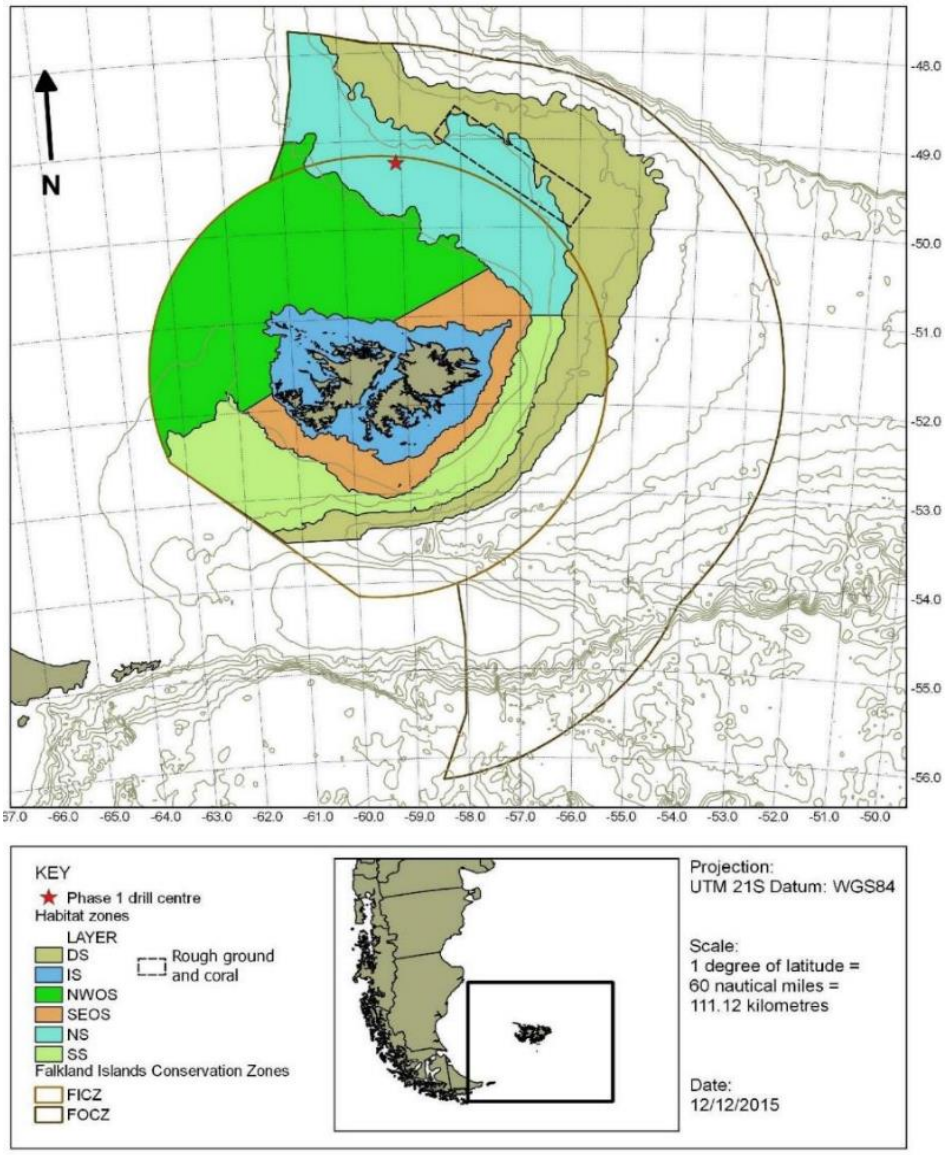

Figure 7-47: Map delineating habitat zones within Falkland Islands waters. Rectangle illustrates the area of rough ground and corals ***(Source: Arkhipkin, et al., 2012a. Inner shelf (IS), north-western outer shelf (NWOS), south-eastern outer shelf (SEOS), northern (NS) and southern slope (SS) and deep water slope (DS))***

[29] Individual Transferable Quota: a quota that limits the amount of fish a fisher can catch or the amount of fishing effort they can use. ITQs are often specific to a type of fish and are used to manage fish stocks and prevent overfishing.

7.4.4.2.2 Seasonal abundances around the Falkland Islands

Despite the biological productivity of the Falkland Islands waters only a small number of predators (fish and squid) spend all year around the eastern Patagonian Shelf and only consume a relatively small proportion of this bounty. Most of the productivity is exploited by non-resident migrating species that move to the area from distant spawning grounds to take advantage of the highly productive waters (Arkhipkin, *et al.,* 2012b). Sharks, skates, squid, tunas and gadoids migrate to the area at different times of the year to feed. A number of deepwater species of fish and squid feed within the area as juveniles and move to deeper waters as they mature and become adults.

7.4.4.2.2.1 Seasonal abundances on the Northern Slope

The six sub-Antarctic and seven temperate fish and squid species found in abundance in Falkland Islands waters primarily utilise these areas as productive feeding grounds, migrating within and out of these waters as food availability changes and to follow seasonal spawning migrations. The Northern Slope (NS) area, where the Sea Lion Field is located, is an important feeding area for a number of species, whose abundance in the NS varies seasonally. Table 7.9 summarises the relative abundance of the main fish species throughout the six main habitat zones over the four seasons. Within the table, high abundances are highlighted in turquoise, moderate abundance is highlighted in light blue and low abundance is white. Note however that cell highlights relate only to the relative abundance within the NS.

The NS provides an important foraging area for some species throughout the year, with the spring season showing lowest species abundance with only hoki and yellownose skate found in higher abundances (Table 7.9 below). Most species have relatively wide distributions being present in several habitat areas within each season, suggesting that no species is solely reliant on the NS area as a feeding ground. However, during the autumn and spring more than 50 % of the hoki population inhabit the NS over other areas (Arkhipkin, *et al.,* 2012b).

Although the productive waters of the Falkland Islands support the foraging of a diverse and abundant assemblage of fish and squid, an unusual aspect of Falklands fish ecology is the migration of the majority of higher trophic species, such as southern and common hake, hoki and kingclip, to spawn elsewhere. Only a few large predators such as red cod (SEOS), several skates, loligo (IS) and greater hooked squid (DS), spend their entire life cycle in the shelf ecosystem (Arkhipkin, *et al.,* 2012b).

7.4.4.2.2.2 Other commercial and non-commercial fish species on the Northern Slope

Although not currently commercially harvested, grenadiers, particularly the Ridge scaled rattail (*Macrourus carinatus*), are abundant in the NS and may be subject to a future fishery (Payá, 2009). Other species not mentioned above include a number of skate species, morid cods and psychrolutid fish. Lantern fishes (Myctophidae), black smelts (bathylagids) and other bentho-pelagic fish also contribute to the fish community on the NS. Little is known about their biology and life history in the Falkland Islands but they likely play a significant role in the ecology, through the consumption of primary consumers and vertical migrations, which could play a major role in exporting carbon from the surface layers to deeper water. These are important features of the ecosystem on the North Slope (P. Brickle *pers. obs.*), that were evident in many of the drop-down camera surveys undertaken in the Sea Lion area (Gardline, 2013a).

Table 7.9: Summary of seasonal abundance of fish species in the six FOCZ/FOCZ habitat zones, indicating abundance on the Northern Slope habitat zone (which contains the Sea Lion Field)[1]

Species	Spring (Oct – Dec)[2]	Summer (Jan – Mar)[2]	Autumn (Apr – Jun)[2]	Winter (Jul – Sept)[2]
Sub-Antarctic species				
Southern blue whiting[3]	SEOS / SS / NWOS	NS/ SS/ NWOS/ SEOS	NS / SS / DS	SEOS / SS / NWOS
Southern hake[3]	SS/ NWOS/ NS/ DS	NWOS / SS / DS	SS / NWOS	SS / NWOS / NS
Hoki (whiptail hake) [3]	NS/ NWOS/ SS/ SEOS			SS / NS / NWOS
Patagonian toothfish[3]	DS/ SS / SEOS/ NS/ NWOS	NWOS/ NS/ DS/ SS	NS/ DS/ SS/ NWOS	DS/ SS/ NS/ NWOS/ SEOS
Greater hooked squid	DS / NS / SS	DS/ NWOS/ NS/ SS/ SEOS	DS/ SS/ NWOS/ SEOS/ NS	DS / SS / NS
Loligo squid[3]	IS / SS	IS / SEOS / SS	SEOS / IS	SS / SEOS / NS
Temperate species				
Common hake[3]	NWOS / NS	NWOS / NS	NWOS / NS	NWOS / NS
Kingclip[3]	NWOS/ SS/ NS/ SEOS	NWOS / SS / NS	NWOS / SS / NS	NWOS / NS / SS
Southern rock cod[3]	NWOS / SEOS / NS	NWOS/ NS/ SS/ SEOS	NWOS / NS / SS	NWOS/ SS/ NS/ SEOS
Argentine shortfin squid[3]	Absent	NWOS / NS	NWOS / NS	NS
Yellownose skate	NS/ NWOS/ SS/ SEOS	NWOS	NS / SS / NWOS	NS / NWOS / SS
Spur dog	NWOS / NS / IS	NWOS	NWOS	NWOS / NS
Slender tuna	Absent	IS / SEOS / NWOS	NS / NWOS / SEOS	Absent

[1] The habitats are identified in order of abundance for each species, and cell highlights relate only to the relative abundance within the NS. Habitat Zones: IS - Inner Shelf, NWOS - North-Western Outer Shelf, SEOS - South-Eastern Outer Shelf, NS - Northern Slope, SS - Southern Slope and DS - Deepwater Slope.

[2] Turquoise = High abundances in the NS. Light blue = Moderate abundances in NS White = Low abundances.

[3] Commercially important species.

7.4.4.2.3 Species-specific summary of fish migration patterns, diet and life-cycle characteristics

Information on the migration patterns of fish around the Falkland Islands has been summarised from Arkhipkin *et al.* (2012b), based on data collected from 13,044 commercial bottom and pelagic trawls between 2000 and 2010 and from 1,272 research trawls between 1999 and 2011. See Table 7.10 below for a summary of the data below and life history and behavioural characteristic. Unless specifically stated, the International Union for the Conservation of Nature (IUCN) status of the species listed below has not been evaluated.

7.4.4.2.3.1 Sub-Antarctic fish and squid

Southern blue whiting

Southern blue whiting (*Micromesistius australis*) was until recently an abundant pelagic migratory species associated with south-west Atlantic waters. Since 1990 (total catch of 71,876t), catches within Falklands waters have been declining to all time low in 2023 (total catch of 15t). Targeted licenced

fishing for southern blue whiting ceased in 2017 and since then, the only catch is bycaught in other finfish fisheries (FIG, 2024b). Recent data show signs of stronger recruitment to the stock (FIG, 2024b). It is unclear what caused the decline but over-fishing is likely to be a contributing factor. Its spawning grounds are to the south-west of the Falkland Islands where it congregates during the spring. Once spawning is complete, the Southern blue whiting migrate onto the South-Eastern Outer Shelf (SEOS), and to a lesser extent in the Southern Slope (SS), where they feed on the abundant plankton resources (Brickle, *et al.,* 2009). During the summer (Dec-Feb), the main proportion of southern blue whiting migrates to the NS, and then further north with the Falkland Current beyond the southern Patagonian Shelf.

Southern hake

Southern hake (*Merluccius australis*) is a large bentho-pelagic predator consuming prey both in the water column and near the seabed, particularly smaller fish. Its greatest abundance observed in Falkland Islands waters is found during the austral summer when it migrates to forage in the SEOS, NWOS and SS. In autumn they almost disappear from the NWOS but remain abundant in the SS. The lowest biomass is observed during winter when they migrate into Chilean waters to spawn (Arkhipkin, *et al.,* 2003; Payá and Ehrhardt, 2005; Bustos, *et al.,* 2007; Brickle, *et al.,* 2016).

Hoki (whiptail hake)

Hoki or whiptail hake (*Macruronus magellanicus*) is one of the most abundant fish in the seas around southern South America. Spawning typically occurs during the winter months in areas outside of southern Patagonian Shelf waters. During spring hoki migrate to their feeding areas on the Falklands continental slope where it occurs in significant numbers in the NS and also in the SS and NWOS. Hoki is an opportunistic predator primarily consuming zooplankton, small fish and squid (Brickle, *et al.,* 2009). It has been suggested that approximately 20-25 % of the population migrate to the warm waters of the NWOS during the spring and summer. During autumn, the majority of hoki return to the upper slope and are found in large numbers over the NS. In winter, most of the population migrates outside the southern Patagonian Shelf to spawn with low numbers remaining on the SS. Unlike southern blue whiting, hoki appear both in shallow waters of IS and deep waters of the slope (DS); especially in autumn.

Patagonian toothfish

Patagonian toothfish (*Dissostichus eleginoides*) is a near bottom predator that has a wide distribution around the sub-Antarctic. The overall seasonal distribution of toothfish does not change significantly between the various habitat zones. In winter toothfish stay mainly in deepwater (DS) and slope region (NS) and start to migrate to shallower waters of the NWOS, SS and SEOS in spring. In summer, toothfish migrate to the warmer waters of NWOS and NS to forage on southern rock cod and other species, moving back to the slope regions (mainly NS) in autumn (Arkhipkin, *et al.,* 2012a). For the population as a whole a small percentage undertake large scale movements including towards the spawning grounds in the south. However, a significant proportion are resident (Brown, *et al.,* 2013; Troccoli, *et al.,* 2020; Lee, *et al.,* 2022; Kim, *et al.,* 2024) and this pattern will likely be similar for the NS.

Greater hooked squid

The greater hooked squid (*Moroteuthopsis ingens*) is an abundant species throughout the Southern Ocean and feeds predominantly on fish species (Arkhipkin, *et al.,* 2012b). The IUCN status of this species has been assessed as 'Least Concern' (Barratt and Allcock, 2014a). It is a relatively large squid (maximum reported mantle (body/tube) length of 61 cm) found from the surface to the deep waters (at 1,100 m; Jackson, 1993). Although abundant, this species is not commercial due to the high concentrations of ammonia in its flesh. However, it is one of the main prey items for shelf and slope cetaceans (Clarke, 1980). Following the winter spawning period the adults die, and in spring the juveniles move from the deepwater spawning area to shallower waters on the NS and SS. In summer,

the maturing juveniles forage mainly on the NWOS, NS and SS to depredate on southern rock cod. By autumn, the now fully mature greater hooked squid make their migration back to deep waters to spawn, gradually disappearing from shelf and upper slope areas, and reaching their highest abundance in DS (Arkhipkin, *et al.,* 2012a).

Red cod

Red cod (*Salilota australis*) is a relatively large demersal fish. On the Falkland Islands Shelf red cod's abundance is highest in spring in the SEOS, SS and NWOS, during their spawning and post spawning period. In the summer they disperse mostly over the NWOS to feed (Arkhipkin, *et al.,* 2001). In autumn they are mainly dispersed across the shelf and then in winter adult fish start to migrate back to the SEOS to spawn (Arkhipkin, *et al.,* 2010 and 2012b; Brickle, *et al.,* 2011).

Patagonian long-finned squid (loligo)

Patagonian long-finned squid, known locally as loligo, is an important domestic commercial species that spends its whole life cycle in the waters of the Falkland Islands (Arkhipkin, *et al.,* 2012b). The loligo population comprises two different spawning groups, the first spawning during spring and the second spawning during the autumn season. Their abundance on the NFB is high in winter, when pre-spawning animals forage for zooplankton in SS, SEOS and less significantly on the NS. During the spring the abundance is very low as many animals move to inshore areas to spawn and die (Section 7.4.4.3.2.1). The population increases again during summer as the newly hatched juveniles move from inshore waters to the SEOS and SS to feed on the abundant zooplankton, whilst avoiding depredation pressure from the larger fish (Arkhipkin, *et al.,* 2012b). During August the second spawning group migrates into inshore waters to spawn, whilst the maturing juveniles from the spring spawning group replace them on the SEOS feeding grounds.

7.4.4.2.3.2 Temperate fish and squid

Common hake

Common hake (*Merluccius hubbsi*), like the austral hake, is a near bottom predator that inhabits the temperate waters of the Patagonian Shelf and slope (Cohen, *et al.,* 1990). During autumn and winter, common hake migrate to their main foraging grounds in the NWOS, and to a lesser extent to the NS, to feed on southern rock cod. During spring and summer common hake abundance decreases significantly in the FICZ as they migrate north-west to their spawning grounds on the northern Patagonian Shelf (Arkhipkin, *et al.,* 2003; Arkhipkin, *et al.,* 2012a).

Kingclip

Kingclip, also known as the pink cusk eel (*Genypterus blacodes*), is a large eel-like benthic predator that occurs in the temperate shelf and slope waters of southern South America (Renzi, 1986). The greatest abundances are found in the NWOS, SS and SEOS, which are the main foraging areas for this species. During the summer approximately 60 % of the adult population migrate to their spawning grounds in the northern Patagonian Shelf outside Falkland Islands waters. In autumn, their abundance is at a minimum with remaining individuals possibly skipping spawning in the NWOS and SS. In winter, kingclip migrates back to the Falkland Islands to forage primarily on southern rock cod with increased abundances in NWOS, NS and SS. They then move from the NS further south to SS to continue feeding during spring (Arkhipkin, *et al.,* 2012b).

Southern rock cod

The southern rock cod (*Patagonotothen ramsayi*) is a bentho-pelagic species consuming prey both in the water column and near the seabed on the shelf and upper slope (50-500 m depths). The abundance of southern rock cod had increased several-fold since 2005 with the coincident decline in southern blue whiting catches in the Falkland Islands, however its importance as a fishery has been replaced by common hake since 2012 (FIG, 2013c). It is hypothesised that the regional decline in southern blue

whiting is a factor in rock cod's increased abundance (Laptikhovsky, *et al.,* 2013). Southern rock cod is itself an important prey species for all predatory fish (Laptikhovsky, *et al.,* 2013) and juvenile phases of loligo squid. This temperate species has a flexible diet with the ability to switch between main food sources as their abundance varies with the seasons (Arkhipkin and Laptikhovsky, 2013). During the spring and summer months, rock cod feed primarily on zooplankton crustaceans and benthic organisms in the NWOS and NS coinciding with peak zooplankton production during these months (Arkhipkin, *et al.,* 2012b). During the late summer and autumn months gelatinous plankton form an important part of their diet reflecting their overall seasonal abundance in the oceans (Arkhipkin and Laptikhovsky, 2013). The abundance of rock cod decreases particularly in the upper slope areas (NS and SS) during autumn, due to a migration out of Falkland Islands waters in preparation for the winter spawning period. A small proportion of the stock remains on the SS during the winter months.

Argentine shortfin squid

The Argentine shortfin squid has an annual life cycle (Hatanaka, 1986) and is the most abundant squid species in the south-west Atlantic, IUCN status 'Least Concern' (Barratt and Allcock, 2014b). It is closely associated with the temperate waters of the Patagonian Shelf and highest abundances are recorded on the NWOS and NS during summer where it migrates to the southern part of its range to forage on zooplankton, in particular krill (e.g., *Thysanoessa gregaria*, *Euphausia vallentini* and *E. lucens*) and pelagic amphipods (such as *Themisto gaudichaudii*). In autumn, they make their way north along the slope as part of their pre-spawning migration and abundances in the NWOS and NS decreases. During the rest of the year this species is largely absent from the Patagonian Shelf and slope (Arkhipkin, *et al.,* 2012b; Chemshirova, *et al.,* 2023).

Yellownose skate

The yellownose skate (*Dipturus chilensis*) is a relatively large skate that is moderately abundant in water depths between 100 and 300 m on the temperate shelves around southern South America (Nakamura *et al.,* 1986) but rarely found in depths >500 m. A migratory species, the yellownose skate makes long spawning migrations out of Falkland Islands waters to warmer waters in the summer (Arkhipkin, *et al.,* 2013). The skate returns in autumn during their feeding migration to prey on other fish and squid, which are abundant in Falkland Islands waters. The yellownose skate reaches maximum abundance around the Falkland Islands in austral winter (July to September) primarily on the NWOS (Arkhipkin, *et al.,* 2013). Throughout the spring, their abundance gradually decreases in the northern regions with some movement likely to the southern slope. This species has been assessed as 'Vulnerable' on the IUCN Red List and the population is thought to be in decline and subject to commercial fishing pressure (Kyne, *et al.,* 2007). The yellownose skate is one of the four species dominating the multispecies skate fishery in the Falkland Islands, which is currently managed by limiting the fishing effort and numbers of licences. The late maturation of females at 14 years old and low reproductive capacity makes this species vulnerable to overfishing and other factors that contribute to mortality.

Spur dog

The spur dog (*Squalus acanthias*) is a small shark that is associated with temperate waters of the Patagonian Shelf (Nakamura, *et al.,* 1986). It reaches its maximum abundance in Falkland Islands waters in the NWOS during spring, with smaller aggregations in the NS. In summer through to autumn this species migrates out of Falkland Islands waters onto the Argentine Shelf and into international waters (Arkhipkin, *et al.,* 2012b). This species has been assessed as 'Vulnerable' on the IUCN Red List and the population is thought to be in decline (Fordham, *et al.,* 2016). Although naturally abundant, it is vulnerable to over-exploitation by fisheries due to its late maturity, low reproductive capacity, longevity, long generation time (25 to 40 years) and hence a very low rate of population increase (2-7 % per year).

Slender tuna

The slender tuna (*Allothunnus fallai*) is a medium sized tuna growing to a maximum total length of approximately 100 cm. This species is widespread and locally abundant in the Southern Ocean and is assessed as Least Concern by IUCN (Collette, *et al.,* 2011). Slender tuna has the most southerly distribution of tunas in the South Atlantic, and feeds predominantly on zooplankton and is recorded in the IS in summer with the greatest abundance appearing in autumn in the NS. During the winter and spring months the slender tuna is completely absent from the Falkland Islands waters (Arkhipkin, *et al.,* 2012b).

7.4.4.2.4 Summary of offshore fish and invertebrate ecology

A summary of the abundance and behaviour of offshore fish and invertebrate species in provided in Table 7.10.

Table 7.10: Summary of offshore fish and invertebrate species around the Falkland Islands

Species	Domain	Migratory[1]	High abundance on NS	Behaviour on NS	Diet	Commercially targeted

[1] In and out of the Falkland Islands EEZ.

7.4.4.3 Berkeley Sound fish and invertebrate ecology

Commercial fishing is not permitted within coastal waters around the Falkland Islands (within three miles of the coastline, Section 7.5.1.2). Nonetheless, commercial species may utilise inshore waters for feeding or spawning. Additionally, there are numerous inshore species (20 species, mostly crustaceans and molluscs) that, although currently not heavily exploited in the Falklands, have the potential for commercial exploitation (Neely, *et al.,* 2010b; Davidson, 2016). All species contribute to the diverse inshore community however.

This section provides a description of the most abundant species of fish and invertebrates off the east coast of the Falkland Islands and in Berkeley Sound. For each, a summary of their ecology is provided in terms of:

- Their seasonal abundances in relation to the Berkeley Sound area,
- Their seasonal spawning migrations, and
- Their principal diet.

7.4.4.3.1 Fish species

There are relatively few fish species found within inshore waters in and around Berkeley Sound. The exceptions being, rock cod, mullet, smelt and sprat.

7.4.4.3.1.1 Southern rock cod

Detail on the offshore distribution and abundance of this species is provided in Section 7.4.4.2.3.2 above.

The genus *Patagonotothen* contains 14 species in the waters off southern South America of which *P. ramsayi* is the most abundant (Ekau, 1982; Norman, 1937; Hart, 1946; Brickle, 2005c). Little is known about the biology and ecology of these species. Bargelloni *et al.* (2000) estimated that the divergence time of Subantarctic *P. tessellata* from Antarctic *Lepidonotothen nudifrons* at 9 million years. Stankovic *et al.* (2002) added *P. brevicauda* to their analysis and estimated that the divergence time of *Patagonotothen* from its Antarctic sister is approximately seven million years well after the formation of the Antarctic Polar Front, which formed 20 – 25 million years ago.

Inshore, eight species of rock cod (*Patagonotothen*) have been recorded (Neely and Brickle, 2013). The have very different niches and include the abundant *Patagonotothen tessellata* which inhabit open water outside of the kelp line. Within kelp forests, *P. cornucola* inhabit the benthic environment particularly in algal litter (i.e., algal detritus and drift algae), *P. squamiceps* inhabits the kelp canopy and *P. sima* inhabits the intertidal. The inshore species range in size from 5 to 6 cm (*P. sima*) to 40 cm (*P. wiltoni*) in total length (P. Brickle, *pers. obs.*). These species are important prey for a number of inshore predators. In late summer huge shoals of post larval *P. tessallata* are prey for sei whales, dolphins, seals and slender tuna (P. Brickle, *pers. obs.*).

7.4.4.3.1.2 Falklands mullet

The Falkland Islands mullet (*Eleginops maclovinus*) belongs to the primitive monotypic notothenioid family Eleginopidae (Balushkin, 1992). Unlike most other notothenioids, *Eleginops* never became associated with the margins of the Antarctic plate (Eastman, 1993). It is the only notothenioid fish (apart from the Australian freshwater Pseudaphritidae), in which its entire evolution occurred in temperate nearshore environments (Balushkin, 1994) away from Antarctic waters.

The Falklands mullet is one of the most unusual notothenioids, only one of two euryhaline species (adapted to live in a range of salinities) in the entire suborder. The fish lives in coastal waters around the Falkland Islands (Boulenger, 1900; Hart, 1946) and in estuaries and rivers along the South American coast as far north as Uruguay on the east coast and Talcahuano, Chile on the west coast (Regan, 1913;

Norman, 1937; Andriashev, 1964). DeWitt *et al.* (1990) reported that a specimen had also been recorded from Tristan da Cunha in the Atlantic Ocean.

The Falkland mullet is an important component of Falkland Islands inshore ichthyofauna and preys on smelt, larval notothenioids, echiurid worms, polychaetes and crustaceans including *Grimothea* spp. Mullet are prey to sea lions and inshore dolphins (see Brickle, *et al.,* 2003; 2005a; 2005b; Brickle and MacKenzie, 2007 for more detail on mullet biology and ecology in the Falkland Islands).

The local mullet has been subject to a small inshore fishery in the Falkland Islands which continues. Catches vary and have been up to 15 tonnes per year (Brickle, *et al.,* 2003). Note that there is no large scale commercial (bottom trawl and longline) fishing allowed within three miles of the Falkland Islands baseline.

7.4.4.3.1.3 Smelt

There are two species of smelt or silversides (family Atherinopsidae) *Odontesthes smitti* and *Odontesthes nigicans* that inhabit the coastal waters of the Falkland Islands. Their biology and ecology are not well known and are taken occasionally as bycatch in beach seine nets for mullet (P. Brickle, *pers. comm.*).

7.4.4.3.1.4 Falklands sprat

Sprattus fuegensis is an abundant near shore and shelf herring like fish in the family Clupeidae. Falkland sprat was subject to a trawl fishery in the late 90s and is an important prey item for inshore predators and migrating predatory fish, mammals and seabirds in the Falklands Islands (P. Brickle, *pers. obs.*). This is particularly the case in mid to late summer when young fish of the year are plentiful and preyed upon by many species of higher predator including large baleen whales.

7.4.4.3.2 Invertebrate species

7.4.4.3.2.1 Loligo (Patagonian long-finned squid (Doryteuthis gahi))

Loligo is a demersal cold-water squid, which forms the basis of a substantial fishery on the Patagonian Shelf to the south, east and north-east of the Falkland Islands, with highest catches concentrated on the shelf break in waters between 150 and 200 m in depth.

Loligo is a key species in the Falkland Islands ecosystem (van der Grient, 2023; Büring, *et al.,* 2024) and therefore important to the functioning of the nearshore and shelf environment. Loligo routinely cannibalise themselves, eat krill, *Themisto*, arrowworms, copepods, many other zooplankton and fish species (Brickle *et al.*, 2001).

A small squid species (typical mantle length of 13–17 cm), loligo is an important domestic commercial species that spends its whole life cycle in Falkland Islands waters (Arkhipkin, *et al.,* 2012b) staying offshore to feed and coming inshore to spawn and die. The loligo population comprises two different spawning cohorts, the first spawning during spring and the second spawning during the autumn. Detail on the loligo distribution and abundance in the NFB is provided in Section 7.4.4.2.3.1 above. During August the second spawning group migrates into inshore waters to spawn, while the maturing juveniles from the spring spawning group replace them on the feeding grounds.

Despite being of great commercial significance, little is known about the breeding behaviour of Falklands' loligo. However, it was believed that unlike other loliginid squid they do not lay their eggs directly on the substrate, instead the eggs are attached to kelp stipes and likely on rocky outcrops. This is believed to be an adaptation to reduce the predatory pressure from benthic invertebrates. Also curious is the observation that although egg masses can be encountered anywhere in the kelp year-round (Tingley, *et al.,* 1996), they are never seen in great numbers at a single site. It is believed that each female lays clusters of eggs in many different locations. This appears to be an adaptation to the unpredictable inshore marine environment and may also reduce the predatory pressure from the

abundant populations of seabirds and marine mammals in the region (Brown, *et al.,* 2010). It is acknowledged that the distribution of loligo spawning grounds is poorly known in the Falkland Islands. Despite regular observations of *D. gahi* egg masses among kelp forests around the Falkland Islands (Arkhipkin, *et al.,* 2000; P. Brickle, *pers. obs.*), they have never been found in numbers required to support the large fishery that currently exists for this species around the Falklands. This fishery is one of the most important loliginid fisheries in the world and yields some 82 -99 % of the catch of the species in Atlantic Ocean (Arkhipkin, *et al.,* 2006).

Therefore, the question remains: are kelp forests the only spawning grounds for this species? First doubts appeared when a loligo egg mass was found attached to the tube of the polychaete *Chaetopterus variegatus* collected by bottom trawl at the depth range 68-71 m (Laptikhovsky, 2008). Investigation of Loligo sp. egg masses in Argentine waters revealed the existence of two types of clusters; those allocated to *D. gahi* (based on egg size) were found attached to the ropes with artificial egg clusters to attract females (demonstrating possible confusion with kelp stipes), and also a few were found attached to (artificial) hard substrata (Barón, *et al.,* 2001). Although spawning in this species on rocky ground is plausible, the prevalence of these bottom–attached masses remains unclear. On 11 January 2011 during a benthic SCUBA survey, undertaken by SMSG, off Tussac Island, Port William (54°40'496 S 057°43'689 W, depth 9.8 m) a loligo egg mass was observed attached to the bedrock. It is likely that loligo spawn on rocky outcrops in deeper water outside of the kelp zone. Further surveys are required to establish the spatial / bathymetric distribution and habitat characterisation of these spawning grounds.

7.4.4.3.2.2 Other commercially exploitable invertebrates

The Inshore Fisheries Research Project was initiated to investigate the distribution and abundance of 20 potentially exploitable inshore invertebrate species (Neely, *et al.,* 2010b). As part of this collaborative project between SAERI, the Falkland Islands Fisheries Department and SMSG, dive surveys have been conducted within the eastern half of Berkeley Sound (Davidson, 2016).

Of the potentially commercial species, only the Chilean sea urchin, ribbed mussel (*Aulacomya atra*), blue mussel (*Mytilus chilensis*), keyhole limpets (*Fissurella* spp.), and piure (*Pyura chilensis*) were found in any appreciable numbers and in several locations.

Chilean sea urchin

Chilean sea urchins (*Loxechinus albus*) were found at all 10 of the dive sites. The recorded density ranged between 36 and 940 urchins per 60 m^2. The higher densities were found in the eastern half of the survey area, with lower densities in the west.

Ribbed mussel

The ribbed mussel (*Aulacomya atra*) was present at eight of the 10 dive sites. The recorded density ranged between 6 and 1,350 mussels / 60 m^2. The densities were higher further towards the west of the survey area, with lower abundances in the east.

Blue mussel

Blue mussels (*Mytilus chilensis*) were only found at three of the 10 dive sites. The density, at the sites where they were found, ranged from 12 to 280 mussels per 60 m^2.

Keyhole limpet

Keyhole limpet species (*Fissurella* spp.) were found at three of the 10 sites. The density, at the sites where they were found, ranged from 5 to 29 limpets per 60 m^2. The distribution of keyhole limpets was skewed to the east of the area surveyed.

Piure

Piure (*Pyura chilensis*) were found at four stations but was not found in high densities anywhere. The highest density recorded was 20 piure per 60 m^2.

7.4.4.4 Fish and squid in Stanley Harbour and surrounding areas

Five fish species were recorded during recent surveys (Brickle, *et al.,* 2011; SMSG, 2013); the tessellated rock cod (*Patagonotothen tessellata*) was the most common with blue-spotted rock cod (*P. cornucola*), kelp rock cod (*P. squamiceps*), humped rock cod (*P. sima*), and orange fin rock cod (*P. brevicauda*) occurring less frequently. Mullet (*Eleginops maclovinus*) is also caught by recreational fishers at the western end of Stanley Harbour.

Commercial fishing is an important industry within the Falkland Islands and a number of commercial species of fish and squid are exploited. In general, it is considered that commercial species are not found in Stanley Harbour in significant numbers, although there is the potential for them to be present in low numbers.

A number of inshore non-commercial cephalopod species are potentially present with *Enteroctupus megalocyathus* and *Muusoctopus eureka* occurring in similar environments to the TDF development such as Mare Harbour (Brickle, *et al.,* 2011). Spawning of Patagonian Longfin Squid or loligo (*Doryteuthis gahi*), the main cold water commercial squid species in the Falkland Islands is known to occur within relatively shallow near-shore waters. Egg masses are known to occur in algal beds (Arkhipkin, *et al.,* 2000). However, there is no evidence to suggest that there are spawning grounds within the area of the TDF development or Stanley Harbour more widely.

7.4.4.5 Summary of inshore fish and invertebrate species

A summary of the abundance and behaviour of inshore invertebrate and fish species in provided in Table 7.11.

Table 7.11: Summary of inshore fish and invertebrate species around the Falkland Islands

Species	Domain	Migratory	High abundance in BS	Behaviour in BS	Diet	Commercially targeted

7.4.5 At sea surveys, seabird vulnerability and tracking

7.4.5.1 Introduction

The productive waters around the Falkland Islands provide globally important feeding areas for significant aggregations of seabirds (White, *et al.,* 2002). The Islands themselves hold internationally important breeding populations of a number of seabird species, and coastal and offshore waters support numerous species of non-breeding visitors (BirdLife International, 2014a). Of the 82 seabird species recorded in the Falkland Islands, 22 / 23 breed in the archipelago, 24 are annual non-breeding visitors and the remainder rare visitors or vagrants. (White, *et al.,* 2002; Woods and Woods, 2006).

Three species of albatross and petrel covered by the Agreement on the Conservation of Albatrosses and Petrels (ACAP) breed on the Falkland Islands. Over 70 % of the global population of black-browed albatross (*Thalassarche melanophris*), and 43 % of the global population of southern giant petrels (*Macronectes giganteus*) breed on the Islands (Wolfaardt, 2012; Stanworth and Crofts, 2017; Crofts, 2020).

After New Zealand, the Falkland Islands support more penguin species than any other region in the world. For most of these species, the populations breeding on the Falkland Islands represent a significant proportion of the global total. Approximately 34 % and 36 % of the global populations of gentoo (*Pygoscelis papua*) and rockhopper penguins (*Eudyptes chrysocome*), respectively, breed in the Falkland Islands (Baylis, *et al.,* 2013a & b). Furthermore, a significant proportion (possibly 10 %) of the global population of Magellanic penguins (*Spheniscus magellanicus*) breed on the Islands (Woods and Woods, 1997). The small breeding population of king penguins (*Aptenodytes patagonicus*) on the Falkland Islands, is almost entirely confined to a single colony on the east coast of East Falkland, adjacent to Berkeley Sound at Volunteer Point.

In addition to the large number of seabirds that breed on the Islands, many non-breeding seabirds have been observed (White, *et al.,* 2002) or tracked migrating into the waters of the Falkland Islands from elsewhere, particularly South Georgia (Croxall and Woods, 2002; Phillips, *et al.,* 2006).

The avifauna of the Patagonian Shelf region is well studied and documented, and seabird distribution, breeding and foraging patterns are relatively well understood in comparison to other species (Croxall, *et al.,* 1984; Woods, 1988; Woods and Woods, 1997; Strange, 1992; White, *et al.,* 2001 & 2002; FIG, 2008a; BirdLife International, 2015; Baylis, *et al.,* 2019a). However, it is acknowledged that there are data gaps.

This section provides a summary of the seabird species found in the Falkland Islands, their abundance, distribution, feeding and breeding ecology, conservation status and sensitivities. Throughout, the nomenclature and IUCN status follow BirdLife International's datazone (BirdLife International, 2020a). A list of all the bird species mentioned in the text with current (October 2024) IUCN status can be found in Appendix 1.

Note: The baseline for seabirds was constructed from a large number of datasets using different methodologies and represents a large volume of data. Seabirds are considered amongst the most sensitive of receptors so presenting the detail here was considered necessary. Synthesising and rationalising this further would require a significant reduction in important detail.

7.4.5.2 Seabirds in the NFB and Sea Lion Field

7.4.5.2.1 Seabird abundance and distribution surveys and tracking

Numerous surveys have been conducted since the late 1990s in an effort to determine the distribution and abundance of seabirds in the Falkland Islands. In particular, the JNCC Seabirds At Sea Team (SAST)

was commissioned to conduct seabird and marine mammal surveys in advance of the first exploratory round of drilling for oil within Falkland Islands waters.

In addition to the SAST surveys, seabird abundance and distribution within the Sea Lion area has been informed by at-sea surveys conducted by Rockhopper Exploration and Desire Petroleum during seismic survey campaigns in the PL001 licence area (Geomotive and MRAG, 2011) and the wider NFB licence blocks (Polarcus, 2011) and numerous satellite tracking projects (Baylis, *et al.,* 2019a; Baylis, *et al.,* 2021a) conducted through the GAP project and subsequent projects like the Darwin Plus 'Improving Falklands marine management effectiveness for marine higher predators (DPLUS139)' project.

It is important to acknowledge that the GAP project established a tracking programme filling in spatial and life history gaps for vulnerable birds (such as penguins) and fur seals (and only for Falkland Islands breeding species). GAP also assimilated and consolidated *c.* 20 years of tracking data from a variety of collaborators as part of this process and this has resulted in one of the largest datasets of its sort in the South Atlantic. However, some gaps still remain.

Although the JNCC Seabirds At Sea Team (SAST) surveys are 24 years old, it is unlikely that broad-scale animal distribution and movement patterns have changed significantly. Baylis, *et al.* (2019a) highlights that for nine-species tracked, the probability of occurrence is highest on the Patagonian Shelf, shelf slope and the Burdwood Bank (Figure 7-53). These findings are similar to the at-sea distribution presented for the same species (White, *et al.,* 2002). This is likely to reflect productivity on the Patagonian Shelf as a whole, being linked to the Patagonian Shelf, slope and Burdwood Bank (static features, associated with predictable areas of enhanced productivity) (e.g., Figure 7-53). Based on the predictive models, and knowledge of local oceanography, the importance of the Patagonian Shelf around the Falkland Islands is unlikely to have changed over the past 24 years, hence animal distribution is still likely to be associated with the Patagonian Shelf. Hence, the SAST data remains useful to characterise occurrence of species, particularly where no tracking data exists. The SAST data set is also useful in that it includes species that do breed in the Falkland Islands but use its waters for foraging or as migrations corridors. Given the GAP project focused on Falkland Islands breeding species, these data sets complement each other and make for the basis of a more informed assessment process.

It is acknowledged that previously some stakeholders have indicated that they would prefer that additional data acquisition to replicate and update the SAST data acquisition programme be undertaken before the project is approved. However, for a single operator this is not considered financially or logistically practicable. Acquisition of data on this scale would require an FIG / pan-industry collaborative approach.

Given this, data gaps remain and it is accepted that the assessments should deal with these in a rigorous and precautionary way (FIG, 2016e)[30], by highlighting and integrating gaps in data and understanding through the assessment process. It is also important to note here that the EMMP (Chapter 15) aims to collect further data in the field, specifically using Seabird and Marine Mammal Observers on two vessels for the initial years of the project (post sanction, pre-First-Oil and post-First-Oil).

[30] Schedule 4 of the Offshore Minerals Ordinance requires the EIS to describe the project and the environmental features likely to be affected by it *'to the extent that the applicant might reasonably be required to compile the information (having regard to current knowledge and methods of assessment). In other words, the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they address the gaps in the risk assessment. Therefore, the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained. When carrying out the risk assessment data gaps can be taken into account*.'

7.4.5.2.1.1 JNCC Seabirds At Sea Team (SAST) surveys

In advance of the first exploratory round of drilling for oil within Falkland Islands waters, the JNCC were commissioned to conduct seabird and marine mammal surveys. Surveys commenced in 1998 and continued for three years, with three dedicated observers employed throughout the project. The surveys covered an area of over 20,900 km^2 and recorded over 399,700 individual birds of 57 species. These data were published in the form of distribution maps; to display the seasonal dispersion of all species recorded (White, *et al.,* 2002). Over a two year period between 2003 and 2005, additional data was collected by one of the original SAST observers using the same methodology *en route* between the Falkland Islands and South Georgia (Black, 2005b). This work represents the most comprehensive survey of the at-sea distributions of seabirds within Falkland Islands waters and is considered here as the baseline to which additional information has been added, and should continue to be in the future. It is acknowledged that the age of the Seabirds-at-Sea dataset (collected over 24years ago), and inherent limitations of the survey method, mean that there are some questions regarding how representative the data are of present-day populations. Consequently, information relating to each species described below has been supplemented by more recent references on a species-by-species basis.

The SAST distribution atlas (White, *et al.,* 2002) and associated database remain the most useful description of seabird distributions within Falkland Islands waters, in terms of broad scale spatial and temporal patterns of distribution of breeding and non-breeding birds. There remain gaps in the SAST coverage but it is possible to infer the species assemblages that are likely to be found in these areas with the data available, therefore, White, *et al.* (2002) has been used as a reference in the EIS. Questions have been raised about the age of the SAST data. In order to ensure that the JNCC SAST data provided an appropriate dataset on which to base the environmental impact assessment, POEPL commissioned Genesis to undertake a review of the data (Genesis, 2017).

The review assesses the adequacy of the existing seabird data presented in the EIS for the purposes of impact assessment, i.e., is the quality and quantity of seabird data presented in the EIS fit for purpose?

The review concluded that the survey methods used, the coverage and the age of the data are comparable with existing datasets used to inform similar impact assessments undertaken in the UK. As a whole, the volume of data collected in the waters off the Falkland Islands is significantly smaller than the equivalent European Seabirds At-Sea (ESAS) data set, being based on three years of survey effort as opposed to over 30 years for the ESAS data. However, the survey effort is not dissimilar to the level of effort from the Atlantic Frontier waters located off the north and west coast of Scotland, where O&G exploration is also relatively new and developing. It is important to note that, in addition to the SAST data, a significant amount of recent tracking data was collected and synthesised through the GAP process, which is also utilised in the impact assessment. These data represent the largest of its type for southern South America and specifically the Patagonian Shelf. Hence, the SAST data are considered to be complementary to more recent occurrence data when undertaking the assessments in this ES. Limitations of the SAST data are described in the section below.

The EMMP (Chapter 15) will collect further data in the field, specifically using SMMOs on two vessels for the first three years of the project (post sanction, pre-First-Oil and post-First-Oil). Data collected here will allow of a comparison of the SAST data going forward'.

With permission from Falklands Conservation (FC) and JNCC, the SAST survey data was re-examined in 2020 to highlight the species recorded in the vicinity of the Sea Lion area. An imaginary 'box' (between 49-50°S and 58.5-59.5°W) was used for this purpose. The number of birds recorded per kilometre of survey track, on a seasonal basis, was calculated to indicate relative abundance in the immediate area around the Sea Lion Field and is presented in Table 7.12 (the highlights in shades of blue indicate relatively High, Medium and Low abundance). For the purposes of this analysis, the months of March,

April and May are considered to be autumn, June, July and August are winter, September, October and November are spring and December, January and February are summer. As in White *et al.* (2002), clear seasonal patterns of abundance, and therefore risk from O&G related activity, were identified for most species recorded in the region.

In total, over 2,050 km of survey track were observed over Sea Lion Field waters. Effort was spread across all months with a high of 504 km achieved in July and a low of 41 km in May.

Over 4,880 seabirds of at least 27 species, were recorded and are summarised on a seasonal basis in Table 7.12.

Data limitations with seabird distribution and vulnerability information

There are a number of limitations associated with the SAST surveys which are described by White, *et al.* (2001 and 2002) and must be taken into consideration when interpreting the data. The SAST surveys

were conducted opportunistically. Therefore, the distribution of survey effort was closely linked to the activity of patrol vessels. Occasionally, some vessel time was dedicated to covering the NFB but there remain some gaps in coverage. As a result, coverage within some of the key Licence Blocks was not as high as had been hoped at the outset of the project (White, *et al.,* 2001; 2002). In particular, the Drilling Campaign Area was not covered during April, May and September.

The detection and identification of cryptic species, such as penguins and diving-petrels (*Pelecanoides* spp.), at-sea was highlighted as one of the most significant challenges for observers, as these birds can be difficult to spot from vessels (White, *et al.,* 2002). However, simultaneous projects to satellite track penguins were conducted, to complement at-sea observations and fill any gaps. The recorded distribution of penguins during SAST surveys are supported by satellite tracking data (for example Pütz, *et al.,* 2000; 2002a & b). Additional tracking has been carried out in subsequent years, and as part of the GAP project (Section 7.2.4.2), which is summarised in Baylis, *et al.* (2019a & b; 2021). Preliminary results showing the range of each species, as derived from probability of occurrence data, support the known distributions of the species concerned. The seabird tracking database in the Falklands Islands is always evolving and therefore further data and analyses could complement the baseline in future years.

Visual surveys also rely on good conditions for observing. When conditions are too rough or dark to continue, surveys stop. Therefore, the activity of birds at night is not recorded. Some species are known to return to colonies at dusk, this behaviour is well known from observations from land and can be observed at sea when close to land late in the day. With sufficient survey effort, the movements of birds to and from colonies will be captured in the data.

The SAST data were collected over 24 years ago. Whether this influences the validity of the data is a matter for debate. During the three years of the project major inter-annual variations in species distribution were not identified, perhaps because the study covered a relatively short time frame.

Recent studies suggest that there may be significant inter-annual and spatial variation in foraging and migration patterns, for individuals of the same species breeding on the same island (Masello, *et al.,* 2010) and on island breeding sites that are in close proximity (Granadeiro, *et al.,* 2011; Catry, *et al.,* 2013). However, these were over small spatial scales. This is likely to be the case for individual birds but whether this is reflected in the foraging ranges of populations as a whole remains to be seen and future data would of course help clarify this. The three years of SAST surveys did detect some inter-annual variation but most of these concerned non-breeding visitors to Falkland Islands waters. Species such as great shearwater (*Ardenna gravis*) and soft-plumaged petrel (*Pterodroma mollis*) are likely to show greater inter-annual variation than those breeding at the Falklands. This suggests that a combination of satellite tracking and at-sea observations is likely to provide the best overview of seabird distribution within the waters of the Falklands Islands. Substantial tracking datasets now exist to support more detailed analysis of movements - particularly during the breeding season. However, limitations associated with tracking data are discussed in Section 7.4.5.3.1.3.

It is important to note that data from the extensive tracking database collected for the Falkland Islands (Baylis, *et al*., 2019), at larger geographic scales, show findings are similar to the at-sea distribution presented for the same species (White, *et al*., 2002). This is likely to reflect productivity on the Patagonian Shelf as a whole, being linked to the Patagonian Shelf, slope and Burdwood Bank (static features, associated with predictable areas of enhanced productivity) (Section 7.4.5.2.1).

Despite limitations, one of the great advantages of at-sea surveys is that all species are recorded. Therefore, it is possible to assess the risk to species that have not been tracked. For example, many of the smaller species of petrels are vulnerable to oiling and light-induced bird strikes, but little tracking

data exists. An example the availability of tracking data for individual species is provided in Table 7.13, highlighting the SAST data is the only baseline for numerous small petrel and prion species.

7.4.5.2.1.2 Seabird surveys from seismic vessels in NFB during 2011

A total of 242 seabird surveys were conducted from January until May 2011 during a 3D seismic survey in the licence area PL001, which is adjacent to the block containing the Sea Lion Field (Geomotive and MRAG, 2011). In addition, 226 individual seabird surveys were conducted over a larger area covering many of the NFB licence blocks from the end of November 2010 to May 2011 (Polarcus, 2011). Survey methods were based on standardised protocols developed by the JNCC and used by SAST in the Falklands. Additionally, a mixture of line transect and point surveys were conducted in March and April 2012 as part of the Sea Lion Field environmental baseline survey (Gardline, 2013a). The objective of these surveys was to add to the knowledge of seabird abundance and distribution within the PL001 licence area during the summer season. However, the activity of the vessels, towing seismic gear at slow speed (4.5 knots), is likely to have resulted in some biases due to birds persistently associating with the vessels. It is difficult to directly compare the data presented in Geomotive and MRAG (2011) and Polarcus (2011) with that in White *et al.* (2002) as it is presented in a different format. Nonetheless, there are similarities in the ranks of species abundance from all three datasets. Table 7.13 lists the 27 most abundant seabird 'species' recorded during the PL001 survey and the corresponding rank of abundance of those species in the NFB survey.

The most abundant families of seabirds recorded during the surveys were albatrosses, shearwaters, petrels, skuas and fulmars (Table 7.13). Three species of penguin (Magellanic, gentoo and rockhopper) were recorded in low numbers during both surveys. However, it must be noted that penguins are more difficult to detect because of their diving behaviour. Black-browed albatross, great shearwaters, soft-plumaged petrels, white-chinned petrels (*Procellaria aequinoctialis*) and giant petrel species (*Macronectes* spp.) were all ranked highly in both surveys, and are all known to follow and be attracted to vessels (Polarcus, 2011).

Table 7.13: Number of seabird sightings during the PL001 and NFB Surveys

7.4.5.2.1.3 Satellite tracking studies

At about the same time that the SAST surveys were being initiated in the Falklands, a number of seabird satellite tracking studies of seabirds commenced. These focused on a range of species, including black-browed albatross (Huin, 2002), Magellanic (Pütz, *et al.,* 2000; 2002a), rockhopper (Pütz, *et al.,* 2002b) and gentoo penguins (Clausen and Pütz, 2003). In subsequent years, tracking projects have continued

on a number of species at various sites around the Islands (see Blockley and Tierney, 2016). Indeed, tracking studies formed a major part of the GAP Project, which collated existing tracking data, and undertook further tracking to fill gaps (see Section 7.2.4.2). The initial results of the GAP project are presented in Blockley and Tierney (2016) and Baylis, *et al.* (2019a & b). However, further work could potentially be undertaken to interpret this data with the aim of producing vulnerability maps.

Tracking data for different age-classes, breeding stages and breeding colonies are limited for most species. This is particularly the case for immature / juvenile birds, periods outside of the breeding season and species that breed elsewhere (noting that most of the IUCN Endangered, Vulnerable and Near Threatened species encountered within Falklands waters do not breed on the Islands). So, although there has been a considerable research effort on tracking seabirds in recent years, there remain substantial data gaps. Generally, small sample sizes and data gaps limit the ability to assess vulnerability for all age-classes, breeding stages and in some instances, species. Further work is required to address priority tracking data gaps in the Falklands (Section 7.2.4.2), so that these data can be used in future assessments. Notable additions to seabird tracking data since the GAP project, include a recent SAERI led tracking project (DPLUS139) that included six species and 5 breeding colonies (Table 7.14). Combined with the GAP project data, this yields over 360,000 at-sea locations from 10 species (Figure 7-48). This data is yet to be formally analysed but could be integrated into future assessments.

In addition, the Falkland Islands provides important foraging habitat for seabird species that breed elsewhere, particularly at South Georgia (e.g., Berrow, *et al.,* 2000; Phillips, *et al.,* 2006; Ratcliffe, *et al.,* 2014). BirdLife International manages the Global Procellariiform Tracking Database (BirdLife International, 2004), which serves as a central repository for albatross and petrel tracking data from all over the world. The Global Procellariiform Tracking Database model has recently been extended to penguins (and other seabirds). Work is currently underway in the Falklands to collate, and determine how best to use, the tracking data available for seabirds breeding and visiting the Falkland Islands (Section 7.2.4).

Where possible the published accounts of tracking projects have been used to describe the distribution of species and their foraging ecology. However, for some species there is little information in the published literature that adequately describes the distribution of the populations involved.

Table 7.14: Summary of deployments from a recent multi-colony tracking project[1]

Species	Colony	Year	Individuals	Trips	Duration (days)	Duration (SD)	Max distance (km)

7.4.5.2.1.4 GAP project overview and data availability

The recommendations of the GAP analyses group were to initiate further tracking work to fill the obvious and highest priority taxon gaps. Briefly, the main priority gaps were:

- Seabirds: those species most susceptible to oil contamination, such as penguins, should be afforded the highest priority, particularly Gentoo, Magellanic and Rockhopper penguins,
- Pinnipeds: fur seals and sea lions were considered a priority for immediate tracking work given their breeding distribution in the north of the Falklands and given that little was known about their at-sea distribution (Section 7.4.6.3.2.3), and
- Collate existing tracking data.

The GAP analysis integrated data from four types of biologging tags - geolocator tags (GLS), satellite tags (PTT), Fastloc-GPS tags and GPS tags. The type of biologging tag selected was a compromise

between tag size, battery life, cost, and location accuracy. A detailed description of differences between biologging tags are described in the GAP Phase I report (Blockley and Tierney, 2016). However, in brief:

GLS tags record light levels and time. Light levels allow sunrise and sunset to be estimated, which can be used to calculate longitude. Time provides a measure of day length, which can be used to calculate latitude. Locations derived from GLS tags have errors of hundreds of kilometres. However, their small size makes them ideal to track migratory movements of seabirds.

Satellite tags (PTTs) are one of the most widely used tags because they provide real-time location data remotely *via* Argos satellites anywhere in the world. Locations are estimated using the Doppler-shift in frequencies between the tag and polar-orbiting satellites. Satellite tags transmit data when the animal is at the surface. The number of satellite links influences the error associated with the estimated position (error ranges from hundreds of meters to kilometres). For species that do not spend a long time at the surface, location quality can be consistently poor.

Fastloc-GPS tags are a compromise between satellite tags and GPS tags. Fastloc-GPS tags (Wildtrack Telemetry System Limited, Leeds, UK) require only seconds at the surface to take a snapshot of the radio signals produced by GPS satellites. Fastloc GPS tags process these signals onboard the tag (identifies satellites and their pseudo-ranges), and then transmits data *via* the Argos satellite system and final locations are post-processed. The location accuracy of Fastloc-GPS tags is typically less than 100 m (Costa, *et al.,* 2010).

GPS tags utilise a constellation of satellites that orbit the earth and transmit navigational data. Due to the time required for a GPS tag to be at the surface to obtain a satellite fix and maintain the almanac, they are typically best suited to flying seabirds. The location accuracy of GPS tags is typically less than 50 m. Data processing steps varied depending on the type of tag used, but in general involved three main steps:

- Identification of foraging trips,
- Use of a speed filter to remove obviously erroneous locations, and
- Implementation of a movement model to account for location error and produce a best-fit/most likely track.

Given GLS tags are associated with a very large location error (> 150 km), here we focus on data derived from other tags (satellite tags, Fastloc-GPS tags and GPS tags). For a detailed overview of how telemetry data was analysed, please refer to Baylis and Tierney, 2018 and Baylis, *et al.,* 2019.

GAP Results - Telemetry data (all species)

In total, 687 individuals were tracked, with 1,891 foraging trips identified, from 21 colonies (listed in Table 7.15). To summarise the observed distribution of individuals at-sea, telemetry data was split into groups according to species, sex, season and breeding status / stage Table 7.16 and Figure 7-49 provide an overview of the data available from satellite tags, Fastloc-GPS tags and GPS tags, and the various groups that were defined.

Individual species maps, showing the animals' tracks, are presented in Figure 7-50, Figure 7-51 and Figure 7-52. Maximum foraging trip distance ranged from 79 km for chick-rearing gentoo penguins to 1,325 km for incubating black-browed albatross (Table 7.16). Over 60 % of sampled colonies (13 of 21) were in the north-east of the Falkland Islands (Figure 7-49). The proportion of colonies from which animals were tracked for each species ranged from <10 % for South American sea lions and gentoo penguins (4 of 71 and 6 of 81 colonies, respectively) to 30 % for black-browed albatross (4 of 12 colonies).

Figure 7-49 represents the core foraging areas (50 % utilisation distributions) for the animals tracked (refer to Table 7.16). Core foraging areas extended as far north as 42 °S, 1,000 km to the north of the Falkland Islands, and as far south as 56°S, 360 km to the south. Foraging trips were, however, predominantly confined to the Patagonian Shelf, including the Burdwood Bank (Figure 7-49).

The highest overlap of core areas, both among groups and species was on the Patagonian Shelf to the north of the Falkland Islands (Figure 7-49). In total, 83 % of locations (species range was 67 – 99 % of locations) were associated with bathymetric depths less than 400 m, which highlighted a preference for the Patagonian Shelf and Burdwood Bank for most species. The exceptions were southern elephant seals, where 68 % of foraging trip locations were associated with water depths between 400 m and 800 m (i.e., shelf-slope waters; Figure 7-52), and a small proportion of rockhopper penguins, which foraged beyond the Patagonian Shelf and slope during incubation, in water > 600 m deep (Figure 7-50). Most foraging trip locations (74 %) were within the Falkland Islands Conservation Zones. The remaining locations were within the Argentine Exclusive Economic Zone (23 %), and the high seas (3 %).

Predictive models

Tracking data was not available for all breeding colonies at the Falkland Islands. For example, gentoo penguins and South American sea lions breed at over 70 sites around the Falkland Islands, but were tracked from only six and three sites, respectively. It is unlikely that the existing telemetry data accurately depicts the space use of animals from other colonies, especially distant colonies; however, it is impractical to track all breeding colonies. To predict the space use from colonies not tracked, Baylis, *et al.* (2019) modelled habitat selection using Generalised Additive Models (GAMs).

In brief, space use was modelled as a function of dynamic and static environmental indices that described habitat. The seven environmental indices used were sea surface temperature, sea level anomaly, eddy kinetic energy, bathymetry, slope and distance from colony. Predicting from GAMs, the predicted distribution of animals was mapped from both sampled and unsampled colonies. Note that male fur seals and sea lions roam widely and use multiple colonies. Therefore, predictive models were not developed for male seals. For a detailed overview of how models were developed and details on the environmental indices used, please refer to Baylis *et al.* (2019a & b).

Model results are presented below (Figure 7-53) as an overview, and in the species accounts in Section 7.4.5.2.2 for seabirds and Section 7.4.6.2.2.1 for pinnipeds. The results depict the probability of occurrence, proportional to the likelihood of absences – perhaps best interpreted simply as predicted presence and absence. Results from both tracking data and predictive models demonstrated that the shelf area around the Falkland Islands (which includes parts of the North Falkland Basin) was important habitat for marine higher predators breeding at the Falkland Islands. The large area of shelf used by marine predators reflects the ubiquitous breeding distribution of some species, combined with the long-distance movements of most species tracked.

Limitations of telemetry data

Telemetry data were collected over different years, and for some species and some breeding colonies, available telemetry data was unlikely to fully represent core areas used based on the representativeness analysis detailed in Baylis *et al.* (2019a & b). Given data collection was opportunistic rather than systematic, inconsistencies in the temporal coverage of data between species could obscure potentially important areas of use. Ultimately, it would be ideal to track species at the same time, stratifying data collection across colonies within species, such that good geographical coverage was achieved, with more data collected from larger colonies. However, the resources required to undertake simultaneous tag deployments on multiple predator species from multiple colonies is typically not feasible.

Limitations of predictive models

Although the predictive models generally performed well (see Baylis, *et al.,* 2019 a & b), caveats and constraints exist with the predictive modelling approach. For example, the models developed by Baylis, *et al.,* 2019 could have been extended by including additional terms to account for correlation structures inherent in telemetry data, including (1) individual and colony-level slopes (random effects); (2) a term to model temporal / serial autocorrelation and (3) terms to describe spatial autocorrelation. However, including these terms has so far proved impracticable in studies that have analysed datasets of similar size due to computational constraints and lack of convergence (Raymond, *et al.,* 2015; Arthur, *et al.,* 2017; Trathan, *et al.,* 2018; Warwick-Evans, *et al.,* 2018).

Table 7.15: Colony location abbreviations used in Table 7.16 and Figure 7-49 below

Colony	Abbreviation	Colony	Abbreviation
Bird Island	BIRD	Volunteer Point	VPT
New Island	NEW	Volunteer Rocks	VRK

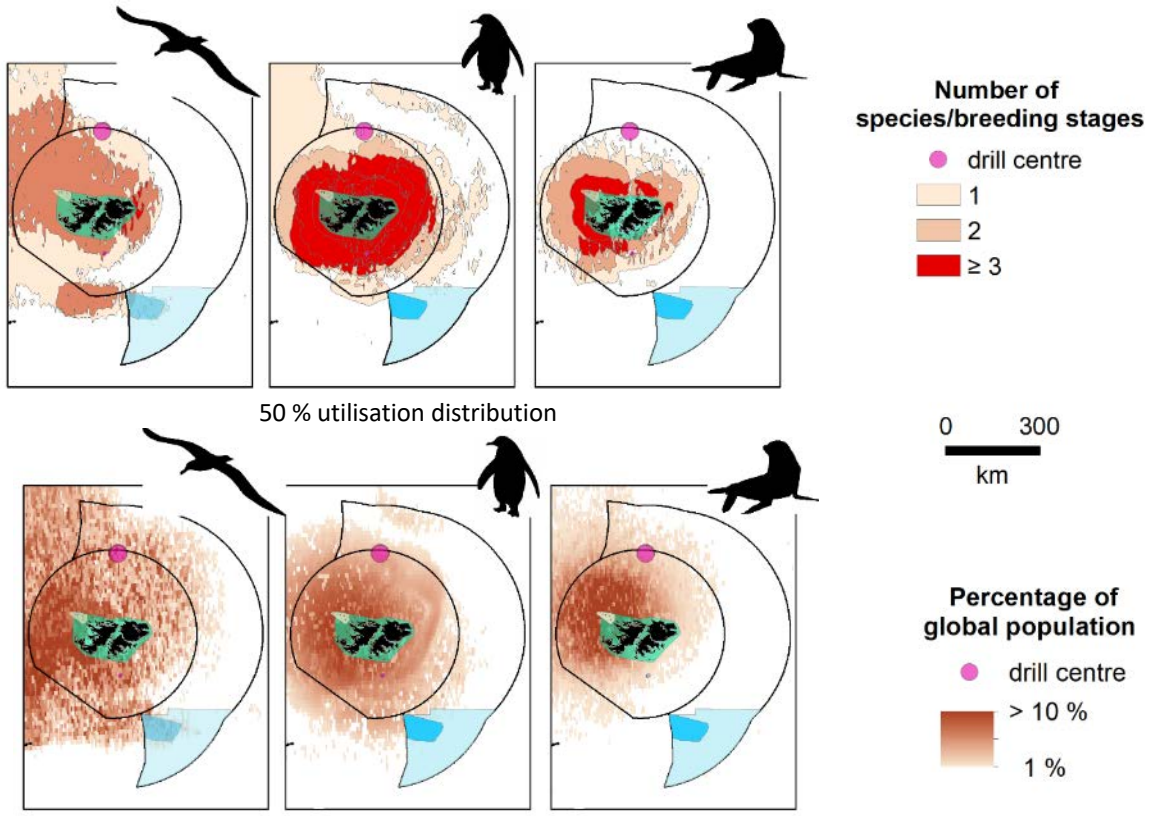

Figure 7-53: An overview of the GAP data from Baylis, *et al.,* 2019 and Baylis, *et al.,* 2021a. Predicted distribution (red shading relates to overlap in species/stages) and proposed Marine Managed Areas (MMAs) for flying seabirds (Black-browed Albatross and Sooty Shearwaters), penguins (Gentoo, King, Magellanic and Rockhopper Penguins) and pinnipeds (Southern elephant seals, Southern sea lions and South American fur seals). Upper panels, 50 % utilisation distribution; lower panels, percentage of global population. The lower panels exclude Southern elephant seals, Southern sea lions, Magellanic Penguins, and King Penguins, given these species did not meet IUCN Key Biodiversity Area (KBA) criterion D1a (demographic aggregations ≥1 % of the global population size). Green, inshore MMA, yellow, Jason Islands group MMA; blue, Burdwood Bank MMA. Thin black lines are the Falkland Islands Inner and Outer Conservation Zones. Also shown is the location of Phase 1 & 2 Development drill centre

7.4.5.2.2 Species-specific distribution and abundance

In this section, a brief account is provided of the abundance and distribution for each species, listed in order of autumn abundance (Table 7.12 above). This information is based primarily on the results of the SAST surveys (White, *et al.,* 2002) but is also informed by additional at-sea surveys and tracking data.

The population size of species are given where data are available, however, it should be noted that accurate population estimates and trends are only available for a few species. In the Falklands, the populations of penguins and ACAP species (black-browed albatross and southern giant petrel) are relatively well known, thanks to several island-wide censuses (Baylis, 2012; Baylis, *et al.,* 2013a & b; Stanworth and Crofts, 2017) and Falklands Conservation's Seabird Monitoring Programme (Crofts and

Stanworth, 2019). The populations and breeding sites of most other species of seabird are less well known and this is acknowledged as a data gap.

Table 7.17 provides a summary of the key ecological characteristics of the most abundant seabird species within the NFB and particularly the Sea Lion area to help understand how O&G operations may pose a threat to these species, and how the potential impacts may be avoided or mitigated.

Black-browed albatross (BBA)

The Falkland Islands are home to the world's largest breeding population of black-browed albatrosses (*Thalassarche melanophris*). The most recent census, in 2010, estimated the breeding population to comprise approximately 500,000 breeding pairs, which represents approximately 75 % of the global population (Wolfaardt, 2012).

During SAST surveys, black-browed albatross were regularly recorded throughout the year in the vicinity of the Sea Lion area (Table 7.12 above) and were ranked in the top three species recorded in all seasons. In the autumn (March to May), the number of birds recorded per kilometre travelled was substantially greater than in other seasons. Black-browed albatross were also the most numerous species recorded during seismic surveys (Table 7.13).

Black-browed albatrosses were tracked from four Falklands colonies. The results were used to produce the predicted distribution shown in Figure 7-54. The data indicates that birds forage predominantly over the Patagonian Shelf. During chick rearing the range of adult birds is more restricted than during the incubation period, when birds are likely to be away from the colonies for longer periods of time. SAST surveys recorded a similar overall distribution but recorded differences in the abundance of black-browed albatrosses across the Patagonian Shelf.

Of note, besides the local breeding population of black-browed albatross, the South Georgia population also occurs in the Falkland Islands (Frankish, *et al*., 2020a). The black-browed albatross from South Georgia is an ACAP Priority Population (i.e., where the territory has >10 % of the global total for each species and / or the population is declining at a rate of >3 % per annum) (GSGSSI, 2016).

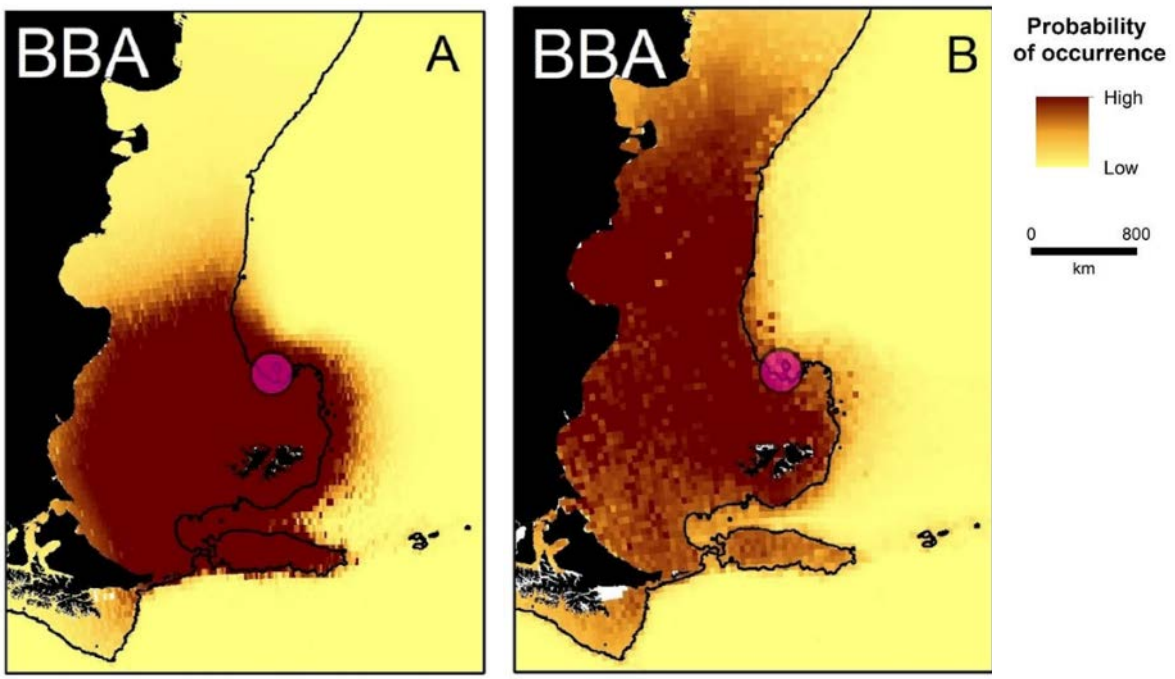

Figure 7-54: Black-browed albatross predicted habitat use (predicted presence) for birds breeding on the Falklands from the available biotelemetry and biologging data (A = chick rearing, B = incubation). The pink dot represents the drill centre *(adapted from Baylis et al., 2019a)*

Great shearwater (GS)

Great shearwaters (*Ardenna gravis*) are largely non-breeding visitors to Falkland Islands waters, although there is a very small local breeding population (50 -100 pairs, Woods and Woods, 1997). Virtually the entire global population of five million pairs breed on the Tristan da Cunha group of islands (BirdLife International, 2016). After breeding, the population embarks on a clockwise circum-Atlantic migration.

Great shearwater was the second most numerous species recorded in the summer and autumn (Table 7.12 and Table 7.13). The seasonal presence of this species within Falklands waters was consistent from year-to-year, although the number of birds can vary inter-annually (White, *et al.,* 2002).

White-chinned petrel (WCP)

There is a very small breeding population of white-chinned petrels (*Procellaria aequinoctialis*) in the Falkland Islands, estimated at 55-100 pairs (Reid, *et al.,* 2007). The small numbers of breeding pairs include 331 (95 % CI: 52 – 1043) and 199 (95 % CI: 33 – 594) at Kidney Island and Top Island respectively (Kuepfer, *et al.,* 2024). Most of the birds present within Falkland Islands waters come from the much larger breeding population at South Georgia (Berrow, *et al.,* 2000; Phillips, *et al.,* 2006), which is in decline and estimated to comprise approximately 900,000 pairs (Martin, *et al.,* 2009).

White-chinned petrels were one of the most regularly recorded species throughout most of the year in the vicinity of the Sea Lion area, except for the winter months when their numbers are considerably reduced (Table 7.12).

Of note, a recent tracking study demonstrated movements of the South Georgia white-chinned petrel population to Falkland Islands waters (Frankish, *et al*., 2020b).

Cape petrel (CP)

Cape petrels (*Daption capense*) are non-breeding visitors to Falkland Islands waters from their Antarctic breeding grounds. Although recorded in every season, Cape petrels do not arrive in large numbers until May. Numbers start to decline in September and are virtually absent during the summer months (Table 7.12; White, *et al.,* 2002).

Wilson's storm-petrel (WP)

Wilson's storm-petrels (*Oceanites oceanicus*) are extremely widespread and abundant in the southern hemisphere. The Falklands are thought to support a modest breeding population of something in excess of 5,000 pairs (Woods and Woods, 1997).

Although present throughout the year, numbers of Wilson's storm petrels were greatly reduced during the winter months. In the summer months, high densities of Wilson's storm-petrel were found over the Patagonian Shelf to the north-east of East Falkland, close to the Sea Lion area (White, *et al.,* 2002).

Antarctic fulmar (AF)

Like Cape petrels, Antarctic fulmars (*Fulmarus glacialoides*) are non-breeding visitors to Falkland Islands waters from their Antarctic breeding grounds. Antarctic fulmars were one of the most common species recorded during the winter months but were almost entirely absent during the summer (Table 7.12).

Grey-backed storm-petrel (GBSP)

Like Wilson's storm-petrel, the Falklands support what is thought to be a small breeding population (1,000-5,000 pairs) of grey-backed storm-petrels (*Garrodia nereis*) (Woods and Woods, 1997). During the summer months, high densities of this species were encountered over the shelf break to the north-east of the Islands, which extends close to the Sea Lion area. Although recorded in all seasons, fewer grey-backed storm-petrels were recorded in the winter (Table 7.12).

Grey-backed storm-petrels were the most frequently recorded species feeding in association with patches of free-floating kelp (Gillon, *et al.,* 2001).

Soft-plumaged petrel (SPP)

Soft-plumaged petrels (*Pterodroma mollis*) are regarded as summer and early autumn visitors to Falklands waters (Table 7.12; White, *et al.,* 2002). The nearest breeding location of this species to the Falklands is on the Tristan da Cunha group. Soft-plumaged petrels were one of the few species recorded by White, *et al.* (2002) that showed inter-annual variation in the number of birds recorded within Falklands waters. Like several other species with breeding populations in the Tristan da Cunha group, the majority of soft-plumaged petrels recorded were encountered over oceanic waters to the north-east of the Falklands.

Sooty shearwaters (SS)

The best known and probably largest colony of sooty shearwaters (*Ardenna griseus*) is found on Kidney Island, in the mouth of Berkeley Sound, which is estimated to comprise 139,000 pairs (Wakefield, *et al.,* 2017; Clarke, *et al.,* 2019). Sooty shearwaters are known to breed elsewhere in the Falklands but very little is known about the size and location of many breeding sites. Although present throughout the year, the majority of the breeding population are absent from Falklands waters from April to August (Table 7.12; White, *et al.,* 2002). Generally, the highest densities of sooty shearwaters were recorded over inshore waters, where large flocks raft on waters adjacent to breeding colonies.

Twenty sooty shearwaters were tracked from Kidney Island during the summer months. Results indicate that the birds were largely restricted to the east coast of the Falklands and Burdwood Bank (Figure 7-51 and Figure 7-55). SAST surveys also recorded the highest densities of sooty shearwaters over inshore waters off the east coast of the Islands, but they were also encountered throughout

inshore waters around the Falklands. Sooty shearwaters were present in lower number over the wider Patagonian Shelf (White, *et al.,* 2002).

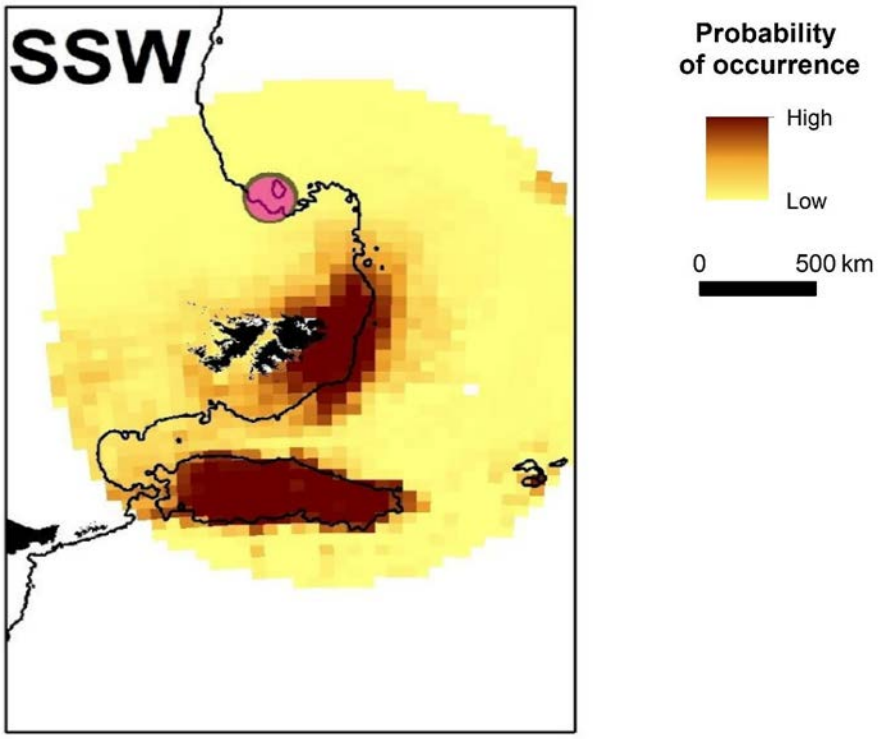

Figure 7-55: Sooty shearwater predicted habitat use (predicted presence) for birds breeding on Kidney Island from the available biotelemetry and biologging data. The pink dot represents the drill centre *(adapted from Baylis et al., 2019a)*

Prion species (Pr)

Several species of prion (*Pachyptila* spp.) are known to frequent Falkland Islands waters. However, they are difficult to identify to species level at-sea and therefore most prions were recorded as 'prion species'. Throughout most of the year, prions are one of the most numerous 'species' encountered within Falklands waters; however, there is a distinct decline in numbers during the autumn (Table 7.12; White, *et al.,* 2002).

Two species of prion breed within the Falkland Islands: thin-billed (*P. belcheri*) and fairy prions (*P. turtur*). The population of thin-billed prions is estimated to comprise approximately two million pairs on New Island alone (Catry, *et al.,* 2003) with other smaller colonies elsewhere in the Islands, making thin-billed prion the most numerous breeding seabird in the Falklands. Fairy prions have a far smaller breeding population at one confirmed breeding site, on Beauchêne Island (Woods and Woods, 1997). In addition, Antarctic prions (*P. desolata*) are likely to visit Falkland Islands waters.

Locally high densities of prions can be found close to the Sea Lion area in the summer months but densities of this 'species' are generally much higher elsewhere within Falklands waters, notably to the west and south-west of the Islands (White, *et al.,* 2002).

Southern (SRA) and Northern royal albatrosses (NRA)

Southern and northern royal albatrosses (*Diomedea epomophora* and *D. sanfordi*) are both non-breeding visitors to the south-west Atlantic from their breeding sites in New Zealand and have been observed in Falkland Island waters (Nicholls, *et al*., 2002; 2005; Bose, *et al*., 2023). They are classified

as Vulnerable and Endangered, respectively, under the IUCN Red List framework. Both species are recorded throughout the year in Falklands waters, with the largest numbers of birds recorded between March and June (Table 7.12; White, *et al.,* 2002). However, southern royal albatross are considerably more numerous than the northern species (White, *et al.,* 2002). During this period, royal albatrosses were found in highest densities over Patagonian Shelf waters to the west of the Falklands. At other times, royal albatrosses appear to disperse throughout Falklands waters.

Southern giant petrels (SGP)

The Falklands support the largest breeding population of southern giant petrels (*Macronectes giganteus*) in the world, with approximately 20,970 breeding pairs (Stanworth and Crofts, 2017) or approximately 40 % of the global population. The presence of white morph birds (white plumaged birds) during the winter months indicates that some birds that breed in higher latitudes move to Falklands waters during the winter (White, *et al.,* 2002).

Southern giant petrels were recorded in all seasons (Table 7.12) and were noted for being extremely persistent followers of vessels. The true density of birds within Falklands waters is likely to have been underestimated as birds in close attendance to fishing vessels were not recorded (White, *et al.,* 2002). This species was not recorded in high numbers in the vicinity of the Sea Lion area but the presence of an oil rig, platform or supply vessels may attract these scavenging birds, and consequently increase their presence in the area.

Magellanic penguin (MP)

Magellanic penguins (*Spheniscus magellanicus*) are regarded as summer breeding visitors to the Falkland Islands, which support approximately 10 % of the global population (Woods and Woods, 1997). During their breeding season, highest densities of Magellanic penguins were recorded in inshore waters but patches of locally high density were also encountered over Patagonian Shelf and shelf-break waters. Following the post-breeding moult, Magellanic penguins migrate northwards in the autumn to over-winter on the northern Patagonian Shelf (Pütz, *et al.,* 2000; Blockley and Tierney, 2017). They do not start to return to the Falklands until September. It is during these migrations that many birds will pass through the NFB.

Sixty-three Magellanic penguins were tracked from six locations during the summer months. The results of the predictive model indicate the presence of this species throughout Patagonian Shelf waters but also an area of relatively high probability of occurrence in shelf-slope waters to the north of the Sea Lion Field (Figure 7-56, Baylis, *et al.,* 2019a). This reflects the data collected during SAST surveys (White, *et al.,* 2002).

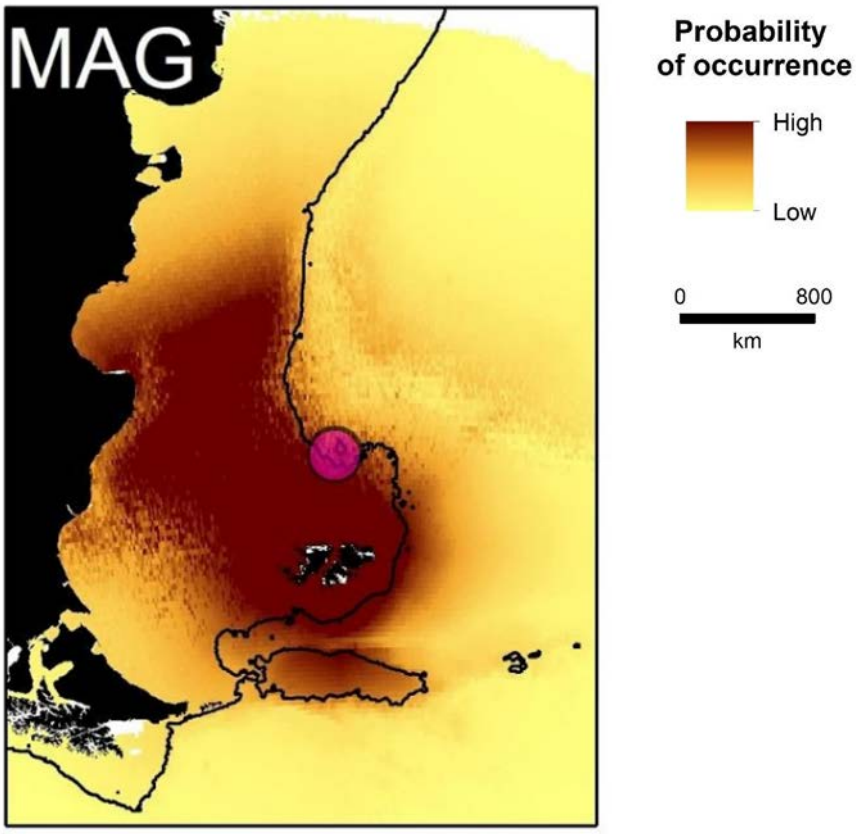

Figure 7-56: Magellanic penguin, predicted habitat use (predicted presence) for birds breeding on the Falklands from the available biotelemetry and biologging data. The pink dot represents the drill centre *(adapted from Baylis, et al., 2019a)*

Grey-headed albatross (GHA)

Grey-headed albatrosses (*Thalassarche chrysostoma*) are non-breeding visitors to Falkland Islands waters (Clay, *et al.,* 2016). The closest breeding populations are on islands off the southern coast of Chile and South Georgia, with approximately 50 % of the global population of this Endangered species breeding on the latter (Poncet, *et al.,* 2017).

The presence of this species within Falklands waters is highly seasonal, with the majority of birds recorded between May and September (White, *et al.,* 2002). During this period, most of the birds recorded were encountered over the shelf-break to the south and east of the Islands (White, *et al.,* 2002).

In addition to being IUCN-Endangered, since 2011 the grey-headed albatross from South Georgia is an ACAP Priority Population (GSGSSI, 2016).

Long-tailed skua (LTS)

Long-tailed skua (*Stercorarius longicaudus*) breed in the Arctic during the boreal summer and spend the non-breeding season in the South Atlantic and South Pacific. The vast majority of birds observed in the vicinity of the Falklands were recorded between December and March (Table 7.12). The Falklands lie towards the southern limit of this species' range, and the majority of sightings were recorded over oceanic and shelf-break waters to the north of the Islands. Like several other non-breeding summer visitors to the Falkland Islands, considerable inter-annual variations in the number of this species were recorded (White, *et al.,* 2002).

Wandering albatross (WA)

Wandering albatrosses (*Diomedea exulans*) are classified globally as Vulnerable under the IUCN Red List and are non-breeding visitors to Falkland Islands waters. The closest breeding site is at South Georgia where the population is in decline, with approximately 1,278 pairs breeding in 2014 / 15 (Poncet, *et al.,* 2017). Indeed, the wandering albatross from South Georgia is considered locally to be Endangered, at high risk from pelagic long-line fisheries (Jiménez, *et al*., 2016) and is an ACAP Priority Population (GSGSSI, 2016). Observations of banded individuals at-sea indicate that a large proportion of the South Georgia population utilise Falklands waters at some point during the year (Croxall, *et al.,* 1999; Otley, *et al.,* 2007; Carneiro, *et al*., 2022).

Wandering albatrosses are found in low numbers throughout the year, primarily over the shelf-break waters surrounding the Falkland Islands. Few birds were recorded in the vicinity of the Sea Lion area (Table 7.12) but it is likely that many birds pass through this area during the course of a year.

Antarctic skua (AS)

The presence of Antarctic skuas (*Stercorarius antarctica*) within the study area is highly seasonal, with the vast majority of birds recorded between November and April (Table 7.12). The density of birds recorded was highest over inshore waters, close to breeding sites. However, locally high densities were encountered at-sea throughout the remainder of the Falklands Conservation Zones (White, *et al.,* 2002).

Atlantic petrel (AtP)

The large breeding population of Atlantic petrels (*Pterodroma incerta*) is restricted almost entirely to Gough Island, in the Tristan da Cunha group, where the population of 1.8 million pairs is in decline due to mouse depredation (BirdLife International, 2015). Atlantic petrel is currently classified as Endangered according to the IUCN Red List.

Although not recorded in the vicinity of the Sea Lion Field, this species will be infrequently present in the area. Atlantic petrels have been recorded in every month but there was a distinct peak in numbers during spring, which corresponds with the post-breeding period of this winter breeding species. Most Atlantic petrels were recorded in oceanic waters to the north-east of the Falklands (White, *et al.,* 2002).

Diving-petrel species (DP)

Two species of diving-petrel (*Pelecanoides species*) are regularly encountered within Falkland Islands waters: common diving-petrel *Pelecanoides urinatrix* and Magellan diving-petrel *P. magellanicus*; Georgian diving-petrel *P. georgicus* has also been recorded. Given reasonable views, Magellan diving-petrels can be readily identified at-sea but the other species are difficult to separate and therefore most birds were recorded as 'diving-petrel species'.

In general, far more diving-petrels are recorded during the spring and summer than during the autumn and winter months. The highest densities of birds were recorded to the west and south of the Falklands (White, *et al.,* 2002). Diving-petrels were only recorded in low numbers in the vicinity of the Sea Lion area (Table 7.12).

Southern rockhopper (RP) and Macaroni penguins (MAC) (R/M)

The Falklands support approximately 40 % of the global population of southern rockhopper penguins (*Eudyptes chrysocome*) (Baylis, *et al.,* 2013b). Outside the breeding and moulting periods, between May and August, these birds were only encountered in low numbers within Falklands waters. During the spring, rockhopper penguins were dispersed throughout Falklands waters (White, *et al.,* 2002), during which time the highest number of birds were recorded in the vicinity of the Sea Lion area (Table 7.12). During the austral summer months, the distribution of rockhopper penguins was linked to the shallower waters of the Patagonian Shelf.

Tracking of rockhopper penguins at several sites around the Falklands during incubation and chick-rearing indicates distinctive patterns of distribution in these two periods. During incubation, birds disperse more widely and are present in the relatively deep waters of the shelf-slope. During chick-rearing, the model predicts that the area of high probability of occurrence is concentrated over the Patagonian Shelf (Figure 7-57). The distribution predicted from the tracking data reflects the distribution pattern recorded during SAST surveys (White, *et al.,* 2002).

During the non-breeding period, rockhopper penguins were tracked to an area of the Brazil – Falklands Confluence Zone, off the coast of northern Argentina (*c.f*. Magellanic penguins; Blockley and Tierney, 2017). It is during the migration between winter grounds and breeding sites (September and October) that many rockhopper penguins breeding on East Falkland pass close to the Sea Lion Field.

During the austral winter months, some macaroni penguins (*E. chrysolophus*) from the breeding population on South Georgia move into the oceanic waters of the Falklands Conservation Zones (White, *et al.,* 2002). These observations are supported by satellite tracking of birds from South Georgia (Ratcliffe, *et al.,* 2014). It was not always possible to be certain of the identity of *Eudyptes* penguins when encountered at-sea and therefore many birds were recorded as rockhopper / macaroni penguins. It is likely that some of these birds were in fact macaroni penguins.

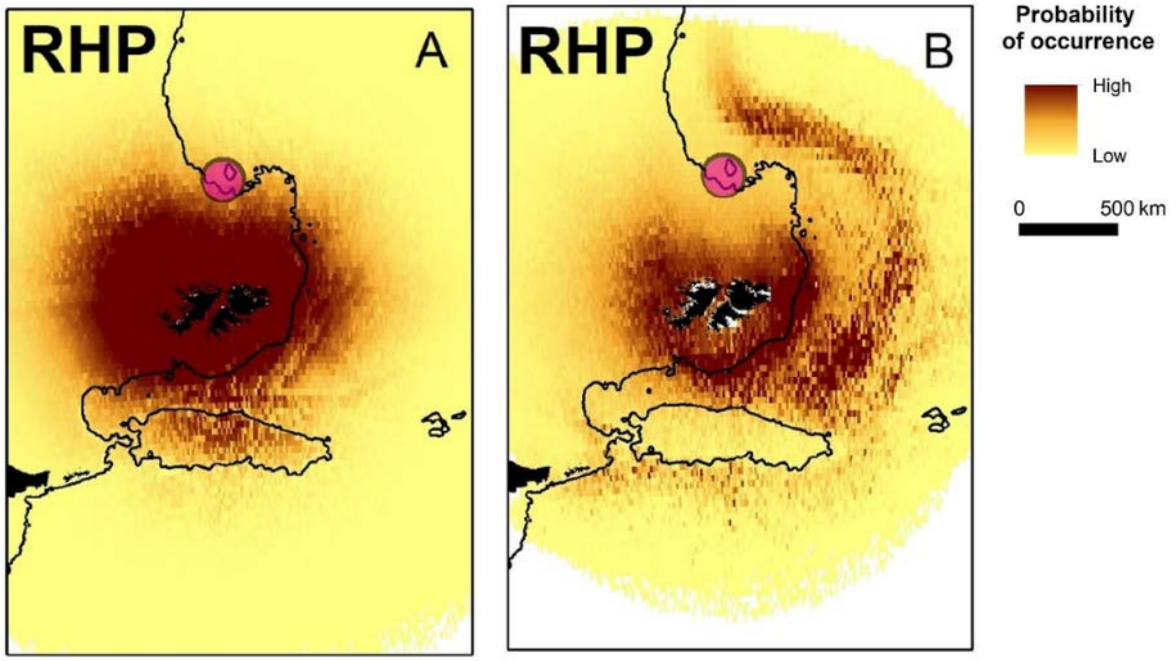

Figure 7-57: Rockhopper penguins, predicted habitat use (predicted presence) for birds breeding on the Falklands from the available biotelemetry and biologging data (A = Chick rearing, B = Incubation). The pink dot represents the drill centre *(adapted from Baylis, et al., 2019a)*

Northern giant petrel (NGP)

Northern giant petrels (*Macronectes halli*) are non-breeding visitors to Falkland Islands waters. The closest breeding sites are found on South Georgia, which supports the world's largest breeding population of this species (15,398 pairs or 71 % of the global population, Poncet, *et al.,* 2019). Satellite tracking during the breeding season indicates that these birds visit the Patagonian Shelf on foraging trips (González-Solís, *et al.,* 2000). Like southern giant petrels, this species was recorded in all months but in lower numbers. During the autumn and winter months, highest densities of this species were

recorded over the Patagonian Shelf. In the spring and summer, birds were dispersed throughout the waters surveyed (White, *et al.,* 2002).

Little shearwater (LS)

Little shearwaters (*Puffinus assimilis*) are rare non-breeding visitors to Falkland Islands waters, the nearest breeding population being found on the Tristan da Cunha group. White *et al.* (2002) only recorded this species during the summer and autumn months with a peak in sightings during March. The majority of records were of birds in the waters to the north of the Islands.

Black-bellied storm-petrel (BBSP)

Black-bellied storm-petrels (*Fregetta tropica*) are non-breeding visitors to Falklands waters. The presence of this species is almost entirely restricted to the summer months, when they are most frequently sighted over oceanic waters to the north of the Islands (White, *et al.,* 2002). Very few birds were recorded in the vicinity of the Sea Lion area (Table 7.12).

Two additional species were recorded during austral winter and spring surveys but not during the austral autumn.

King penguin (KP)

Although there is a small resident breeding population of king penguins (*Aptenodytes patagonicus*) in the Falkland Islands, encounters with king penguins at-sea were highly seasonal. Virtually all of the birds recorded were seen between June and September (White, *et al.,* 2002). The timing of these sightings and the number of birds encountered suggest that many of the king penguins present within Falklands waters originated from South Georgia. This is supported by data from birds tracked from South Georgia in the winter.

Most of the king penguin records within Falklands waters come from oceanic and shelf-break waters to the north of the Islands (White, *et al.,* 2002).

Eight king penguins from Volunteer Point were tracked during the winter. The tracks indicate that for most of the time the birds' activity was concentrated over the shelf-break to the north of the Falklands with some birds travelling further afield, mostly into deep, oceanic waters (Figure 7-50). The predictive model suggests high probability of occurrence over a wider area of the Patagonian Shelf (Figure 7-58).

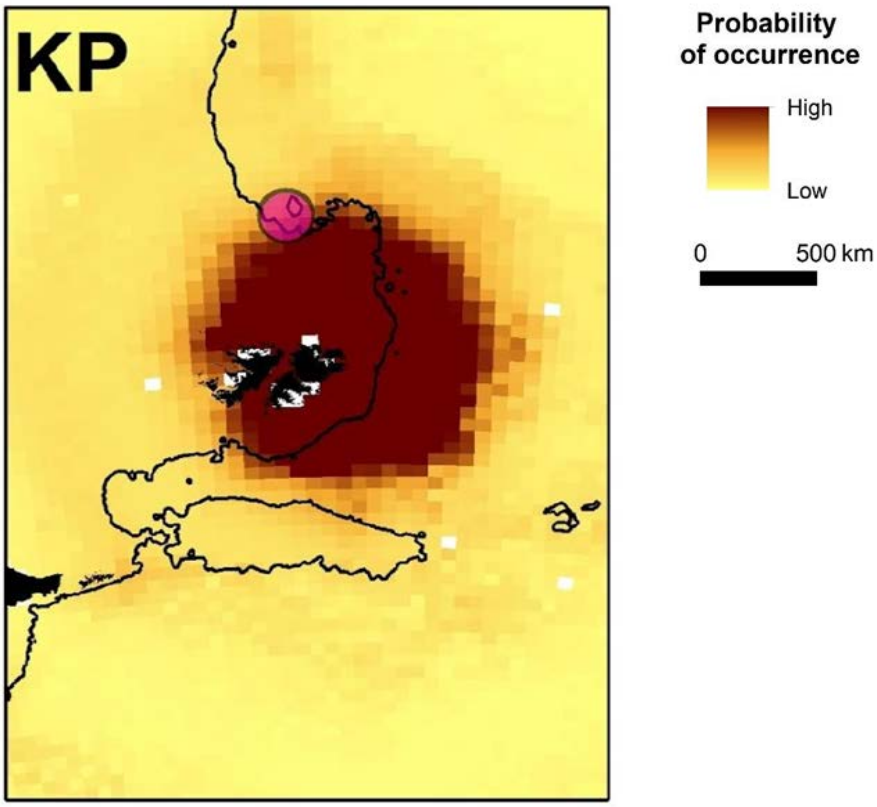

Figure 7-58: King penguin, predicted habitat use (predicted presence) for birds breeding at Volunteer Point from the available biotelemetry and biologging data. The pink dot represents the drill centre *(adapted from Baylis, et al., 2019a)*

Kelp gull (KG)

Kelp gulls (*Larus dominicanus*) are resident breeders in the Falkland Islands. During the austral summer (November to April), kelp gulls are confined to inshore waters. In the austral winter (May to October), kelp gulls were recorded in far higher numbers, but the majority of sightings still occur over inshore waters. However, birds also range much further offshore; it is at this time that they are recorded in the vicinity of the Sea Lion area (Table 7.12).

Gentoo penguin

The Falkland Islands are home to a globally important population of gentoo penguins (*Pygoscelis papua*). Although present throughout the year, returning to shore regularly during the winter, JNCC surveys recorded clear seasonal trends in the distribution of this species. Between December and March, all records were within 100 km of the nearest land, while between April and November gentoo penguins were recorded at greater distance, up to 316 km, from land. However, despite their wider distribution, gentoo penguins were rarely observed in waters greater than 200 m in depth (White, *et al.,* 2002).

Over the winter and early summer periods (June-November), Gentoo penguins tracked during the GAP project typically stayed relatively close to the Falkland Islands, not travelling more than 200 km offshore. However, there was considerable individual variation in foraging trip distances and some individuals traveled further afield, reaching distances of over 450 km, foraging in the north-west of the Islands (Figure 7-59; Blockley and Tierney, 2017). Gentoo penguins were not recorded near the Sea Lion Field.

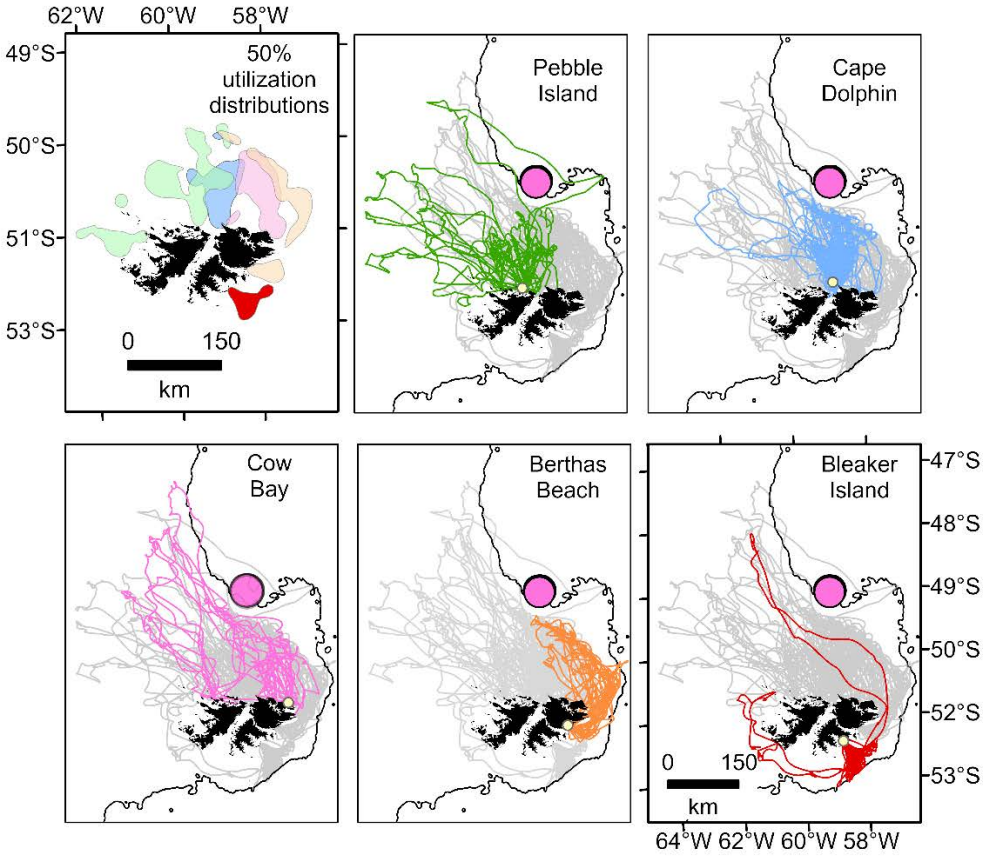

Figure 7-59: The locations of 25 gentoo penguins tracked during the winter and early summer from five locations. Utilisation distributions show areas where penguins spent most (>50 %) of their time (Blockley and Tierney, 2017). The pink dot represents the area of the drill centres *(Source: Baylis, et al., 2021b)*

Kerguelen petrel

Kerguelen petrels (*Aphrodroma brevirostris*) are non-breeding visitors to the waters of the Falkland Islands, with the majority of sightings occurring between May and November (White, *et al.,* 2002). A small population was recently discovered breeding on South Georgia (Black, *et al.,* 2012) but the nearest substantial population is found on Gough Island in the Tristan da Cunha group. Kerguelen petrels can be encountered throughout Falklands waters during the winter months, but they are more frequently seen over offshore / oceanic waters.

Blue petrel

Like Kerguelen petrels, blue petrels (*Halobeana caerulea*) are seasonal non-breeding visitors to Falklands waters, with the majority of sightings between May and November (White, *et al.,* 2002). This species is rarely encountered over Patagonian Shelf waters, most records come from oceanic waters to the east and south-east of the Islands. The nearest breeding colonies of blue petrels are found on islands off the southern coast of Chile and South Georgia, the origin of birds seen in the Falklands is unknown.

7.4.5.2.3 Summary of offshore bird abundance, distribution, life-cycle and behavioural characteristics

Table 7.17 provides a summary of bird abundance, distribution, life-cycle and behavioural characteristics in the NFB and around the Sea Lion Field.

Table 7.17: Summary of offshore bird abundance, distribution, life-cycle and behavioural characteristics

Species	IUCN status	ACAP species[1]	FI priority species[2]	Seasonal occurrence and distribution	Breeding cycle	Feeding mode	Persistent ship associate[3]	Breeding sites	Falklands population	Global population and trend[4]
Black-browed albatross (*Thalassarche melanophris*)	LC	✓[5]	✓	Present year-round in high numbers across the Patagonian Shelf, less numerous over deeper waters. 	Annual breeder. First breeding at 7 yrs. 1 egg laid mid Oct. Chicks fledge Apr/May.	Surface seizing and shallow dives (to *c.* 19 m) from the surface	✓	In the Falklands, 17 breeding sites, very large colonies on Jason Islands and Beauchêne Island, and South Georgia	c. 500,000 pairs. *c.* 75 % global population	700,000 pairs Stable
Great shearwater (*Ardenna gravis*)	LC	X	X	Widespread over waters to the north of the Falklands between Dec – Apr, absent in the winter and spring. Vast majority of birds observed are non-breeders. 	Adults return Sept. 1 egg laid end Oct. Chicks and adults depart late April.	Surface seizing and pursuit diving (to *c.* 20 m)	✓	Kidney Island only known site in the Falklands	20 pairs <0.1 % global population	5 million pairs Stable
White-chinned petrel (*Procellaria aequinoctialis*)	VU	✓	✓	Widespread over shelf and oceanic waters in winter, shallower waters in spring summer. Most birds present are non-breeding visitors. 	Adults return Sept. 1 egg laid Oct/Nov. Chicks and adults depart Apr/May.	Surface seizing and pursuit diving (to *c.* 20 m)	✓	Kidney Island, New Island, Bottom Island, South Georgia	55-100 pairs <0.1 % global population	1.2 million pairs Decreasing

Species	IUCN status	ACAP species[1]	FI priority species[2]	Seasonal occurrence and distribution	Breeding cycle	Feeding mode	Persistent ship associate[3]	Breeding sites	Falklands population	Global population and trend[4]
Cape petrel (*Daption capense*)	LC	X	X	Common winter visitor to Falklands waters, few present in the summer months. Spring / Summer / Autumn / Winter	Single egg laid Nov/Dec. Fledge Feb/Mar.	Surface seizing and shallow dives	✓	Antarctica	Non-breeder	2 million individuals Stable
Wilson's storm-petrel (*Oceanites oceanicus*)	LC	X	X	Present throughout the year but abundance far higher during the summer months. Spring / Summer / Autumn / Winter	Adults return Nov. 1 egg laid Nov-Jan. Chicks fledge Feb/Mar.	Foot paddling (surface seizing)	✓	Rat free tussock islands e.g., Beauchêne and Jason Islands	5,000+ pairs	4 – 10 million pairs Stable
Antarctic fulmar (*Fulmarus glacialoides*)	LC	X	X	Common autumn and winter visitor. Highest densities found over Patagonian Shelf waters but found throughout Falklands waters. Spring / Summer / Autumn / Winter	Single egg laid Nov/Dec. Fledge Mar/Apr.	Surface seizing	✓	Antarctica	Non-breeder	4 million individuals Stable
Grey-backed storm-petrel (*Garrodia nereis*)	LC	X	X	Present throughout the year but abundance highest between Sep – Mar. Spring / Summer / Autumn / Winter	Adults return Oct/Nov. Egg dates Nov/Dec. Fledging Feb/Apr.	Foot paddling (surface seizing)	X	Rat free tussock islands; e.g., Beauchêne and Kidney Islands	1-5,000 pairs	200,000 individuals Decreasing
Soft-plumaged petrel (*Pterodroma mollis*)	LC	X	X	Primarily in deep waters north of the Falkland Islands (Nov–Apr, peak Jan). Spring / Summer / Autumn / Winter	Egg laid Nov/Dec. Fledge May.	Surface seizing and shallow dives	X	Tristan da Cunha, Gough Island	Non-breeder	5 million individuals Stable

Species	IUCN status	ACAP species[1]	FI priority species[2]	Seasonal occurrence and distribution	Breeding cycle	Feeding mode	Persistent ship associate[3]	Breeding sites	Falklands population	Global population and trend[4]
Sooty shearwater (*Ardenna griseus*)	NT	X	✓	Present throughout the year but most of the population depart between Apr – Aug. Spring | Summer | Autumn | Winter	Start breeding at 4 yrs. Adults return Sept. 1 egg laid late Nov. Adults depart Mar. Chicks fledge April.	Surface seizing and pursuit diving (to *c.* 50 m)	X	Tussock islands notably Kidney Island	139,000 pairs 0.1 % global population[5]	20 million individuals (*c.* 4.4 million breeding pairs)[5] Decreasing
Prion species (*Pachyptila* spp.)	LC	X	X	Most numerous 'species' of seabird in Falklands waters, recorded throughout the year. Spring | Summer | Autumn | Winter	Return Sept. Egg dates Oct/Nov. Fledge Feb/Mar.	Picking at the surface on the wing and shallow dives	X	e.g., New Island, Jason Islands	2 million + pairs of thin-billed prion	20+ million pairs Stable
Southern royal albatross (*Diomedea epomophora*)	VU	✓	X	Present throughout the year. Highest density found over Patagonian Shelf north-west of Islands between March and June. Spring | Summer | Autumn | Winter	Biennial breeder. Age at first breeding 6-12 years. Single egg laid Nov/Dec. Fledge Oct to Dec.	Surface seizing	✓	New Zealand	Non-breeder	7,900 pairs Stable
Northern royal albatross (*Diomedea sanfordi*)	EN	✓	X	Present throughout the year. Highest density found over Patagonian Shelf north-west of Islands between March and June. Spring | Summer | Autumn | Winter	Biennial breeder. Mean age at first breeding 8 years. Single egg laid in Nov. Fledging Sept / Oct.	Surface seizing	✓	New Zealand	Non-breeder	17,000 individuals Decreasing

Species	IUCN status	ACAP species[1]	FI priority species[2]	Seasonal occurrence and distribution	Breeding cycle	Feeding mode	Persistent ship associate[3]	Breeding sites	Falklands population	Global population and trend[4]
Southern giant petrel (*Macronectes giganteus*)	LC	✓	✓	Recorded in all months, highest densities March-June over Patagonian Shelf waters, west and south of Falkland Islands. Spring / Summer / Autumn / Winter	Annual breeder. Age at first breeding 5-11 years. Adults return Sept. 1 egg laid Oct/Nov. Chicks fledge Mar.	Surface seizing	✓	38 locations, primarily islands in Falkland Sound	20,970 breeding pairs 41 % global population	50,819 pairs Increasing
Magellanic penguin (*Spheniscus magellanicus*)	LC	X	✓	Majority recorded between Nov and Mar, absent during winter, feeding Patagonian Shelf and shelf break, Argentine coast. Spring / Summer / Autumn / Winter	Adults arrive Sept. 2 eggs laid Oct. Chicks fledge Mar. Adults depart Apr.	Dive to depths of 140 m	X	Over 90 locations on the Falkland Islands	c.140,000 pairs 10 % global population	1.3 million pairs Decreasing
Grey-headed albatross (*Thalassarche chrysostoma*)	EN	✓[6]	X	Present year-round but highest abundance from May to Sept, when found over the shelf edge and deeper waters. Spring / Summer / Autumn / Winter	Biennial breeder. Age at first breeding 12 yrs on South Georgia. Single egg laid in Oct. Fledge Apr/May.	Plunge diving, Surface seizing and surface dives	✓	Southern Chile and South Georgia	Non-breeder	250,000 individuals Decreasing
Wandering albatross (*Diomedea exulans*)	VU	✓[6]	X	Non-breeding visitor present throughout, mostly over waters >200 m in depth. A high proportion of the South Georgia population are recorded within Falklands waters during the course of the year. Spring / Summer / Autumn / Winter	Biennial breeder. Age at first breeding 8+ years. Single egg laid Dec/Jan. Fledge following Dec.	Surface seizing	✓	South Georgia	Non-breeder	6,100 pairs Decreasing

Species	IUCN status	ACAP species[1]	FI priority species[2]	Seasonal occurrence and distribution	Breeding cycle	Feeding mode	Persistent ship associate[3]	Breeding sites	Falklands population	Global population and trend[4]
Atlantic petrel (*Pterodroma incerta*)	EN	X	X	Recorded in all months, majority Oct to Mar during post-breeding dispersal. Most numerous over deep waters to north-east, and south-east.	Single egg laid Jun/Jul.	Surface seizing and shallow dives	X	Tristan da Cunha, Gough Island	Non-breeder	1.8 million pairs Decreasing
Diving-petrel species (*Pelecanoides* spp.)	LC	X	X	Present in all months, greater number between Sept and Feb to the west of the Falklands.	Returns Sept. Egg date Oct.	Pursuit diving to *c.* 60 m	X	Tussock Islands, e.g., Beauchêne Kidney and Jason Islands	5-10,000 pairs	16 + million individuals
Northern giant petrel (*Macronectes halli*)	LC	✓	X	Recorded in all months with slightly higher density recorded from March to August, over Patagonian Shelf waters.	Annual breeder. Age at first breeding 4-11 years. Single egg laid Aug to Oct. Fledge Mar/Apr.	Surface seizing Persistent ship associate	✓	South Georgia	Non-breeder	21,682 pairs Increasing
Rockhopper penguin (*Eudyptes chrysocome*)	VU	X	✓	Winter foraging between Straits of Magellan and 39°N (1,400km).	Mating Oct 2 eggs laid mid Nov Chicks fledge Mar Adults depart April	Pursuit diving to *c.* 100 m	X	Primarily outer islands of West Falkland	320,000 pairs 36 % global population	1.23 million pairs Decreasing
	LC	X	X	May-June migrate south of Polar Front.	12 month - Mating Oct		X	Primarily Volunteer	<1,000 pairs 0.04 %	2 million pairs

Species	IUCN status	ACAP species[1]	FI priority species[2]	Seasonal occurrence and distribution	Breeding cycle	Feeding mode	Persistent ship associate[3]	Breeding sites	Falklands population	Global population and trend[4]
King penguin (*Aptenodytes patagonicus*)					1 egg laid Nov-Mar 55 day incubation	Pursuit diving to *c.* 350 m		Point in the Falklands	global population	Increasing
Gentoo penguin (*Pygoscelis papua*)	LC	X	✓	Resident, primarily within 10 km up to 300 km in winter. Spring Summer Autumn Winter 	Nest building Sept 1-2 eggs laid late Oct 34 day incubation	Pursuit diving to *c.* 100 m	X	79 locations throughout the Falklands	121,500 pairs, 34 % global population	387,000 pairs Stable

[1] See Section 7.4.5.5.2

[2] See Section 7.5.3

[3] Indicates species that are attracted to vessels, as a potential source of food, and can form large flocks in the wake of ships.

[4] From BirdLife International, 2024.

[5] **Post-consultation footnote (July 2025):** the global population of sooty shearwaters is now recorded as 8.8 million mature individuals such that the stable Falkland Islands population, as a percentage of the global population, is estimated to be 3.2 % (BirdLife International, 2025).

[6] Note that the South Georgia Population is an ACAP Priority Population.

7.4.5.3 Birdlife of Berkeley Sound

Although the largest seabird colonies in the Falklands are found on offshore islands in the south and west of the Falklands archipelago, the area of Berkeley Sound does support some significant colonies of seabirds; particularly sooty shearwater, white-chinned petrel, rockhopper, gentoo and king penguins (see Section 7.5.2.3.1.1).

Total island-wide censuses have been undertaken by Falklands Conservation for a number of seabird species including gentoo (Baylis, *et al.,* 2013a), rockhopper (Baylis, *et al.,* 2013b), macaroni and king penguins (Pistorius, *et al.,* 2012), black-browed albatross (*Thalassarche melanophris*; Baylis, 2012), southern giant petrel (*Macronectes giganteus*; Reid and Huin, 2005), and white-chinned petrel (Reid, *et al.,* 2007). A small number of colonies are monitored annually as part of Falklands Conservation's Seabird Monitoring Programme (e.g., Crofts and Stanworth, 2017). The results of this work provide vital baseline data and help to put the importance of Berkeley Sound colonies into the context of the wider Falkland Islands.

This section provides a summary of the distribution of birds in Berkeley Sound (and adjacent waters), their abundance, distribution, feeding and breeding ecology and sensitivities.

7.4.5.3.1 Seabird distribution and abundance surveys

Data from numerous surveys and studies have been used to identify the distribution of birds in Berkeley Sound. The surveys include:

- Four seasonal coastal bird surveys carried out between 2016 and 2019 by SAERI (SMSG and SAERI, 2016; SAERI, 2019),
- The JNCC SAST data, each trip commenced from Stanley and therefore significant effort was directed at coastal waters adjacent to Berkeley Sound,
- Satellite tracking of penguin species, and
- Annual Seabird Monitoring Programme carried out by Falklands Conservation.

The relevant results from the above are summarised below with the data collated into species-specific summaries in Section 7.4.5.3.2.

7.4.5.3.1.1 Berkeley Sound coastal bird survey, summer 2016

Under contract to POEPL, the South Atlantic Environmental Research Institute (SAERI), conducted a series of seasonal coastal bird surveys summer 2016, winter 2017, spring 2018 and autumn 2019 to determine the distribution of potentially sensitive receptors around the Berkeley Sound coast. The methodology used during the 2016 coastal bird survey was adapted from that described in Tabak *et al.* (2015) and Neely (2010). The aim of each survey was to record the distribution of birds and marine mammals along the entire coastline of Berkeley Sound. In order to achieve this, two approaches were taken: one land-based and one boat-based. These two approaches were required to obtain the best available coverage given issues of boat access and steep terrain (as cliffs are difficult to survey from land). Land and boat surveys both recorded all birds and marine mammals sighted within a strip transect, which extended 100 m seaward and 25 m landward of the high tide line. The distribution of survey effort achieved in each survey is shown in Figure 7-60.

Berkeley Sound contains a wide range of habitat types; from rat free tussock islands, exposed rocky coasts, cliffs, gently sloping farmland, sheltered bays and mud flats. As is supported by this survey, each habitat type is expected to support a distinct assemblage of birds. The distribution of all birds recorded in each survey is shown in Figure 7-61. The results of these surveys indicate that there are clear differences in the species and abundance of birds found along the coasts of the outer and inner Sounds. The outer Sound is numerically dominated by imperial shag, rock shag, rockhopper and gentoo

penguins in the spring and summer. During the winter and autumn surveys the coasts of the outer Sound supported relatively few birds. The inner Sound supported lower numbers of birds but a greater diversity of species, which was numerically dominated by Falkland steamer duck, rock shag, kelp gull, Magellanic penguin and upland goose. The distribution of individual species are described in Section 7.4.5.3.2.

The species and number of individuals recorded during the survey are shown in Table 7.18.

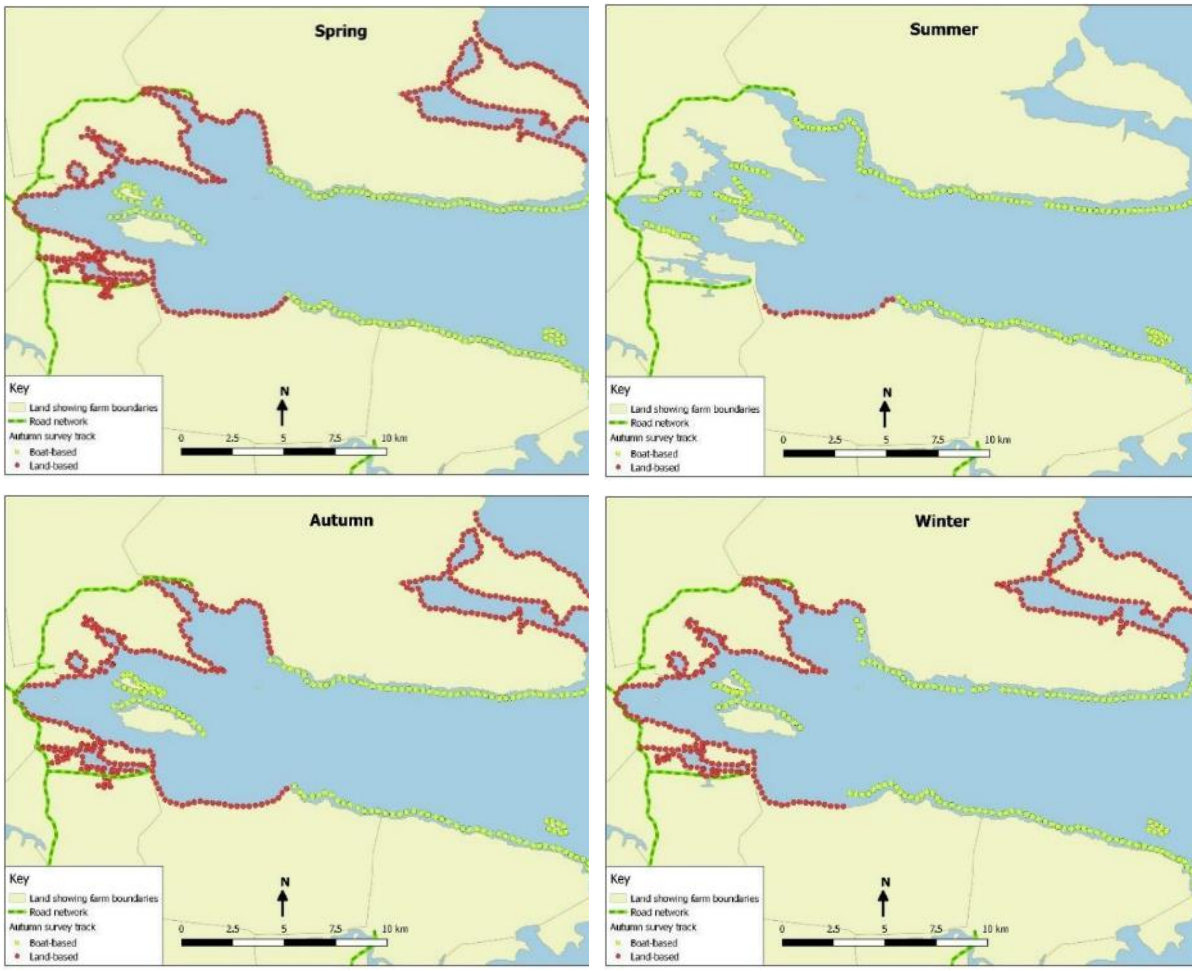

Figure 7-60: Distribution of coastal bird survey effort achieved in each season

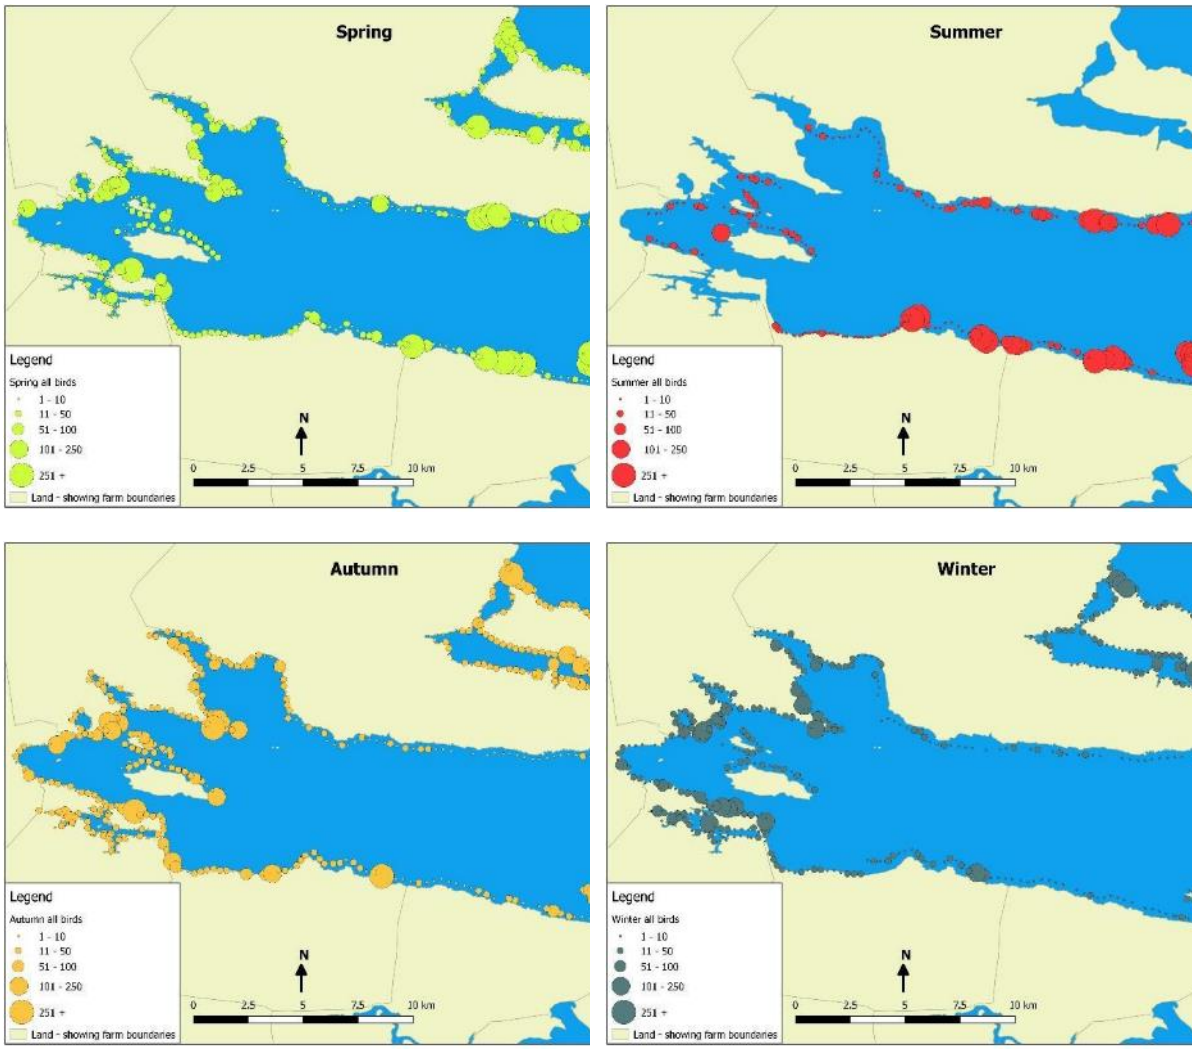

Figure 7-61: The distribution of all bird records in each season

JNCC SAST surveys

JNCC SAST surveys started and ended in Stanley and therefore contribute to our knowledge of seabird and marine mammal distributions over inshore waters near Berkeley Sound.

In total, over 2,688 km of survey track were observed, within the area shown in Figure 7-62, over the seven year life of SAST surveys. Each observation made is linked to one of the point locations shown

in Figure 7-62, which each represent approximately 3 km of survey track. Effort was spread across all months with a high of 329 km achieved in July and a low of 152 km in May.

Over 26,800 seabirds were recorded within the area adjacent to Berkeley Sound, seasonal relative abundance for all the species recorded is shown in Table 7.19.

Many of the species recorded displayed clear temporal and spatial patterns of distribution, which are described below.

The majority of the most numerous species shown in Table 7.19 are Falkland Islands breeding species but some abundant visiting species; include great shearwaters (*Puffinus gravis*), Antarctic fulmars and Cape petrel, also feature. From a conservation perspective, some of the most significant species are those covered under the Agreement for the Conservation of Albatrosses and Petrels (ACAP) (Section 7.4.5.3.2). Eight ACAP species were recorded; black-browed albatross, southern giant petrel, white-chinned petrel, northern giant petrel, southern royal albatross, grey-headed albatross, wandering albatross and northern royal albatross.

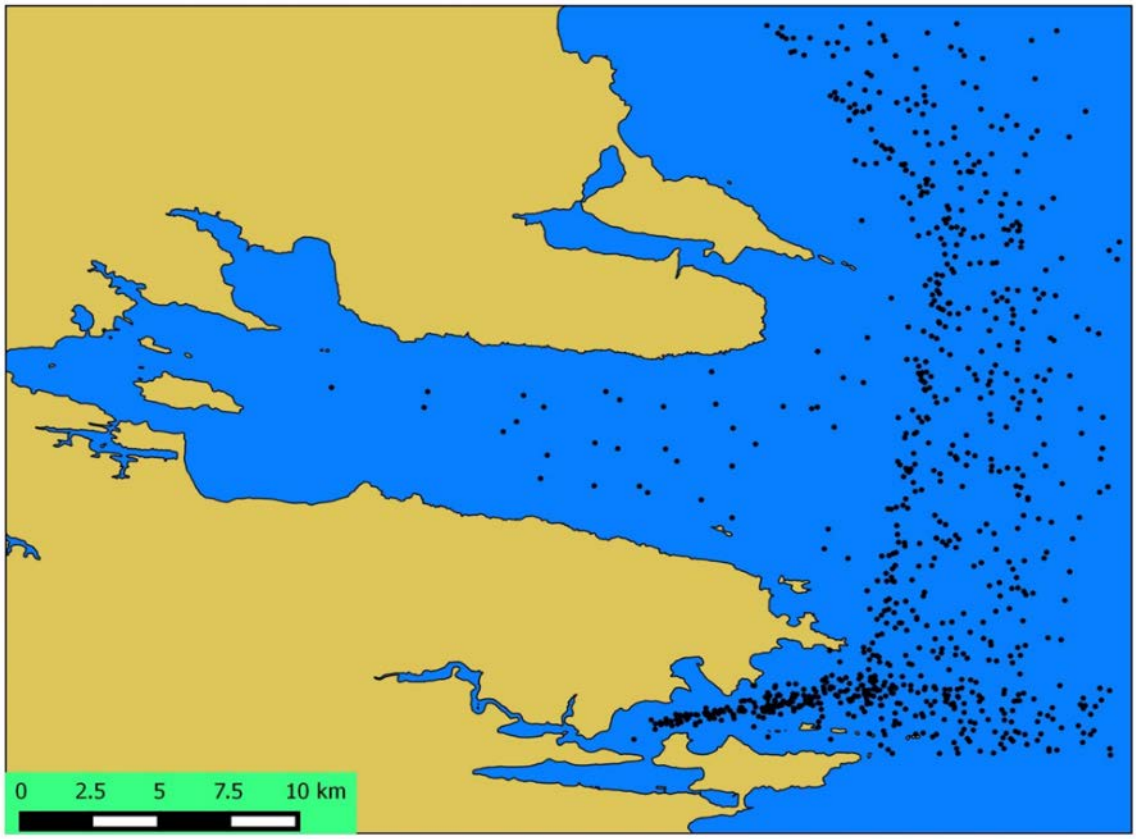

Figure 7-62: Total survey effort achieved during JNCC surveys in coastal waters near Berkeley Sound, each point represents a 10-minute observation period (or approximately three km of survey track)

Table 7.19: Relative seasonal abundance of seabirds recorded in the waters adjacent to and within Berkeley Sound during JNCC surveys (JNCC data) [1,2]

[3] The species names relating to the species codes are found in the species accounts subheaders in Section 7.4.5.3.2 and in Appendix 1.

7.4.5.3.1.2 Falklands Conservation annual monitoring programme

On behalf of the Falkland Islands Government, Falklands Conservation undertake an annual Seabird Monitoring Programme across the Falkland Islands and currently monitor gentoo penguins at 11 breeding sites (16 colonies), Magellanic penguins at one site (single colony) and rockhopper penguins at five sites (13 colonies). King penguins and black-browed albatross are monitored at single but key sites in terms of colony size, in relation to the Falklands population, southern giant petrels are monitored at one site (three colonies), imperial shag at three sites and brown skua at one site (Crofts and Stanworth, 2019). Data from these monitoring sites give information on the breeding success and population trends over a number of years, indicating the current status of the populations.

Within Berkeley Sound, three rockhopper colonies on the north coast of the Sound (Diamond Cove, Rugged Hill and Eagle Hill; Figure 7-63) are monitored annually (Crofts and Stanworth, 2018). Island wide-censuses were undertaken every five years until 2010, but no subsequent island-wide census has occured since 2010. Gentoo and king penguins are monitored annually at Volunteer Point (Figure 7-63). In recent years, monitoring has commenced at the imperial shag colony at Rugged Hill.

The number of pairs of seabirds breeding at each of these colonies is compared with the Falkland Islands population as a whole in Table 7.20. Annual monitoring at selected sites by Falklands Conservation has recorded high variability in the number of breeding pairs and breeding success in gentoo and rockhopper penguins between and within monitored sites (Crofts and Stanworth, 2019). However, monitoring during the 2016 / 17 breeding season recorded dramatic reductions in the number of breeding pairs of gentoo and rockhopper penguins recorded across virtually all sites (declines of 35 % and 31 % respectively since 2015), including those in Berkeley Sound. There is some evidence that food availability has been poor in the 2015/16 season, evident from below average breeding success and starvation in moulting adult penguins (Crofts and Stanworth, 2017). Seabirds in poor physical condition are likely to defer breeding, which may account for the apparent crash in the breeding populations. However, adult mortality may also be a contributing factor. Local factors such as food supply or stochastic events, such as toxic algal blooms, can have dramatic influence at a regional level within the Falklands archipelago. However, the archipelago wide decline in the number of breeding birds hints at a more significant environmental perturbation. There is evidence that the seawater temperature around the Falklands was lower than usual in 2016 (Crofts and Stanworth, 2017), which may have resulted in reduced food availability to adults preparing to moult in early 2016 and breed in 2016 / 17. The most recent 2022 census indicates that rockhopper and gentoo penguin breeding pairs have not recovered from the decline in breeding pairs reported in 2015/16 – although there is considerable variability in the number of breeding pairs over time (Kuepfer and Stanworth, 2023).

[1] Kuepfer and Stanworth, 2023.
[2] The table shows the long-term trend (1995-2022) and short-term trend (2010-2022). The 2010 versus 2022 counts, may appear to contradict the population trend in the table (stable, increase or decline). However, comparing two years (e.g., 2010 versus 2022), is not the same as a trend over time (e.g., 12 years between 2010 and 2022).
[3] Short-term decline due to a dramatic crash in the number of breeding pairs since 2015 (Crofts and Stanworth, 2019), prior to 2015 the number of breeding pairs was increasing.

7.4.5.3.1.3 Bird distribution data gaps and limitations

Coastal bird surveys have been conducted on a seasonal basis, which gives an indication of seasonal changes in bird presence and abundance. However, additional surveys would give greater confidence in the results and help to determine inter-annual variation in bird distribution.

There are a number of advantages and disadvantages associated with each of the survey methods described above. However, when interest is focused on a relatively small area; such as Berkeley Sound, it is likely that visual surveys along fixed transects will provide the most useful data for future monitoring. Nonetheless, further survey work is required to better understand baseline bird distributions within the Sound.

7.4.5.3.2 Species-specific distribution and abundance

The following collates the data from the surveys above to provide a species-specific summary of the distribution and abundance of the most significant bird species encountered within Berkeley Sound. A summary of the abundance, distribution, life-cycle and behavioral characteristics is provided in Section 7.4.5.3.3.

Southern rockhopper penguin (RP)

In total, 8,793 rockhopper penguins were recorded during the course of all four coastal bird surveys, making this the most numerous species recorded during the project. Points of high density were associated with known colonies on the coasts of the outer Sound, Cochon and Kidney Islands. Few rockhopper penguins were recorded in the inner Sound (Figure 7-64).

During the spring, far more rockhopper penguins were recorded than at any other time (Table 7.18 above). The summer survey coincided with the start of the moult period in this species and adult birds were congregating in colonies ashore but it was thought that many were still at-sea.

Very few rockhopper penguins were recorded during the autumn survey and none was recorded in the winter survey.

Satellite tags have been deployed on rockhopper penguins breeding at a number of colonies around the Falklands, including two on the south side of Berkeley Sound. The tracks obtained indicate that birds breeding in Berkeley Sound tend to forage over the shelf and shelf-slope to the north of the Falklands (Pütz, *et al.,* 2003). However, trip length (and range) may vary throughout the breeding season, depending on the energy demands of chicks and adults. Nevertheless, rockhopper penguins breeding within Berkeley Sound will be departing from and returning to their colonies throughout the breeding season and are therefore potentially at risk over this entire period.

The GAP project fitted rockhopper penguins from Berkeley Sound with geolocators over the winter period. The results indicate that these birds depart from Falklands waters and overwinter off the coast of South America (Blockley and Tierney, 2017).

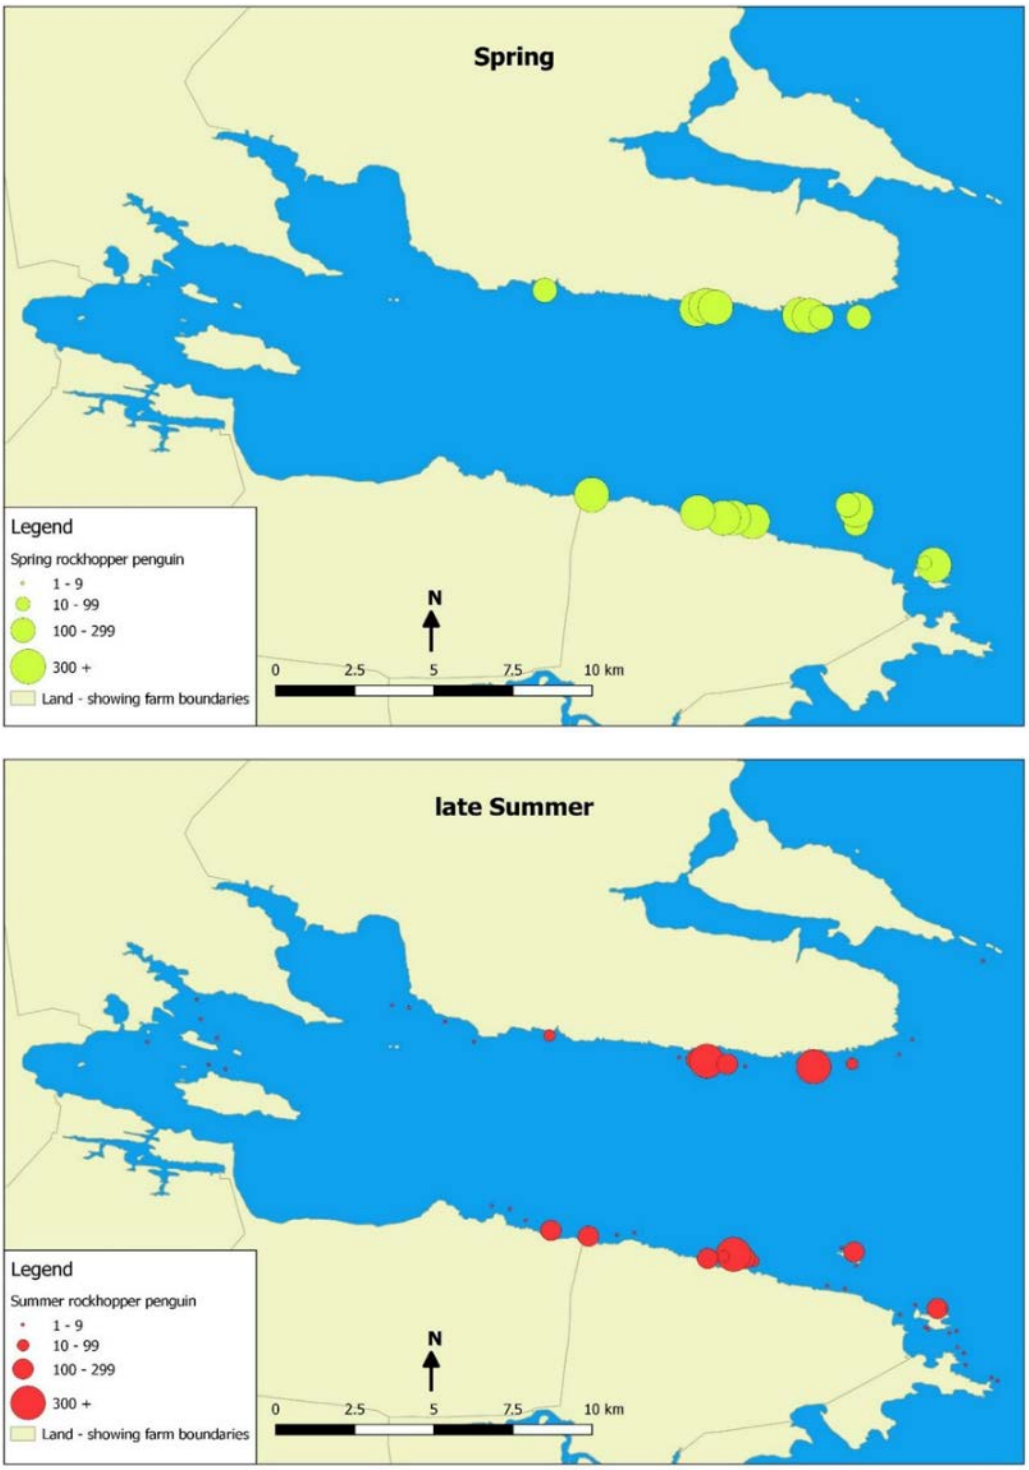

Figure 7-64: Distribution of rockhopper penguins recorded during coastal bird surveys (Note: very few rockhopper penguins were recorded in the autumn survey and none in the winter)

Rock shag (RS)

Rock shags were the second most numerous species recorded during the coastal bird survey project, with 7,608 birds recorded (Table 7.18). The distribution of rock shag records from each survey is illustrated in Figure 7-65. Although recorded throughout the areas surveyed, rock shags show seasonal shifts in distribution. In spring and summer, more rock shags were recorded in the outer than the inner

Sound. In the autumn, rock shags apparently disperse and relatively fewer were recorded in the outer Sound. During the winter, the number of rock shags present in the outer Sound was greatly reduced. Of note, a stretch of cliff on the south coast of the outer Sound supported higher numbers than elsewhere (Figure 7-65).

Rock shags have a coastal distribution and were infrequently recorded during JNCC surveys, which were rarely conducted within this species' range. Tracking in Argentina suggests that this species forages in water less than 10 m in depth, with a gravelly sand bottom within 5 km of the colony (Birdlife International, 2020b). Although there is likely to be some inter colony differences in foraging range, all the available evidence suggests that rock shags are restricted to coastal waters.

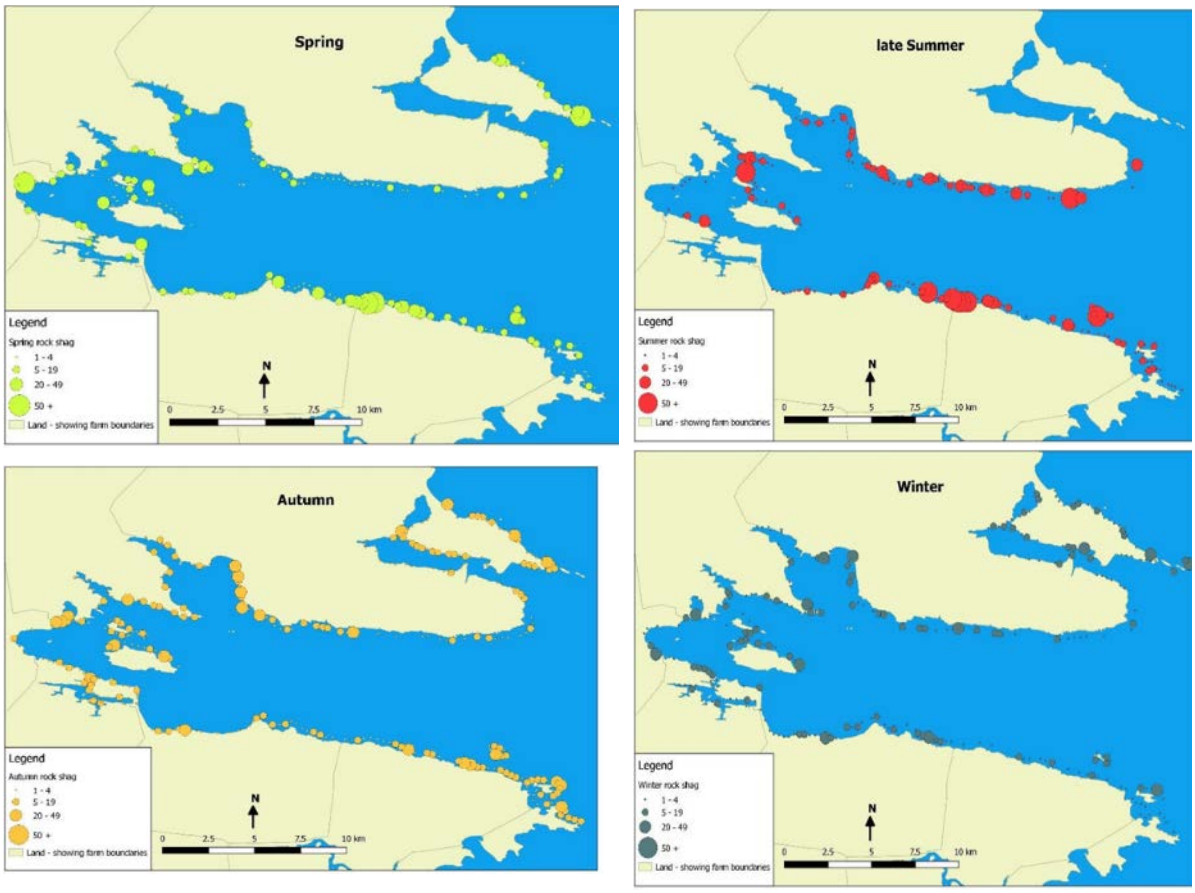

Figure 7-65: Distribution of rock shags recorded in each season

Imperial shag (IS)

Imperial shag was the third most numerous species recorded during the series of coastal bird surveys, with 6,770 birds recorded (Table 7.18). During the spring and summer, Cochon Island supports a large population of this species and the highest density was observed on the cliffs of the north coast of this island. Other smaller colonies were recorded on the north coast of Kidney Island, Volunteer Point and the north and south coasts of the outer Sound (east of Strike-off Point). Elsewhere, imperial shags were only recorded as single birds or small groups (Figure 7-66). During the survey, large groups of imperial shags (likely to be feeding aggregations) were observed on the waters of the outer Sound. These birds were not recorded as they fell outwith the coastal survey transect.

By contrast, during the autumn and winter, imperial shags were only recorded in low numbers within Berkeley Sound (Figure 7-66). The only large group observed was seen roosting on the north coast of Volunteer Rocks, however these birds fell outwith the survey transect.

Perhaps surprisingly, imperial shag was the second most numerous species of seabird recorded by the SAST in the vicinity of Berkeley Sound (Section 7.4.5.3.1.1) and were consistently recorded as one of the most numerous species present in all months of the year (Table 7.18). Although imperial shags were not observed on the shoreline in the winter, they are still abundant within inshore waters during the winter months. Like several other species distributions described here, large groups of imperial shags were recorded in the waters off Mengeary and Volunteer Points, which suggests that these are important foraging areas for numerous species of seabirds.

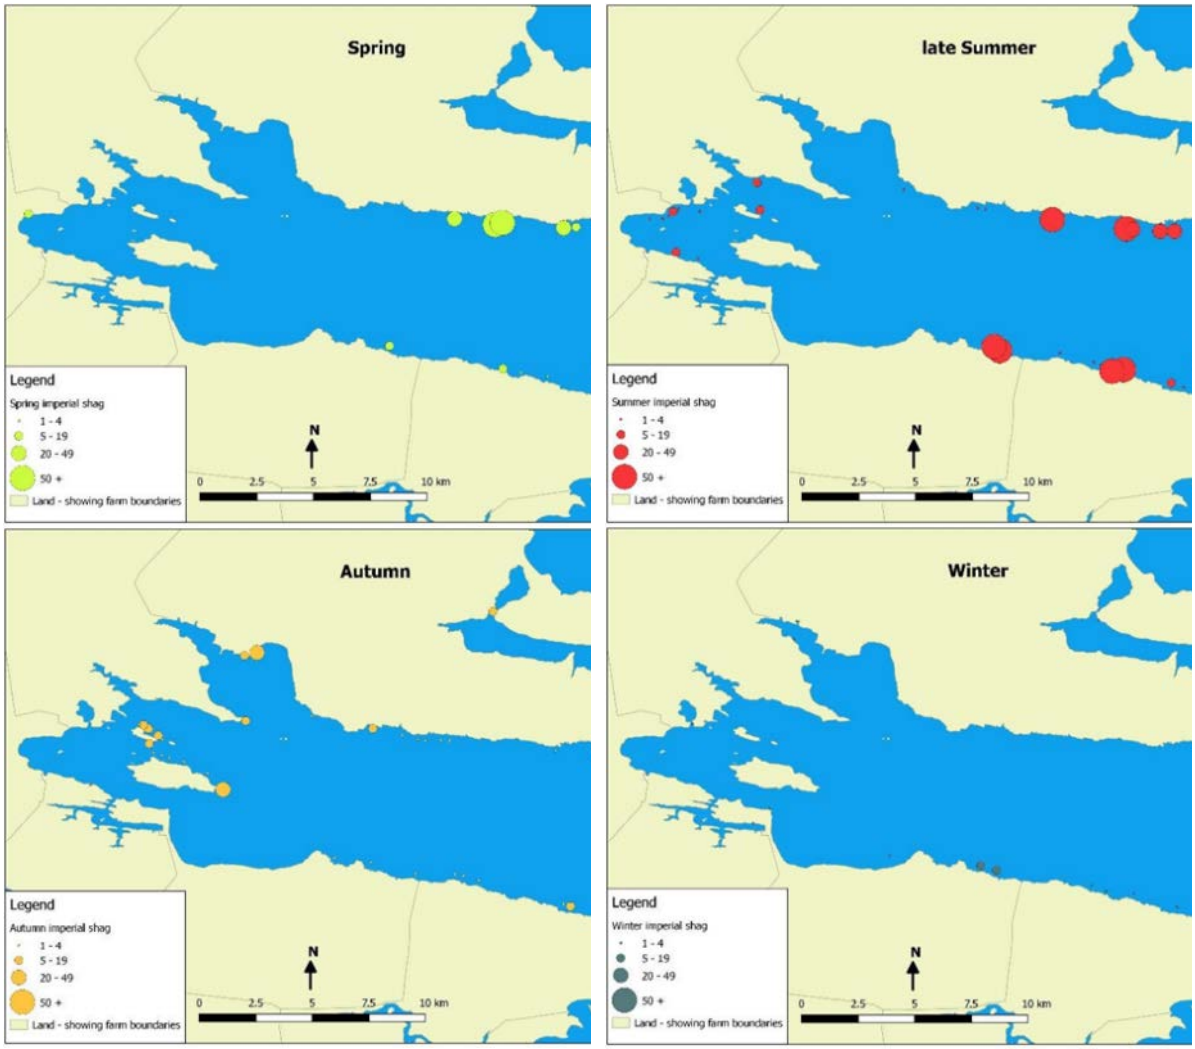

Figure 7-66: The distribution of all imperial shag recorded in each season

Falkland steamer duck (FSD)

The Falkland steamer duck is one of only three endemic bird species in the Falklands (the others being Cobb's wren and Tussac bird). Overall, Falkland steamer duck was the fourth most numerous species recorded during the coastal bird surveys (Table 7.18). Throughout the year, steamer ducks were the most numerous species recorded in the inner Sound during the coastal bird surveys, and were also recorded around the coast of Kidney Island, but appeared to be largely absent from the more exposed coasts of the outer Sound (Figure 7-67). Adult steamer ducks occupy territories throughout the year and pairs are recorded at regular intervals around the entire coast of the inner Sound and Volunteer Lagoon. Larger aggregations of young or non-breeding birds were encountered in all seasons but the group size recorded was larger in the spring than at other times.

This species was the fifth most numerous species recorded by the SAST although the distribution of records was restricted exclusively to the inshore waters of Port William. The lack of records in Berkeley Sound however, reflects the distribution of survey effort which was rarely within 2 km of the coast.

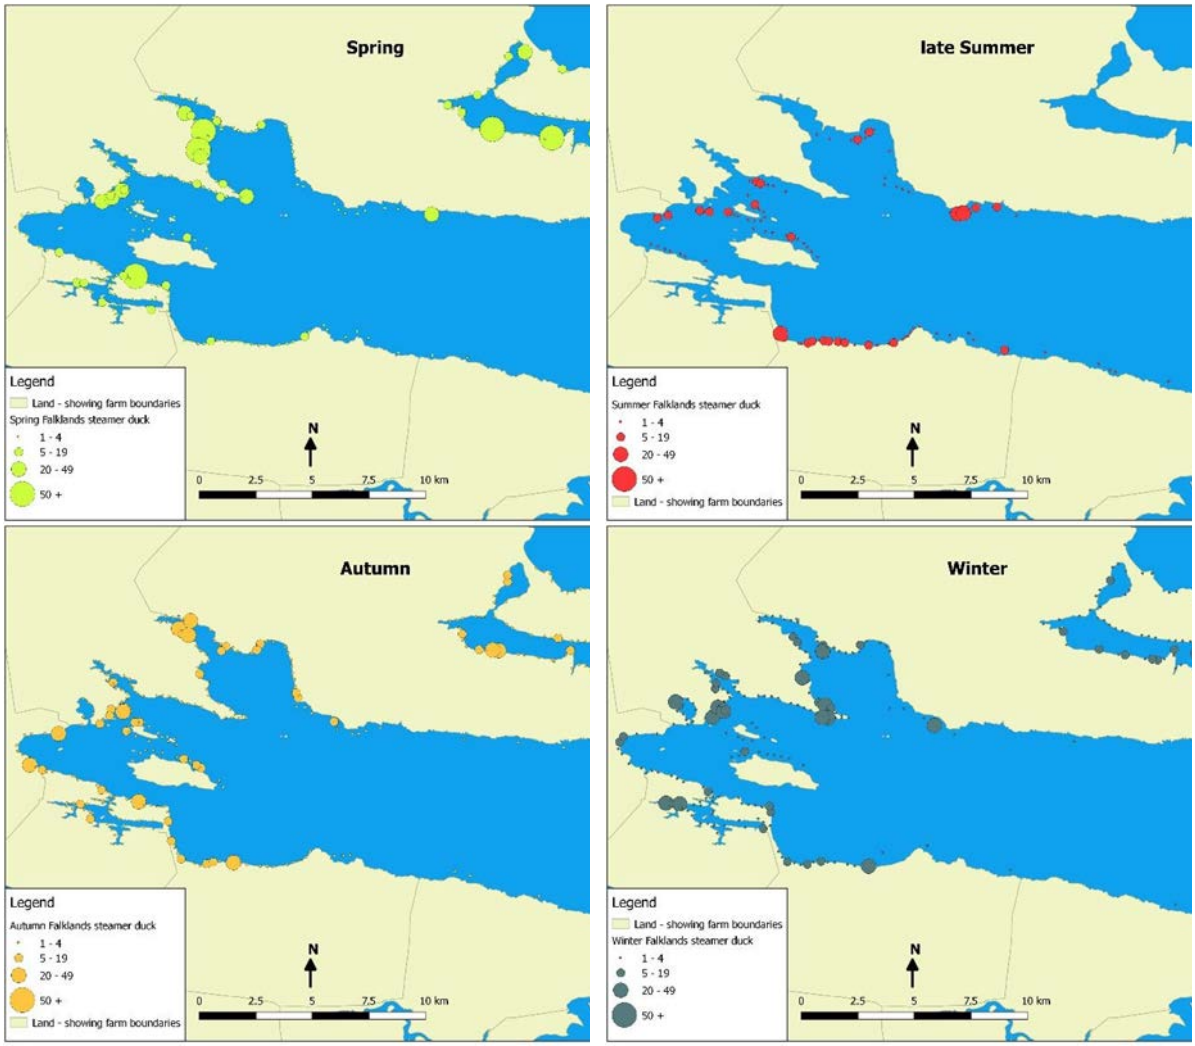

Figure 7-67: The distribution of all Falkland steamer duck records in each season

Gentoo penguin (GP)

Gentoo penguins are resident in the Falklands and regularly return to shore throughout the year. Gentoo penguin were consistently one of the most numerous species in each coastal bird survey (Table 7.18). However, they were only recorded in association with known breeding sites; primarily Kidney Cove and Lagoon Sands.

Satellite tags have been deployed on gentoo penguins breeding at a number of colonies around the Falklands, including Kidney Cove. It is generally regarded that during the breeding period (September to February) gentoo penguins forage inshore and return to colonies on a daily basis. Although not derived from tracking, detailed observations of birds breeding at Volunteer Point recorded mean minimum and maximum foraging trip lengths were between 2.0 - 3.0 days and 0.7 - 1.8 days during the incubation and brood periods respectively (Otley, *et al.,* 2005). Comparable foraging trips were longer at other sites studied in the South Atlantic (Otley, *et al.,* 2005).

During the winter, tracking from Kidney Cove has shown that birds may disperse away from the breeding colony but still return regularly to land elsewhere in the Falklands (Clausen and Pütz, 2003).

Foraging trips were more variable in length and range during the winter, when compared with the breeding birds. Although gentoo penguins are present at Berkeley Sound colonies throughout the winter, they may not be the same birds that breed there during the summer.

Magellanic penguin (MP)

Generally, Magellanic penguins favour relatively sheltered vegetated areas that have access to the open sea. During coastal bird surveys, the area with the highest density of breeding Magellanic penguins recorded was on the greens behind Volunteer Beach. Magellanic penguins were apparently absent from the study area during the autumn and winter surveys (Table 7.18).

Magellanic penguins were recorded in low numbers throughout the waters surveyed by the SAST; however, large groups were encountered within Port William and across the entrance of Berkeley Sound (Figure 7-68). Tracking and at-sea observations indicate that the majority of Magellanic penguins migrate northwards following moulting and overwinter outwith the waters of the Falkland Islands (Pütz, *et al.,* 2000). This is reflected in the number of birds recorded in each season (Table 7.19 above), which indicates that very few Magellanic penguins are present between May and September.

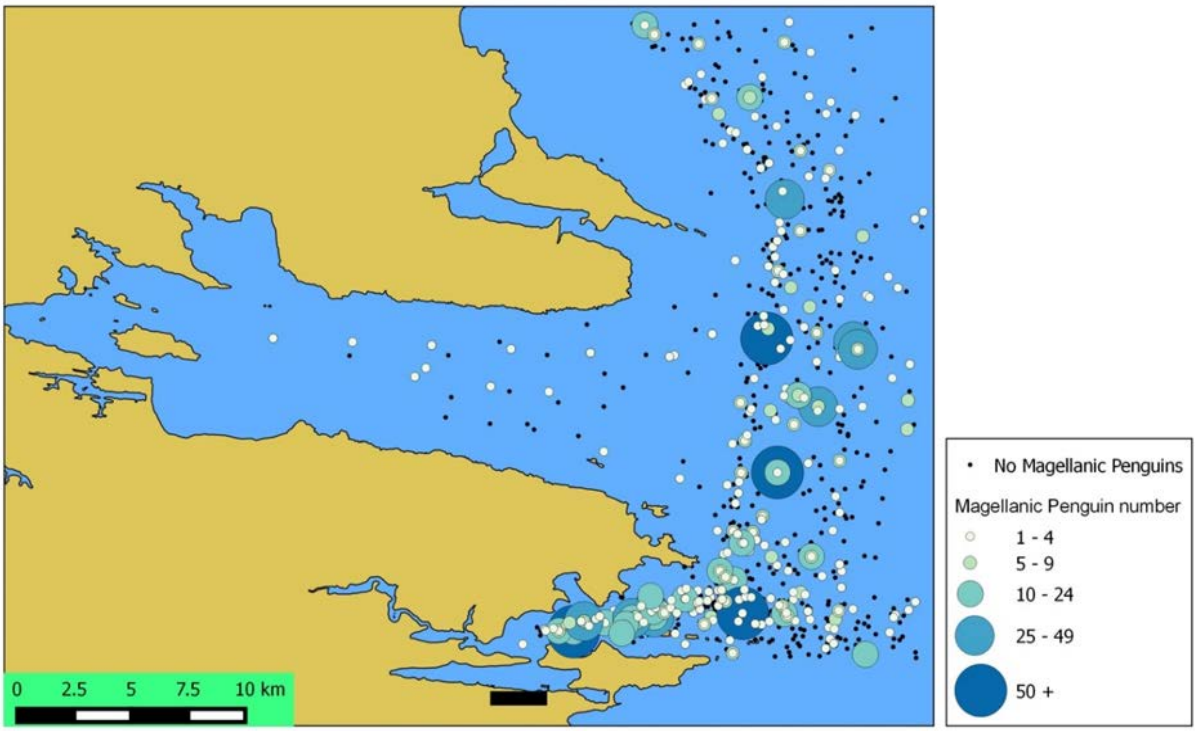

Figure 7-68: The distribution of all Magellanic penguin records in the vicinity of Berkeley Sound

King penguin (KP)

Unlike the other species of penguin breeding in the Falklands, king penguins raise chicks throughout the year, therefore, colonies are occupied throughout the year. The largest king penguin colony in the Falklands is located close to Berkeley Sound, behind Volunteer Beach. The majority of the king penguins recorded during coastal bird surveys were recorded close to this site or the far smaller colony at Volunteer Sands. The fact that no king penguins were observed during the summer coastal survey (Table 7.18) was due to the lack of survey effort near these colonies (Figure 7-20).

Several tracking studies have been conducted on king penguins (*Aptenodytes patagonicus*) breeding at Volunteer Point, which have identified seasonal shifts in distribution associated with phases of the breeding cycle (Pütz, 2002; Pütz and Cherel, 2005; Baylis, *et al.,* 2014; summarised in Table 7.21.

Although the distribution may change during the course of the year (Pütz, 2002), king penguins are generally found offshore over the continental slope. The recorded distribution is thought to be closely linked to the distribution of the primary prey species, myctophids or lantern fish (Cherel, *et al.,* 2002). While these offshore foraging areas are likely to be beyond the influence of activities within Berkeley Sound, breeding birds return regularly to shore and it is here (in inshore waters) that they are at greatest risk. It is likely that the length of foraging trips and therefore the frequency of visits to the colony are of greater interest when assessing the impact of inshore activity than the location of feeding grounds.

Table 7.21: Summary of king penguin foraging trips from Volunteer Point

Season	Months	Duration (days)			Min distance travelled (km)			Maximum distance from colony (km)		
		Mean	SD	Median	Mean	SD	Median	Mean	SD	Median
Early winter[1]	Mar, Apr, May	19.8	15.5	15	2,014.5	1,279	1,370	664.6	419.7	485

[1] Pütz, 2002.
[2] Pütz and Cherel, 2005.
[3] Baylis, *et al.,* 2014.

Black-browed albatross (BBA)

Although seen throughout the year by the SAST, the number of black-browed albatrosses recorded was generally lower during the winter months (Table 7.19 above). Usually recorded individually or in small numbers, larger groups were occasionally encountered (Figure 7-69).

Black-browed albatrosses have been tracked from a number of colonies in the Falklands; Beauchêne, Saunders Island, New Island and Steeple Jason (BirdLife International, 2004; Baylis, *et al.,* 2019a). Results have confirmed that this species forage primarily over Patagonian Shelf waters. Birds tracked from Beauchêne are of especial interest as this is the second largest colony in the Islands and the closest to Berkeley Sound. To date, tracking indicates that the east coast of the Falklands is not a core foraging area for this species (BirdLife International, 2004).

As stated above, besides the local breeding population of black-browed albatross, the South Georgia population also occurs in the Falkland Islands (Frankish, *et al*., 2020a). The black-browed albatross from South Georgia is an ACAP Priority Population (GSGSSI, 2016).

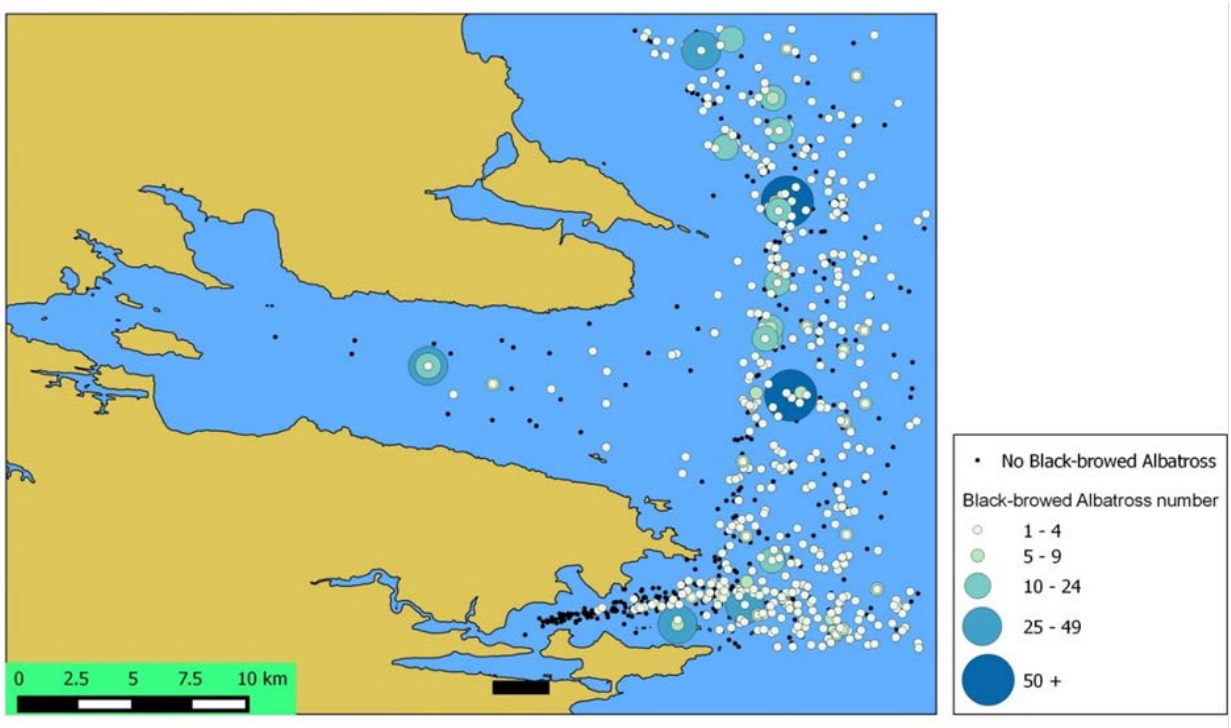

Figure 7-69: The distribution of all black-browed albatross records in the vicinity of Berkeley Sound

Southern giant petrel (SGP)

Southern giant petrels were present throughout Berkeley Sound in low numbers. Most sightings were of single birds flying along the coast but several larger aggregations (mostly associated with Kidney Island) and breeding colonies were recorded. The presence of a small breeding colony near the entrance to Volunteer Lagoon was confirmed and a potentially 'new' breeding site was identified on Peat Island, to the east of Hog Island (Figure 7-3 above). The first site is close to a known breeding site at Black Rincon within Volunteer Lagoon, this colony consisted of nine nests in the 2004 / 05 season (Reid and Huin, 2005). However, the present colony appears to have moved to the opposite side of the Lagoon and is on the point to the west of Lagoon Sands. At the second site, birds were seen on nests but the presence of eggs was not confirmed.

White-chinned petrel (WCP)

Although only two white-chinned petrels were recorded during the coastal bird surveys, the Falkland Islands largest known colony of this species is found on Kidney Island (Reid, *et al.,* 2007) which supports 331 (95 % CI: 52 – 1043) breeding pairs (Kuepfer, *et al*., 2024). Breeding takes place between September and May and this is when the number of white-chinned petrels visiting the Island will be highest. JNCC surveys in inshore waters adjacent to Berkeley Sound recorded white-chinned petrels at moderate to high densities from spring to autumn with fewer observed during the winter. Like many other species of petrel, rafts of white-chinned petrels congregate in inshore waters near breeding colonies.

White-chinned petrels are classed as 'Vulnerable' by the IUCN and therefore represent one of the most sensitive of the Falklands breeding species.

As stated above, a recent tracking study demonstrated movements of the South Georgia white-chinned petrel population to Falkland Islands waters (Frankish, *et al*., 2020b).

Sooty shearwater (SS)

As was evident during the SAST surveys (Section 7.4.5.3.1.1), the sooty shearwater is the most numerous breeding seabird species in the vicinity of Berkeley Sound with a population estimate of 139,000 pairs) breeding on Kidney Island (Wakefield, *et al.,* 2017). Although the behaviour was never recorded during SAST surveys, huge rafts of sooty shearwaters gather off Kidney Island at the entrance to Berkeley Sound during the breeding season, where they wait until dusk before returning to their nesting burrows ashore. This behaviour makes sooty shearwaters vulnerable to the effects of any surface pollutants and / or the effects of artificial light.

Figure 7-70 shows the distribution of all sooty shearwater records in the vicinity of Berkeley Sound during JNCC surveys with very high abundance recorded at the entrance to Port William. This reflects the proximity to the breeding site on Kidney Island but also, to some extent, reflects the route taken by the SAST survey vessels. Despite this species' diurnal habit of dispersing to feed during the day before returning to breeding colonies in the evening, very high densities of sooty shearwaters were recorded throughout the day in waters adjacent to Berkeley Sound, within Berkeley Sound and off Volunteer Point.

Between May and August, the number of sooty shearwaters recorded is greatly reduced (Table 7.19 above) as many birds migrate to the northern hemisphere at this time (Hedd, *et al.,* 2014).

Contrary to the SAST surveys, very few sooty shearwaters were recorded during the coastal bird surveys. Although sooty shearwater was the most numerous species observed, virtually all of the birds seen were outwith the transect. For instance, while surveying the coast of Kidney Island (known to be an important breeding site) on 26th October a raft of approximately 15,000 sooty shearwaters was observed to the north of the island. A large number of sooty shearwaters was also observed passing off the coast of Johnsons Rincon on 22nd October. The presence of these birds deep within the Sound may have been related to the wind direction on the day (south-easterly), as they were not present in the same area on the 26th.

In 2007, 44 sooty shearwaters from Kidney Island were fitted with geolocator tags (Hedd, *et al.,* 2014) (Section 7.4.5.3.1.3). The results allow information regarding at-sea distribution, foraging trip length and activity (time spent on the water) to be collected. For instance, differences in the foraging strategies of male and female birds were found. The greatest differences between the sexes occur in the early stages of breeding, before the egg is laid (in late November). At this time, males forage closer to, and spend significantly more time at, the breeding sites than females. Key results of the tracking studies are summarised in Table 7.22.

The results of further tracking of sooty shearwaters from Kidney Island during the GAP programme are shown in Figure 7-70.

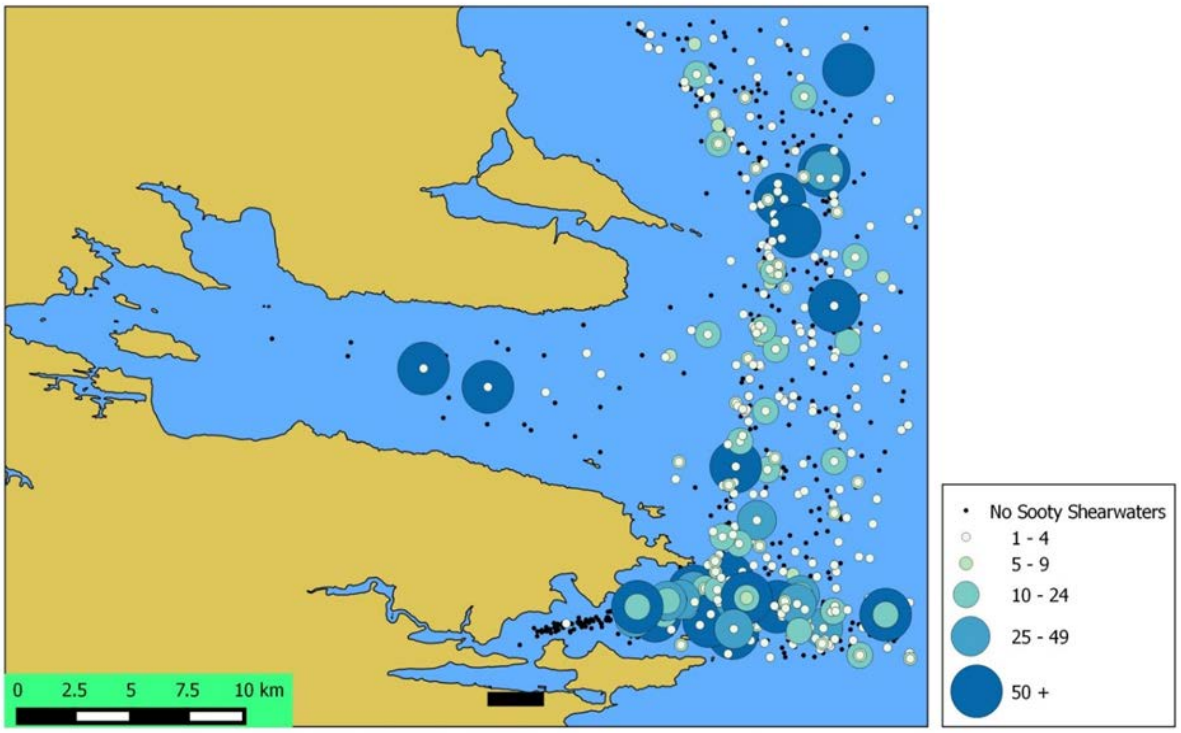

Figure 7-70: The distribution of sooty shearwater records in the vicinity of Berkeley Sound (held on the SAST database)

Table 7.22: Sooty shearwater behaviour derived from geolocator tags ***(Source: Hedd, et al., 2014)***

Period	Date	Trip length		Range / distance		Overlap in distribution
		Male	Female	Male	Female	
Pre-Breeding	Return late Sept	Daily	Variable	-	-	Low
Pre-laying exodus	Leave early Nov	12 + 8.7 days	22.4 + 3.5 days	2,830 + 1.997 km	5,906 + 1,412 km	Low
Incubation	Lay 22 Nov	7.6 + 2.7 days		Range 491 + 273 km		High
Chick rearing	Hatch 18 Jan	1.4 + 1.3 days		Max. 410 km		High

Kelp gull (KGu)

Kelp gulls were recorded throughout the areas covered by all of the coastal bird surveys; however, highest numbers were recorded in the inner Sound. Several notable concentrations were recorded in the summer on Long Island or the adjacent mainland. During the winter, kelp gulls appeared to be more dispersed.

Dolphin gull (DG)

Dolphin gulls were recorded in low numbers during all of the coastal surveys, always associated with groups of shags or penguins. The Falklands are the global stronghold of this species with approximately 85 % of the world's population breeding in the Islands.

Brown-hooded gull

Brown-hooded gulls were infrequently encountered; however, when sighted they were usually in groups. Brown-hooded gulls were most frequently encountered in the inner Sound.

South American tern (SAT)

All of the South American terns recorded during the summer 2016 coastal survey were sighted close to Kidney Island. It appeared that there may be a colony of this species on a small island off the north-west tip of Kidney Island. South American terns were not recorded during the winter 2017 survey.

South American terns were recorded at moderate to high densities in coastal waters near Berkeley Sound from the spring to autumn.

Antarctic skua (AS)

Antarctic skuas were occasionally observed during the summer 2016 coastal survey (Section 7.4.5.3.1.1) but there was no discernible pattern to the distribution of this species. This species was absent during the winter of 2017.

Tussac bird (TB) (Blackish cinclodes)

Tussac bird was recently given endemic status, having been split from the blackish cincloides found on mainland South America. During the coastal surveys, tussac birds were recorded around three islands within the Sound: Cochon, Kidney and Hog Islands. Tussac birds only thrive on islands without rats, although they can be seen in adjacent rat-infested areas. Cochon and Kidney Islands are known to be rat-free, however, the status of Hog Island is unknown.

Cobb's wren (CW)

Although rarely recorded during the summer 2016 coastal bird surveys, Cobb's wren is one of the most sensitive species found in the Berkeley Sound area. This species is endemic to the Falkland Islands and has restricted distribution within the Islands due to being extremely vulnerable to predation by introduced rats and cats. The distribution of these birds is therefore extremely patchy and largely restricted to small rat free tussock islands, such as Cochon and Kidney Islands. The small range and susceptibility to rat invasions means that the species is classified as 'Vulnerable'[31] by the International Union for the Conservation of Nature (IUCN). A species action plan has been written for Cobb's wren by Falklands Conservation and FIG (2008c).

The behaviour of Cobb's wrens, favouring dense coastal tussock backing boulder beaches, not only makes them susceptible to rats. The small size and habitat preferences of these birds also make them impossible to survey accurately from a moving boat. Eggs are laid between early October and December, and there are probably two broods per season (Woods, 1988; Woods and Woods, 1997).

Although Cobb's wrens were not recorded during the winter 2017 survey, they are known to be present on Cochon and Kidney Islands at this time.

Kelp goose (KGo)

Kelp geese were recorded throughout the areas surveyed during the summer 2016 coastal survey. This species is territorial and therefore was only recorded in pairs, or small family groups. During the winter 2017 survey, kelp geese were recorded more frequently in the sheltered waters of the inner Sound.

All other species

A number of other species of duck, shorebirds and land birds were recorded opportunistically during both coastal surveys (Table 7.18 above). However, due to difficulties in seeing these species from a moving boat, the results of this survey are not reliable enough to map the distribution of these species.

[31] **Post-consultation note (July 2025):** The Cobb's wren is now listed as IUCN 'Least Concern' as surveys indicate the endemic species is now present on more than 120 islands within the archipelago. While it is only found on predator-free islands, rat eradication programmes appear to have helped this species and the population trend appears to have been stable for some time (BirdLife International, 2025).

7.4.5.3.3 Summary of inshore bird abundance, distribution, life-cycle and behavioural characteristics

Table 7.23 provides a summary of inshore bird abundance, distribution, life-cycle and behavioural characteristics.

Table 7.23: Summary of inshore bird abundance, distribution, life-cycle and behavioural characteristics

Species	IUCN status	ACAP species[1]	FI priority species[2]	Seasonal occurrence and distribution[1]	Breeding cycle	Feeding mode	Persistent ship associate[3]	Berkeley Sound breeding sites	Falklands population	Global population and trend[4]
Sooty shearwater (*Ardenna griseus*)	NT	X	X	Present throughout the year but most of the population depart between Apr – Aug. Spring | Summer | Autumn | Winter 	Start breeding at 4 yrs. Adults return Sept. 1 egg laid late Nov. Adults depart Mar. Chicks fledge April. 7.4.5.4 Birds in Stanley Harbour and surrounding areas

Many of the common species of land birds of the Falklands can be found breeding around the coast of Stanley Harbour. Of these, species of duck (such as Patagonian crested ducks; *Lophonetta specularoides*) and kelp geese (*Chloephaga hybrida*) rely on the marine environment for food and are therefore susceptible to marine pollution. There are relatively few seabirds found within the Harbour, when compared with other inshore waters of the Falkland Islands. However, a number of breeding pairs of endemic Falkland steamer ducks have been recorded, and small breeding colonies of Magellanic penguins and rock shags. In 2013, two coastal bird surveys, one in the winter (August) and the other in the summer (December), were conducted along the entire coastline of Stanley Harbour (Poncet, 2014). More recent surveys were initiated in 2020 and are at-present, ongoing (Poncet, 2021). The more recent surveys were carried out in summer and winter and cover over 40 km of coastline (22 km within Stanley Harbour and 21 km along Port William and Cape Pembroke Peninsula). The results of these surveys form the basis of this baseline description of birdlife within Stanley Harbour.

The coastline was divided into 14 transects, which varied from 1 to 6.46 km in length (Poncet, 2021) (Figure 7-71). All birds within 100 m to seaward and 25 m inland of the coast were recorded as surveyors walked each transect. The results of the surveys are summarised in Table 7.24 below. The results of the survey data indicate that both Stanley Harbour and Cape Pembroke host a high number of bird species in both summer and winter (number of species > 20).

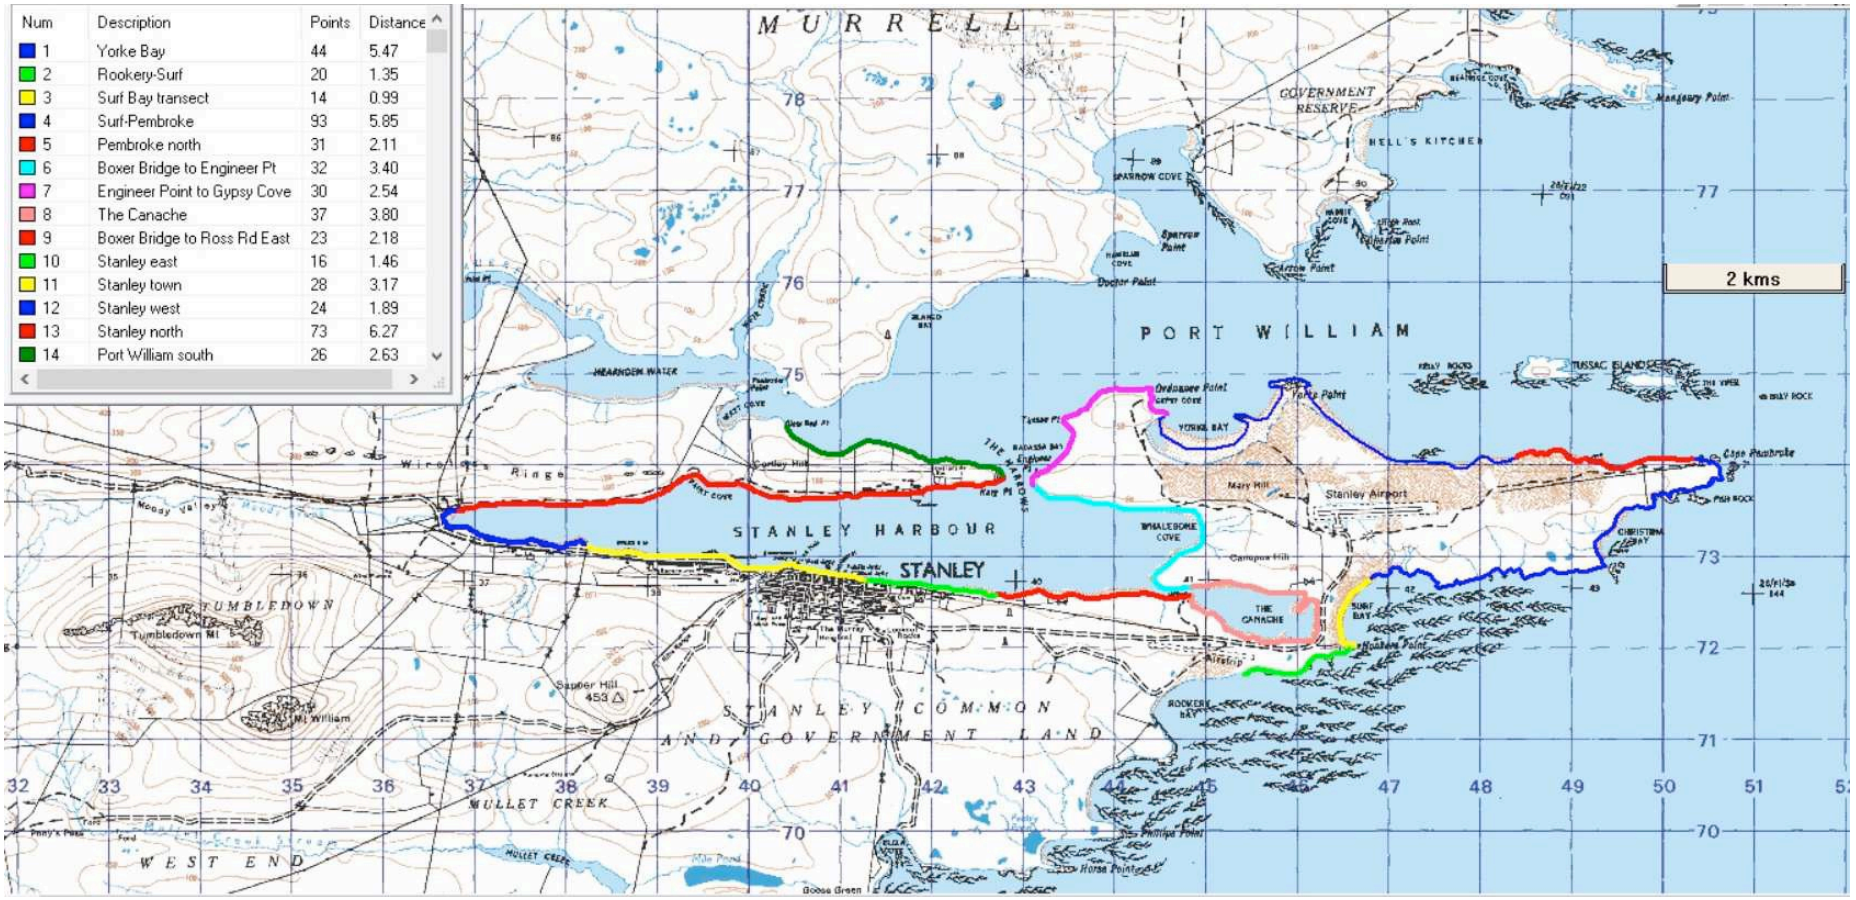

Figure 7-71: The Stanley Harbour coastline showing the coastal bird survey transects ***(Source: Poncet, 2021)***

7.4.5.4.1 Falkland steamer duck

Overall, Falkland steamer ducks were the most numerous coastal bird in summer and winter within Stanley Harbour (max count was n=215 in summer). The summer survey recorded steamer duck breeding territories at regular intervals around much of the Stanley Harbour coastline, with the exception of the coastline along the Stanley waterfront and the Canache where this species was relatively scarce. Breeding territories are occupied by the same pair throughout the year. At least 28 breeding pairs were reported in Stanley Harbour during summer (Poncet, 2021). In addition, aggregations of non-breeding steamer ducks were recorded at 'traditional' sites around the coast, mostly in the western end of the Harbour but also near the entrance to the Canache.

7.4.5.4.2 Kelp goose

Very few kelp geese appear to breed within Stanley Harbour and the number of birds present during the summer is relatively low within Stanley Harbour. However, during the winter kelp geese disperse and more birds can be found feeding in the sheltered waters of Stanley Harbour. Kelp geese were more numerous outside of Stanley Harbour, on outer coasts, being the most frequently recorded coastal bird during summer Cape Pembroke surveys (Poncet, 2021).

7.4.5.4.3 Passerines

Seven species of passerine (perching birds such as: Falkland thrush, black-chinned siskin, black-throated finch, long-tailed meadowlark, grass wren, Falkland pipit and house sparrow) were recorded along all coastlines. The town of Stanley with its trees, shrubs and buildings provide good habitat for passerine birds.

7.4.5.4.4 Waders

Although found in low numbers elsewhere, The Canache proved to be a local hot-spot for waders. This shallow embayment reveals inter-tidal mudflats at low tide, which attracts feeding waders. Although present year-round, the number of waders within The Canache is higher during the winter than the summer.

7.4.5.5 Seabird population and conservation status

Most seabird species are highly mobile, travelling thousands of kilometres across international waters and multiple Exclusive Economic Zones and generally only return to land to breed and moult. They face many serious conservation challenges throughout their migratory range and across all phases of the lifecycle, and are currently considered the most threatened group of birds (BirdLife International, 2014b). The species accounts in the previous section include the IUCN Red List threat categories for each species. It is important to note that these threat categories refer to the status of the global population, and not specifically the Falklands population. It is also useful to note that there are often regional differences in population trends. For example, on the basis of the most recent archipelago-wide census, the population trend for the black-browed albatross population in the Falklands is positive (Wolfaardt, 2012; Crofts, 2020), whereas the South Georgia population continues to decline (Poncet, *et al.,* 2006).

The population status of many of the abundant breeding seabirds in the Falkland Islands is relatively well understood thanks to a number of long-term monitoring projects conducted by Falklands Conservation and other research institutions, especially those conducting research at New Island. The 2010 archipelago-wide surveys of seabirds breeding in the Falkland Islands revealed that, black-browed albatrosses, rockhopper and gentoo penguins had increased since 2005. More recent archipelago-wide censuses have been undertaken, but the results are yet to be published. Archipelago-wide censuses are complemented by a number of annual monitoring studies, which highlight that the number of gentoo and rockhopper penguin breeding pairs have, overall, declined at annually

monitored sites over the past 10 years. However, a high degree of inter-annual and inter-site variability in population numbers and breeding productivity over the past 10 years exists. The king penguin population in the Falkland Islands, which is arguably insignificant in global terms, but is one of the islands' most important tourist attractions, has also been increasing since annual monitoring began in 1991 (Pistorius, *et al.,* 2012, Crofts and Stanworth, 2018). However, these increases should not be taken to mean that the seabird populations in question are not susceptible and vulnerable to current and future threats, and indeed to the effects of multiple threats.

It is important to note that the population sizes and trends of the majority of Falklands breeding species are poorly known.

7.4.5.5.1 Threats to seabirds

Seabirds face threats both at sea and on land, at their breeding sites. Arguably one of the greatest threats to seabirds, particularly albatrosses and petrels, is the incidental mortality associated with fisheries (bycatch). Fisheries bycatch has been recognised as a critical threat to seabirds in the waters of the Falkland Islands (Sullivan, *et al.,* 2003; Reid, *et al.,* 2004). Following the introduction of effective mitigation measures and the adoption of a National Plan of Action for Reducing Incidental Catch of Seabirds in Capture Fisheries (NPOA-S, Longline), seabird bycatch associated with longline fishing in the Falkland Islands has been significantly reduced. Since 2007, there have been no reported seabird mortalities in the longline fishery (FIG, 2024b).

Significant levels of seabird mortality have also been recorded in the finfish and loligo trawl fishery in the Falkland Islands (Sullivan, *et al.,* 2003). Although mitigation measures, and a NPOA-S (Trawl), have been adopted, and have contributed to a substantial reduction in mortality, seabirds are still killed incidentally in the trawl fisheries of the Falklands Islands. The estimated number of birds killed in trawl fisheries (mostly black-browed albatrosses) varies considerably from year-to-year (Figure 7-72; FIG, 2017b; 2019a), with the lowest extrapolated mortalities since 2004 recorded in 2018. Mortalities have remained relatively low since then, with 195 and 99 mortalities estimated in 2019 and 2020 respectively, which were solely from the loligo fleet, and 875 estimated mortalities in 2022 from both fleets (no estimates were reported in 2021) (FIG, 2019a; 2020; 2021b; 2022a; 2023n). Inter-annual differences in estimated mortality are due to fluctuations in the recorded mortality rate rather than fishing effort (FIG, 2015a). Note that in 2019 observer seabird dedicated effort was <2% and no seabird mortality was observed; in this case minor injury contacts were used as a mortality proxy (Parker, *et al.,* 2013). Seabird mortalities were reported as summarised in Table 7.25.

The use of the 3:1 rule for estimating mortalities from heavy contacts has meant that extrapolated mortalities has increased back to pre-2017 level. However, it should be noted that this new rule has not been tested since first published in 2013. It remains that inter-annual differences in estimated mortality are likely due to fluctuations in the recorded mortality rate rather than fishing effort (FIG, 2015a; 2016b).

Other potential threats to seabirds include competition with commercial fisheries for food, habitat modification, introduced predators, disease and contamination from various forms of pollution. Research conducted in the early years of commercial fisheries in the Falklands found that although a number of seabirds utilise species that are commercially harvested, there was no conclusive evidence that competition with fisheries was having a negative impact on seabird populations (Thompson, 1992; Thompson and Riddy, 1995). Incidents of disease and harmful algal blooms have been recorded for several seabirds in the Falklands, but these tend to be isolated, rather than persistent factors. Although a number of seabird species have been found oiled in the Falkland Islands, to date, the numbers recorded have been relatively low, especially in relation to possible population level impacts.

7.4.5.5.2 Agreement for the Conservation of Albatrosses and Petrels (ACAP)

In recognition of the threat of fisheries related mortality and land-based threats at breeding sites a multilateral Agreement for the Conservation of Albatrosses and Petrels (ACAP, 2019) was established in 2004, which seeks to conserve albatrosses and petrels by coordinating international activity to mitigate known threats to their populations. ACAP is a daughter agreement to the Convention on the Conservation of Migratory Species of Wild (CMS) (also known as the Bonn Convention) which is an environmental treaty of the United Nations that provides a global platform for the conservation and sustainable use of terrestrial, aquatic and avian migratory animals and their habitats. All of the UK Overseas Territories and Crown Dependencies are covered by the CMS, with the exception of Anguilla and British Antarctic Territory[32]. The CMS's primary objective is to conserve migratory birds throughout their range; it identifies migratory species threatened with extinction (CMS, Appendix I) and strives to strictly protect these species. CMS also acts as a framework Convention for other regional agreements for migratory species that need international co-operation (CMS, Appendix II) to conserve them over their entire range, such as ACAP.

ACAP aims to stop or reverse population declines by co-ordinating action between States within migratory ranges to mitigate known threats to albatross and petrel populations. To achieve this ACAP promotes an Action Plan which describes a number of conservation measures including research and monitoring, reducing incidental mortality in fisheries, eradicating non-native species at breeding sites and reducing disturbances, habitat loss and pollution.

Currently, ACAP covers 31 species, which comprise 22 albatrosses, seven petrels and two shearwaters. Of these species, eight were recorded over the waters within or adjacent to Berkeley Sound during JNCC surveys (White, *et al.,* 2002; Black, 2005b). Two of these eight species have breeding populations

[32] Oversea Territories Conservation UK: https://www.ukotcf.org.uk/conventions/cms-2/.

within Berkeley Sound; a small but nationally important breeding population of white-chinned petrels on Kidney Island and two small colonies of southern giant petrels, one at the entrance to Volunteer Lagoon and the other on Peat Island. Table 7.26 shows the species listed under ACAP that occur within Falkland Island waters.

Of importance, in 2011, ACAP identified nine seabird Priority Populations (i.e., populations which represent >10 % of the total global population and / or are declining at a rate of >3 % per annum) for conservation. The wandering albatross is a non-breeding visitor to Falkland Islands waters and individuals from the South Georgia populations of grey-headed and black browed albatross are also known to forage in Falkland Islands waters. All three of these South Georgia populations are considered to be ACAP priority populations (GSGSSI, 2016).

Table 7.26: ACAP species (ACAP, 2016) that have been recorded within the waters of the Falkland Islands

Common name	Scientific name	Local status	IUCN status
Black-browed albatross	*Thalassarche melanophris*	Common breeder	LC
Grey-headed albatross	*Thalassarche chrysostoma*	Regular visitor	EN
Grey petrel	*Procellaria cinerea*	Regular seasonal visitor	NT
Light-mantled sooty albatross	*Phoebetria palpebrata*	Regular visitor	NT
Northern giant petrel	*Macronectes halli*	Common visitor	LC
Northern royal albatross	*Diomedea sanfordi*	Regular visitor	EN
Sooty albatross	*Phoebetria fusca*	Rare visitor	EN
Southern giant petrel	*Macronectes giganteus*	Common breeder	LC
Southern royal albatross	*Diomedea epomophora*	Common visitor	VU
Wandering albatross	*Diomedea exulans*	Common visitor	VU
White-capped albatross	*Thalassarche steadii*	Rare seasonal visitor	NT
White-chinned petrel	*Procellaria aequinoctialis*	Rare breeder/Common visitor	VU

7.4.5.6 Seabird vulnerability to oil spill

One of the potential threats that need to be considered in relation to hydrocarbon developments is the impact of oil pollution. To date, reports of oiled seabirds in the Falkland Islands concern a small number of birds. However, millions of seabirds have been killed globally by oil pollution (García-Borboroglu, *et al.,* 2006 and 2008; Wolfaardt, *et al.,* 2009). With the development of the O&G industry in the Falkland Islands, the risk posed to seabirds is an important consideration, especially given the global importance of this area for seabirds and the logistical challenges associated with responding to oil spill events.

Birds are vulnerable to oiling from surface oil pollution, which can cause direct toxicity through ingestion, and hypothermia as a result of a bird's inability to waterproof its feathers. Oil pollution can also impact birds indirectly through contamination of their prey (NRC, 2003). Seabird species vary greatly in their responses and vulnerability to surface pollution, therefore in assessing their vulnerability it is important to consider species-specific aspects of their feeding, breeding and population ecology (White, *et al.,* 2001). Species that spend a greater proportion of their time on the sea surface are considered to be at greatest risk from the effects of surface pollution. Penguins are therefore more likely to be affected than the highly aerial petrels. Species that are wholly dependent on the marine environment for feeding and resting are considered more vulnerable to the effects of surface pollution than species that use offshore areas only seasonally or move offshore only to rest or roost. In addition, the potential reproductive rate of a species will influence the time taken for a

population to recover following impacts. Other factors such as natural mortality rate, migratory behaviour, species abundance and conservation status (e.g., IUCN global Red List status) will also determine the effects of an oil spill on seabird populations.

7.4.5.6.1 JNCC Oil Vulnerability Index (OVI)

To assess the relative risk to different species, the JNCC developed an index to assess the vulnerability of bird species to the threat of oil pollution (Williams, *et al.,* 1994). One of the main outputs of the SAST surveys in the Falkland Islands was the production of an Oil Vulnerability Atlas (White, *et al.,* 2001)[33]. This analysis scored each species on four factors to produce an Oil Vulnerability Index (OVI)[34]. Recently, JNCC have updated the OVI to include recent survey data and using a new method, which has been named the Seabird Oil Sensitivity Index (SOSI). The OVI method is described below as this is the one that has been applied here. The OVI was applied to the density of that species recorded within each ¼ ICES square (an area measuring approximately 15 x 17 nautical miles), this data is summed to give the Area Vulnerability Score (AVS) for each ¼ ICES square. The AVS's for each square were plotted on a monthly basis to highlight areas that support vulnerable assemblages of seabirds throughout the Falklands Conservation Zones (White, *et al.,* 2001). The results of the original analysis were published in White *et al.* (2001) and the vulnerability maps for each month are presented in Figure 7-73 to Figure 7-76. These maps place the Sea Lion Field and Berkeley Sound into the wider context of Falkland Islands waters and generally, seabird density and consequently AVSs decreased with increasing water depth.

7.4.5.6.1.1 AVS in the Sea Lion Field

During the austral summer (December to February; Figure 7-73), the vulnerability of the area in the immediate vicinity of the Sea Lion Field increased, from low in December to high in February. The species contributing most to this relatively high score were prion species, black-browed albatrosses, Magellanic penguins, Wilson's and grey-backed storm-petrels and great shearwaters. Areas to the north and west of the Field were low and moderate respectively. However, an area of very high vulnerability was identified to the south-east in January.

In the austral autumn (March to May; Figure 7-74), the immediate area around the Sea Lion Field received relatively low survey effort. In March, the area was regarded as moderate to high vulnerability, due to the presence of high densities of black-browed albatrosses, Magellanic penguins and great shearwaters with lower densities of rockhopper penguins, Wilson's and grey-backed storm-petrels and white-chinned petrels. In April and May, the area received lower survey coverage. At this time, low to moderate densities of Cape petrels and black-browed albatrosses were recorded with lower numbers of grey-headed albatrosses, Antarctic fulmars and prions also present.

During the austral winter months (June to August; Figure 7-75), the area of the Sea Lion Field is classed as an area of moderate vulnerability, at which time a patchy distribution of species typical of the Patagonian Shelf in winter, was recorded. The most numerous species in this area at this time were; prion species, black-browed albatross, Antarctic fulmar and Cape petrel.

Surveys during the austral spring (September to November; Figure 7-76) recorded relatively lower densities of seabirds than at other times of the year. The area of the Sea Lion Field is therefore classed as moderately vulnerable. The seabirds present during this period include: rockhopper/macaroni penguins, prion species, Wilson's storm-petrels, black-browed albatrosses and Magellanic penguins.

[33] Note that the Vulnerability Atlas was based on two years' worth of data. Ideally data from multiple years should be utilised to account for variability in the distribution of abundance.

[34] Note: Seabird Oil Sensitivity index (SOSI) has not been used as this would require new data acquisition. SOSI would be an appropriate approach should new data be available in the future.

7.4.5.6.1.2 AVS in Berkeley Sound

The JNCC analysis has not been performed specifically for coastal waters due to the lack of dedicated survey effort close inshore. Vulnerable areas within Berkeley Sound, for seabirds, are linked to the location of colonies and aggregations associated with these colonies. This information has been used to indicate the areas of greatest concern regarding seabird interactions with Oil and Gas activity within the Sound and Figure 7-73 to Figure 7-76 show high or very high vulnerability throughout the year. The data available regarding known breeding populations allows some inferences regarding seasonal oil spill vulnerability within Berkeley Sound. High densities of resident species, such as gentoo penguin, rock and imperial shags (*Phalacrocorax magellanicus* and *P. atriceps*) and black-browed albatrosses are found in coastal waters year-round. During the summer, these are joined by large breeding populations of seabirds that spend the winter elsewhere, which results in the very high vulnerabilities.

7.4.6 Marine Mammals

7.4.6.1 Introduction

Marine mammals can be divided into two main categories:

- Cetaceans (whales, dolphins and porpoises) which can be further divided into:
  - Baleen whales (Mysticeti) such as the humpback whale, sei whale and right whale, which feed by extruding plankton and small schooling fish from seawater which is filtered through baleen plates, and
  - Toothed whales and dolphins (Odontoceti) such as killer whales, sperm whales, dolphins and porpoises which all have teeth for prey capture.
- Pinnipeds (seals, sea lions and fur seals):
  - Fin-footed, semi-aquatic marine mammals that spend part of their time hauled out on land to rest, moult and breed.

The following describes the cetacea and pinnipeds known to be present in the NFB and in, and around, Berkeley Sound.

7.4.6.1.1 Cetaceans

Although cetaceans are not tied to land to breed, many species return to specific areas to calve, reproduce or feed each year. During the non-breeding period, many of the larger species make ocean-wide migrations to exploit specific feeding grounds, often at high latitudes. It is believed that many of the baleen whales recorded offshore within Falkland Islands waters are on passage through the area to and from these feeding / breeding grounds including Falklands inshore waters (e.g., Weir, *et al.,* 2019; Weir, *et al.,* 2024).

The relative abundance and availability of prey, including plankton, fish and squid, can, therefore, be of prime importance in determining the number and distribution of marine mammals and it is thought that the productive inshore waters around the Falkland Islands (including Berkeley Sound) are of importance as feeding areas for visiting and resident species (Weir, 2017; Segre, *et al*., 2021).

Confirmed sightings and stranding records indicate that at least 25 species of cetacean occur within Falkland Islands waters. Many of these species are locally rare and / or inconspicuous with some only known from stranded animals (Otley, 2012). It is generally considered that there are insufficient data available to describe the foraging and breeding areas, seasonal distribution and abundance, and diet of most marine mammal species in the Falklands (FIG, 2008a). However, two recent projects studying dolphins and sei whales in inshore waters have increased our knowledge of these animals. Therefore, the dispersion of marine mammals within Berkeley Sound is reasonably well known, but there is greater uncertainty more widely around the Falkland Islands and offshore. Nonetheless, the available data is sufficient to indicate likely species presence on a seasonal basis. Both the visual and acoustic survey methods described below have recognised limitations which need to be acknowledged. However, the datasets have been used in a complementary manner to provide a better overall picture.

7.4.6.1.2 Pinnipeds

At least, six pinniped species have been recorded in the Falkland Islands in recent years, three of which are known to breed on the islands. These are the:

- South American fur seal (*Arctocephalus australis*),
- South American sea lion (*Otaria flavescens*) (also referred to as the southern sea lion), and
- Southern elephant seal (*Mirounga leonina*).

Two of the species listed above, the fur seal and the sea lion, are known to breed within Berkeley Sound (Thompson *et al.,* 2005; Strange, 1992).

In addition to this, seasonal and vagrant visitors include:

- The Antarctic fur seal (*Arctocephalus gazella*) - seasonal visitor,
- The leopard seal (*Hydrurga leptonyx*) - seasonal visitor, and
- The Ross seal (*Ommatophoca rossii*) - vagrant.

It is possible that other species from the Antarctic or sub-tropics occur as rare visitors or vagrants also, for instance sub-Antarctic fur seal, (*Arctocephalus tropicalis*).

Fur seals and sea lion are eared seals (Otariidae), while the elephant, leopard and Ross seals are earless or 'true seals' (Phocids), which are less agile on land than eared seals, due to their less flexible hind limbs.

7.4.6.2 Marine mammals in the NFB and Sea Lion Field

7.4.6.2.1 Cetacean relative abundance and distribution surveys in the NFB and Sea Lion Field

The Falkland Islands support a diverse range of marine mammal species. Much of the information regarding the status of marine mammals in the Falklands comes from anecdotal reports and records of stranded animals (Otley, 2012; Augé, *et al.,* 2016). However, there have also been a number of at-sea surveys that have collected information on the abundance and distribution of marine mammals. From February 1998 to January 2001, a team of Joint Nature Conservation Committee (JNCC) observers systematically conducted at-sea surveys of seabirds in the waters of the Falkland Islands (White, *et al.,* 2002). Although these surveys and the methodology used were designed specifically to map seabird distribution, all marine mammals observed were recorded.

The results of these surveys have been used to map and describe the distribution of marine mammals in the Falkland Islands (White, *et al.,* 2002). However, the age of the dataset, and inherent limitations associated with at-sea surveys, raise uncertainty as to how representative it is of present-day populations. In recent years, the collection of data by marine mammal observers on seismic vessels (Polarcus, 2011; Geomotive and MRAG, 2011) and the deployment of acoustic monitoring devices (Hipsey, *et al.,* 2013) have added to our knowledge of the distribution and abundance of marine mammals in the region.

Key outcomes from the following surveys are described below:

- Marine mammals recorded during JNCC seabirds at-sea team (SAST) surveys,
- Acoustic monitoring survey of marine mammals in the vicinity of the Sea Lion Field (including a description of the acoustic baseline determined during the survey), and
- Marine mammal observations during seismic surveys in the NFB.

7.4.6.2.1.1 Marine mammals recorded during JNCC SAST survey

Visual surveys were conducted during 91 cruises covering a total area of 20,907 km^2. Figure 7-77 shows the area covered and the total survey effort between 1998 and 2001 in relation to the Sea Lion Development area. Since the end of the JNCC supported project, some additional seabird and marine mammal surveys have been conducted within Falkland Islands waters, using the same methodology. However, these datasets have yet to be collated and analysed as a whole. There is evidence that the number of large cetaceans present around the Falkland Islands (Augé, *et al.,* 2016) and more generally within the South Atlantic (e.g., Zerbini, *et al.,* 2019) have increased since the time of the JNCC surveys.

The JNCC surveys documented 6,550 individuals, comprising 17 species of marine mammal, including 14 species of cetacean and three pinniped 'species'.

Survey effort was generally greatest during the summer months due to longer daylight hours. Survey effort was lowest during the autumn months when the survey bases (Fishery Patrol Vessels, FPVs) were required elsewhere. Figure 7-78 shows the relative occurrence of sightings for each species throughout the year. These data are adjusted to account for the differences in monthly survey effort. Although several species appear to be present throughout the year (for example, sperm whales and Peale's dolphins), others exhibited a marked seasonality (for instance, hourglass dolphin (*Lagenorhynchus cruciger*) and southern bottlenose whale (*Hyperoodon planifrons*)). Baleen whale sightings were relatively infrequent between May and September, which is likely due to the migratory behaviour of these species.

It is possible to broadly describe the seasonal occurrence and general distribution of most species of cetacean. Combined with more recent survey data, a better understanding of Falkland Islands cetacean populations is developing but much remains to be learnt regarding the rarer species.

The three commonest species recorded during the JNCC surveys were all dolphins and accounted for 68.4 % of all cetacean records. The most commonly recorded species was Peale's (644 sightings) with hourglass (150 sightings) and Commerson's dolphins (*Cephalorhynchus commersonii*) (84 sightings) also regularly recorded. Southern right whale dolphins (*Lissodelphis peronii*) were only observed on five occasions. The three most frequently recorded dolphin species each exhibited a distinct spatial pattern of dispersion with very restricted overlap in their ranges (see species accounts below). However, there was evidence of seasonal variation in the dispersion pattern of hourglass dolphin.

The JNCC surveys did not record all cetacean species that are known or believed to occur around the Falkland Islands. A number of species have been found stranded in the Falkland Islands (Otley, *et al.,* 2012; Otley, 2012; Augé, *et al.,* 2016) but were not observed during the JNCC surveys (White, *et al.,* 2002). In addition to seven beaked whale species (Otley, *et al.,* 2012), dusky (*Lagenorhynchus obscurus*) and bottlenose dolphins (*Tursiops truncatus*), spectacled porpoise (*Phocoena dioptrica*), and pigmy right whale (*Caperea marginata*) each have between 1-4 stranding records in the Islands (Otley, *et al.,* 2012). The majority of the stranded species that were not recorded during JNCC surveys were beaked whales which are notoriously difficult to observe at-sea and even more difficult to identify to species level. Apart from southern bottlenose whale, which is reasonably easy to identify, the majority of beaked whales sighted were recorded as 'beaked whale species'. None-the-less, Gray's (*Mesoplodon grayi*) and strap-toothed beaked whales (*M. layardii*) have been positively identified during at-sea surveys in the south-west Atlantic, outside Falkland Islands waters. All 17 of the 'unidentified beaked whales' recorded within Falkland Islands waters during the JNCC surveys were encountered in waters greater than 1,000 m deep to the east of the Islands.

There are a number of limitations of visual surveys, which should be considered whenever using these data. Experienced and skilled observers are required as many species spend considerable periods of time below the surface, where they are undetectable. Sea state and visibility will also affect the reliability of visual surveys. The use of multiple observers and distance sampling survey techniques can increase the reliability of the data collected during dedicated marine mammal surveys, but these techniques were not applied during JNCC surveys. Acoustic methods may help to quantify the abundance of marine mammals, but these methods also have limitations. The vocal range of many of the species encountered within Falkland Islands waters is unknown. The combination of visual and static acoustic monitoring can provide a more rigorous survey methodology through amalgamation of both datasets.

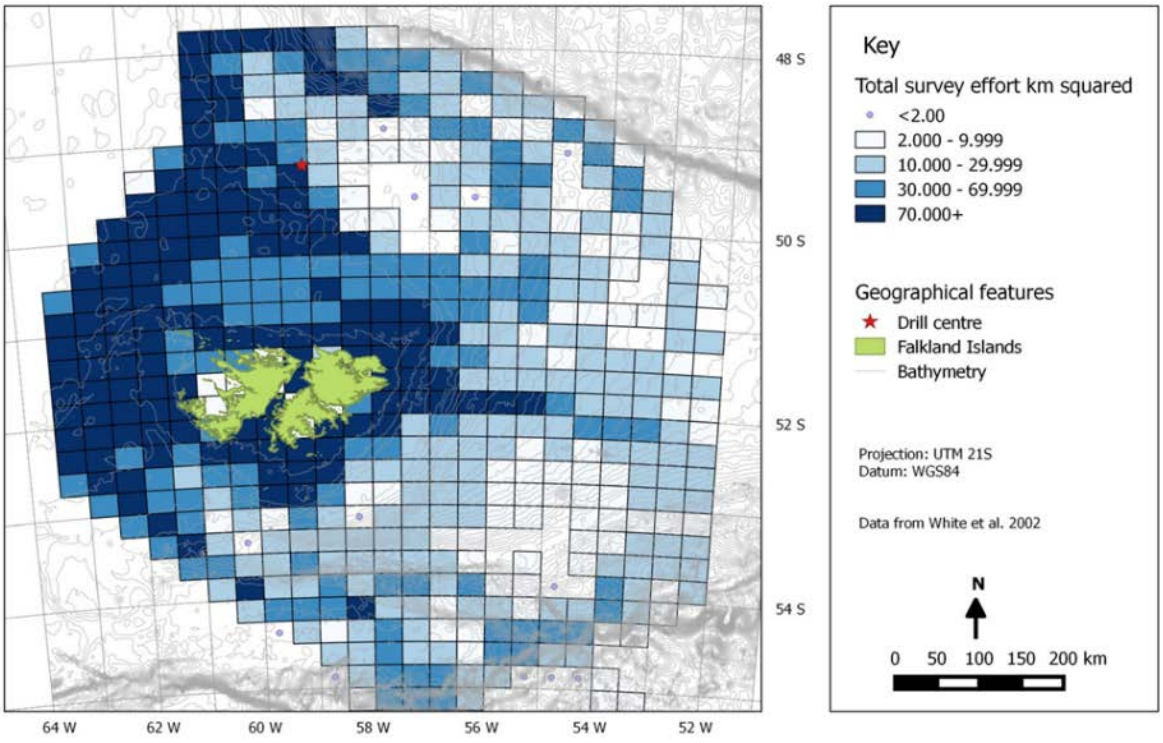

Figure 7-77: Total survey effort achieved during JNCC surveys between February 1998 and January 2001 (White, *et al.*, 2002)

Species	Month											
	Jan	Feb	Mar	Apr	Mar	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Southern Right Whale												
Humpback Whale												
Fin Whale												
Minke Whale												
Sei Whale												
Large Whale Species												
Sperm Whale												
Southern Bottlenose Whale												
Beaked Whale species												
Long-finned Pilot Whale												
Killer Whale												
Commerson's Dolphin												
Peale's Dolphin												
Hourglass Dolphin												
Southern Rightwhale Dolphin												
Fur Seal Species												
South American Sea Lion												
Southern Elephant Seal												

Key: Temporal distribution of marine mammal sightings (standardised for effort), percentage of sightings in each month (Data from White et al. 2002)

Not observed	1-5%	6-10%	11-15%	16-20%	21-25%	26-30%	30-40%	40+ %

Figure 7-78: Relative incidence of marine mammal sightings, by species, adjusted for monthly survey effort. Note that this is based on percentages of sightings for each month *(adapted from White, et al., 2002)*

7.4.6.2.1.2 Acoustic monitoring surveys of marine mammals in the vicinity of Sea Lion Field

From 2012 to 2013, Rockhopper Exploration conducted a one-year static acoustic monitoring programme in the Sea Lion Field, using wideband acoustic recordings to examine the spatial and temporal distribution of resident and transitory marine mammal populations from their vocalisations. Full details of the monitoring survey and results are described in Hipsey *et al.* (2013). The aim of the acoustic survey was to enhance the existing marine mammal dataset collected during the three-year JNCC SAST surveys and more recent seismic surveys, to provide a more comprehensive dataset for assessing potential impacts from future hydrocarbon related development of the area. A persistent, autonomous passive acoustic monitoring programme was selected as it provides an almost continuous survey methodology, which is not hampered by factors restricting the effectiveness of visual surveys, (such as, nightfall, poor visibility due to rain and fog, and long mammal dive periods) and the approach does not require the permanent presence of vessels with trained human observers. Additionally, since sound can travel significant distances underwater, the spatial coverage of a static recording programme typically extends much further than the visual horizon. Acoustic detection ranges vary by species, but low-frequency cetaceans (mostly baleen whales) can be detected tens to hundreds of kilometres away from a suitably sensitive recording instrument (Stafford, *et al.,* 2007). Signals from species vocalising and echolocating at higher frequencies may also be detected but usually at shorter ranges of hundreds to thousands of metres (Zimmer, *et al.,* 2008; Kyhn, *et al.,* 2009).

The one-year acoustic monitoring programme was split into three, four month recording phases, with mooring and recording equipment deployed at the beginning and retrieved at the end of each phase. During each of the three recording phases, five moorings were laid in 413 to 423 m of water, two moorings deployed a deepwater Autonomous Multichannel Acoustic Recorder (AMAR, JASCO Applied Sciences) and three a deepwater variant C-POD cetacean click detector (Chelonia Ltd.).

Although acoustic monitoring provides a number of advantages for marine mammal detection over visual surveys, there are also some limitations. The results of the survey record the number of vocalisations, which implies relative abundance but do not indicate the location or number of animals present. There is no assessment of inter-species, seasonal, sexual or age-related differences in vocalisations, which are likely in species such as baleen whales that rely more on sound for communication than navigation or prey detection. Additionally, there is limited knowledge regarding the range of vocalisations produced by each species. For example, Hipsey, *et al.* (2013) did not record any sei whales, although they are known to be regularly sighted during visual surveys. Since the data was analysed in 2013, the known range of vocalisations produced by Antarctic minke whales has been extended to include what are known as 'bioduck sounds' (Risch, *et al.,* 2014b). Therefore, the acoustic data may contain records of this, and other, species that were previously overlooked. Additionally, the survey only covered a period of one year and further data is required to gain a better understanding of inter-annual variation in cetacean presence / abundance.

The acoustic surveys recorded six species of marine mammal; a summary of the results is presented below in Figure 7-79 to Figure 7-84 and Table 7.27. Presented here is the combined hourly distribution of sound files with marine mammal call detections based on the manual analysis of 5 % of the acoustic data recorded 31 July 2012 to 24 July 2013 within the Sea Lion Development Area for both Autonomous Multichannel Acoustic Recorders (AMARs). Note that AMAR 1 was not operational after 19 March 2013. Grey areas represent hours of darkness.

(Source: Hipsey, et al., 2013)

Baseline underwater sound levels from acoustic monitoring

Ambient noise levels from each AMAR were examined to document baseline underwater sound conditions in the Sea Lion area. Recorded ambient noise levels were generally consistent with a remote, deep continental shelf location in a temperate climate with occasional fishing activity but little or no regular mercantile shipping traffic (Hipsey, *et al.,* 2013). The results from the analysis of both AMARs were generally very similar throughout the recording period, which would be expected given the generally homogenous environmental and bathymetric conditions across the Sea Lion area.

The spectral distribution of sound levels recorded at both AMAR sites suggested a general absence of anthropogenic noise, and that the ambient noise spectrum was heavily influenced by weather conditions. Noise events such as vessels were infrequent and sporadic, except during the second half of February. During this period an increased but small number of detections were made at both AMAR sites (Hipsey, *et al.,* 2013).

7.4.6.2.1.3 Marine mammal observations during seismic surveys in the NFB

In addition to the year-long acoustic monitoring programme in the Sea Lion Field, Marine Mammal Observations (MMO) were conducted as mitigation to minimise the potential impacts of seismic surveys being conducted in the NFB. Seismic surveys were conducted between January 2011 and May 2011 in the NFB (Geomotive and MRAG, 2011), and between v in Licence Block PL001 (Polarcus, 2011), which is adjacent to PL032 (Figure 7-1).

Marine mammal observations by MRAG observers, totalling 1,310 hours and 11 minutes, recorded 142 encounters of 12 different marine mammal species in the NFB (Geomotive and MRAG, 2011).

The concurrent survey within Licence Block PL001 was conducted over a period of 109 days, totalling 794.5 hours of observations. Marine mammals were sighted on 109 occasions, corresponding to 462 individuals, and representing 11 species (Polarcus, 2011).

The MMO data from the seismic surveys provides additional information relating to the presence of marine mammals in the NFB during the austral summer and autumn, which complement the acoustic monitoring data for the Sea Lion Field.

7.4.6.2.1.4 Species-specific summary of cetacean distribution offshore

The following section collates the data from above to provide species-specific accounts of distribution within Falklands waters. A summary of the abundance, distribution, life-cycle and behavioural characteristics of cetacea offshore is provided in Table 7.28 below.

Southern right whale

There is evidence that the population of southern right whales (*Eubalaena australis*) that breed off Peninsula Valdes, Argentina, was increasing, with a doubling time of 10-12 years (Reilly, *et al.,* 2013). However, since 2005 a high calf mortality rate has been observed, which has slowed the population growth and may lead to a decline in the future (IWC, 2014a). The cause of calf deaths is unknown but several factors; including, a decrease in food availability, biotoxins, disease and kelp gull attacks, have been proposed (IWC, 2014a). The migratory behaviour of southern right whales suggests that animals may travel through Falklands waters on passage between their Patagonian spring breeding grounds and summer feeding grounds near South Georgia and Antarctica. However, whaling catches and satellite tracking show that southern right whales utilise the entire SW Atlantic region. They likely forage in pelagic Falkland Islands waters year-round as well as using the area during migrations and, especially, as a wintering destination (for breeding and socialising) in nearshore waters. Satellite telemetry indicated the spatial and temporal extent to which southern right whales aggregate in Falkland Islands waters during winter and supports growing evidence that the region is key habitat for breeding behaviour (Weir, *et al.,* 2024).

The JNCC surveys recorded southern right whales on four occasions over the three-year survey period (White, *et al.,* 2002). Southern right whale up-calls were recorded in the Sea Lion area on 11 different days during the year-long monitoring period (Hipsey, *et al.,* 2013). Individual southern right whales were also recorded by the MMO during seismic surveys, with 10 individuals sighted in PL001 and four individuals during the wider NFB survey (Geomotive and MRAG, 2011; Polarcus, 2011). These results suggest that this species may be more common now than recorded by JNCC visual surveys, with animals present within the NFB in low numbers throughout most of the year. The migratory behaviour of southern right whales suggests that there will be peaks in numbers as these animals travel between their Patagonian spring breeding grounds and summer feeding grounds near South Georgia and Antarctica.

During the winter of 2017, an unusually high number of southern right whales was recorded in coastal waters around East Falkland (Section 7.4.6.3.1.1). Though it should be noted that this is when empirical data collection started, which may account for some bias in the numbers recorded.

Blue whale

Historically, blue whales (*Balaenoptera musculus*) would have been present within Falkland Islands waters. At present they are sighted extremely rarely (Augé, *et al.,* 2016; Costa and Cazzola, 2018) within Falklands waters. Whaling in the Atlantic sector of the Southern Ocean killed many thousands of blue whales (Moore, *et al.,* 1999). Although there is anecdotal evidence that the number of encounters with blue whales are increasing, the paucity of blue whale sightings in the wider Scotia Sea indicates that the population of these animals has not yet recovered.

Fin whale

Acoustic monitoring recorded fin whales (*B. physalus*) in the Sea Lion area during late August 2012, and consistently in late winter and early spring (August and September) (Hipsey, *et al.,* 2013). Detections stopped abruptly in April and did not resume before the end of the monitoring in July. Fin whales were not sighted in August and October during the JNCC surveys (White, *et al.,* 2002). Five individuals were observed in September but most sightings occurred from November to January (White, *et al.,* 2002). Fin whales were sighted by MMOs during both of the seismic surveys in the NFB, with largest numbers (12 individuals) recorded in waters adjacent to but west of the Sea Lion area (Geomotive and MRAG, 2011).

The acoustic monitoring programme recorded fin whales as present in the Sea Lion area from September until March, suggesting that past visual surveys (White, *et al.,* 2002) underestimated their occurrence north of the Falkland Islands, or, that there is inter-annual variation in the occurrence of

fin whales in this area, or, that the number of animals present has increased since 2002. In the nearby waters of the Scotia Sea (south-east of the Falkland Islands), large numbers of fin whales have been observed in recent years (A. Black, *pers. obs.*). However, most of these sightings are offshore and the exact location of these animals can show considerable inter-annual variation, which is likely to be linked to the distribution of food resources. Fin whales have been detected acoustically in the Scotia Sea and off the western Antarctic Peninsula starting in February and peaking in late summer and the autumn (Širović, *et al.,* 2009). Large aggregations of feeding fin whales were also observed in the autumn (March–April 2012) off Elephant Island at the tip of the Antarctic Peninsula (Burkhardt and Lanfredi, 2012; Herr, *et al.,* 2022).

The presence of these animals in waters to the south of the Falklands is seasonal and therefore it is reasonable to assume that many migrating animals will pass through Falkland Islands waters. The peak in Falklands recordings in March followed by the cessation of all detections could therefore indicate a pulse of migrating whales from those feeding grounds.

Fin whales have recently been downgraded to 'Vulnerable' on the IUCN Red List, due to increasing population size, and are also afforded conservation status and management under the Convention on International Trade in Endangered Species (CITES) and the Convention on the Conservation of Migratory Species of Wild Animals (CMS).

Sei whale

JNCC surveys recorded 45 sei whales (*B. borealis*). Most of these were off the east coast of the Islands in relatively shallow inshore waters (White, *et al.,* 2002). Sei whale was the most frequently sighted, and third most abundant, species recorded by the MMO during the PL001 seismic survey with 67 individuals recorded (Geomotive and MRAG, 2011). During the NFB seismic survey, they were the third most frequently sighted and fourth most abundant, species recorded (Polarcus, 2011). Conversely, analysis of the acoustic data from the Sea Lion area did not contain any confirmed sei whale calls. However, it is believed that this is due to the potential overlap in calls from sei and fin whales (Watkins, 1981; Baumgartner, *et al.,* 2008) and it is possible that the fin whale detection records included some sei whale calls (Hipsey, *et al.,* 2013). With the recent PAM work conducted in Berkeley Sound by Cerchio and Weir (2022) these data could be used to determine whether sei whales were detected in the NFB Hipsey *et al.* (2013) study.

For many years large numbers of sei, and possibly fin, whales have been observed in inshore waters around the Falkland Islands (White, *et al.,* 2002; Otley, 2012; Augé *et al.,* 2016; Cerchio and Weir, 2022). These animals are only present on a seasonal basis and are likely to pass through the NFB during their migration. Recent projects have surveyed the distribution of sei whales, and other cetaceans, in inshore waters (Thomson and Munro, 2014; Weir, 2017; Costa and Cazzola, 2018; Weir, *et al.,* 2018; Weir, *et al.,* 2021). The preliminary results and anecdotal observations indicate that sei whales are frequently encountered in inshore waters during the summer and autumn months (see Section 7.4.6.3.1 for further details). Sei whales are listed as 'Endangered' on the IUCN Red List and are also afforded conservation status and management under CITES and CMS.

Minke whale

Antarctic minke whales (*B. bonaerensis*) were encountered widely within Falklands waters and recorded throughout the year, although most animals were recorded between September and April (White, *et al.,* 2002). Minke whales were recorded during both of the marine mammal surveys conducted during seismic operations in the NFB (Geomotive and MRAG, 2011; Polarcus, 2011) but were not detected by acoustic surveys (Hipsey, *et al.,* 2013). The lack of minke whales in the acoustic record is unexpected but could be due to poor knowledge of the vocal range of this species in the South Atlantic at the time of the analysis. This interesting as Risch *et al.* (2014a) regularly detected minke whales on PAM as they migrate in the north Atlantic. In addition, at least one stranding in the

Falklands has been genetically attributed to *B. acutorostrata* (common minke whale) (C. Weir, *pers. comm*.) and it is likely that both species utilise Falklands waters.

Humpback whales

Humpback whales (*Megaptera novaeangliae*) have been infrequently recorded within Falklands waters. JNCC surveys encountered seven animals in Patagonian Shelf waters, all between October and March. Acoustic monitoring and marine mammal observations from seismic vessels did not record humpback whales in the NFB.

Satellite tracking (Zerbini, *et al.,* 2006) and photo-identification indicate that animals from the population breeding off the coast of Brazil migrate to feed off South Georgia and the South Sandwich Islands in the summer months. Satellite tracks and the lack of sightings of these animals suggest that few of these whales pass through Falklands waters during this migration.

Sperm whale

Sperm whales (*Physeter macrocephalus*) were observed on 21 occasions in the JNCC surveys, the highest number of sightings occurring in October. About half of the sightings occurred in an area just north of the Sea Lion area. Although this seems to be a small number of sightings over a three-year survey, the distribution of the records indicates that animals are present in the deeper waters of the FOCZ year-round. A single sperm whale was observed during the MMO in PL001, and four individuals were observed during MMO in the NFB seismic survey (Geomotive and MRAG, 2011; Polarcus, 2011). The low number of sightings is likely to be due to the behaviour of the animals, which spend much of their time below the surface, and the limited survey effort in their preferred habitat type. Nevertheless, because sperm whales echolocate almost continuously while diving, and dive for extended periods of time, acoustic monitoring is a powerful survey method for this species (Whitehead, 2003). Indeed, Hipsey *et al.* (2013) found sperm whales were the most commonly recorded species during their year-long study. Detections occurred throughout the acoustic monitoring period without any obvious seasonal trend.

Sperm whales are notorious for depredating Patagonian toothfish in the local longline fishery (Yates and Brickle, 2007). All the available evidence suggests that sperm whales, likely to be mature males, are present within the deeper waters of the Falklands Conservation Zones throughout the year.

Southern bottlenose whale (beaked whale)

The JNCC surveys recorded southern bottlenose whales (*Hyperoodon planifrons*) between September and February. All encounters occurred in waters over 1,000 m deep. This species was apparently absent from Falklands waters in the winter months. It was not detected during acoustic monitoring and only a single animal was observed during seismic operations (Geomotive and MRAG, 2011).

Nonetheless, sightings of *Hyperoodon* have occurred in waters to the north, northeast and east of the Falkland Islands (White, *et al*., 2002).

Other (unidentified) beaked whales

Beaked whales (namely *Mesoplodon, Ziphius and Berardius* spp.) are notoriously difficult to identify at-sea and none of the 15 animals recorded during JNCC surveys were specifically identified. Nonetheless, stranding records indicate that a number of beaked whale species could be present within Falkland Islands waters (Otley, *et al.,* 2011). All sightings during the JNCC surveys occurred in waters over 1,000 m deep, with the majority coming from the region of the Falkland Trench to the south-east of the Islands. However, Otley (2012) suggests that in the Falkland Islands, beaked whales also use shallower waters while Filatova *et al.* (2024) suggest that beaked whales can specialise in the use of coastal habitat (e.g., depths <300m).

Killer whale

The JNCC surveys recorded seven killer whale (*Orcinus orca*) sightings over three years, primarily on the Patagonian Shelf, (White, *et al.,* 2002). Killer whales were detected in the Sea Lion area on ten different days during the year-long acoustic monitoring period, with seven of the records occurring between July and mid-October (Hipsey, *et al.,* 2013). Killer whales were observed during the PL001 and NFB seismic surveys on two and one occasion respectively (Geomotive and MRAG, 2011; Polarcus, 2011). Killer whales are known to regularly depredate longlines in the Falkland's Patagonian toothfish fishery when vessels are fishing in the north of the FOCZ, relatively close to the Licence Blocks (Yates and Brickle, 2007). Observers on fishing vessels recorded killer whales only to the north-east of the Islands despite a considerable amount of fishing in other areas throughout the year (Yates and Brickle, 2007). The evidence suggests that a small resident population of killer whales may occur in the region of the shelf-break to the north of the Falkland Islands.

Satellite tracking indicates that Type B killer whales migrate just east of the Falkland Islands when travelling between the Antarctic Peninsula and sub-tropical waters of the South Atlantic (Durban and Pitman, 2012). These animals appear to travel rapidly through the region, but they could account for some of the acoustic detections and sightings.

Long-finned pilot whale

Long-finned pilot whale (*Globicephala melas*) sightings occurred primarily between February and September during the JNCC surveys (White, *et al.,* 2002). Acoustic detections from the Sea Lion area also indicated the presence of pilot whales during the austral autumn and winter, with the majority of detections occurring from mid-February until late August (Hipsey, *et al.,* 2013). Pilot whales were recorded on approximately 35 days throughout the year-long monitoring period (Hipsey, *et al.,* 2013). Several small groups of pilot whales were also observed during the seismic survey MMO, with a total of 88 individuals over three sightings in PL001 and 75 individuals over four sighting occasions in the NFB survey (Geomotive and MRAG, 2011; Polarcus, 2011). In contradiction to most survey results, while observing on fishing vessels working in the deeper waters of the FOCZ, pilot whales were observed on a daily basis in large numbers during the summer but rarely during the winter months (A. Black, *pers. obs.*).

The large number of pilot whale strandings on the Falkland Islands (Otley, 2012) suggests that there is a sizeable population associated with Falklands waters. This species is regularly sighted in large groups from fishing vessels operating over the continental slope (A. Black, *pers. obs.*). White, *et al.* (2002) often recorded other species of cetacean in association with pilot whales, especially hourglass dolphins and to a lesser extent southern right whale dolphins.

Peale's dolphin

Peale's dolphin (*Lagenorhynchus australis*) was the most commonly recorded marine mammal species during the JNCC survey period with 1,952 animals recorded during 644 encounters. Peale's dolphins were almost exclusively restricted to Patagonian Shelf waters and were only regularly recorded in waters deeper than 200 m to the south-west of the Falkland Islands (Figure 7-85). Peale's dolphins were regularly recorded at the western boundary of the Falklands EEZ, a strong indication that the distribution of the species is continuous between the Falkland Islands and mainland South America. However, genetic sampling from inshore waters indicates little genetic mixing between the Falklands and South American populations (Costa and Cazzola, 2018). There was no clear evidence of any seasonal changes in the abundance, distribution or behaviour of these animals.

Peale's dolphin was also the most frequently recorded marine mammal on both seismic vessel surveys (Geomotive and MRAG, 2011; Polarcus, 2011).

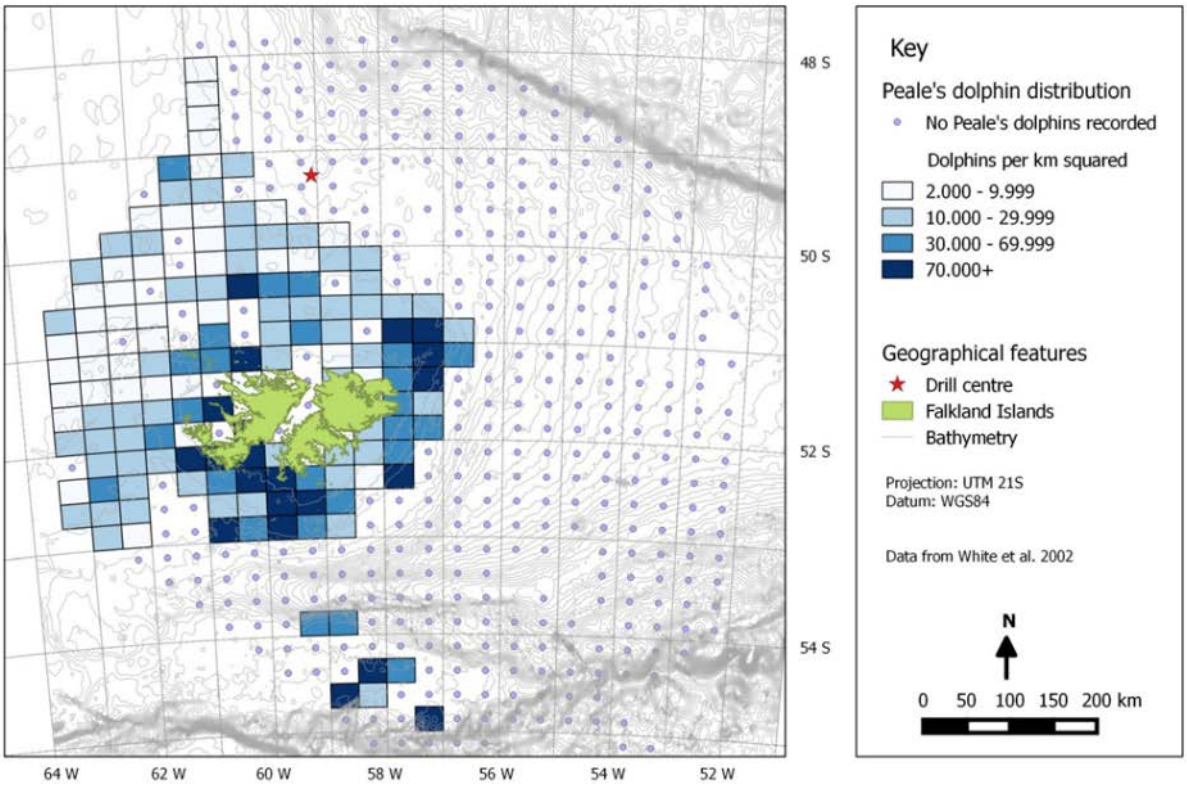

Figure 7-85: Peale's dolphin distribution recorded during JNCC surveys, all months

Hourglass dolphin

A total of 150 sightings of 792 hourglass dolphins (*L. cruciger*) was recorded during the JNCC surveys. Between September and February, hourglass dolphins were recorded frequently during surveys in oceanic waters. Outside this period, hourglass dolphins were only rarely recorded, suggesting that they occur seasonally within Falklands waters. The majority of hourglass dolphin records were in continental shelf slope and oceanic waters (Figure 7-86). The JNCC surveys clearly identified spatial segregation between Peale's and hourglass dolphins, with virtually no overlap in the ranges of these two species (White, *et al.,* 2002). Hourglass dolphins were also one of the most frequently recorded species from seismic vessels (Geomotive and MRAG, 2011; Polarcus, 2011).

The acoustic monitoring survey recorded an unidentified odontocete species (toothed whales, killer whales and dolphins), which could not be definitively identified to species level (Hipsey, *et al.,* 2013). The occurrence of the odontocete calls closely matched the dolphin C-POD detections and the click characteristics and habitat preferences suggest the hourglass dolphin as the potential source (Hipsey, *et al.,* 2013).

It is likely that hourglass dolphins would occur in the deeper waters surrounding the Sea Lion area.

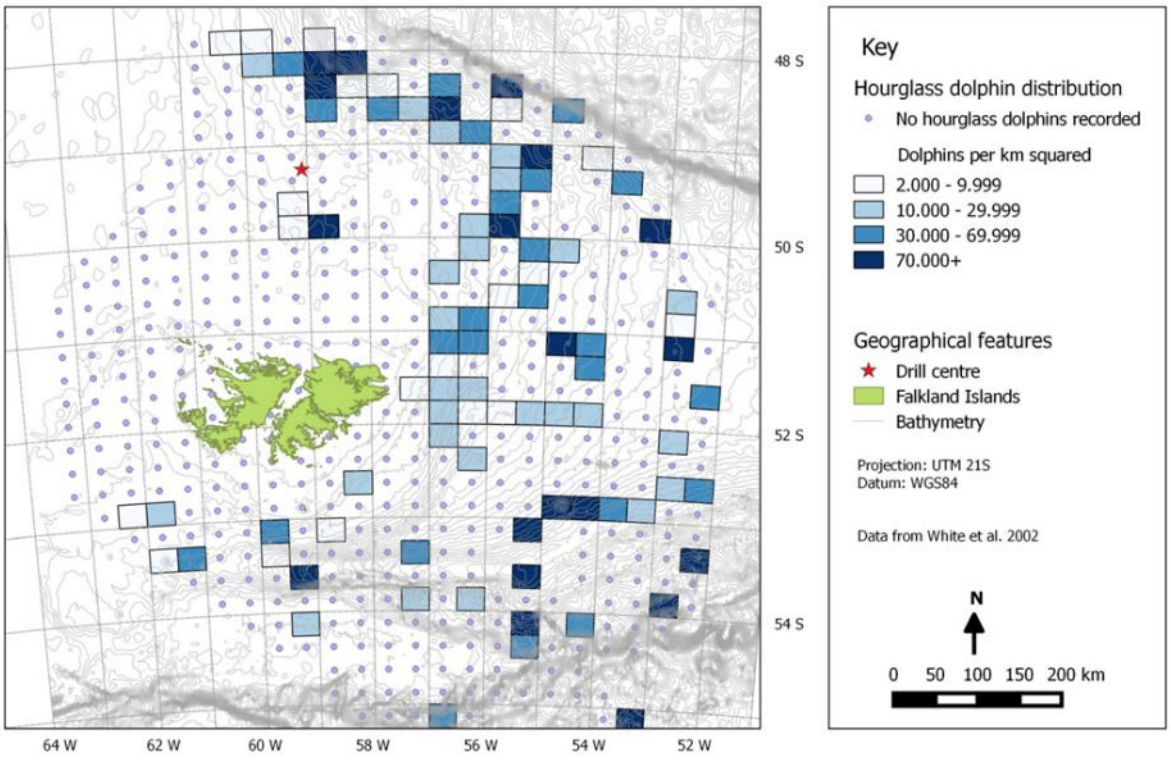

Figure 7-86: Hourglass dolphin distribution recorded during JNCC surveys, all months

Commerson's dolphin

Commerson's dolphins (*Cephalorhynchus commersonii*) were recorded during JNCC surveys in every month of the year except May. A total of 276 animals was recorded in 84 encounters. All records of Commerson's dolphins were from either partially enclosed or coastal waters in the immediate vicinity of the Falkland Islands (Section 7.4.6.3.1.5).

Southern right whale dolphin

Southern right whale dolphins (*Lessodelphis peronii*) were only recorded on five occasions during JNCC surveys, all in waters over 200 m deep. However, the tendency for this species to occur in large groups resulted in a total of 231 animals recorded. Over half of these were in a single group of 120 animals, the largest group of any dolphin species recorded during surveys. On all five occasions when southern right whale dolphins were recorded they were in the company of long-finned pilot whales.

7.4.6.2.2 Pinniped abundance and distribution surveys in the NFB

The presence of pinnipeds in the NFB was recorded during:

- The JNCC SAST surveys described above,
- Acoustic monitoring within the Sea Lion Field, and
- Using satellite tracking studies.

7.4.6.2.2.1 Species-specific pinniped distribution and abundance in the NFB

The following describes the distribution and abundance of pinniped species in the NFB.

South American sea lion

Sea lions (*Otaria flavescens*) were recorded in all months but the majority of records came from inshore waters (White, *et al.,* 2002). Sea lions were also recorded in low numbers during surveys from seismic vessels (Geomotive and MRAG, 2011; Polarcus, 2011).

Tracking of adult female sea lions indicates a high degree of specialisation regarding foraging strategy, which is consistent over a number of years. Although largely restricted to Patagonian Shelf waters, adult female sea lions displayed either inshore or offshore strategies, with offshore foragers consistently tracked to the edge of the Patagonian Shelf (waters of approximately 200 m depth). Telemetry and diet data indicate a further specialisation in animals foraging offshore, with individuals displaying either benthic foraging or a mixture of benthic and pelagic foraging (Baylis, *et al.,* 2015).

The predicted distribution, from tracking data, is shown in Figure 7-87, which supports earlier results of tracking and at-sea observations.

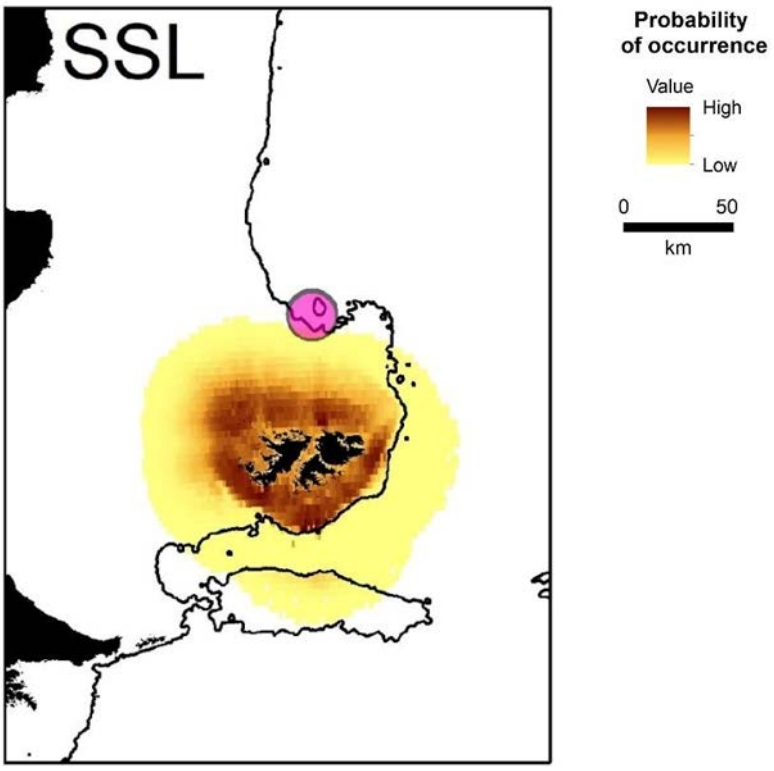

Figure 7-87: South American sea lion, predicted habitat use (predicted presence) for sea lions breeding on the Falklands from the available biotelemetry and biologging data. The pink dot represents the drill centre *(adapted from Baylis, et al., 2019a)*

Fur seal species

Fur seals (*Arctocephalus gazella and A. australis*) were the most numerous pinniped species recorded during JNCC surveys. Although the observers were aware that South American and Antarctic fur seals were both present, it was not possible at sea to reliably identify all fur seals to species level and therefore all fur seals were recorded as 'fur seal species'. They were recorded in all months but there was a distinct peak in the number recorded during the winter. It is thought that this marked an influx of Antarctic fur seals into Falklands waters from the South Georgia breeding population, a hypothesis that is supported by tracking data (Staniland, *et al.,* 2012).

Adult female fur seals from North Fur Island, Volunteer Rocks and Bird Island have been tracked during mid to late lactation (winter and spring) when females regularly alternate between foraging at sea and provisioning dependent offspring onshore (Figure 7-88a & b respectively). Throughout the tracking studies, fur seals rarely travelled beyond the edge of the Patagonian Shelf. During late lactation female fur seals appear to disperse more widely, travelling as far as the South American coast, but remain over the Patagonian Shelf (Baylis, *et al.,* 2018).

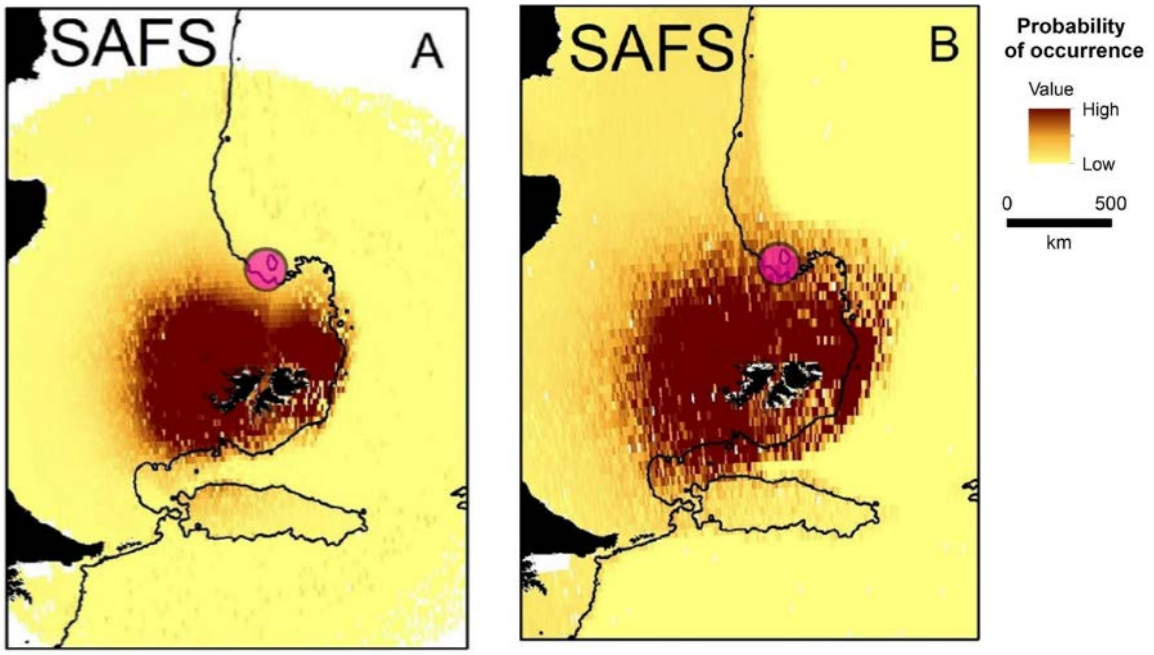

Figure 7-88: South American fur seal, predicted habitat use for breeding on the Falklands from the available biotelemetry and biologging data. A = winter and B = spring. The pink dot represents the area of the drill centres *(adapted from Baylis, et al., 2019b)*

Southern elephant seal

Southern elephant seals (*Mirounga leonina*) spend the majority of the time below the surface, and therefore visual surveys are unlikely to accurately record the distribution of the species. White *et al.* (2002) recorded 13 southern elephant seals and no other visual or acoustic surveys have recorded this species. Most of the records were clustered along the shelf-break to the north of the Islands.

Between 2009 and 2011, 23 female elephant seals were satellite tracked from Sea Lion Island (Galimberti and Sanvito, 2012), the main breeding location for elephant seals in the Falkland Islands. The resulting tracks indicate that the majority of foraging trips of the animals tracked are to the south of the Falklands (some extending into the South Pacific), although three animals were tracked to the shelf-break to the north of the Falkland Islands (Figure 7-89).

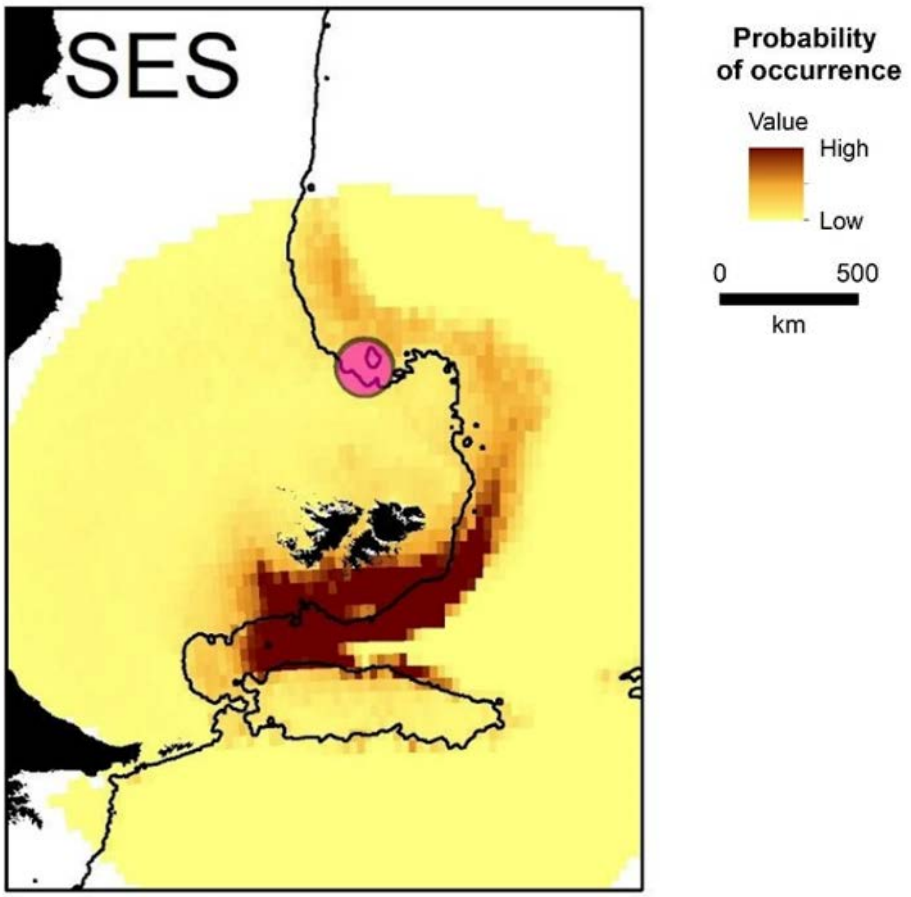

Figure 7-89: Southern elephant seal, predicted habitat use for breeding on the Falklands from the available biotelemetry and biologging data. The pink dot represents the area of the drill centres ***(adapted from Baylis, et al., 2019b)***

Leopard seal

Leopard seals (*Hydrurga leptonyx*) accounted for the greatest number of detections throughout the acoustic monitoring study with the majority of leopard seal detections occurring in March and April, and all detections concentrated in late austral summer and autumn (Hipsey, *et al.,* 2013). In contrast, there were no sightings of this species during the JNCC surveys or by the MMO on the seismic vessels in the NFB (White, *et al.,* 2002; Geomotive and MRAG, 2011; Polarcus, 2011). The characteristics of the recorded calls indicate the calling animals were sexually immature males (Hipsey, *et al.,* 2013). During the summer, leopard seals occur in the Antarctic pack ice and disperse northward with the advancing pack during the winter. Leopard seals are known to be more numerous around sub-Antarctic islands, such as South Georgia, in the winter months (Walker, *et al.,* 1998; Rodríguez, *et al.,* 2003). In the Falklands, individual leopard seals are seen from time-to-time but they are not regarded as anything more than occasional visitors (Strange, 1992). Records elsewhere in the world indicate that this species, particularly young males, have a tendency to wander far from their Antarctic breeding grounds (Aguayo-Lobo, *et al.,* 2011; Rodríguez, *et al.,* 2003; Hamilton, 1939). Cerchio and Weir (2022) suggest that the sounds recorded and attributed to leopard seals could be sei whales based on their passive accoutic monitoring work in Berkeley Sound. However this will warrants further investigation.

7.4.6.2.3 Summary of cetaceans in the NFB

Table 7.28 provides a summary of cetacean abundance in the NFB, distribution, life-cycle and behavioural characteristics.

Table 7.28: Summary of cetaceans in the NFB and Sea Lion Field

Species	IUCN status	Present in the Sea Lion area	Global distribution	Foraging strategy	Auditory type	Behaviour
Southern right whale	LC	✓ Spring | Summer | Autumn | Winter 	Circumpolar in the southern hemisphere[1]	Surface skim-feeding	Low frequency	Slow lumbering swimmers but can be acrobatic, breaching clear of the water or lifting the tail clear of the water. The southern right whale breeds between July-November in Península Valdés (Argentina) and Santa Catarina (Brazil) (Danilewicz, *et al*., 2016; Mandiola, *et al*., 2019; Renault-Braga, *et al*., 2022) and migrates south in the summer. In recent decades, high calf mortality has been reported in Argentina (Cooke and Zerbini, 2018). In the Falkland Islands, regionally important aggregations of southern right whales (including for mating) occur during winter in coastal waters (Weir and Stanworth, 2020). Recently, satellite tags have been deployed on Southern right whales in the Falkland Islands e.g., (Weir, 2022).
Blue whale	EN	✓ Although not recorded in the Sea Lion area during surveys, blue whales are known to be present in very low numbers in the region.	Found in all oceans in low numbers	Lunge feeding	Low frequency	Migrate between low latitude wintering grounds and high latitude feeding grounds in summer
Fin whale	VU	✓ Spring | Summer | Autumn | Winter 	Found in all oceans of the world	Lunge feeding	Low frequency	Capable of swimming at speeds of 19 knots. Movements poorly understood but most frequently encountered offshore or where deep water is found near the coast (White, *et al.,* 2002). Seen in small groups many of

Species	IUCN status	Present in the Sea Lion area	Global distribution	Foraging strategy	Auditory type	Behaviour
						which may be present within a small area (tens of km^2)
Antarctic minke whale	NT	✓ Spring / Summer / Autumn / Winter	Southern Hemisphere distribution	Lunge feeding	Low frequency	Movements poorly known but some populations appear to be resident year-round. It is acknowledged that common Minke whales likely utilise Falklands waters too
Sei whale	EN	✓ The most abundant large whale seen in inshore waters also frequently sighted offshore. Spring / Summer / Autumn / Winter	Found in all oceans, sub-Antarctic waters are favoured feeding grounds in summer[2]	Lunge feeding	Low frequency	Dives more regularly than most large whales, surfacing at approximately one-minute intervals. One of the fastest of the great whales, sei whales swim a few metres below the surface. As with all whale species, progress can be followed by 'fluke prints' left on the surface in the animal's wake. Recently, satellite tags have been deployed on Sei whales in the Falkland Islands and highlights the importance of coastal nearshore waters (https://falklandsconservation.com/sei-whale-tracking/).
Humpback whale	LC	✓ Although not recorded in the Sea Lion area during surveys, humpback whales are known to be present in low numbers in the region. Spring / Summer / Autumn / Winter	Found in all oceans of the world	Lunge feeding	Low frequency	A population breeding off the coast of Brazil is thought to migrate to feed off the South Sandwich Islands in the summer months. Recent boat-based surveys in the Falkland Islands highlight annual variability in occurrence of Humpback whales (Weir, 2022).
Sperm whale	VU	✓ Spring / Summer / Autumn / Winter	Found from the Arctic to the Antarctic	Deep diving	Mid frequency	Sperm whales are encountered in the deeper water of the Falkland Islands throughout the year (White, *et al.,* 2002). All the animals present are males that

Species	IUCN status	Present in the Sea Lion area	Global distribution	Foraging strategy	Auditory type	Behaviour
						periodically migrate to warmer waters to breed; however, these movements are not coordinated.
Beaked whales (Southern bottlenose whale)	LC	✓ Spring / Summer / Autumn / Winter	Found throughout the Southern Ocean	Deep diving (some evidence for shallow water too)	Mid frequency	Present in the deeper waters of the Falklands during the spring and summer months (White, *et al.,* 2002). A number of other species of beaked whale are present on the basis of stranding data, but these animals are rarely seen (Otley, *et al.,* 2011).
Long-finned pilot whale	LC	✓ Spring / Summer / Autumn / Winter	High latitudes in the northern and southern hemisphere	Deep diving	Mid frequency	Can be encountered in large groups (100 + animals). There appears to be seasonal changes in distribution within Falklands waters, but movements poorly understood (White, *et al.,* 2002).
Killer whale	DD	✓ Spring / Summer / Autumn / Winter	Found in all oceans of the world.	Shallow / deep dives	Mid frequency	Killer whales are known to pass through Falklands waters on rapid transit from Antarctic Peninsula to sub-tropical waters (Durban and Pitman, 2012). Additionally, there are likely to be resident populations. Seen year-round from longline vessels fishing to the north-east of the Sea Lion Field.
Commerson's dolphin	LC	X	Only southern South America, the Falklands and Kerguelen	Shallow dives	High frequency	Only observed in coastal waters (Franchini, *et al.,* 2020).
Peale's dolphin	LC	✓ Largely restricted to the Patagonian Shelf (waters <200 m).	Restricted to southern South America and	Shallow dives	High frequency	Thought to be resident with no discernible seasonal movements detected in the survey data. More numerous inshore but found

Species	IUCN status	Present in the Sea Lion area				Global distribution	Foraging strategy	Auditory type	Behaviour
		Spring	Summer	Autumn	Winter	the Falkland Islands			across the Patagonian Shelf (waters <200 m) (Franchini, *et al.,* 2020). Very enthusiastic bow-riders.
Hourglass dolphin	LC	✓ Most likely dolphin species to be encountered in the Sea Lion Field.				Found throughout the Southern Ocean	Shallow dives	High frequency	Thought to undergo seasonal movements, migrating northwards in winter and south in summer. Often seen accompanying other cetaceans, especially long-finned pilot whales.
		Spring	Summer	Autumn	Winter				

[1] **Post-consultation note (July 2025):** Studies carried out by Falklands Conservation between 2017 and 2025 (and ongoing) indicate that regionally important aggregations of southern right whale are now documented during winter in coastal waters, particularly along the north and northeast coast of East Falkland (Weir and Stanworth, 2020; Weir, 2024). These surveys indicate that this population comprises >1% of the global population (Weir, 2024).

[2] **Post-consultation note (July 2025):** Studies carried out by Falklands Conservation between 2017 and 2025 (and ongoing) indicate that aggregations of sei whales in the Falkland Islands nearshore waters comprise >0.1% of the global population.

Key: Relative abundance of marine mammals within Falklands waters

Not recorded	Low	Moderate	High	Very High

7.4.6.3 Marine mammals in and around Berkeley Sound

7.4.6.3.1 Cetacean abundance and distribution surveys in and around Berkeley Sound

In recent years, several projects have focused on studying inshore cetaceans.

- A series of coastal bird surveys within Berkeley Sound also recorded marine mammals (SAERI, 2016; 2017; 2018; 2019),
- Anecdotal observations of cetaceans around the Falklands have been collated to give an indication of trends in species abundance.
- Falklands Conservation surveys:
  - BEST sei whale survey (Weir, 2017), and
  - Dedicated surveys of sei whales, and other cetaceans, in Berkeley Sound (Franchini, *et al.,* 2020; Weir and Stanworth, 2020).
- The 'Dolphins of the kelp' (DOKE) project focused on Commerson's and Peale's dolphins but also recorded other cetaceans within Berkeley Sound and elsewhere around the Falklands (Costa and Cazzola, 2018), and
- Tracking of fur seals from Volunteer Rocks and sea lions from colonies to the north and south of Berkeley Sound (Baylis, *et al.,* 2015), which help to determine the use of inshore waters by these animals.

These sources supersede the marine mammal data collected in or adjacent to Berkeley Sound by JNCC SAST surveys (1998 - 2004), although this data still helps to provide historical perspective with detail provided below.

The relevant results from the above are summarised below with the data collated into species-specific summaries in Section 7.4.6.3.1.5.

7.4.6.3.1.1 Cetaceans recorded during Berkeley Sound coastal bird surveys

The Berkeley Sound coastal surveys are designed to record animals along the coastal fringe, within 100 m of the shoreline, and therefore are not specifically designed to record cetaceans. Although Commerson's dolphin, Peale's dolphin and sei whales were recorded, these sightings add little to the findings of dedicated cetacean projects (see Sections 7.4.6.3.1.3 and 7.4.6.3.1.4 below). The exception, however, was the winter of 2017, which saw an influx of southern right whales into coastal waters off the east coast of the Falklands. Animals had been present for a number of weeks prior to the survey in late July and were recorded on several different days in the outer Sound (Figure 7-90). Southern right whales have also been recorded by several other independent surveys during the winter of 2017. It is important to note that empirical data on whales started in 2017 (see Sections 7.4.6.3.1.3 and 7.4.6.3.1.4 below). It is acknowledged that whale populations have increased over time since the cessation of whaling. However, it is not possible to determine whether abundances were similar prior to the commencement of the BEST Sei whale project that commenced in 2017 (Weir, 2017).

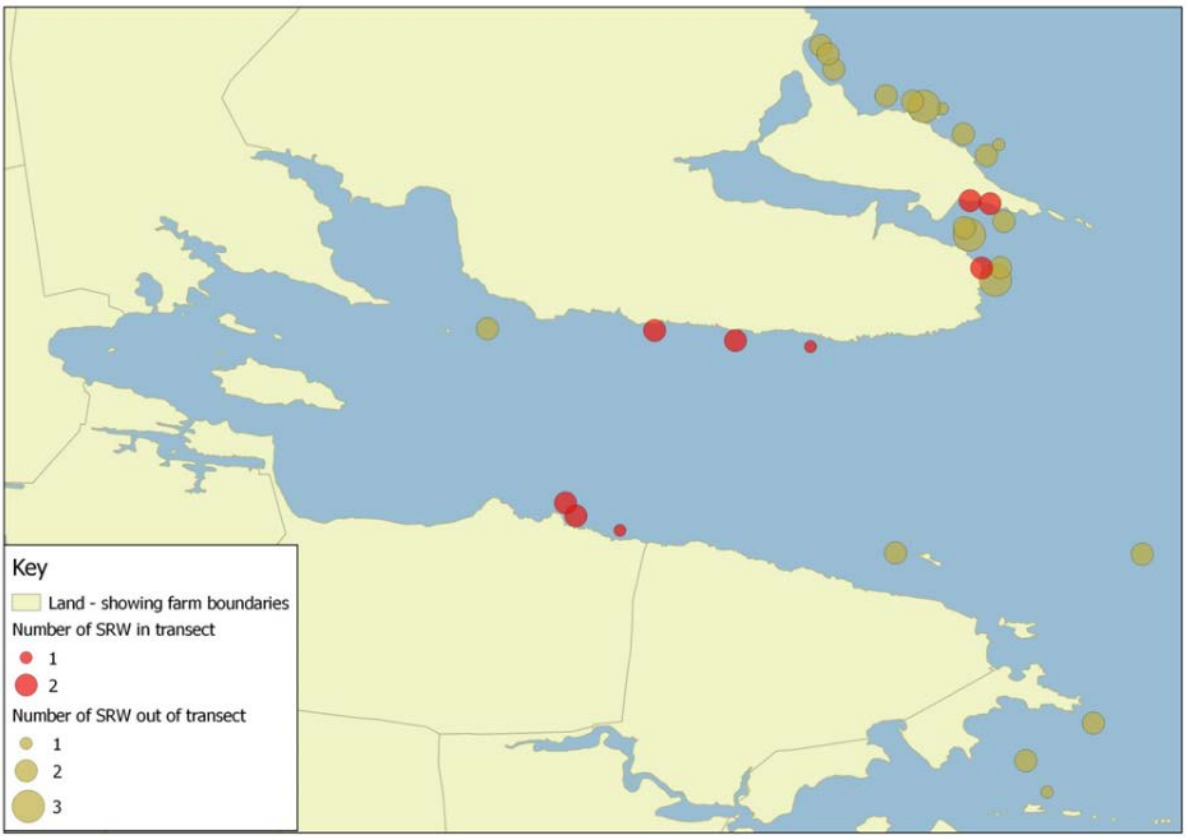

Figure 7-90: The distribution of southern right whale records during the winter 2017 survey

7.4.6.3.1.2 Anecdotal inshore cetacean sightings

In order to inform the development of the Falkland Islands Marine Spatial Plan, a project to record local ecological knowledge regarding large cetacean sightings culminated in 2016 (Frans and Augé, 2016). The results highlight a clear increase in numbers of whales sighted, from no observations in the 1970s to 350 observations between 2010 and 2015 (mostly of IUCN 'Endangered' sei whales and IUCN 'Vulnerable' fin whales) for similar observer effort.

Although seen throughout the inshore waters of the Falklands (see Thomson and Munro, 2014; Costa and Cazzola, 2018; Weir, 2018), several areas of high sighting density in recent years (since the 1990s) were identified, including Berkeley Sound (Figure 7-91a). There is some indication however, that some areas of high sighting density reflect the distribution of observers rather than the absolute density of the cetaceans in these areas. For example, the hotspot in the middle of Falkland Sound is on the route of the ferry between East and West Falklands; the area near Stanley is adjacent to the only major centre of human habitation and the focus of shipping activity.

It is difficult to attribute observer effort to anecdotal observations. Frans and Auge (2016) asked contributors to the frequency of visits to an area on a decadal basis, which were scored from 1 to 5 (Once to Frequent; see Table 7.29). These scores were then averaged for all observers, which has produced some unusual results as areas of high activity have lower average frequency scores than anticipated (Figure 7-91b).

Table 7.29: Descriptions of visits and sightings categories ***(Source: Frans and Auge, 2016)***

Frequency	Effort Value	Category	Description
Of visits (per decade)	1	Once	One instance or specific event per decade
	2	Few	2 - 5 visits per decade
	3	Occasional	One or a few visits per year
	4	Often	Visiting over long periods (<6 months) per year
	5	Frequent	Residing or passing through the location >6 months per year
Of sightings (across visits)	-	Once	One sighting in a given decade, or for a specific visit
		Seldom	Rare sightings (e.g., 2-3 sightings across visits)
		Occasional	Seen for <1/2 the visit frequency
		Often	Sighting for >1/2 the visit frequency
		Always	Sighting at almost each visit

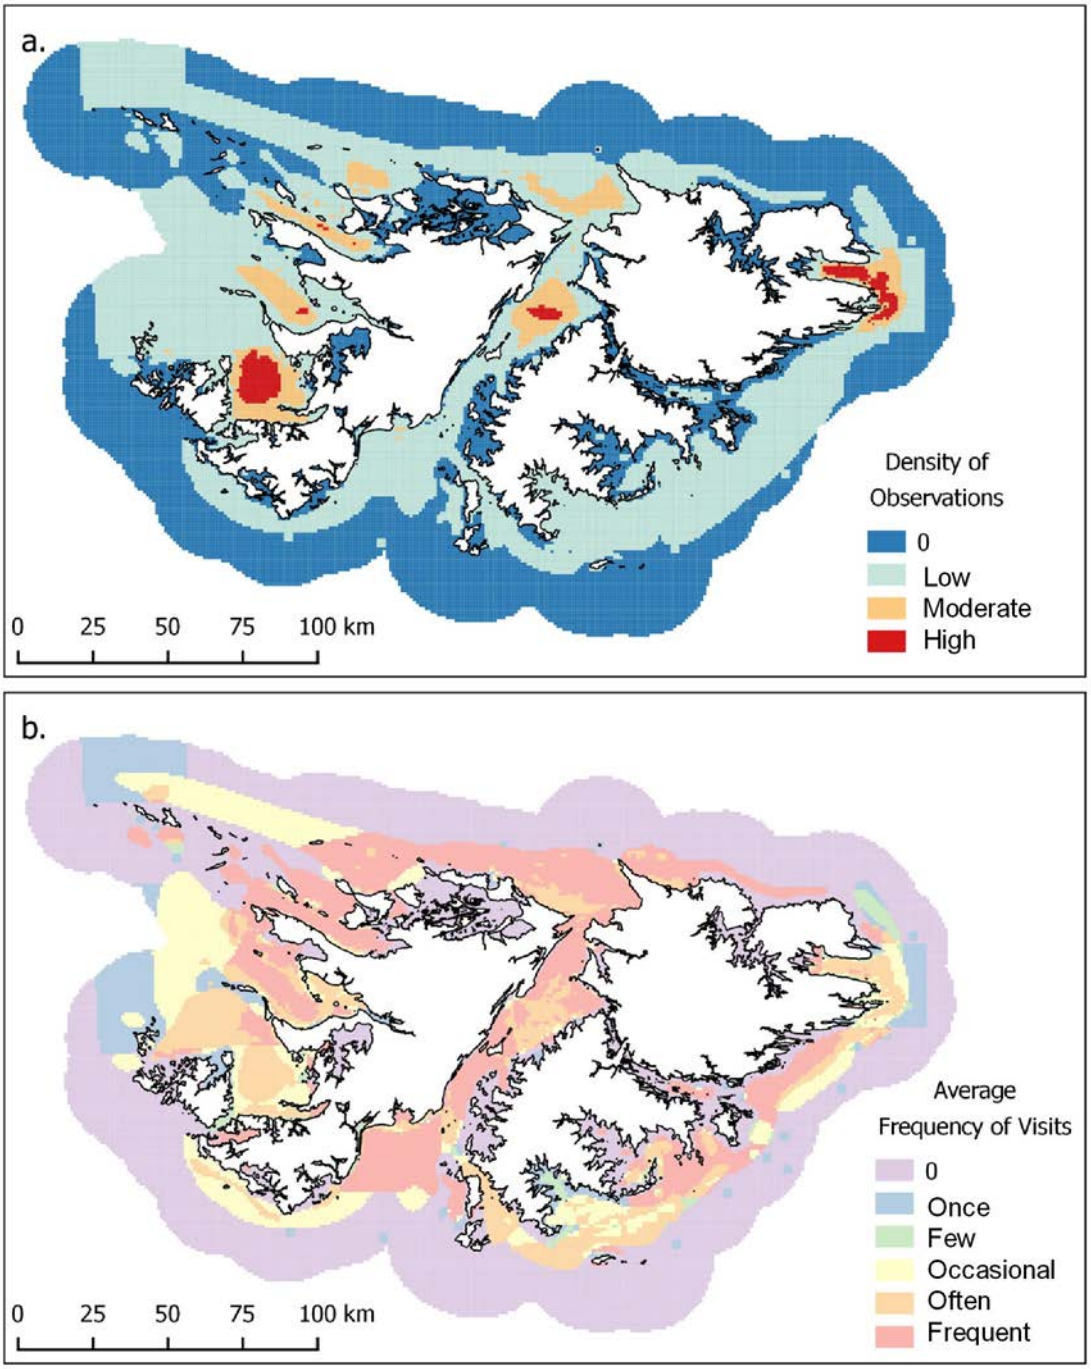

Figure 7-91: Distribution of anecdotal large cetacean records around the Falkland Islands ***(Source: Frans and Augé, 2016)***

7.4.6.3.1.3 Falklands Conservation cetacean surveys in Berkeley Sound

During early 2017, Falklands Conservation initiated a project entitled 'Developing a site-based conservation approach for sei whales (*Balaenoptera borealis*) at Berkeley Sound, Falkland Islands'. The project aims to improve knowledge of sei whales in the Falkland Islands, increase awareness and provide information on the potential for interaction between whales and human activities. The results are presented in Weir (2017).

Surveys were conducted between January and June, utilising land-based, aerial and boat-based techniques. All species of cetacean were recorded but the project focused on sei whales and the initial locations of sightings are shown in Figure 7-92. Data collected indicate that sei whales occur throughout Berkeley Sound (east of Long Island) and adjacent coastal waters, including the approaches to Port William. Although surveys were only undertaken during the first half of the year, the results support previous reports of seasonal presence of sei whales, with all sightings occurring between January and May. The majority of animals observed were seen in water depths of 20 – 50 m, with relatively few in water less than 15 m in depth. Behavioural observations indicate that the area is used as a feeding ground and analysis of faecal material confirmed that lobster krill are the primary prey species.

Between February and May 2017, 26 boat-based surveys resulted in 2,841.6 km of survey effort and 149 sightings of sei whales (300 individuals). In total, 87 individual sei whales were recognised by photo-identification with the number of identifiable animals recorded on any one day ranging between 0 – 20 individuals. This is a minimum indication of the number of animals using Berkeley Sound as many animals could not be photographed or would pass through the area between surveys. Most (64.6 %) of the sei whales that were photo-identified in Berkeley Sound were captured on one survey date only and the most frequently recorded individual was recorded on eight dates. The available evidence suggests that the majority of individuals are present within Berkeley Sound for brief periods but some remain for longer periods or return after a period of absence.

Observers also recorded blow rates and dive times (Weir, 2017), which could eventually be used to correct abundance estimates and develop ship-strike models. Over 20 observation periods, a mean breathing rate of 32.2 blows / hr was recorded, which equates to a mean dive cycle of 112 seconds. The maximum dive time recorded within Berkeley Sound was 13.5 minutes. The recorded swimming speed in Berkeley Sound averaged 6 km / hr with the maximum observed speed of 22 km / hr (12 knots). It is clear that dive profiles and swimming speed will vary depending on an animal's activity; however, observations indicate that movements of sei whales in and out of Berkeley Sound are likely to occur rapidly.

In 2018, visual and photographic surveys were conducted on the sei whale population in Queen Charlotte and King George Bays, to the west of the Falklands (Weir, 2018). The results indicate that sei whales are present in considerable number around the Falklands coastline. Two individuals that were identified in Berkeley Sound during 2017 were resighted to the west of the Falklands, indicating repeat visits to the Falklands in different years and hints that animals may move around the entire Falklands coastline. This was subsequently supported by satellite tagging efforts by Falklands Conservation, which although preliminary (see https://falklandsconservation.com/sei-whale-tracking/), revealed long-distance movements of sei whales around the Falkland Islands. A mark recapture study (photo identification) revealed movement of a single sei whale between Brazil and the Falkland Islands (Weir, *et al.,* 2019).

Predictive models are a useful tool to explore probable distribution of sei whales over larger areas. Sei Whale abundance was predicted to be highest in the Falkland Sound and over much of the northern coastline of the Falkland Islands, and Queen Charlotte Bay, West Falklands (Figure 7-93) (Baines and Weir, 2020). This is also seen in the sightings data shown in Figure 7-94 and is further supported by hotspots indicated from 350 opportunistic observations collated between 2010 and 2015 (Frans and Augé, 2016) (Figure 7-95).

Of note, marine mammal work conducted by Falklands Conservation has resulted in two Important Marine Mammal Areas (IMMAs) which are further described in Section 7.5.2.3.5.

7.4.6.3.1.4 Dolphins of the Kelp (DOKE)

The 'Dolphins of the Kelp' (DOKE) project ran between 2016 and 2018 under the auspices of SAERI. The projects aimed to establish baseline data on the abundance, distribution, natural history and genetic diversity of the Falklands inshore cetacean populations to provide a scientific basis for conservation and ecosystem-based marine management initiatives (Costa and Cazzola, 2018).

The project was broadly split into three phases:

- A Falklands-wide aerial transect survey to map the distribution of all cetaceans within 10 km of the coast,
- Focused studies on Commerson's and Peale's dolphins at three sites to investigate seasonal site fidelity, local abundance and movements which included:
  - Repeat boat-based transect surveys,
  - Photo-ID, and
  - Passive Acoustic Monitoring.
- Tissue sampling to determine genetic diversity and relatedness with other South American populations.

Island wide aerial transect survey

In total, 217 transects running perpendicular to the coast, spaced 5 to 6 km apart, were superimposed over the inshore waters (Figure 7-96). These transects were followed by a Falkland Islands Government Air Service (FIGAS) plane at an altitude of 150 m and speed of 90 knots between March 18th and May 8th 2017. Observers recorded all animals sighted using distance sampling techniques. On completion of the survey, the total length of survey track was 4,317 km and 454 sightings, of seven species, were made (Table 7.30). The abundances are a function of sightings and submergence times. This relationship is different for each species. Figure 7-97 shows the distribution of Commerson's and Peale's dolphins recorded and Figure 7-98 shows the distribution of baleen whales recorded.

Table 7.30: Summary of cetacean sightings made during the Dolphins of the Kelp aerial survey

Species	Number of sightings[1]	Estimated population[1]
Commerson's dolphin	238	5,789
Peale's dolphin	60	1,896
Sei whale	74	341
Fin whale	12	64
Minke whale	2	13
Blue whale	2	N/A
Southern right whale	1	N/A
Unidentified baleen whale	65	N/A

[1] Population is estimated using a ratio between the number of sightings, dive (submergence) times. The ratio is different for each species.

Focused studies on Commerson's and Peale's dolphins

Repeated boat-based transect surveys were designed to determine the habitat types favoured and seasonal movements by Commerson's and Peale's dolphins. Six surveys were completed at each of the three sites between November 2016 and July 2018 (Figure 7-99). In total, 5,417 km of survey effort was achieved, which produced 348 Commerson's dolphins, 162 Peale's dolphin, 23 southern right whale, 20 sei whale, three minke whale and one killer whale sightings.

Preliminary results suggest that:

- Commerson's dolphins are present all along the coastline but where 'hotspots' exist the number of animals present was higher in summer than winter:
- Peale's dolphins showed a restricted distribution (Port William seems to be a 'hotspot' for this species), although recorded in summer and winter more animals were sighted in the winter, and

- Where the two species overlap, Commerson's occupied the inner part of the bay and Peale's the outer.

Passive acoustic monitoring devices (C-PODs) were deployed in Many Branch Harbour to further investigate the behaviour of Commerson's dolphins, in particular diurnal patterns of behaviour. It was found that activity within the most sheltered areas peaked during daylight hours in February and March, the calving period for this species in the Falklands.

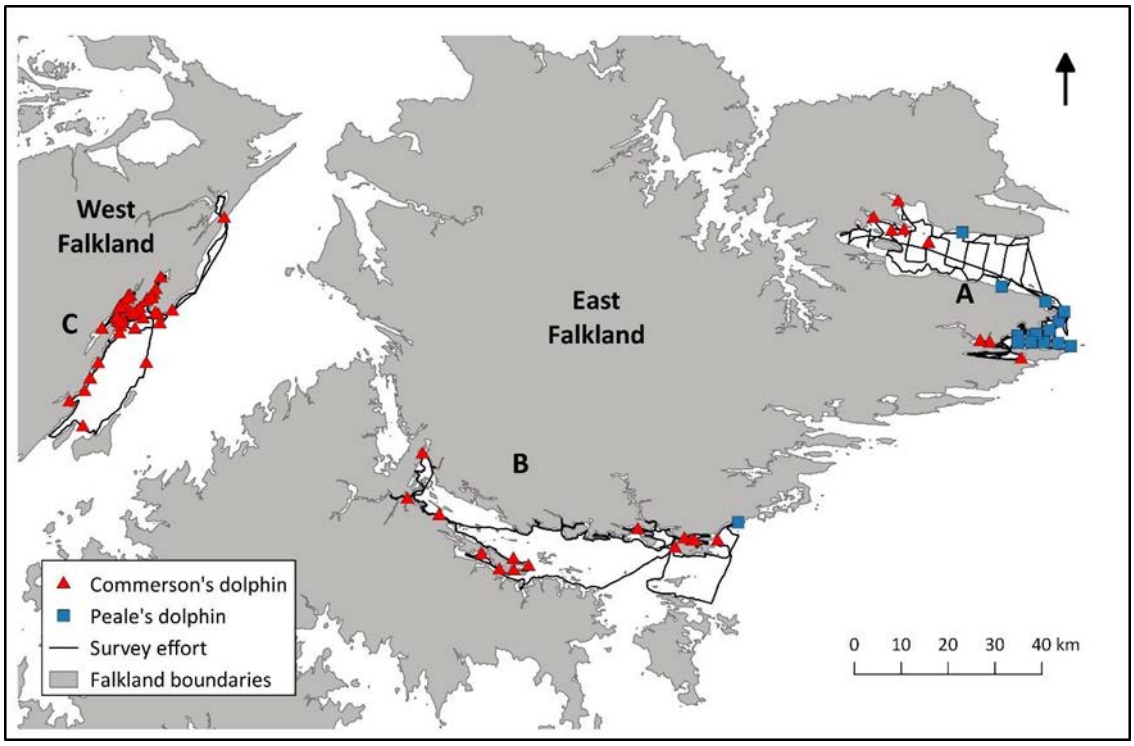

Figure 7-99: Survey effort and dolphin sightings between 21st November and 22nd December 2016, in the three focal areas; A, Port William and Berkeley Sound; B, Choiseul Sound and Bertha's Beach; C. Port Howard and many Branch Harbour ***(Source: Costa and Cazzola, 2018)***

Genetic diversity

Tissue samples were collected from Commerson's and Peale's dolphins at the sites shown in Figure 7-100. Primary results suggest:

- There are highly significant differences between Peale's dolphins sampled in the west and east of the Falklands,
- Commerson's dolphins did not show evidence of population differentiation between sampling locations, and
- Both species have limited sharing of haplotypes with mainland South American populations.

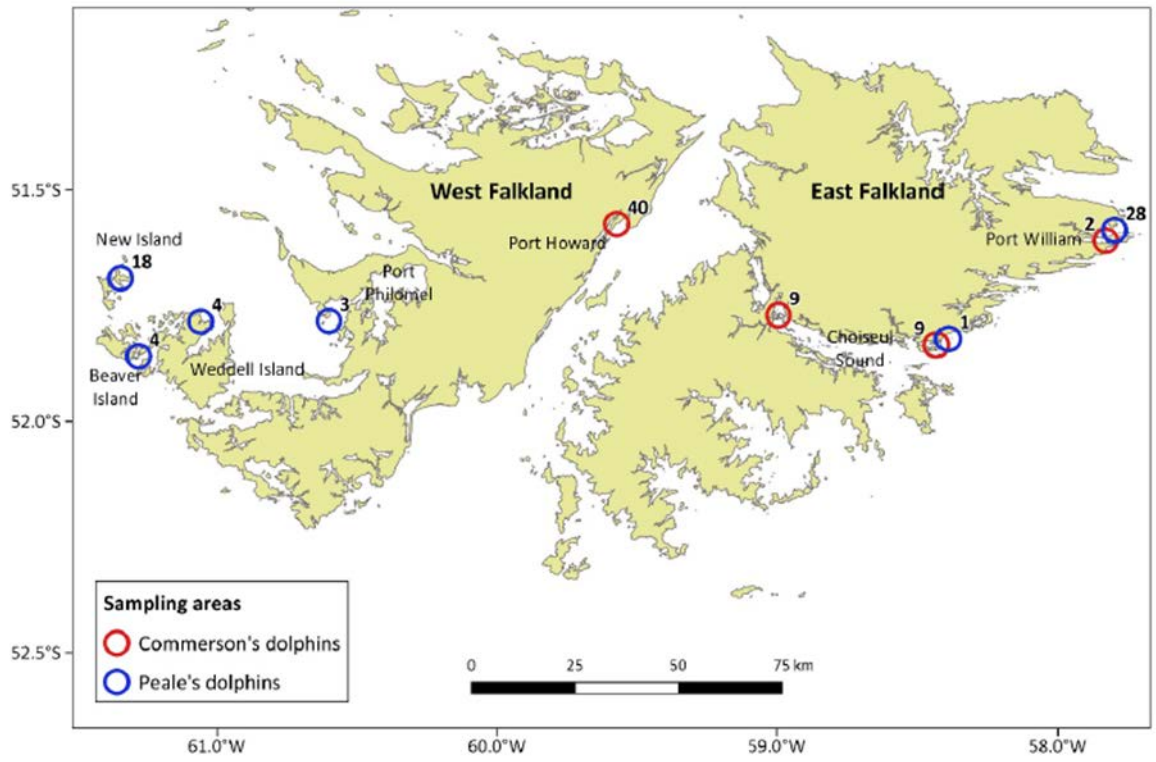

Figure 7-100: The location and number of tissue samples collected from Commerson's and Peale's dolphins for genetic analysis

7.4.6.3.1.5 Seal tracking studies

South American fur seals tracked at Volunteer Rocks in 2015 typically undertook extended foraging trips to the Patagonian Shelf slope to the north of the Falkland Islands. The mean foraging trip duration was 15.2 ± 2.7 days, with a mean trip distance of 314 ± 70 km over the 188 days they were tracked. Key foraging areas were on the Patagonian Shelf slope to the north and east of the Falkland Islands. Inshore waters around Volunteer Rocks were found to be important for commuting to and from the breeding colony. However, in 2015, fur seal foraging effort appeared to be over deeper waters associated with the shelf slope (mean foraging trip bathymetric depth was 263 ± 28 m), suggesting that the use of inshore waters for foraging was limited. This differs to behaviours seen at other fur seal breeding colonies, such as North Fur Island, seals from which were tracked at the same time. These had shorter foraging trip distances and durations, with more time spent within inshore waters. However, it is important to highlight study caveats, in particular the small sample size of only four fur seals tracked from Volunteer Rocks. Hence, a larger sample size and longer temporal tracking data set is required to establish the importance of inshore waters around Volunteer Rocks as foraging habitat for fur seals.

Of note, sea lion tracking was unsuccessful such that no tracking data exist for sea lions from Berkeley Sound.

7.4.6.3.1.6 Cetaceans recorded during JNCC SAST survey

Observations of marine mammals were made and recorded during JNCC SAST surveys between 1998 and 2004, described in Section 7.4.5.2.1.1. Although the methodology used was not specifically designed to survey the distribution of marine mammals, all animals sighted were recorded and White *et al.* (2002), remains the most comprehensive account of the at-sea distribution of marine mammals within Falkland Islands' waters.

It should be noted, however, that the survey vessels rarely entered Berkeley Sound or coastal waters (i.e., those less than 2 km from shore). An examination of the data collected in waters adjacent to Berkeley Sound gives a hint at the seasonal abundance of marine mammals in this restricted area; however, little dedicated survey effort was achieved within Berkeley Sound during the JNCC surveys, most effort is associated with the route taken in and out of Port William. Table 7.31 shows the number of individuals of each marine mammal species recorded on a monthly basis. Figure 7-101 shows the distribution of cetaceans in the waters adjacent to Berkeley Sound and shows an apparent association between many of the cetacean records and headlands, namely Volunteer Point, Mengeary Point and Cape Pembroke. It is possible that mixing created by currents and bottom topography make these areas particularly productive.

Table 7.31: Cetacean observations in waters adjacent to Berkeley Sound

Species	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total

7.4.6.3.1.7 Species-specific summary of cetacean distribution inshore

In addition to the many cetacean species that have been recorded in the wider NFB and near the Sea Lion Field (Section 7.4.6.2), a number of species have been recorded specifically within and around Berkeley Sound, as recorded in the surveys described above.

Notably, of the species that are regularly observed within Berkeley Sound, sei whales are listed as 'Endangered' on the IUCN Red List. Further, two species of dolphin, Peale's and Commerson's dolphins, are regularly observed within Berkeley Sound and these species, and all other cetaceans, are listed as species of conservation priority and are the subject of a Falkland Islands Cetacean Action Plan[35].

[35] The 2008 Cetacean Species Action Plan expired in 2018 and the new version is currently in draft.

The following provides a species-specific account of the collated survey results. Further, a general summary of the abundance, distribution, life-cycle and behavioural characteristics is provided in Table 7.32 below.

Sei whale

For many years large numbers of sei whales (*B. borealis*) have been observed in inshore waters around the Falkland Islands (White, *et al.,* 2002; Frans and Augé, 2016). Although they can be seen throughout much of the year, their abundance is far higher during the summer and autumn (November to April), peaking in March such that their presence is considered to be seasonal.

The results of inshore surveys (Thomson and Munro, 2014; Costa and Cazzola, 2018; Weir, 2018) and anecdotal observations by Frans and Augé (2016) indicate that, during the summer and autumn months, sei whales are encountered throughout most of the inshore waters of the Falklands. Interviews with local residents indicate several hotspots of sightings including Berkeley Sound (Frans and Augé, 2016). Further, the anecdotal observations hint that sei whales are now more numerous within Falklands waters than they were at the time of the JNCC's at-sea surveys (Frans and Augé, 2016).

The results of Falklands Conservation's 2017 project (Weir, 2017) support much of the existing knowledge of sei whales but add considerably to our understanding of sei whale movements and behaviour within Berkeley Sound. There is clearly a large number of sei whales using the inshore waters of the Falkland Islands, such as Berkeley Sound, as a late summer / autumn feeding ground. However, photo-identification within Berkeley Sound indicates that the animals are transitory with most animals spending a short period of time within Berkeley Sound (Weir, 2017) and some remaining for longer (Weir, 2022). Return visits by individuals in different years was confirmed and more evidence of large-scale movements by individuals within Falklands waters was achieved in 2018 (Weir, 2018). Therefore, it is assumed that a high proportion of the overall population of sei whales could be exposed to any human induced environmental change if it were to coincide with the seasonal presence of these animals.

Cerchio and Weir (2022) isolated more than 2,000 low-frequency sei whale calls for manual classification. Five categories of stereotyped call types in the 15–230 Hz range were described. Acoustic properties and behavioural characteristics indicate that this is likely a male breeding display similar to songs and singing of other balaenopterids.

Sei whales are listed as 'Endangered' on the IUCN Red List and have priority conservation status in the Falkland Islands.

Fin whale

Fin whales (*Balaenoptera physalus*) are known to seasonally occur in the offshore waters around the Falkland Islands (Section 7.4.6.2.1.4) and there are fewer confirmed sightings from inshore waters (Weir, 2017; Costa and Cazzola, 2018). Local knowledge indicates however that fin whales have been seen inshore throughout the year with a definite peak in numbers in March (Frans and Augé, 2016). There are two apparent hotspots of fin whale sightings in inshore waters; one to the west of the Islands and the other in Berkeley Sound (Frans and Augé, 2016). However, Weir (2017) did not record fin whales within Berkeley Sound and suggests that the sightings reported in Frans and Augé (2016) could be misidentified. Like all large whales, there is a perception that the number of fin whales present in the waters around the Falklands has increased over the past twenty years or so.

Fin whales are listed as Vulnerable on the IUCN Red List and also have priority conservation status in the Falkland Islands.

Antarctic minke whale

Antarctic minke whales (*B. bonarensis*) were encountered widely within Falklands waters with most animals recorded between September and April (White, *et al.,* 2002). Inshore, sightings have predominantly occurred during the summer and autumn months (Frans and Augé, 2016). Anecdotally, minke whales are frequently sighted off the eastern coast of Kidney Island (A. Black, *pers. obs.*; Frans and Augé, 2016). Dedicated inshore cetacean surveys conducted during 2017 recorded minke whales in low numbers (Weir, 2017; Costa and Cazzola, 2018).

Southern right whale

Once they arrive in the Falklands Islands, southern right whales (*Eubalanus australis*) tend to be found in coastal or inshore waters (*c.f.* Black, 2005b). Several right whales have been sighted within Stanley Harbour (A. Black, *pers. obs.*; Frans and Augé, 2016) and one was sighted in Berkeley Sound during July 2015 (BSL, 2015). Interviews conducted by Frans and Augé (2016) however, indicate that southern right whales are rarely sighted and their presence in Falklands waters is very seasonal (late summer / early autumn). Although more sightings occur to the west of the Falklands (Frans and Augé, 2016), until 2017 the available evidence suggests that southern right whales are periodically present within Berkeley Sound sometimes recorded using it for socialising.

During the winter of 2017 (May to August), a large influx of southern right whales occurred (see Section 7.4.6.3.1.1 and Weir, 2017). Regionally important aggregations of southern right whales (including for mating) are now documented during winter in coastal waters, particularly to the north of the Falkland Islands (Weir and Stanworth, 2020).

Humpback whales

Humpback whales accounted for approximately 12 % of the whales processed at the New Island shore station in the early 1900s (Weir, 2017). While humpback whales (*Megaptera novaeangliae*) have been recorded within Falklands waters (White, *et al.,* 2002), acoustic monitoring and marine mammal observations from seismic vessels did not record humpback whales in the North Falkland Basin and interviews with local residents did not produce many additional records of humpback whales inshore (Frans and Augé, 2016). An intense period of dedicated inshore cetacean surveys in 2017 /18 did not produce any sightings of humpback whales (Weir, 2017; 2018; Costa and Cazzola, 2018). Despite their historical presence and apparent increase in numbers elsewhere, the available evidence suggests that humpback whales are infrequently encountered within Falklands waters.

Killer whale

The JNCC surveys recorded seven killer whale (*Orcinus orca*) sightings (18 animals in total) over three years, (White, *et al.,* 2002). Killer whales are regularly sighted inshore around Sea Lion Island, to the south of East Falkland (Sanvito and Galimberti, 2018) and occasionally elsewhere inshore. Although there are no official records from Berkeley Sound, killer whales do visit the area and have anecdotally been observed within the Sound and around Volunteer Point.

Satellite tracking indicates that Type B killer whales follow a migration route to the east of the Falkland Islands when travelling between the Antarctic Peninsula and sub-tropical waters of the South Atlantic (Durban and Pitman, 2012). These animals appear to travel rapidly through the region but they could account for some of the acoustic detections and sightings within Falkland waters.

Long-finned pilot whale

Long-finned pilot whale (*Globicephala melas*) strandings have been regularly recorded on the Falkland Islands since 1866 (Otley, 2012). Since 1984, pilot whale strandings have been recorded as a near annual event, with 43 recorded incidents ranging in number from less than ten individuals to up to 500 animals. The mean number of animals involved in each event is 105 (Otley, 2012). There appears to be a seasonal component to the strandings with 50 % occurring during the autumn, 32 % in winter, 12 %

in summer and 6 % in spring. It is unclear what causes these strandings, but the seasonal component suggests that there may be seasonal movements of these animals both inshore and offshore. This is supported by surveys and observations offshore (White, *et al.,* 2002).

The high number of pilot whale strandings on the Falkland Islands (Otley, 2012) hints that there is a sizable population associated with Falklands waters. However, this species is generally regarded as a deepwater species and are not regularly sighted inshore. Pilot whales were not sighted during a period of intense inshore cetacean surveys in 2017/18.

Peale's dolphin

Five groups of Peale's dolphin (*Lagenorhynchus australis*) were recorded during the 2016 coastal survey (Section 7.4.6.3.1.1). There was a cluster of three records close to Monkey Point but this species could be encountered anywhere within Berkeley Sound. Peale's dolphin was recorded both inshore and offshore during the JNCC surveys and was by far the most abundant species of cetacean recorded near the entrance to Berkeley Sound (Figure 7-101 above) and offshore on the Patagonian Shelf (Figure 7-85). There was no clear evidence of any seasonal changes in the abundance, distribution or behaviour of these animals. Little is known about the biology of Peale's dolphins, but these animals are thought to be largely resident and to calve between October and April (Shirihai, 2006).

The results of the DOKE project and Falklands Conservation sei whale project indicate that Peale's dolphins are present within Berkeley Sound but in relatively low numbers and are far more numerous in Port William (Weir, 2017; Costa and Cazzola, 2018; Weir, 2018; Baines and Weir, 2020). The results of genetic analysis indicate significant differences in the genetics between animals sampled in the east and west of the Islands, which hints that these animals do not travel widely.

Dusky dolphin

There have been few confirmed sightings of dusky dolphin (*L. obscurus*) within Falklands waters (Weir and Black, 2018). During inshore cetacean surveys in 2017 and 2018, a single dusky dolphin (identifiable by a large nick in its dorsal fin) was repeatedly observed in Port William and at the entrance to Berkeley Sound (Costa and Cazzola, 2018; Weir and Black, 2018). This animal was always recorded in association with Peale's dolphins, it is believed that this association is unusual. The lack of other confirmed sightings during a period of intensive inshore cetacean surveys in 2017 and 2018 indicates that dusky dolphins are rare visitors to inshore Falklands waters.

Commerson's dolphin

During the JNCC surveys, Commerson's dolphins were recorded in every month except May (Figure 7-78) although very few animals were actually recorded. The number of these animals is very likely to have been underestimated due to their preference for coastal waters and the JNCC surveys were rarely conducted in the core habitats used by this species. Of the observations made, all were in partially enclosed or coastal waters and sightings were most frequently recorded from the waters within, or close to, the north and south entrances to Falkland Sound (Figure 7-102). These results are supported by the pilot inshore cetacean survey, which recorded more Commerson's dolphins between islands than towards open waters (Thomsen and Munro, 2014).

There was no evidence of seasonal variation in the distribution or abundance of Commerson's dolphin and the apparent decreases in some months, for example May, are, again, believed to be due to variation in the distribution of JNCC survey coverage rather than changes in the distribution of the dolphins. Anecdotally, highest densities of Commerson's dolphins are most frequently observed in enclosed coastal waters; such as settlement harbours (A. Black, *pers. obs.*) which were rarely visited on any of the previous boat-based surveys.

The results of the DOKE surveys and Falklands Conservation sei whale project support previous observations (Figure 7-97) and provide evidence of seasonal and diurnal movements within inshore

waters. The results of an Islands-wide survey indicate that Commerson's dolphins are by far the most numerous cetaceans found in waters within 10 km of the coast (Table 7.29, Weir, 2017; Costa and Cazzola, 2018; Weir, 2018; Baines and Weir, 2020).

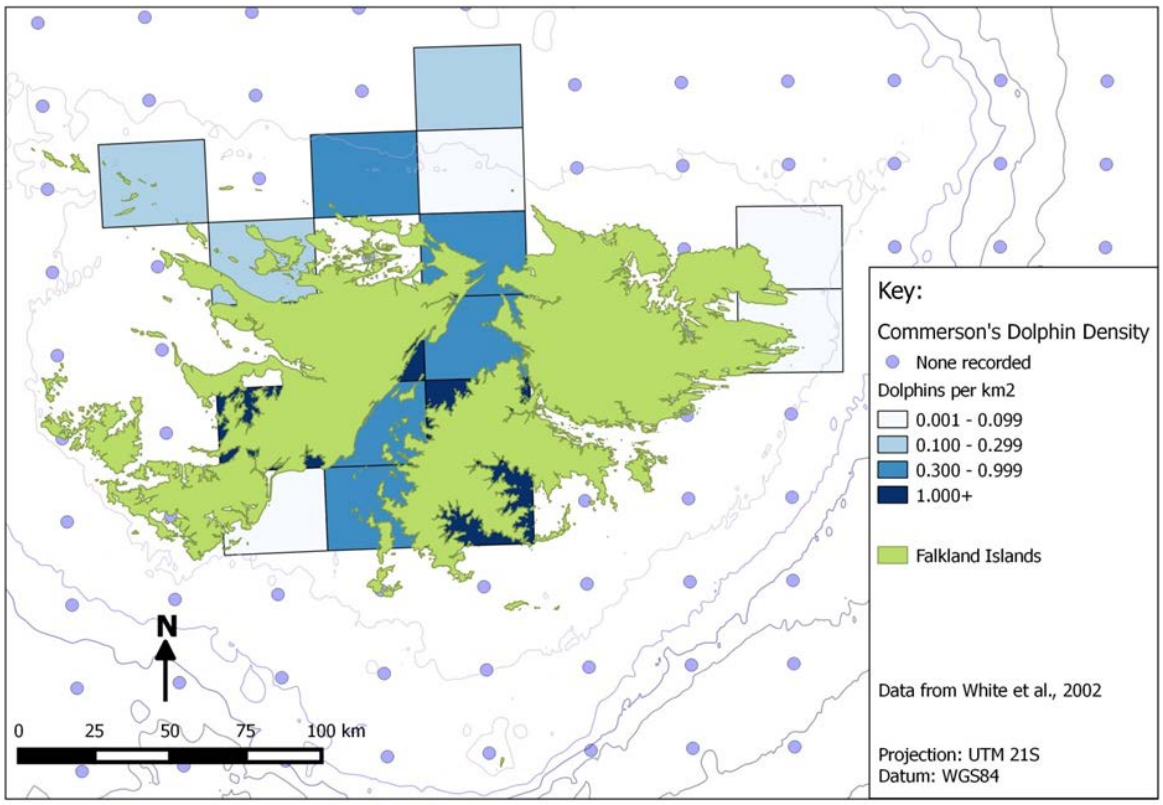

Figure 7-102: Commerson's dolphin distribution recorded during JNCC surveys, all months

7.4.6.3.2 Pinniped abundance and distribution surveys in and around Berkeley Sound

In understanding the baseline distribution and abundance of pinnipeds in Berkeley Sound, data from the following surveys and studies have been used.

These surveys include:

- Coastal bird surveys carried out by SAERI under contract to POEPL,
- The JNCC SAST survey, and
- Tracking studies.

7.4.6.3.2.1 Pinnipeds recorded during the 2016 and 2017 coastal survey

The coastal bird surveys undertaken between 2016 and 2019 (described in Section 7.4.5.3.1) also recorded all pinnipeds observed hauled-out or in coastal waters.

7.4.6.3.2.2 Pinnipeds recorded during JNCC SAST survey

While the SAST did not carry out dedicated marine mammal observations, marine mammals were recorded regularly in low numbers in inshore waters near Berkeley Sound.

7.4.6.3.2.3 Tracking Studies

There has been some limited tracking of fur seals breeding at Bird Island (off the south coast of West Falkland; Thompson *et al.,* 2003). Female sea lions from three locations on East Falkland have also been tracked (Baylis, *et al.,* 2015). The results of tracking associated with the GAP programme are summarised in Baylis, *et al.* (2019a).

7.4.6.3.2.4 Species-specific summary of pinniped distribution inshore

The following species-specific summaries draw on data taken during the surveys described above. A summary of the abundance, distribution, life-cycle and behavioural characteristics is provided in Table 7.32 below.

South American fur seal

Volunteer Rocks at the northern entrance to Berkeley Sound (Figure 7-103) is known to be a breeding site for South American fur seals (*Arctocephalus australis*); where approximately 230 pups are born each year. This represents approximately 0.6 % of the known Falkland Islands population (based on a population of 36,500 animals; Baylis, *et al.,* 2019). Reflecting this, most of the fur seals recorded during the summer and winter coastal surveys were close to this site. Fur seals were the most numerous pinniped recorded during JNCC at-sea surveys (White, *et al.,* 2002).

The results of tracking studies indicate distinct seasonal differences in the distribution of female fur seals breeding at the Bird Island location. South American fur seals commence breeding in early November with the establishment of territories by the dominant bulls. Pups are born around mid-December and are suckled for about 11 months. In the early part of the breeding season, females make short, nocturnal foraging trips. During mid-lactation, the duration of foraging trips increased but the distribution remained close to the breeding site. By the autumn, the duration and range of foraging trips had increased (Thompson, *et al.,* 2003). Along with seasonal differences in food requirements, fur seal foraging strategies are likely to be influenced by local conditions and may therefore vary considerably between colonies.

South American sea lion

Infrequent surveys of the breeding population of South American sea lions (*Otaria flavescens*) have been conducted in the past, which recorded a single breeding site on the north coast of Berkeley Sound (Thompson, *et al.,* 2005). Although pup counts for all colonies are not presented in Thompson, *et al.* (2005), it is estimated that close to 2 % of the Falklands breeding population (2,747 pups produced in 2003) are found at this site. In support of this, during the 2016 coastal survey, most of the 60 South American sea lions recorded were in two groups; one at a haul-out site on Hog Island and the other at the colony on the northern coast of the outer Sound (often referred to as Diamond Cove; Figure 7-103). Sea lions were also observed on Cochon and Kidney Islands (Figure 7-103). During the winter 2017 survey, sea lions were recorded in low numbers throughout the Sound. At-sea, sea lions were recorded in all months during the JNCC surveys with the majority of records came from inshore waters (White, *et al.,* 2002).

Contrary to the accepted view that South American sea lions are generalists, satellite tracking of female South American sea lions has identified that individuals have specialised foraging strategies; in terms of location (inshore *vs.* offshore) and prey type (benthic or pelagic) (Baylis, *et al.,* 2015).

South American sea lions are known to return to land at favoured haul-out sites throughout the year and therefore all animals are susceptible to impacts in inshore waters throughout the year. However, those that specialise as inshore foragers are at greatest risk.

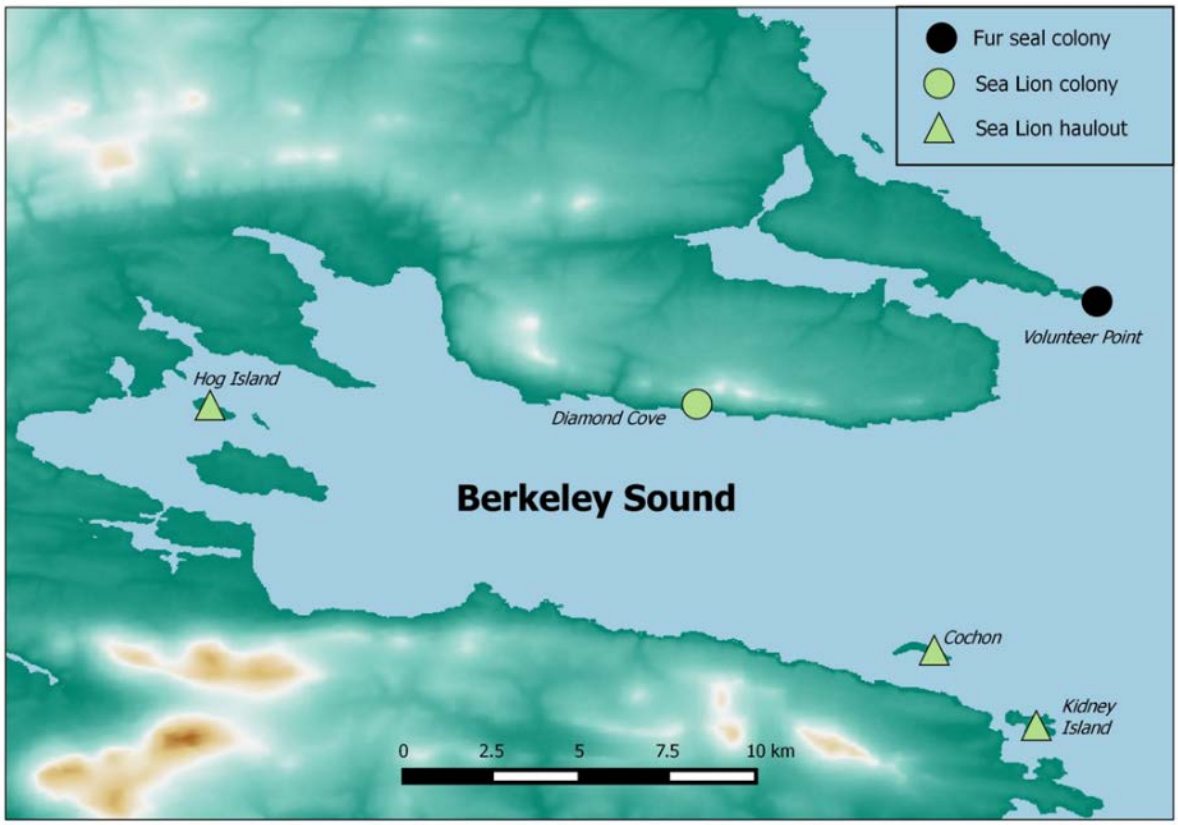

Figure 7-103: Sea Lion and fur seal colonies in Berkeley Sound

7.4.6.3.3 Summary of marine mammals in and around Berkeley Sound

Table 7.32 provides a summary of marine mammal abundance in Berkeley Sound, distribution, life-cycle and behavioural characteristics.

Table 7.32: Summary of marine mammals found inshore around the Falkland Islands

Species	IUCN status	Presence in Berkeley Sound	Global distribution	Foraging strategy	Auditory type	Behaviour
Cetaceans						
Southern right whale (*Eubalaena australis*)	LC	✓ Rarely sighted before 2017 but confirmed to be present in Berkeley Sound and other inshore waters (A. Black *pers. obs.*). Influx of a large number of whales during winter 2017. Spring / Summer / Autumn / Winter 	Circumpolar in the southern hemisphere[1]	Surface skim-feeding	Low frequency	Slow lumbering swimmers but can be acrobatic, breaching clear of the water or lifting the tail clear of the water. The southern right whale breeds between July-November in Península Valdés (Argentina) and Santa Catarina (Brazil) (Danilewicz, *et al*., 2016; Mandiola, *et al*., 2019; Renault-Braga, *et al*., 2022) and migrates south in the summer. In recent decades, high calf mortality has been reported in Argentina (Cooke and Zerbini, 2018). In the Falkland Islands, regionally important aggregations of southern right whales (including for mating) occur during winter in coastal waters (Weir and Stanworth, 2020). Recently, satellite tags have been deployed on Southern right whales in the Falkland Islands e.g., (Weir, 2022).
Fin whale (*Balaenoptera physalus*)	VU	Rarely sighted inshore Spring / Summer / Autumn / Winter 	Found in all oceans of the world	Lunge feeding	Low frequency	Capable of swimming at speeds of 19 knots. Movements poorly understood but most frequently encountered offshore or where deep water is found near the coast (White, *et al.,* 2002). Seen in small groups many of which may be present within a small area (tens of km^2)
	NT	✓				

Species	IUCN status	Presence in Berkeley Sound	Global distribution	Foraging strategy	Auditory type	Behaviour
Antarctic minke whale (*Balaenoptera bonarensis*)		Regularly sighted within Berkeley Sound Spring | Summer | Autumn | Winter	Globally, the most common of the rorquals	Lunge feeding	Low frequency	Movements around the Falkland Islands and South Atlantic region, are currently poorly known, but minke whales appear to be resident year-round (White, *et al.,* 2002).
Sei whale (*Balaenoptera borealis*)	EN	✓ The most abundant large whale seen in inshore waters (including Berkeley Sound) also frequently sighted offshore. Spring | Summer | Autumn | Winter	Found in all oceans, sub-Antarctic waters are favoured feeding grounds in summer[2]	Lunge feeding	Low frequency	Dives more regularly than most large whales, surfacing at approximately minute intervals. One of the fastest of the great whales, sei whales swim a few metres below the surface and progress can be followed by 'fluke prints' left on the surface in the animal's wake. Recently, satellite tags have been deployed on Sei whales in the Falkland Islands and highlights the importance of coastal nearshore waters (https://falklandsconservation.com/sei-whale-tracking/).
Humpback whale (*Megaptera novaeangliae*)	LC	Although not recorded in Berkeley Sound, humpback whales are known to be present in low numbers in the region. Spring | Summer | Autumn | Winter	Found in all oceans of the world	Lunge feeding	Low frequency	A population breeding off the coast of Brazil is thought to migrate to feed off the South Sandwich Islands in the summer months. Recent boat-based surveys in the Falkland Islands highlights annual variability in occurrence of Humpback whales (Weir, 2022).
Long-finned pilot whale (*Globicephalus melas*)	LC	Known to strand regularly (annually) in the Falklands but not within Berkeley Sound Spring | Summer | Autumn | Winter	High latitudes in the northern and southern hemisphere	Deep divers	Mid frequency	Can be encountered in large groups (100 + animals). There appears to be seasonal changes in distribution within Falklands waters, but movements poorly understood (White, *et al.,* 2002).

Species	IUCN status	Presence in Berkeley Sound	Global distribution	Foraging strategy	Auditory type	Behaviour
Killer whale (*Orcinus orca*)	DD	Regularly sighted inshore around Sea Lion Island, off the south coast of East Falkland but no known sightings in Berkeley Sound Spring | Summer | Autumn | Winter	Found in all oceans of the world.	Shallow dives	Mid frequency	Killer whales are known to pass through Falklands waters on rapid transit from Antarctic Peninsula to sub-tropical waters (Durban and Pitman, 2012). Additionally, there are likely to be resident populations. Seen year-round from longline vessels fishing to the north-east of the Sea Lion Field.
Commerson's dolphin (*Cephalorhynchus commersonii*)	LC	✓ Frequently sighted in coastal waters of the Sound Spring | Summer | Autumn | Winter	Only southern South America, the Falklands and Kerguelen	Shallow diving	High frequency	Observed throughout the Falklands in coastal waters (Franchini, *et al.,* 2020).
Peale's dolphin (*Lagenorhynchus australis*)	LC	✓ Frequently sighted throughout the Sound Spring | Summer | Autumn | Winter	Restricted to southern South America and the Falkland Islands	Shallow dives	High frequency	Thought to be resident with no discernible seasonal movements detected in the Falklands population. More numerous inshore but found across the Patagonian Shelf (waters <200 m) (Franchini, *et al.,* 2020). Very enthusiastic bow-riders.
Pinnipeds						
South American fur seal (*Arctocephalus australis*)	LC	✓ Breed on Volunteer Rocks at the northern entrance to the Sound. Spring | Summer | Autumn | Winter	Restricted to southern South America and the Falkland Islands	Shallow dives	Otariid	The Falkland Islands has one of the largest breeding populations of South American fur seals in the South Atlantic (Baylis, *et al.,* 2018). Most breeding sites found off the north-west and south-west of the Falklands. Volunteer Rocks are the only known breeding site off the east coast of the Islands (Baylis, *et al.,* 2018). Adults frequently travel between the Falkland Islands and

Species	IUCN status	Presence in Berkeley Sound				Global distribution	Foraging strategy	Auditory type	Behaviour
									coastline of South America during foraging trips (Riaz, *et al.,* 2024). South American fur seals are non-migratory.
South American sea lion (*Otaria flavescens*)	LC	✓ A small breeding colony is located on the north coast of the Sound. Haul-out sites on Kidney, Cochon and Hog Islands.				Restricted to southern South America and the Falkland Islands	Shallow dives	Otariid	There are 68 breeding sites spread throughout the Falklands. The population has suffered a drastic long-term decline. In 2003, the population was reduced to 3.4 % of the 1937 estimated population. The Falkland Islands population is slowly increasing, with approximately 4,500 pups born annually (Baylis, *et al.,* 2015)
		Spring	Summer	Autumn	Winter				

[1] **Post-consultation note (July 2025):** Studies carried out by Falklands Conservation between 2017 and 2025 (and ongoing) indicate that regionally important aggregations of southern right whale are now documented during winter in coastal waters, particularly along the north and northeast coast of East Falkland (Weir and Stanworth, 2020; Weir, 2024). These surveys indicate that this population comprises >1% of the global population (Weir, 2024).

[2] **Post-consultation note (July 2025):** Studies carried out by Falklands Conservation between 2017 and 2025 (and ongoing) indicate that aggregations of sei whales in the Falkland Islands nearshore waters comprise >0.1% of the global population.

Key: Relative abundance of marine mammals within Falklands waters

Not recorded	Low	Moderate	High	Very High

7.4.6.4 Marine mammals in Stanley Harbour and surrounding areas

Commerson's dolphin (*Cephalorhynchus commersonii*) and Peale's dolphin (*Lagenorhynchus australis*) have frequently been recorded within Stanley Harbour (Falklands Conservation Cetacean Watch records; MMO surveys misc.). Due to their limited range Commerson's dolphin has a greater potential to be impacted by operations than Peale's dolphin. The Peale's dolphin has a greater range of mobility and may move between more sheltered waters, kelp forests, exposed coastlines and shelf waters (White, *et al.,* 2002). However, no quantitative data on density or site fidelity is available.

Female South American sea lions (*Otaria flavescens*) are regularly sighted within the Harbour and hauled-out on existing jetties.

Overall, anecdotal evidence suggests that Commerson's dolphins and sea lions are the main sensitivities within the Harbour and other sighted species, such as southern right whales, are far less common[36].

7.4.6.5 Terrestrial habitats surrounding Berkeley Sound

7.4.6.5.1 Terrestrial habitat mapping and classification

Satellite images (see Figure 7-40 above) were used to map the terrestrial surrounding Berkeley Sound, details of the methodology used can be found in EnvSys (2016).

Using the information from fieldwork the remote sensing data was reanalysed and the terrestrial habitats mapped. A small section of the final map where fieldwork points had been used to guide the classification is provided in Figure 7-104.

The full map of the terrestrial vegetation surrounding the Sound can be seen in Figure 7-105, with the Magellan Cove area highlighted ('boxed'). The proportion of each habitat mapped is shown in Table 7.33.

In the coves and valleys where streams run into the Sound the vegetation comprises a mixture of flushes and marshy grassland close to the stream with species rich or semi-improved grassland in the valley bottoms. Away from the streams, the ground is not marshy but there is more available water than on the slopes and cliff edges and more palatable grass species occur, which flourish under these conditions. These areas attract grazing sheep which tends to lead to a cycle of nutrient enrichment as the sheep gather there; this leads to the semi-improved nature of many of these grasslands. Adjacent to the sandy beach, and in patches on the lower cliffs, are maritime grasslands, which contain a wide range of species.

Only on the low lying peaty and wetter land near Long Island, do the blanket bog and modified bogs reach within the 200 m zone of influence around the Sound, although these habitats are common further inland where the cliff edges flatten out. Cushion forming species generally occur in mosaics with acid grassland; they occur on shallower slopes throughout the Sound but generally in fairly small patches. The vegetation is also modified by penguin colonies which create swaths of bare ground which are often first colonised by sheep's sorrel (*Rumex acetosa*). The nutrient enrichment of these areas generally results in the establishment of the more productive unimproved acid grassland after the penguins move on. The most significant habitats around the Sound are the flushes, which contain a range of less common species, and the areas of tussock grass found on some of the islands.

[36] **Post consultation note (July 2025):** In June 2025 Falklands Conservation commenced data acquisition on the occurrence of dolphins in Stanley Harbour (Falklands Conservation, 2025). This will better inform environmental impact assessments relating to activities in Stanley Harbour. Once available this data will be considered through the EMMP process (Chapter 15) and any identified adaptive management action will be taken as required.

Table 7.33: The area and percentage composition of terrestrial habitat types within 200 m of the Berkeley Sound shore

Habitat	Area (ha)	%
Unimproved acid grassland with mosaic including fern bed	869.07	25.05
Dry dwarf shrub heath	851.49	24.55
Unimproved acid grassland	571.34	16.47
Semi-improved or species rich acid grassland	269.97	7.78
Dry dwarf shrub heath / acid grassland mosaic	197.01	5.68
Wet dwarf shrub heath	138.41	3.99
Marshy grassland	120.15	3.46
Coastal grassland	110.33	3.18
Sand	83.34	2.40
Bare or sorrel dominated	80.00	2.31
Fern bed (tall fern)	40.48	1.17
Flush	33.65	0.97
Tussac grass, dense / continuous	30.72	0.89
Sand / mud	29.66	0.86
Sand dunes	19.72	0.57
Streams / rivers	7.63	0.22
Tussac grass scattered	7.30	0.21
Blanket or modified bog	7.05	0.20
Acid grassland / fern bed mosaic	1.34	0.04
Total	**3,468.66**	**100**

7.4.6.6 Environmental sensitive terrestrial habitats

In terms of the potential impact of oil and gas related activity within Berkeley Sound, any pollutants released or spilt will be marine in origin and therefore have greatest potential of impacting the coastal (littoral) environment. Low lying coastal areas may be at risk of being inundated by the sea and thus height above sea level is an important consideration. Figure 7-106 shows the terrain coloured up according to what might be considered 'risk' zones with the:

- Red areas being within 1 m above the mean high-water line,
- Orange areas within 5 m above the mean high-water line, and,
- Yellow areas being within 20 m above the mean high-water line.

This map clearly shows the low-lying areas where the streams output into the Sound as being most at risk of being impacted by any potential spill and strong winds / high tides. These areas also have some of the most significant vegetation, in terms of the diversity and uncommon species that they support. Although Important Plant Areas (Section 7.5.2.3.2) or Threatened Terrestrial Habitats (Section 7.5.2.4) are not known to occur around the coast of Berkeley Sound, three priority conservation species do occur (Section 7.5.3).

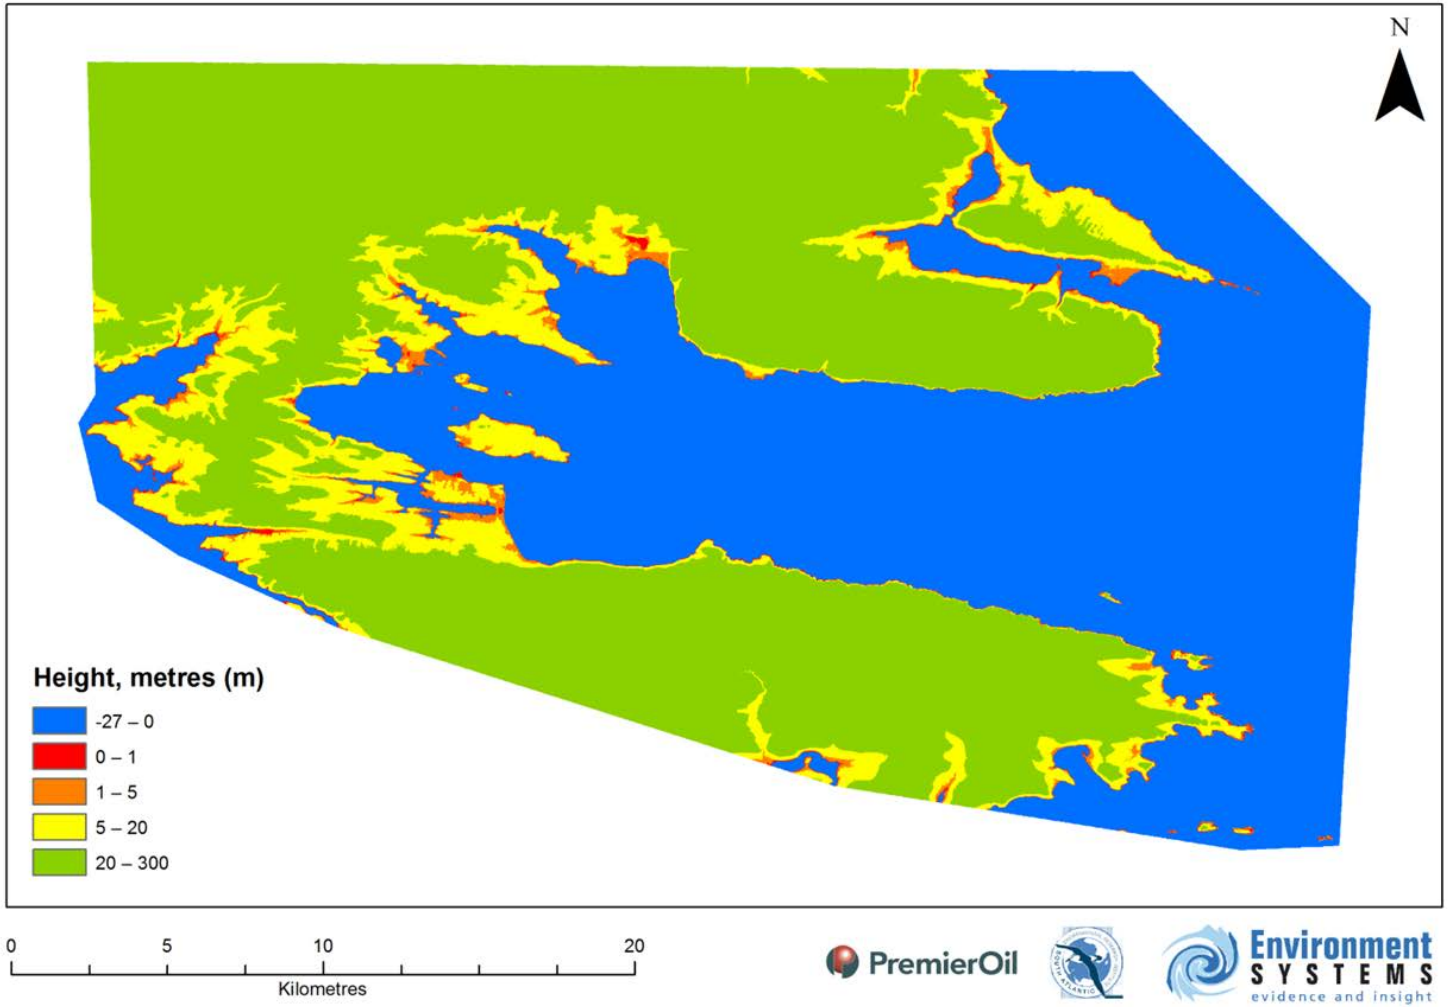

Figure 7-106: Terrain model data coloured to show low-lying land liable to marine inundation

7.5 Conservation Designations for sites, species and habitats

7.5.1 Protected species and sites

7.5.1.1 Benthic marine species

There is little specific protection for benthic marine species (or indeed marine habitats) within the waters of the Falkland Islands. This is partly because the marine environment and species assemblages are relatively poorly described.

Work was carried out to address these data gaps (Section 7.2.4.2). Marine Protected Areas (MPAs) or Marine Managed Areas (MMAs) (Section 7.5.2.2) will be designated in the near future, with some aimed at directly protecting seabed species and habitats among other vulnerable species.

7.5.1.2 Fish species

Fish species in their own right do not have specific protection. However, the Fisheries Ordinance 2005 (Section 3.1.7.3.9) caters for the use of closed areas (for protecting spawning sites). This comprises a combination of closed areas and a three-mile (from the baseline) no-take zone around the entire coastline (Figure 7-107 below).

Therefore, coastal waters, including Berkeley Sound, are not subject to commercial fishing. It should be noted that there was recently a small-scale sea cage growing facility for sea trout (currently not operating), and a small-scale harvesting operation for snow crab (now closed with some recent interest to restart crab fishing) within coastal waters elsewhere in the Islands. However, while there are potentially exploitable resources within Berkeley Sound (Davidson, 2016) these are currently unexploited.

7.5.1.3 Wild bird species

The majority of native wild birds are protected under the Conservation of Wildlife and Nature Ordinance, which was enacted in 1999 (Section 3.1.7.3.8).

The ordinance protects all bird species, except for the:

- Upland goose (*Chloephaga picta*) and feral domestic goose, which may be hunted and killed at any time of the year, and
- Patagonian crested duck (*Lophonetta specularoides*) and yellow-billed (speckled) teal (*Anus flavirostris*), both of which cannot be killed during the closed season (1 July to 31 March) and are therefore protected for part of the year.

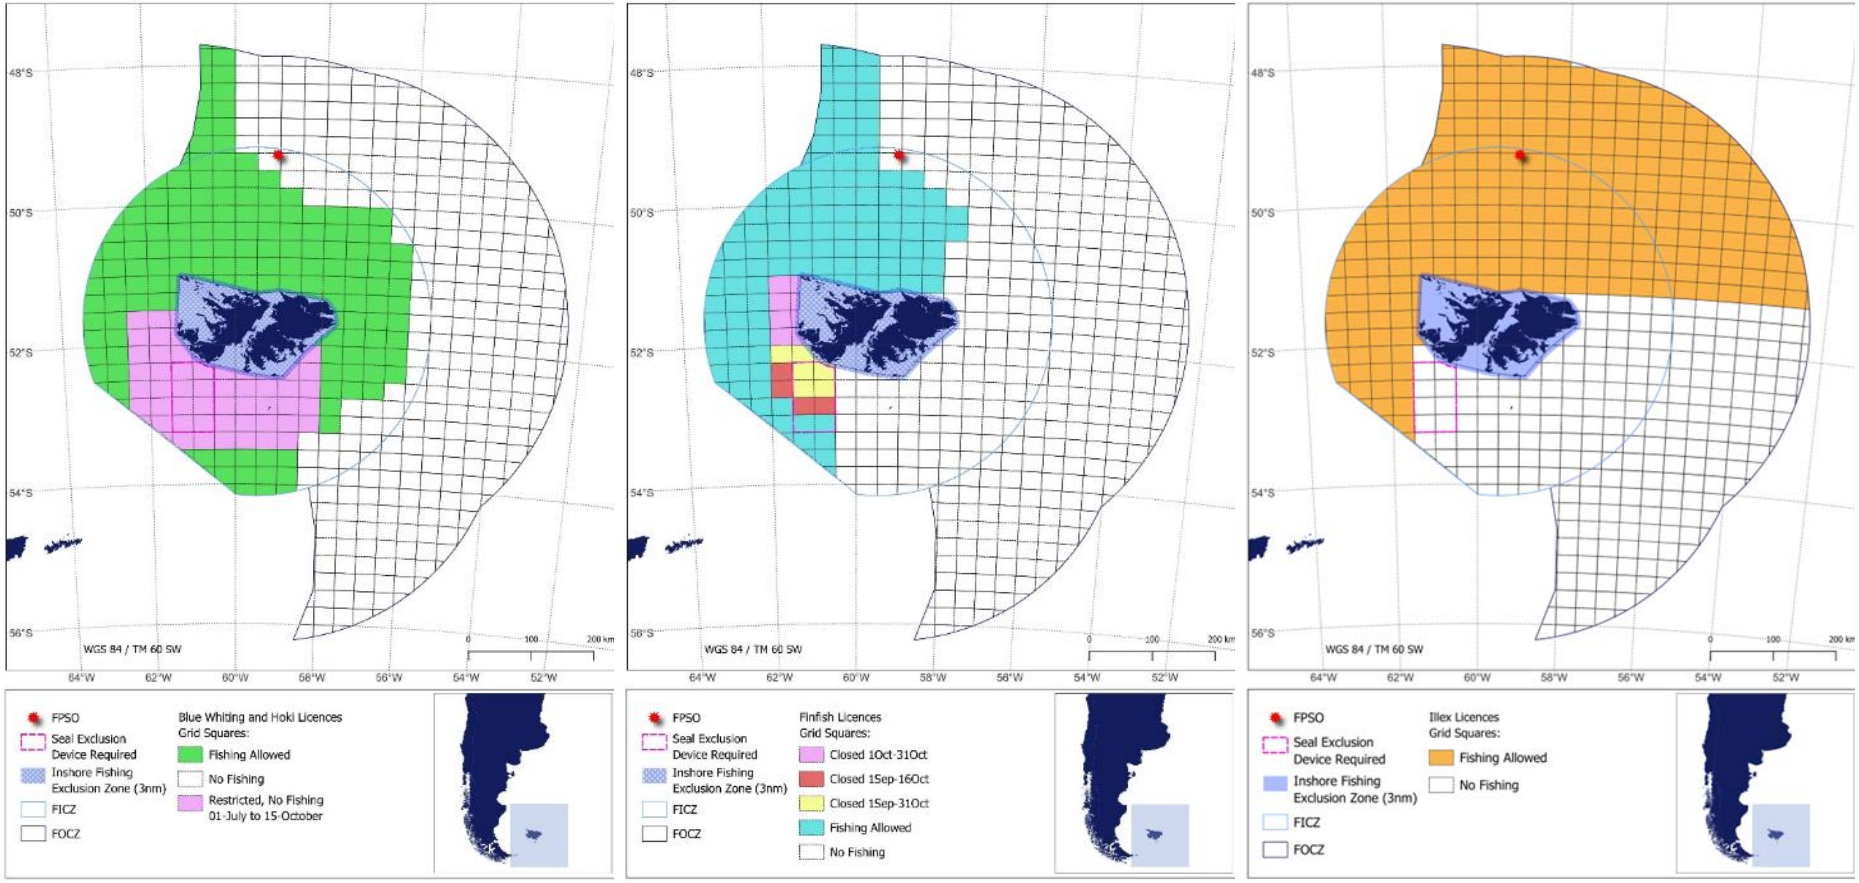
Further, the Ordinance bans the collection of eggs, birds and animals; however, a permit holder may still collect eggs from some species, including Magellanic and gentoo penguins. More recent amendments to the Ordinance forbid the collection of black-browed albatross and rockhopper penguin eggs. The Ordinance extends to cover the territorial waters of the Falklands (up to 12 nm offshore).

Note that the Fisheries Ordinance 2005 (Section 3.1.7.3.9) also requires the use of mitigation measures to prevent the incidental capture of seabirds in longline and trawl fisheries.

7.5.1.4 Marine mammals

The Marine Mammal Ordinance 1992 (Section 3.1.7.3.7) protects all marine mammals within Falkland Islands waters. It is an offence to take, wound or kill any marine mammal. According to the IUCN Red List, which assesses the conservation status of all species, there are four cetacean species that occur within Falkland Islands waters that are formally threatened. Sei and blue whales are 'Endangered' and

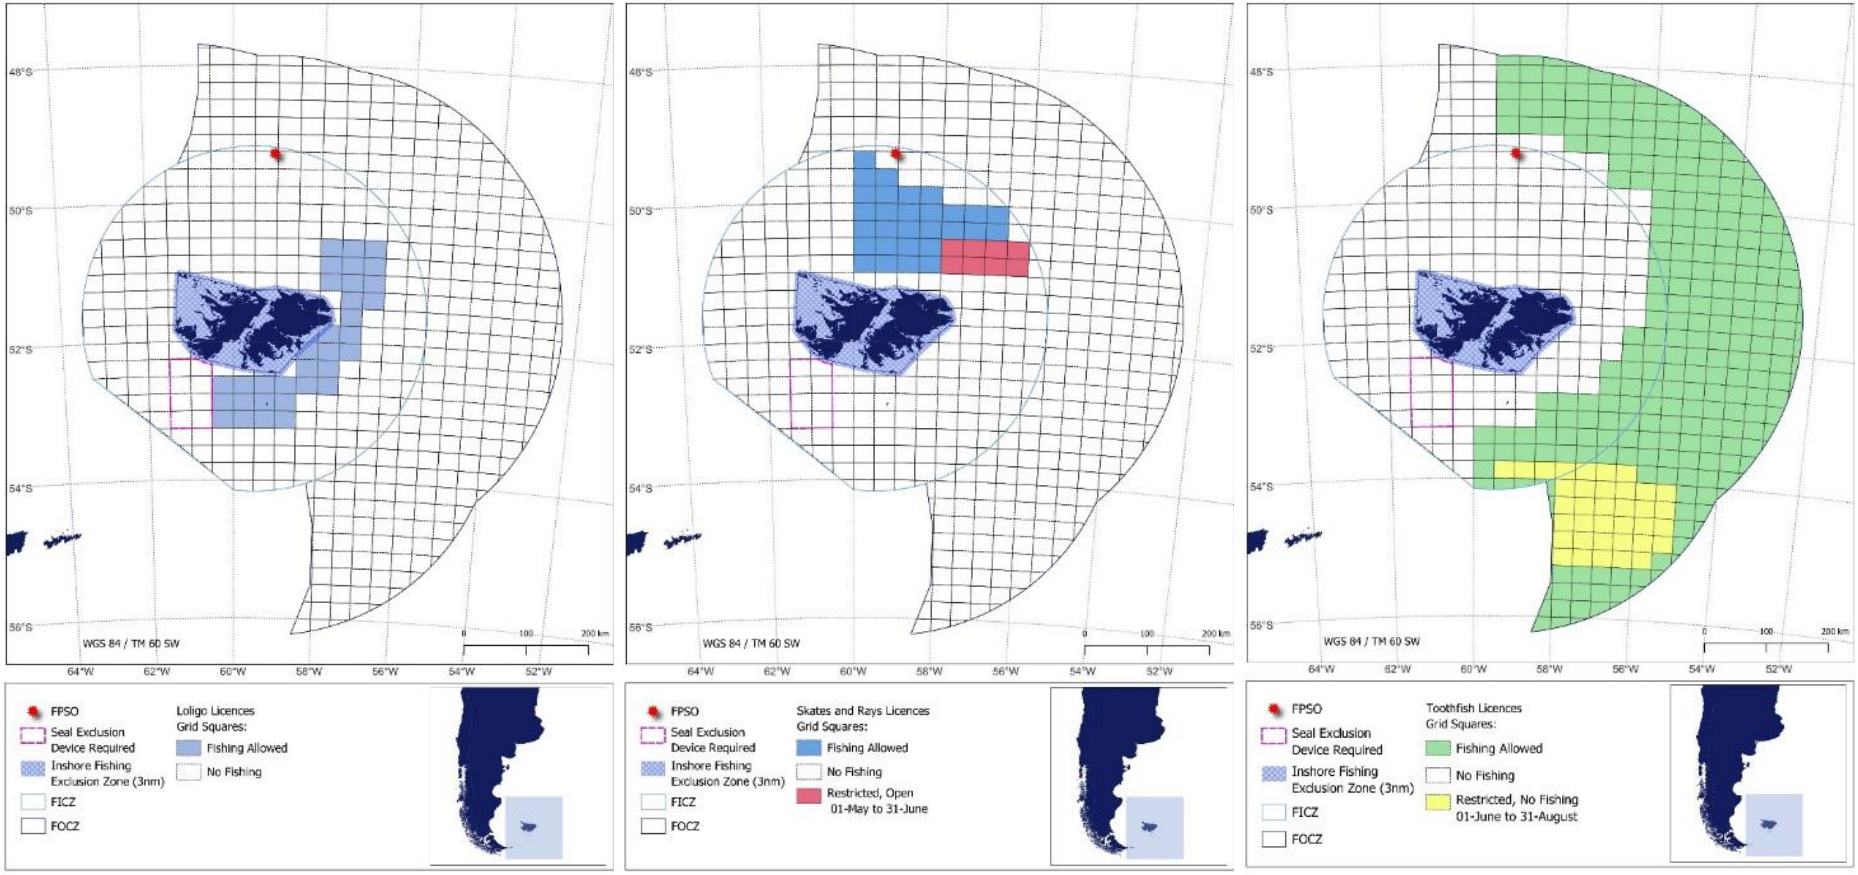
fin and sperm whales are classified as ‘Vulnerable’. Sei whales are regularly sighted within Berkeley Sound (Section 7.4.6.3).



a) Blue whiting and hoki

b) Finfish

c) Argentine shortfin squid (*Illex*)



d) Patagonian squid (loligo) e) Skates and rays f) Patagonian toothfish

Figure 7-107: The Falkland Islands Conservation Zones showing permanent and seasonal no-take zones

7.5.1.5 Terrestrial plants species

The Important Plant Area (IPA) directory for the Falkland Islands (Upson, 2012) identifies a number of endemic plant species and habitats that are of international conservation importance within the Falkland Islands. There are 178 vascular plant species native to the Falkland Islands including 14 endemic species, with 19 species currently protected under the Conservation of Wildlife and Nature Ordinance 1999. Six endemic species, listed below, are categorised as of global conservation concern, mostly due to their small population sizes and restricted ranges (Upson, 2012):

- Antarctic cudweed (*Gamochaeta antarctica*) – IUCN 'Endangered',
- Falkland false-plantain (*Nastanthus falklandicus*) – IUCN 'Endangered',
- Hairy daisy (*Erigeron incertus*) – IUCN 'Endangered',
- Moore's plantain (*Plantago moorei*) – IUCN 'Endangered',
- Falkland rock-cress (*Phlebolobium maclovianum*) – IUCN 'Vulnerable', and
- Falkland nassauvia (*Nassauvia falklandica*) – IUCN 'Unlisted'.

Upson and Lewis (2014) collate all the available information regarding plant distribution in the Falkland Islands into a distribution atlas. The distribution of the six species listed above are described as follows:

- Atlantic cudweed was only found in approximately six locations over the entire Falkland Islands,
- Falkland rock-cress is distributed across the Islands, although none have yet been found in the south of East Falkland,
- False plantain has only been found in the south of West Falkland,
- Hairy daisy is found in several locations along the west of West Falkland and in four locations on East Falkland,
- Falkland nassauvia and its distribution is still being studied, and
- Moore's plantain is also only found at a few locations in the south of West Falkland (Upson, 2012).

Antarctic Cudweed, Falkland Rock Cress and Hairy Daisy are all found in coastal environments and have been confirmed to occur in Port Louis Harbour within Berkeley Sound (Upson and Lewis, 2014). They may occur more widely in the Berkeley Sound area but detailed surveys have not been conducted in all areas. These species could be impacted by beach stranded oil or by vehicular and personnel access for response operations. The remaining three species (False Plantain, Moore's Plantain and Falkland nassauvia) occur only on West Falkland (Upson and Lewis, 2014) and are not significant to the current assessment.

7.5.2 Protected habitats

There are currently three categories of environmental and wildlife protection which are applicable within the Falkland Islands:

- Terrestrial National Nature Reserves (through the Conservation of Wildlife and Nature Ordinance (1999)),
- Marine Protected Areas (MPAs - none in place to date), however there are a number of proposed MMAs (Section 7.5.2.2),
- Scientific designations for globally important habitats:
  - Important Bird Areas (IBAs),
  - Important Plant Areas (IPAs),

- Ramsar sites
- Key Biodiversity Areas (KBAs), and
- Important Marine Mammal Areas (IMMAs).

Note: it is not possible to assess the overall health of the local designated sites without dedicated monitoring and management plans for each site. The development of such plans is the responsibility of the landowners e.g., FIG, private ownership etc., (Section 7.7.2.3).

7.5.2.1 Terrestrial National Nature Reserves (NNR)

National Nature Reserves (NNRs) are established under the Conservation of Wildlife and Nature Ordinance (1999). There are currently 19 NNRs within the Falkland Islands (Table 7.34, Figure 7-108), which are either owned by FIG, private landowners, or organisations, such as Falklands Conservation. There are two NNRs within Berkeley Sound; Cochon and Kidney Islands and Volunteer Point and Cow Bay (Table 7.34, Figure 7-108).

Although the protection of these NNRs is underpinned by legislation, the main mechanism used to facilitate protection and management of these sites is the development and implementation of management plans by both FIG and landowners/stakeholders. FIG can designate marine NNRs (also referred to as Marine Managed Areas (Section 7.5.2.2 below)). Although marine NNRs have yet to be proclaimed, there are some sites currently under review. Terrestrial NNRs may also be extended by 15 miles offshore from the coast.

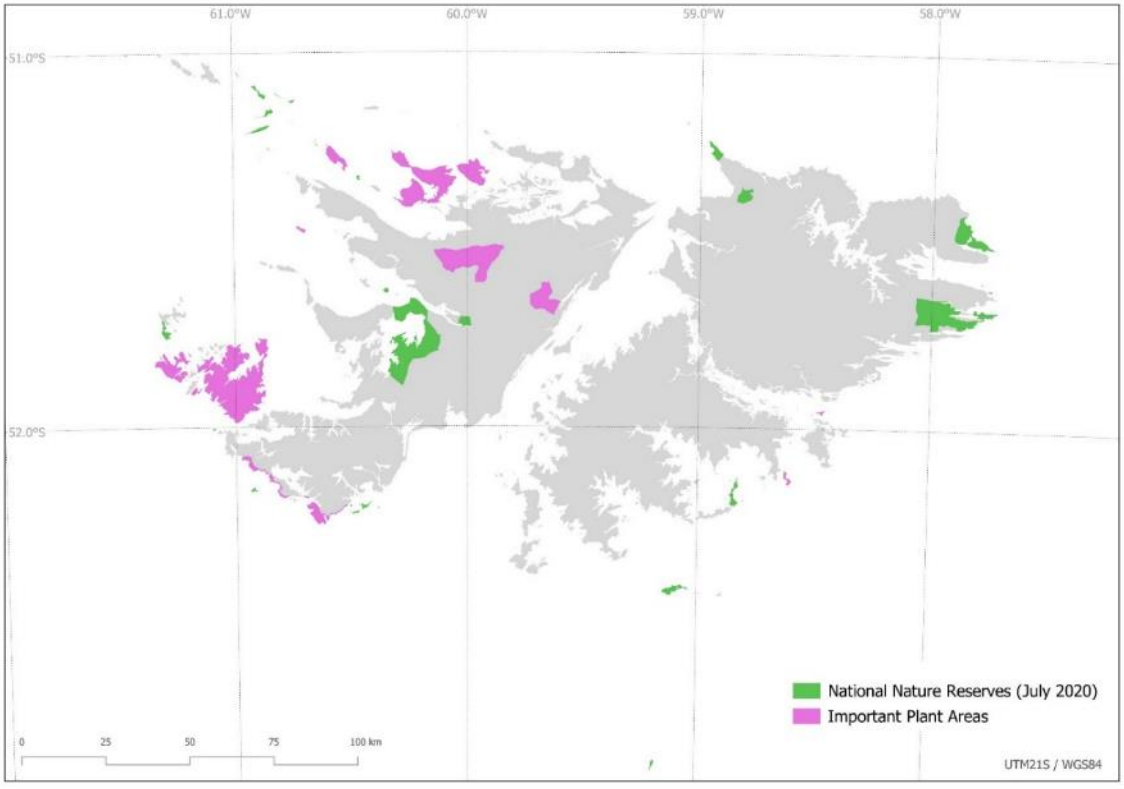

Figure 7-108: Falkland Islands National Nature Reserves and Important Plant Areas

7.5.2.2 Marine Protected Areas (MPAs) / Marine Managed Areas (MMAs)

The Falkland Islands EEZ is rich in marine biodiversity, including globally threatened seabirds and marine mammals. The Fisheries Ordinance 2005 does afford protection to the marine environment and designates a number of no-take zones. However, to date no MPA's have been officially designated in the seas surrounding the Falkland Islands. There is already risk to the Falkland Islands marine environment from resource extraction and such pressures are likely to intensify and include new developments and related changes to coastal land-use. Existing practice and legislation need to be improved to manage current and potential future threats, to protect threatened species, sites and habitats.

The Falkland Islands Biodiversity Framework 2016-30 (FIG, 2016a) sets out the Falkland Islands Government vision with regards to:

> *'Biodiversity namely to 'conserve and enhance the natural diversity, ecological processes and heritage of the Falkland Islands, in harmony with sustainable economic development.'*

The lack of integrated land / sea zoning and management was identified as one of the highest priorities that need addressing in the Falkland Islands in the 2012 workshop report from the FCO/JNCC funded project 'Environmental Mainstreaming' (JNCC, 2012).

The need for a holistic marine management approach across all sectors that promotes sustainable use of Falkland Islands marine resources and that safeguards its biodiversity is recognised. Therefore, a long-term process of Marine Spatial Planning (MSP) began in 2014 with the 'MSP in the Falkland Islands (DPLUS027) project. Following the successful conclusion of DPLUS027, a second MSP phase covered, among other things, the Assessment of Fishing Closure Areas as Sites for wider management (AFCAS) as potential MMAs, using criteria for Marine Protected Areas (MPA's) to help guide the areas selected.

A consultation and post-consultation workshop concluded further data were required to inform the process and this was the genesis of DPLUS071 (Fine scaling the design of Falkland Islands MMAs). Several proposed MMAs are being taken forward by FIG through finer scale policy design and subsequent legislative drafting.

The currently proposed Falkland Island MMAs are showed in Figure 7-109. The proposed MMAs include marine Sustainable Multi-Use zones (SMZs) and National Marine Nature Reserves (NMNRs). The SMZs and NMNRs will have different MMA management levels, if designated.

The MSP/MMA process in the Falklands encapsulates the requirements for both multiple sustainable economic use of the marine environment, and marine conservation and protection. The requirement for a robust evidence-base to make designation of MMAs meaningful from an ecological perspective is also core to this process.

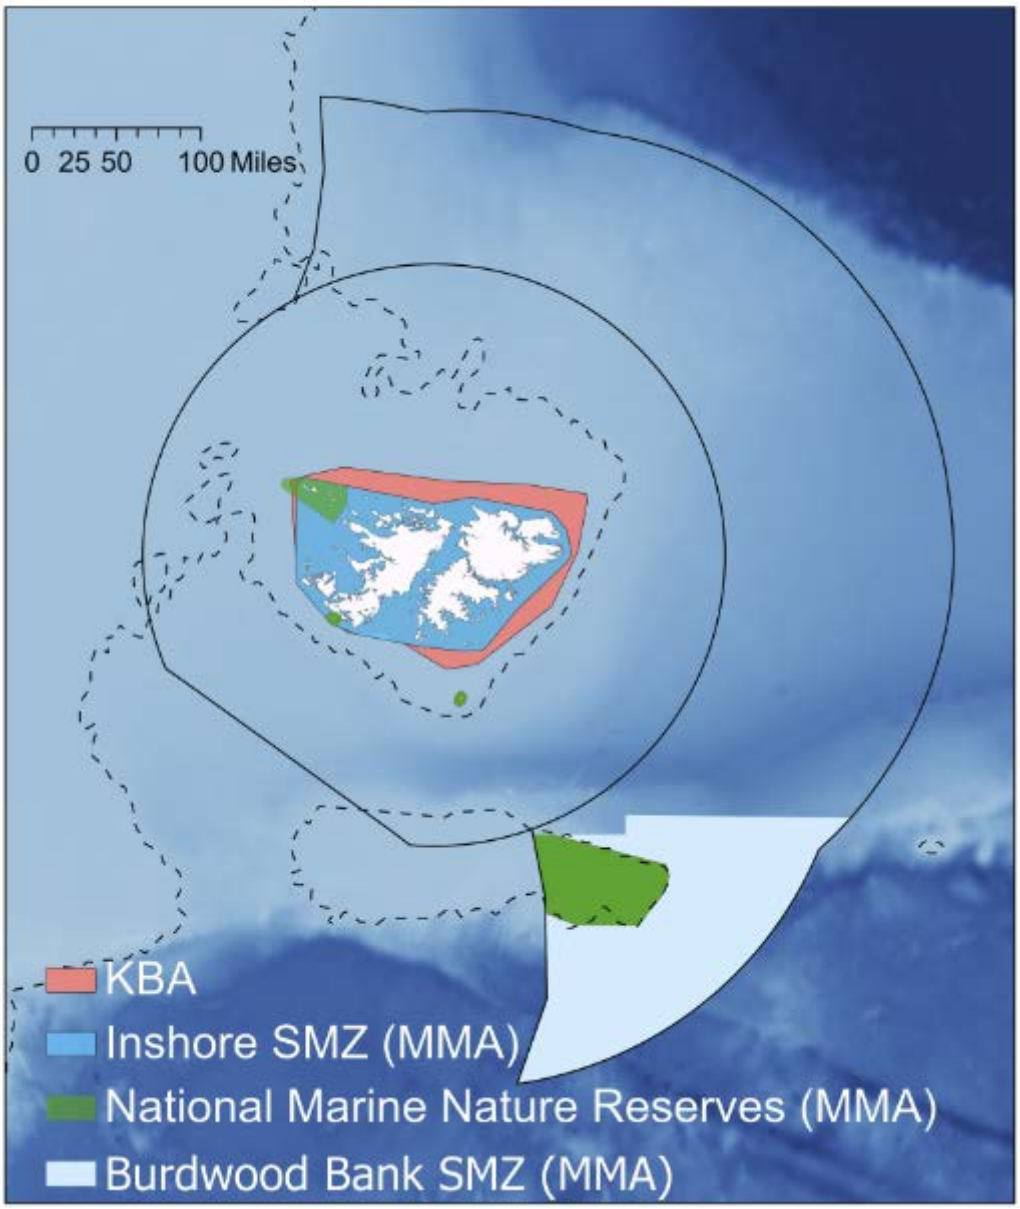

Figure 7-109: The location of currently proposed Marine Managed Areas (MMAs). MMAs include proposed Sustainable Multi-use Zones (SMZ) and National Marine Nature Reserves. Also shown are the non-statutory marine Key Biodiversity Areas (KBA)

7.5.2.3 Scientific designations for globally important habitats and sites

In addition to the NNR system, there are a number of scientific designations that serve to recognise the globally important nature of sites within the Falkland Islands. Important Bird Areas (IBAs) and Important Plant Areas (IPAs) use a set of internationally agreed criteria and regionally defined thresholds to determine whether a particular site meets the requirements. In the Falkland Islands, IBA and IPA status does not provide legal protection *per se*, but should be considered as important informants to forward planning (e.g., Protected Area establishment) and risk assessment initiatives. Ramsar sites are also designated on the basis of meeting a set of criteria, but are slightly different to IBAs and IPAs in that the Falklands are included in the UK ratification of the Ramsar Convention, and have certain responsibilities under the ratification.

7.5.2.3.1 Important Birds Areas (IBAs)

The IBA system was developed by BirdLife International as a means of recognising globally important sites for birds, to inform the protection and conservation of bird species. Within the Falkland Islands, Falklands Conservation is responsible for administering the IBA programme. There are currently 22 IBAs in the Falkland Islands, 17 of which are islands or island groups, and the other five are found on the mainland of East or West Falkland (Table 7.35; Figure 7-110). Any terrestrial based IBA may be extended by 15 miles into the offshore environment. Although there are currently no marine IBAs established, work is ongoing to determine candidate areas. The level of legal protection associated with IBAs varies from country to country. In the Falklands, IBA status does not infer any legal protection but they are useful for informing management decisions.

Table 7.35: Confirmed Important Bird Areas for breeding sites in the Falkland Islands and Berkeley Sound in particular[1]

IBA Code	Site Name	Area (km^2)	IBA trigger seabird Species, life-cycle	Distance from Sea Lion Field (km)
Confirmed IBA – Terrestrial breeding areas (Falkland Islands overall)

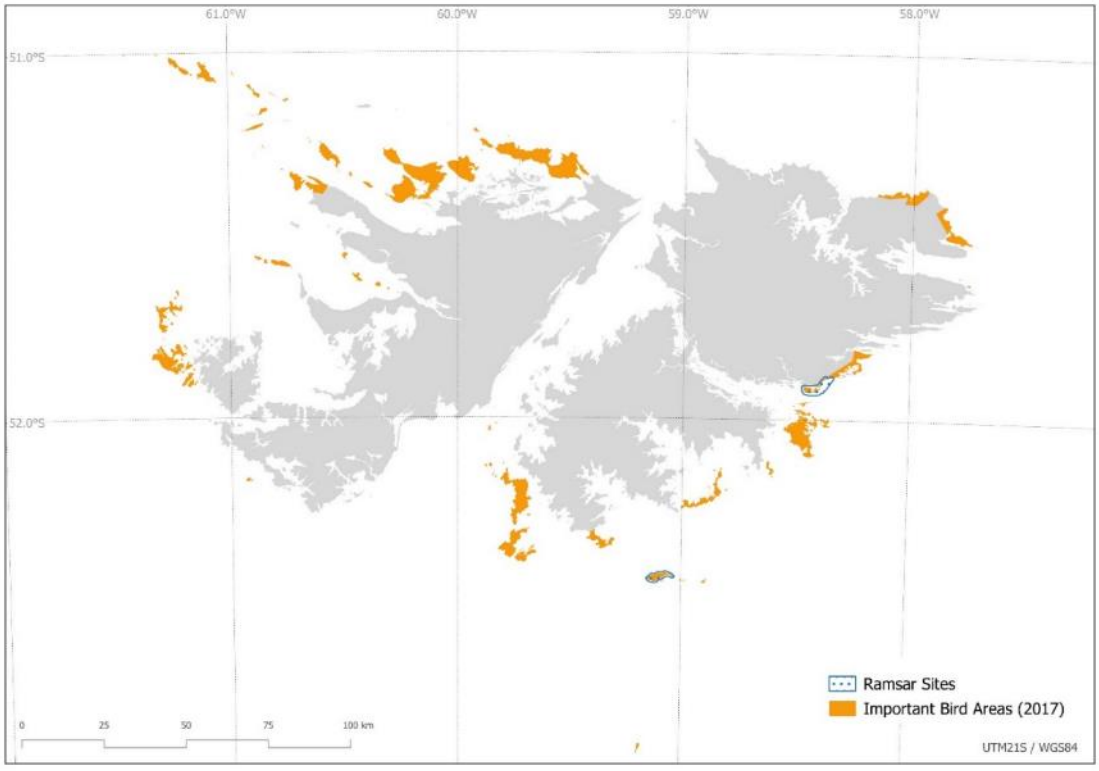

Figure 7-110: Current Important Bird Areas (IBAs) and Ramsar Sites (Bertha's Beach and Sea Lion Island) around the Falkland Islands *(Source: BirdLife International, 2014a)*

7.5.2.3.1.1 IBAs in Berkeley Sound

Kidney Island Group

The Kidney Island Group is composed of two small islands off the southern coast of Berkeley Sound; Kidney and Cochon Islands. Kidney Island lies approximately 400 m off the coast of East Falkland at the mouth of Berkeley Sound, near Mengeary Point, and is 32 hectares (ha) in area. Cochon Island is situated approximately 1,330 m to the north-west of Kidney Island, about one kilometre off the coast of East Falkland, and is eight hectares in area. The Group is owned by the FIG and is designated as a NNR and an IBA.

Kidney Island is low lying and dominated by mature tussac (*Poa flagellata*), which grows to over 2.5 m in height. Tussac grass forms habitat for a number of burrowing seabird species, with sooty shearwaters being the most numerous breeding species on the Island. The population has increased

in size since the 1960s and is now believed to number 139,000 pairs (Wakefield, *et al.,* 2017). Other burrowing seabirds that are known to breed on the Island include: Magellanic penguin, white-chinned petrel, great shearwater, grey-backed storm-petrel and common diving-petrel. The northern coast is fringed by cliffs (18 m in height) and is home to breeding rockhopper penguins, rock and imperial shags.

Kidney Island remains rat-free and is home to breeding populations of the Falklands' three endemic bird species: Cobb's wren, tussac bird and Falkland steamer duck.

The sub-littoral waters around Kidney Island support a diverse range of habitats and species (SMSG, 2012).

Cochon Island largely consists of steep-sided slabs of rock, which rise to 30 m above sea level. There is little soil on the Island and vegetation is largely restricted to patchy tussac grass. The diversity of breeding birds on Cochon Island is not as great as that on Kidney but it does support a small population (250 pairs) of rockhopper penguins and a large colony of imperial shags.

Both Islands are used as haul-out sites for South American sea lions, although they are not known to breed on the Kidney Island Group.

The proximity of these Islands to shipping routes and anchorages in Berkeley Sound mean that there is a risk of impact from accidental oil spills or the introduction of non-native species such as rats. A management plan has been written to address the management issues that affect both of these Islands (FIG, 2013a).

The Kidney Island Group is designated as an Important Bird Area (Falklands Conservation, 2006). The most significant species contributing to the IBA status are shown in Table 7.36.

Kidney Island also has Key Biodiversity Area (KBA) designation. Kidney, Top and Bottom Islands also represent ACAP breeding sites No. 80 and 81 for white-chinned petrels.

Along with the species listed in Table 7.36, Kidney Island is the only confirmed breeding site for great shearwater outside of the Tristan da Cunha Group (Woods, 1970). A very small population, estimated at no more than 15 pairs (Woods and Woods, 1997), breed at the western end of the Island. The sooty shearwater colony on Kidney Island is believed to be the largest in the Falkland Islands.

Table 7.36: Kidney Island Group IBA criteria ***(Source: Falklands Conservation, 2006)***

Species	IBA Criteria	Population estimate	Comment
White-chinned petrel	A1: Vulnerable species	Approx. 1,000	Kidney population mainly along southern coastal slopes
Rockhopper penguin	A1: Vulnerable	512	Kidney (257) increasing slowly, but historic decline since 1930s (c.3,500 pairs), Cochon (264) declining
Magellanic penguin[1]	A1: Near Threatened[1]	unknown	Numerous Kidney, not counted
Sooty shearwater	A1, A4ii: Near Threatened, > 1 % of the global population	>100,000	Kidney population has increased since 1960s, possibly two burrows per square metre
Cobb's wren	A1, A2: Vulnerable, Restricted range	unknown	Widespread and numerous on Kidney not counted
Tussac bird	A2: Restricted range	unknown	Numerous on Kidney beaches not counted
Falkland steamer duck	A2: Restricted range	15	Fluctuates from 6 - 15 pairs
Combined seabirds	A4iii: Supports >10,000 pairs of seabirds	>102,000	-

[1] Note that since the IBA designation, the Magellanic penguin IUCN Red List status has been downgraded to Least Concern (most recently assessed in 2020).

Volunteer Point and Cow Bay

Volunteer Point is a lowland peninsula on the northern coast of Berkeley Sound and marks the northern entrance to the Sound. North of Volunteer Point, lies Cow Bay, which combined represent an NNR and IBA covering 4,060 ha. The land is privately owned by Jan Cheek and is a popular tourist visitor site.

The northern coast of Volunteer Point includes a range of low cliffs, sandy and boulder beaches with extensive kelp beds offshore. The southern side of the peninsula borders Volunteer Lagoon and includes the extensive sand flats and dunes of Lagoon Bar.

Volunteer Green supports the largest colony of king penguins in the Falklands but also supports breeding gentoo and Magellanic penguins. Beyond the penguin colonies on the green, Volunteer Lagoon supports a variety of waterfowl. The species that contribute to the IBA status are shown in Table 7.37.

Table 7.37: Volunteer Point IBA criteria ***(Source: Falklands Conservation, 2006)***

Species	Criteria	Breeding pairs	Comment
Gentoo penguin	A1: Near threatened	1,368	2001 Volunteer Green 766, Lagoon Bar 325, Cow Bay 277
Magellanic penguin[1]	A1: Near threatened[1]	>2,000	2003, extensive coastal colony
Ruddy-headed goose	A2: Restricted range species	>100	Scattered throughout site
Black-throated finch	A2: Restricted range species	Unknown	Breeding in heathland and coastal vegetation, no counts
Falkland steamer duck	A2: Restricted range species	About 75	Volunteer Point 60 along coast, Cow Bay 10

[1] Note that since the IBA designation, the Magellanic penguin IUCN Red List status has been downgraded to Least Concern (most recently assessed in 2020).

7.5.2.3.2 Important Plant Areas (IPAs)

IPAs were established by Plantlife International and the IUCN with a view to identifying locations that will allow the best protection of threatened plant species. The IPAs are chosen based on whether the location has one or more species that are of global conservation concern, or has a rich population of regional flora (Upson, 2012). There are currently 17 IPAs within the Falkland Islands, none are close to Berkeley Sound (Upson, 2012).

7.5.2.3.3 Ramsar sites

The Ramsar convention was established in 1971. It provides for the protection of all habitats that fall under the umbrella description ‘wetlands’, which includes marshes, peat bogs, oases, ponds, lakes and the marine inshore environment. There are currently two Ramsar sites within the Falkland Islands: Sea Lion Island and Bertha’s Beach (Figure 7-110 above), both of which are also designated as IBAs; Sea Lion is also an NNR. There are currently 18 further sites which are being considered for Ramsar designation.

7.5.2.3.4 Key Biodiversity Areas

Key Biodiversity Areas (KBAs) are widely used to help inform conservation planning (IUCN, 2016). KBAs are sites that ‘contribute significantly to the persistence of global biodiversity’. They are one of several conservation prioritisation tools (others include Important Marine Mammal Areas and Ecologically or Biologically Significant Marine Areas). The global KBA program is administered by the KBA partnership, which is comprised of 12 international NGOs. KBAs are non-statutory.

The vision of the KBA Programme is:

> *'a comprehensive network of sites that contribute significantly to the global persistence of biodiversity is appropriately identified, correctly documented, effectively managed, sufficiently resourced and adequately safeguarded.'*

Recently, two marine KBAs have been designated in the Falkland Islands. These are the Falkland Islands Inshore (to 100 m depth) KBA and Beauchene Island. The data underpinning the Inshore KBA assessment and designation were for sei whales (IUCN 'Endangered') and seabirds[37]. The sei whale assessment was based on population estimates using photo-identification, predictive modelling and extrapolations of data from aerial surveys and line transects (Weir, 2021). These data indicated that the seasonal nearshore population of sei whales was >0.1 % of the global population. The Inshore KBA designation for sei whales was therefore based upon the lower KBA threshold (A1c) provided for species which have been assessed as IUCN 'Endangered' 'due only to population size reduction in the past or present'. The seabird KBA triggers were a marine extension of globally important seabird colonies (buffers around colonies) (Weir 2021; Handley, *et al*., 2023).

Overall the KBA assessments concluded that the following 10 species have populations which trigger global KBA criteria:

- Sei Whales (EN),
- Black-browed Albatross (LC),
- Southern Giant Petrel (LC),
- Sooty Shearwater (NT),
- Slender-billed Prion (LC),
- Brown Skua (LC),
- Dolphin Gull (LC),
- Gentoo Penguin (LC),
- Southern-Rockhopper Penguin (VU), and
- Falkland Steamer Duck (LC).

For full details about the assessments for sei whales and seabirds, please see: Weir (2020; 2021) and Handley *et al.* (2023). In addition, marine KBAs were also assessed using the GAP tracking data, which revealed the majority of the Falkland Islands EEZ (over 70 %) qualifies as a KBA (Baylis, *et al.,* 2021a).

However, like many datasets described within this EIS, there are limitations associated with KBA data. For example, while KBA criteria and thresholds are indeed standardised, the methods used to identify areas to assess against these criteria, are not standardised. This means that KBA boundaries could differ by orders of magnitude, depending on the approach used to delineate boundaries. For an in-depth review of KBA methods and challenges in the context of tracking data, see Baylis, *et al.* (2021).

The Falkland Island KBAs are shown in Figure 7-109 above.

7.5.2.3.5 Important Marine Mammal Areas (IMMAs)

IMMAs are areas identified as important habitat for marine mammals, and are defined as:

[37] **Post-consultation note (July 2025):** In 2024, a wintering southern right whale (IUCN 'Least Concern') candidate KBA was proposed as the right whale populations exceeded 1% of the global population (Weir, 2024), thus triggering the KBA designation under Criterion D1a. This KBA was designated but given the overlap in the areas covered, was subsequently subsumed into the existing Inshore KBA (Weir, 2024) which is now designated for the sei whales, seabirds *and* the southern right whale.

'A discrete portion of habitat, important for one or more marine mammal species, that has the potential to be delineated for conservation'.

IMMA designation can be based on both quantitative and qualitative criteria. However, IMMAs are non-statutory, have no legal standing, and do not take into account socio-economic and political concerns. IMMAs are one of several conservation planning and prioritisation tools, and complement and support existing tools such as IBAs, KBAs, and EBSAs and much of the Patagonian Shelf has been designated an IMMA.

Recent marine mammal work conducted by Falklands Conservation has resulted in two Important Marine Mammal Areas (IMMAs) as follows:

- The Falkland Islands Inner Shelf Waters IMMA from the coast to 100 m water depth. It supports a globally-significant and annually-persistent seasonal feeding aggregation of IUCN 'Endangered' sei whales (*Balaenoptera borealis schlegelii*), and provides important year-round habitat used for calving and feeding by Peale's dolphins (*Lagenorhynchus australis*) and Commerson's dolphins (*Cephalorhynchus commersonii*). The coastline provides breeding habitat for a globally-significant South American fur seal (*Arctocephalus australis*) population, and for the post-sealing recoveries of local breeding populations of southern elephant seal (*Mirounga leonina*) and South American sea lion (*Otaria byronia*). It also hosts an important moulting and resting aggregation of southern elephant seals from breeding populations of the South Georgia Stock.
- The North-east Falklands right whale wintering area IMMA which supports a regionally important wintering aggregation of southern right whales (*Eubalaena australis*), which use the region as a mating, socialising and resting area (Weir and Stanworth, 2020; Weir, 2022; Cerchio, *et al.,* 2022). Systematic research of baleen whales in the Islands only commenced in 2017, providing the first indication of the winter presence of right whale aggregations in nearshore areas (Weir, 2017). Since then, full winter seasons of coastal boat surveys to target the species have been carried out during 2019, 2020 and 2022 to assess its ecology and occurrence in the region (Weir and Stanworth, 2020; Weir 2022).

7.5.2.4 Threatened terrestrial Habitats

Under the Falkland Islands Biodiversity Framework, four terrestrial habitats have been identified as vulnerable, these are:

- Mainland tussac,
- Whitegrass-fachine acid grassland,
- Fachine scrub, and
- Boxwood scrub (framework still in draft)

However, this list of threatened habitats is only preliminary as it is based on the current, limited knowledge of these habitats and the extent and degree of threat that they face. A variety of wetland sites may also be under threat, but this requires further investigation. The main threat to terrestrial habitats has been through degradation associated with the introduction of grazing herbivorous animals for farming (RPS Energy, 2009; Upson, 2012).

7.5.3 Priority conservation species and habitats

A number of species and habitat types have been identified through criteria associated with listings under international conventions, global and national conservation status and changes in population, distribution and risk from specific threats as a priority for conservation efforts in the Falklands (FIG,

2008a). The species and habitats concerned are listed in Table 7.38. Specific action plans have been prepared for some, but not all, of these.

Many of these priority species are marine or coastal in distribution and are therefore vulnerable to O&G industry related impacts. Additionally, these species are likely to be the focus of inshore monitoring efforts. However, to date no sub-littoral species or habitats have been identified as a priority for conservation.

Table 7.38: Species and habitats of conservation concern in the Falklands and their action plan status

Comprehensive Action Plan required		Basic Action Plan required	
Mainland tussac grass	-	Endemic plants (13 species)	-
Whitegrass-fachine acid grassland	-	Californian club-rush stands	-
Fachine scrub	-	Mountain bluegrass	-
Boxwood scrub	-	Falklands steamer duck	-
Threatened plant species (22 species)	-	Cetaceans	✓
Black-browed albatross	✓	Peale's and Commerson's dolphins	✓
Striated caracara	-	Seals and sea lions	✓
Southern rockhopper penguin	✓	Southern giant petrel	✓
Cobb's wren	✓	Gentoo penguin	-
Zebra trout	-	Magellanic penguin	-
-	-	Falkland fritillary	-
-	-	Ruddy-headed goose	-
-	-	White-chinned petrel	✓

7.6 Coastal Sensitivity to Oil Spills

7.6.1 Environmental Sensitivity Index (ESI)

IPIECA (2016) provides a framework for coastal sensitivity mapping for oil spill response based upon coastal habitat type and the associated Environmental Sensitivity Index (ESI) developed from Gunlach and Hayes (1978) Oil Sensitivity Index. The ESI is a ranking system whereby different coastal zones with varying characteristics are ranked according to their environmental sensitivity. The ESI ranks habitats, assessed qualitatively, on the ease of cleaning, the rate of natural oil degradation (high / low energy) and the likely probability that an impact will be observed, rather than attempt to quantify the actual absolute impact.

The ESI (Table 7.39), ranging from 1 (low sensitivity) to 10 (very high sensitivity), can be adapted for a range of habitat types and integrates the:

- Shoreline type (grain size, slope) which determines the capacity of oil penetration and / or burial on the shore, and movement,
- Exposure to wave (and tidal energy) which determines the natural persistence time of oil on the shoreline,
- Shoreline slope,
- Ease of clean-up, and
- Ease of restoration.

The assessment was predominantly based upon shoreline type derived from Google Earth imagery and local knowledge along with a subjective assessment of exposure given predominant wind directions. A full breakdown of the methodology and results is given in Marengo (2014a).

Table 7.39: Environmental Sensitivity Index (ESI) definitions

ESI	Estuarine	Riverine
1A	Exposed rocky shores	Exposed rocky banks
1C	Exposed rocky cliffs with boulder talus base	Exposed rocky cliffs with boulder talus base
2A	Exposed wave-cut platform in bedrock / mud / clay	Rocky shoals, bedrock ledges
2B	Exposed scarps and steep slopes in clay (unconsolidated sediment)	-
3A	Fine to medium-grained sand beaches	-
3B	Scarps and steep slopes in sand (unconsolidated sediment)	Exposed, eroding banks in unconsolidated sediments
3D	Scarps / steep slopes in bedrock or flat rocks	-
4	Course-grained sand beaches	Sandy bars and gently sloping banks
5	Mixed sand and gravel beaches	Mixed sand / gravel bars and gently sloping banks
6A	Gravel beaches (granules and pebbles)	Gravel bars and gently sloping banks
7	Exposed tidal flats	-
8A	Sheltered scarps in bedrock, mud or clay. Sheltered rocky shores (impermeable)	-
8B	Sheltered solid man-made structures. Sheltered rocky shores (impermeable)	Sheltered, solid man-made structures
8D	Sheltered rocky rubble shores	-
8E	Peat shorelines	-
8F	-	Vegetated, steeply-sloping bluffs
9A	Sheltered tidal flats	-
9B	Vegetated low banks	Vegetated low banks
9	Hyper-saline tidal flats	-
10A	Salt- and brackish-water marshes	-
10B	Freshwater marshes	Freshwater marshes

7.6.2 Sensitivity of north Falklands coastline to offshore oil (crude/MGO) spills

In 2014, POEPL (now Navitas, Section 2.1.1) conducted an assessment of the environmental sensitivity of the north Falklands coastline to a spill of hydrocarbons from the proposed Sea Lion Development (Premier, 2014a). This sensitivity assessment was carried out using industry developed techniques and was informed by conceptual oil spill modelling studies which predicted the potential distribution of oil, and the risk of oil beaching along the north Falklands coastline, in the unlikely event of a worst-case oil spill from the proposed Development location.

The Falklands Coastline Environmental Sensitivity study (Premier, 2014a) remains relevant to this EIA as it highlights the most sensitive sites along the north Falklands coastline, which will inform management decisions in the unlikely event that an MGO spill response operation needs to be initiated.

During the 2018 coastal bird surveys in Berkeley Sound, observations of typical Falkland Islands shoreline types were recorded and given a classification index for the purposes of oil spill planning that parallels the IPIECA (2011) system of Environmental Sensitivity Index. While this does not affect the assessment, it improves the mitigation in terms of the detailed oil spill contingency plans that will follow approval of the project.

7.6.2.1 Coastal sensitivity assessment outputs

Modelling of an offshore oil spill (Section 12.1) shows that while the likelihood of oil reaching the shoreline is very low, there is a higher probability of oil 'waxlets' beaching on East Falkland than on islands to the west.

The sensitivity study highlighted that the north Falklands coastline is exposed and rocky with wave cut platforms and deep scarps which are considered to be of low sensitivity (ESI 1-3) to oil impacts. High sensitivity areas (ESI 8 – 10) include inland tidal creeks, and sheltered tidal flats and were identified as: Volunteer Lagoon, Swan Pond (Port Louis), Salvador Waters, Brazo del Mar, Limpet Creek, Little Creek, Smylie's Inlet, Inner White Rock Bay, Inner Tamar Pass (North and South), Inner Port Purvis, Victor Creek (Pebble Island), Justice Inlet (Keppel), NE Bay Saunders, Brett Harbour (Saunders), Penguin Island (Saunders) (Figure 7-111 and Figure 7-112). In addition to the general sensitivity of the coastline, there is a range of IBAs, IPAs, NNRs and Ramsar Sites that were considered along with sites of known environmental importance with significant concentrations of wildlife (Section 7.5). While a range of taxa may be impacted by an oil spill, the assessment was predominantly based upon colonial seabirds for which census data are available.

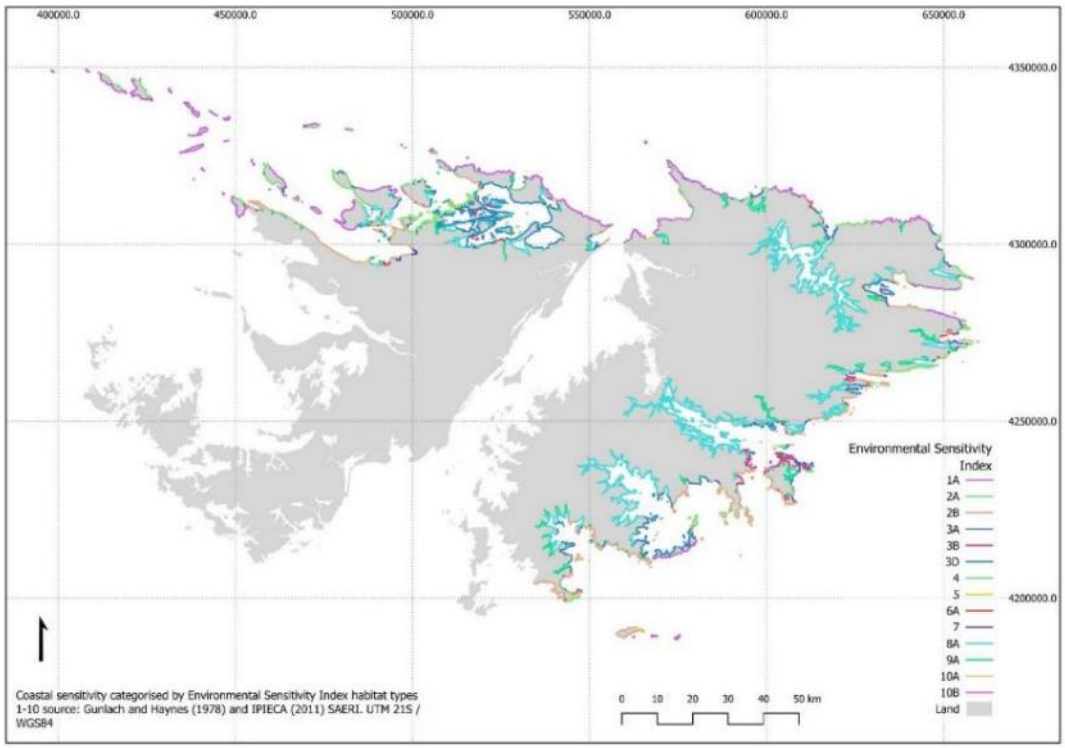

Figure 7-111: ESI North Falklands Coastline. Coastal sensitivity categorised by Environmental Sensitivity Index habitat types 1-10 ***(Source: Gunlach and Hayes, 1978; IPIECA, 2011)***

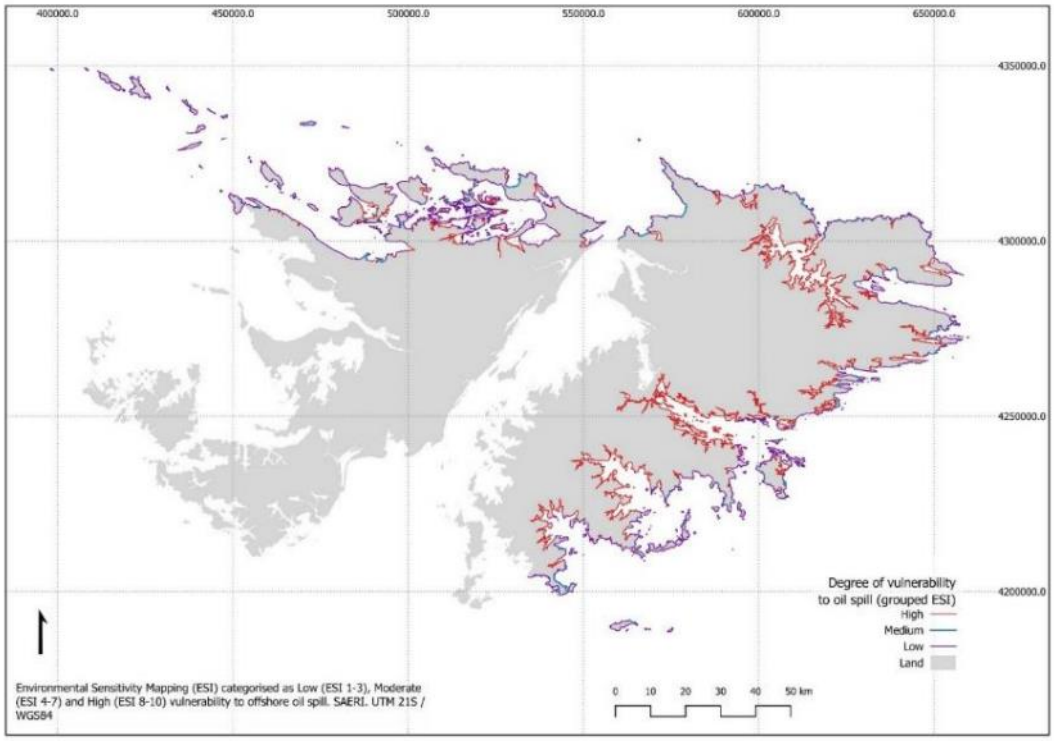

Figure 7-112: North Falklands Coastline. Environmental Sensitivity Mapping (ESI) categorised as Low (ESI 1-3), Moderate (ESI 4-7) and High (ESI 8-10) vulnerability to offshore oil spill

7.6.2.1.1 Environmental sensitivity to offshore oil spill

A review of the seabird colony locations with respect to coastline type, the seasonality of occurrence and the Oil Vulnerability Index (OVI) of the species (Section 7.4.5.6.1) suggest that gentoo penguins may be the most vulnerable to impacts and would be suitable to use as a ranking proxy. Gentoo penguins showed the greatest overlap with sensitive coastline types (ESI), associate with breeding colonies through-out the year, and have a high OVI.

The conservation importance of black-browed albatross and rockhopper penguins was recognised. Due to the tendency of these species to utilise more exposed rocky coastlines of low sensitivity, sites were not prioritised in the first instance. Real-time monitoring during an incident should determine the need for any subsequent re-prioritisation or response intervention on site.

Additional species and taxa were not considered either due to a lack of quantitative data that could be extrapolated to un-surveyed coastlines or to a widespread distribution across the coastal habitat types, which gave little differentiation between coastlines for ranking purposes.

7.6.2.1.2 Socio-economic sensitivity to offshore oil spill

Socio-economic factors were considered and the relative level of tourism utilised to further differentiate the environmental and socio-economic sensitivity of sites. The occurrence of fine-grained sand beaches in proximity to penguin colonies was identified as an important tourism resource, albeit that these sites are of relatively low sensitivity (Figure 7-111 above, ESI 3).

The study also mapped the location of infrastructure that might assist a response and mobilisation to the northern coastline. For example, the location of road, tracks, jetties (and slipways), ports, airstrips, settlements and shanties was detailed and mapped, along with their condition where appropriate. This will enable Navitas to define the level of resources required to mount an appropriate response.

7.6.2.1.3 Prioritisation and management of offshore oil spill response

Due to the spatial extent of the north Falklands coastline and the associated issues with regards to access and response time, it is evident that some prioritisation will be required. Prioritisation should focus response on those areas where capacity can be best deployed to tackle the maximum extent of sites, which are most at risk of biologically significant or socio-economic impacts.

A pragmatic compromise will need to be reached that balances the importance of a site with the level of resources that are required. This may mean that some important sites may not be tackled in favour of other more accessible sites where remedial actions will be able to be conducted over a greater spatial area.

The final long-listing of sites utilised the coastal ESI, location of notable scenic beaches, the occurrence of gentoo penguins, overlap with an environmental land designation and relative level of tourism activity.

The highest ranked sites for response are located at:

- Volunteer Point,
- Pebble Island,
- Saunders Island, and
- Carcass Island.

Important and secondary ranked sites for response are located at:

- Swan Pond and Seal Bay coastline,
- Brazo del Mar and entrance to Salvador Waters,
- Bougainville, Concordia and Limpet Creek coastline,
- Cape Dolphin Swan Pond Beach,
- Smylie's Inlet and Paloma Beach,
- Grave Cove, Dunbar, and
- Steeple Jason.

The grouping of sites into geographical areas will assist in the mobilisation of resources and may permit some secondary ranked sites to be tackled with adjacent higher priority sites. Geographic groupings with multiple sites would include:

- Volunteer Point and Cow Bay,
- Swan Pond and Seal Bay,
- Entrance to Salvador Waters,
- Limpet Creek and Concordia,
- Cape Dolphin and Elephant Beach,
- Paloma Beach, Smylie's and Race Point,
- Pebble Island, and
- Saunders Island.

The ESI classification and location of significant wildlife sites provides the background and basis for prioritising sites for oil spill response. It is however recognised by IPIECA (2011) that the relative importance of ranking criteria will be influenced by local perceptions and that ranking should not rely solely upon a quantitative analysis. A consultative approach incorporating local stakeholders into the planning process and final prioritisation should be conducted.

7.6.3 Sensitivity of Berkeley Sound coastline to inshore oil (MGO) spills

The inshore coastal sensitivity assessment was predominantly based upon shoreline types identified using Google Earth imagery and local knowledge along with a subjective assessment of exposure given predominant wind directions. A full breakdown of the methodology and results is given in Marengo (2014a).

Figure 7-113 maps the coastline of Berkeley Sound to show the distribution of ESI category habitats. Within Berkeley Sound sensitive coastlines are limited to the upper reaches of the Sound to the west of the LTV anchorages and would be less at risk of oil contamination given the prevailing westerly winds. The coastlines of the outer Sound are largely composed of steep-slopes or cliffs, which have low ESI scores (Figure 7-113). To the north of Berkeley Sound, the adjacent Volunteer Lagoon represents an area of higher sensitivity.

Berkeley Sound, and associated coastline (see Figure 7-113), has a total length of 295 km. Of this, 34 % (101 km) was classed as high sensitivity, 10 km (3 %) is moderate sensitivity and 184 km (62 %) is classed as low sensitivity.

In addition, it is important to understand and map the location of internationally recognised sites and nationally designated sites of environmental importance to identify sensitive ecosystems, critical habitats and endangered species. Therefore to highlight environmentally sensitive areas within the coastal zones adjacent to Berkeley Sound, the occurrence of nationally protected areas and the known locations of key faunal and floral species have been mapped throughout this baseline chapter.

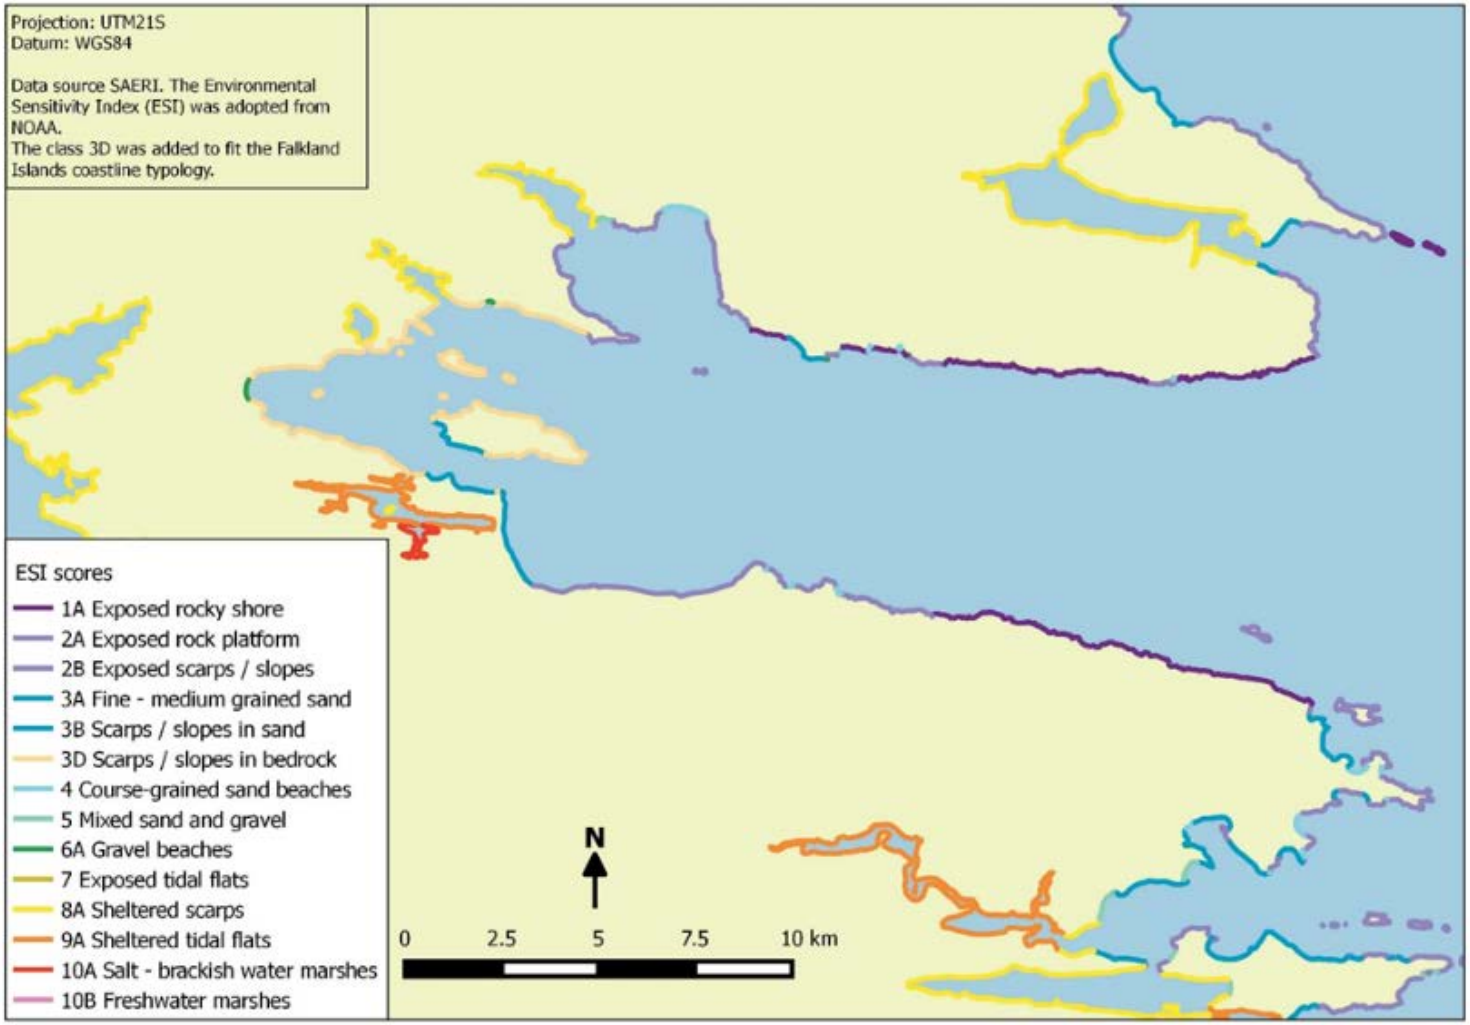

Figure 7-113: ESI Berkeley Sound. Coastal sensitivity categorised by Environmental Sensitivity Index habitat types 1-10

7.6.4 Oil spill history

Eighteen minor oil spills have occurred within Stanley Harbour and Berkeley Sound since the year 2000, all of which involved losses of fuel oil from vessels. The following record of spills was provided by FIMA (February, 2025), however detail on the incidents themselves, the size of the spill and associated fuel oil type were redacted:

- Berkeley Sound – one incident involving a trawler,
- Stanley Harbour (17):
  - FIPASS - 11 separate incidents involving trawlers, long-line fishing vessels, factory vessels, tankers and jiggers,
  - East jetty - Three separate incidents involving ferries, and
  - Stanley Harbour general – three separate incidents involving jiggers and tankers.

7.7 Social Environment

7.7.1 Introduction

In 2012, Rockhopper Exploration commissioned an independent socioeconomic impact assessment to identify potential impacts and mitigation measures to minimise any negative impacts from O&G developments that could be associated with the project (Plexus Energy, 2012). FIG also commissioned an independent socio-economic study of O&G development in the Falkland Islands (Regeneris, 2013). With support from the O&G industry, FIG developed a Social and Economic Monitoring Programme (SEMP), which relies on extensive public consultation. Initial results were published in the Social Economic Monitoring Programme (SEMP report) (Regeneris, 2015). POEPL updated the Sea Lion Socio-economic Impact Assessment in 2019 (Maplecroft, 2019), and FIG published a study on the socio-economic impacts of O&G development in the Falklands looking at a wider perspective, also in 2019 (Simsovic and Ranghetti, 2019).

Navitas are currently working on an update to the Sea Lion socio-economic impact assessment to cover any changes to the project plan and any changes to the socio-economic environment of the Falklands. This section outlines the current social baseline for the Falkland Islands and draws on all of the above reports as well as FIG data, including the recent 2021 Falklands Census. Much of the information presented here is to provide background reference. The EIS focuses on environmental impacts and risks not socio-economic impacts; however, where environmental impacts have the potential for wider socio-economic impact, these are discussed further in the relevant sections.

7.7.2 Human population

7.7.2.1 National identity

The culture of the Falkland Islands is a blend of British culture and elements that have emerged given the Islands' history, location and geopolitical relationships. There is a strong sense of allegiance to Great Britain.

The 2021 Census asked people to state their national identity: 54 % of residents considered themselves Falkland Islanders, 22 % British, 8 % St. Helenian and 5 % Filipino (FIG, 2023l).

There is a strong sense of local community and cohesion due to the small population. High levels of familiarity encourage a safe and welcoming community. While the majority of the population is based in Stanley, the rural life is an important part of Falklands culture. Areas outside Stanley are referred to as 'Camp'.

7.7.2.2 Population size and main settlements

The total usually resident population of the Falkland Islands was recorded at 3,142 (2,818 excluding residents at the Mount Pleasant Complex (MPC)) during the 2021 Population Census (FIG, 2023l). In recent years the economic pull of Stanley, the capital and only city, has attracted people away from Camp (Table 7.40). In 2021, 2,538 people, about 69 % of the total population, resided in Stanley, 8 % in Camp and 9 % (non-military personnel) at MPC, the joint army, air force and navy complex operated by the UK Ministry of Defence (MoD) at Mount Pleasant.

After Stanley the next most populous settlement in the Falkland Islands is Mount Pleasant some 36 miles south-west of Stanley. In 2021, the population in Camp declined since the last census in 2016 from 381 to 280. Goose Green, Fitzroy and North Arm are the most populated settlements on the East; Fox Bay, Port Howard and Hill Cove are the largest on the West (FIG, 2021c). Figure 7-114 shows the main islands in the Falklands archipelago and the locations of the main settlements and connecting roads.

The population of the Falkland Islands is ageing with 33 % of the population in Camp being over 60 years of age and 17 % in Stanley in 2021 (FIG, 2023l).

Alongside the populations of Camp and Stanley there are an estimated 324 civilian contractors who work and reside at MPC. Serving members of the armed forces are not counted in census statistics. The MPC is a largely self-contained community and provides the main airport for international flights to and from the Falkland Islands.

At the last census, 456 work permit holders were recorded in Stanley (FIG, 2023l); work permit holders are those working in the islands on a temporary contract, and they are employed in all sectors in the Falklands. The number of work permit holders is significant to the EIA as accommodation has to be found for all of these people. It is difficult for work permit holders to find affordable accommodation in the private rental sector (A. Black, *pers. obs.*).

In Stanley, just under one third of people in work (487 people) are employed by FIG. Ninety-six percent (96 %) of all employees in the professional, scientific and technical sector have temporary immigration status; other sectors that are reliant on this category of employees are hospitality (85 % of employees), retail (71 %) and tourism services (93 %).

Throughout the Islands, the largest proportion of all workers were employed by FIG (33 %). The next largest primary employment sector was construction (11 %), then agriculture, crop and animal production (10 %). The number recorded as working in the other major economic sectors; fishing and tourism, were lower at 4 and 3 % respectively.

Table 7.40: Location of population, excluding MPC

Location of population present on census night	1991	1996	2001	2006	2012	2016	2021
Stanley	1,557	1,636	1,989	2,115	2,120	2,460	2,538
East Falkland (outside Stanley)	245	233	208	194	202	190	149
West Falkland	196	174	144	127	127	151	95
Outer Islands	52	38	38	42	22	40	36
Total usual resident population	**2,050**	**2,081**	**2,379**	**2,478**	**2,471**	**2,841**	**2,818**
Stanley population	**76 %**	**79 %**	**84 %**	**85 %**	**86 %**	**87 %**	**90 %**

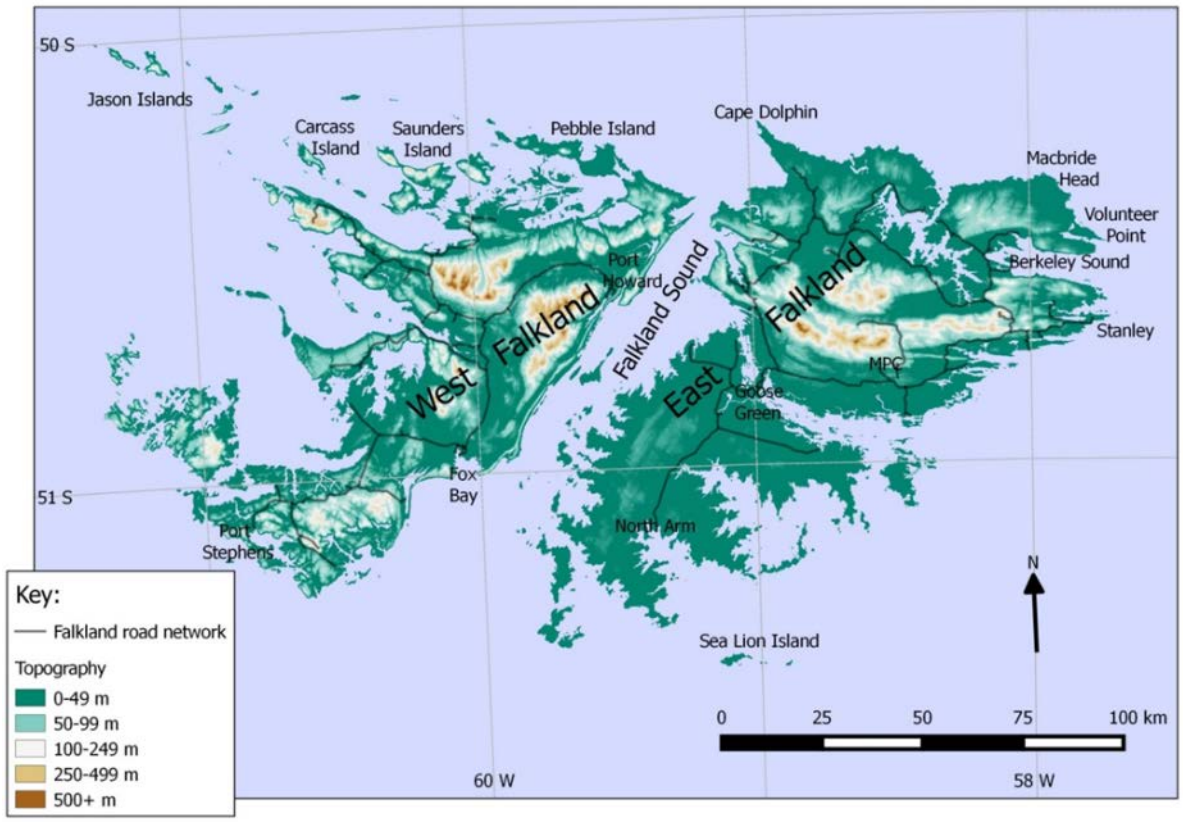

Figure 7-114: Prominent geographic features, major settlements and roads within the Falkland Islands

7.7.2.3 Berkeley Sound residents

The land surrounding Berkeley Sound is divided between six private landowners / farms (Figure 7-115 below) and is primarily used for grazing sheep. However, several farms also run tourism-based businesses, which are described in Section 7.7.4.6.1. Kidney and Cochon islands, at the mouth of Berkeley Sound, are owned by FIG and are both National Nature Reserves.

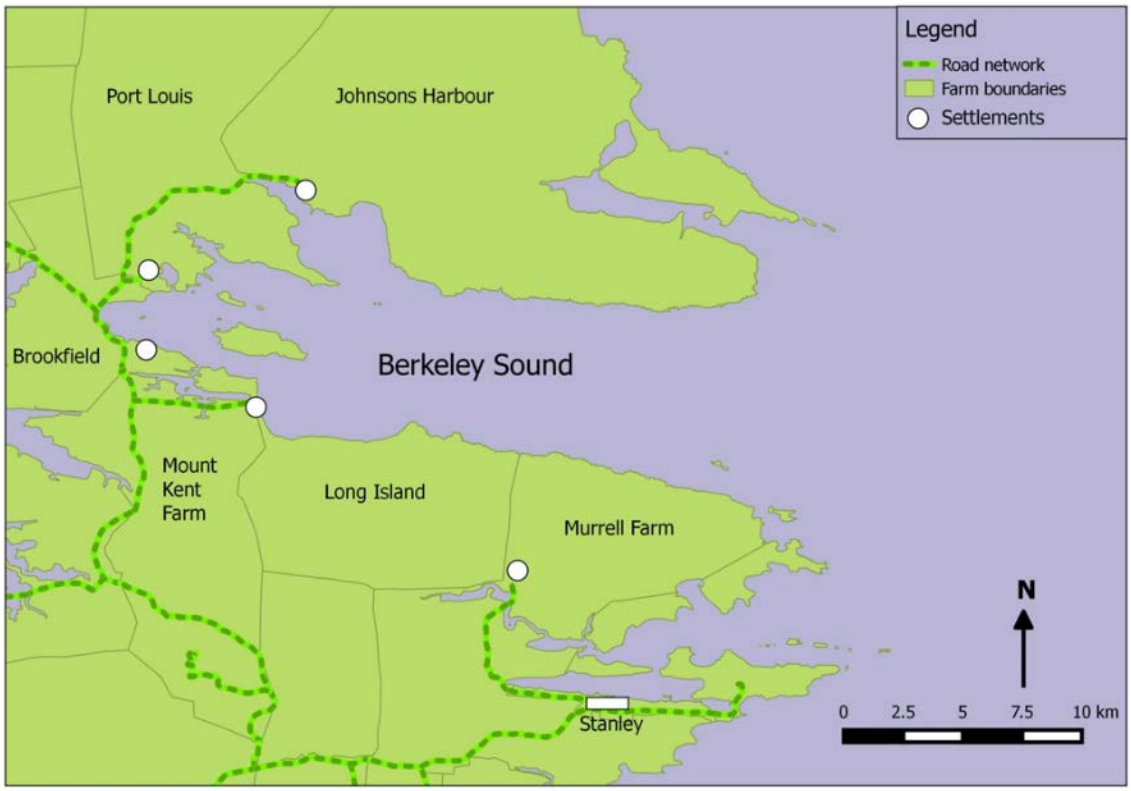

Figure 7-115: Farms with land bordering Berkeley Sound

7.7.2.4 The Falkland Islands economy

Prior to the mid-1980s, the Falkland Islands economy was almost completely based on agriculture, mainly sheep farming and the export of wool for income. Since the late 1970s, the seas around the Falkland Islands have also been an important area for commercial fisheries, with multinational fleets operating in the waters around the Islands. Following the establishment of the Falklands Interim Conservation Zone (FICZ) in 1986 for fishery purposes, and the creation of the Falkland Outer Conservation Zone (FOCZ), the 200 nautical mile Exclusive Economic Zone (EEZ), in 1990, the bulk economic activity shifted to the sale of fishing licences to foreign vessels operating within the Falkland Islands EEZ (Plexus Energy, 2012). The creation of the EEZ was critical in transforming the post-1982 Falklands' economy. The income from license fees fluctuates but currently makes up 25-30 % of the Government's revenue (FIG, 2023l). The other main contributors to the Falkland Islands economy are tourism, wholesale and retail trade, transportation and storage, and accommodation and food services.

It is important to understand current fishing activity within the area of the Sea Lion Field and Berkeley Sound in order to determine to what extent the potential future development of the area might interfere with fishing activities and 'other users of the sea' (Section 11.1 and 11.2). For example, whether or not exclusion of fishing vessels from 500 m radius around the FPSO could translate into loss of revenue for the fishing fleet or FIG as a result of licence sales.

7.7.3 Other users of the sea

7.7.3.1 Other users of the NFB

7.7.3.1.1 Fishing industry

This review is based on the 'Summary Report of Fishing Activity over the Sea Lion Development Area', conducted by Pale Maiden Consulting (April 2013), and the FIG Fisheries Department Catch Report Database from 2013 to 2022 (FIG, 2023n). Some information is also taken from the Fishing and Trawling Risk Study conducted by Jee (2013) on behalf of POEPL.

The Falkland Islands EEZ contains rich fishing grounds, particularly for the two important squid species, Argentine shortfin squid and loligo (Falklands calamari). Table 7.41 presents total catch (tonnes) data for the main target species in the Falkland Islands fishery between 2013 and 2022 (FIG, 2023c). The most notable feature of the data is the considerable inter-annual variation in the catch of a number of species. In particular, if catches between 2013 and 2022 are averaged, Argentine shortfin squid represents the largest catch by weight. However, from one year to the next, the catch of this species varies greatly, from over 357,000 tonnes in 2015 to virtually nothing in 2016. Loligo squid catches are more consistent from year-to-year and steadily increasing, and account for 25.1 % of the total fishery catch by weight between 2013 and 2022.

Patagonian rock cod has previously been an important commercial species but has decreased in importance since the drop in catches in 2015-16. From 2016 the catches of this species have decreased significantly and represented only 5.2 % of the reported catch between 2013 and 2022.

A number of other finfish species are caught but these account for a far smaller percentage of the total catch. Commercially caught finfish species include:

- Whiptail hake (hoki) (2.7 %),
- Hake (12.9 %),
- Skates and rays (1.3 %),
- Red cod (0.9 %),
- Blue whiting (0.7 %),
- Kingclip (0.8 %), and
- Patagonian toothfish (0.5 %) (Table 7.41).

The relative importance of finfish is skewed by inter-annual variation in *Illex* catch.

The Argentine shortfin squid is primarily fished by jiggers from the Far East, whereas the smaller inshore squid species loligo, and other finfish species, particularly hake, have been the target of the European bottom trawling fleet (FIG, 2023n).

For fisheries licensing and management purposes, the FICZ is divided into grid squares. Each grid square is 15' of Latitude by 30' of Longitude, or approximately 15 nautical miles by 17 nautical miles in size. These grid squares are the same as those used for seabird data (Section 7.4.5.6.1) and are referred to as the ¼ ICES squares. Each square can be referred to by a four-letter code (the first two letters denote the latitude and the second two the longitude). FIG Fisheries Department (FIFD) fisheries statistics from 2013 to 2022 indicate that the most important fishing areas corresponding to the highest catch (tonnes) per grid square are concentrated around the 200 m depth contour surrounding the Falkland Islands. The Patagonian toothfish is fished in depths greater than 600 m with the best catch per unit effort achieved off Burdwood Bank to the south and on the Deep Slope area to the north-east (FIG, 2023n).

Table 7.41: Annual fishing catch by target species in the FICZ / FOCZ

Target species	Catch (tonnes)										
	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	% Catch 2013-2022
Argentine shortfin squid	142,619	306,111	357,722	2,360	67,445	54,405	43,449	62,663	172,537	73,053	49.5
Loligo squid	40,168	48,702	30,317	46,447	64,676	79,996	81,908	60,732	95,627	101,166	25.1
Patagonian rock cod	32,435	56,693	29,086	7,039	2,520	2,213	950	737	1,279	1,245	5.2
Hake	12,308	14,875	21,054	23,363	15,589	27,021	53,378	43,327	59,177	62,821	12.9

7.7.3.1.1.1 Fisheries operating within vicinity of the Sea Lion Field

This section provides a description of the fishing activity and catches in the region of the proposed Phase 1 & 2 Development.

The FPSO and drill centres for the Phase 1 & 2 Sea Lion Field Development are located within FIFD grid square XFAK, approximately 20 to 37 nautical miles north-east of the 200 m depth contour line, in water approximately 450 m deep. This grid square has been rarely fished by any licensed vessels in recent years and is currently only open to vessels with a B Licence (*pers. comm.* FIG, 2023). The B licence allows vessels (jiggers) to fish for Argentine shortfin squid and, rarely, for the sevenstar flying squid (*Martialia hyadesii*). Data extracted from the Fisheries department database in 2023 (Table 7.42) indicate that both jiggers and trawlers have fished the area (although B licences for trawlers were removed in 2023), but there is considerable inter-annual variation in fishing effort and catch in the area. In the past some trawlers targeted *Illex*, however the B licences for trawlers were removed in 2023 (P. Brickle, *pers. comm.).* Jiggers fish at sea anchor and deploy light weight lines and therefore do not pose a great risk to subsea infrastructure.

However, further analysis of Vessel Monitoring System (VMS) data indicates that most of the vessels reporting catch in this square were in fact fishing elsewhere. Catches and fishing effort in the grid square occupied by the Sea Lion Field (XFAK) are relatively low (FIG, 2023n). This said, exceptionally high catches of *Illex* squid were made in 2014, 2017, and 2022 reflecting high catches throughout the zone during these seasons. Overall however, these data indicate that generally the area of the Sea Lion Field is rarely fished.

It is clear that the vast majority of fishing effort and catch comes from waters shallower than the Sea Lion Field. However, this is largely due to the distribution of target species, rather than technical difficulty, and trawlers have explored the area, with limited success, in the past.

Table 7.42: Total annual catch and effort in grid square XFAK 2013 – 2022

Species	2013		2014		2015		2016		2017		2018		2019		2020		2021		2022

7.7.3.2 Other users of Berkeley Sound and the east coast

It is important to be aware of other users of the east coast and Berkeley Sound, and whether the inshore activities (LTV and installation vessel activity for a non-consecutive period of up to 13 months) will have the potential to interact with fisheries, tourism and / or areas used for military exercises. For example, in March 2024 there were as many as seven reefers, two tankers and >30 fishing vessels in the Sound on a daily basis (*pers. comm*., FIMA 2024).

7.7.3.2.1 Fisheries

7.7.3.2.1.1 Fisheries operating in the approaches to Berkeley Sound

The Falkland Islands EEZ contains rich fishing grounds, particularly for the two important squid species, Argentine shortfin squid and loligo (Falklands calamari). The majority of fishing effort takes place to the north and west of the Falklands with the exception of the loligo fleet, which operates over the continental shelf to the east of the Islands (FIG, 2023n). As an example, Figure 7-117 shows the distribution of loligo catch over the two fishing seasons in 2022. Two areas; one to the north-east and the other to the south of East Falkland, consistently produce the highest catches. Although there is no fishing within Berkeley Sound itself, activity within the Sound could impact this fishery.

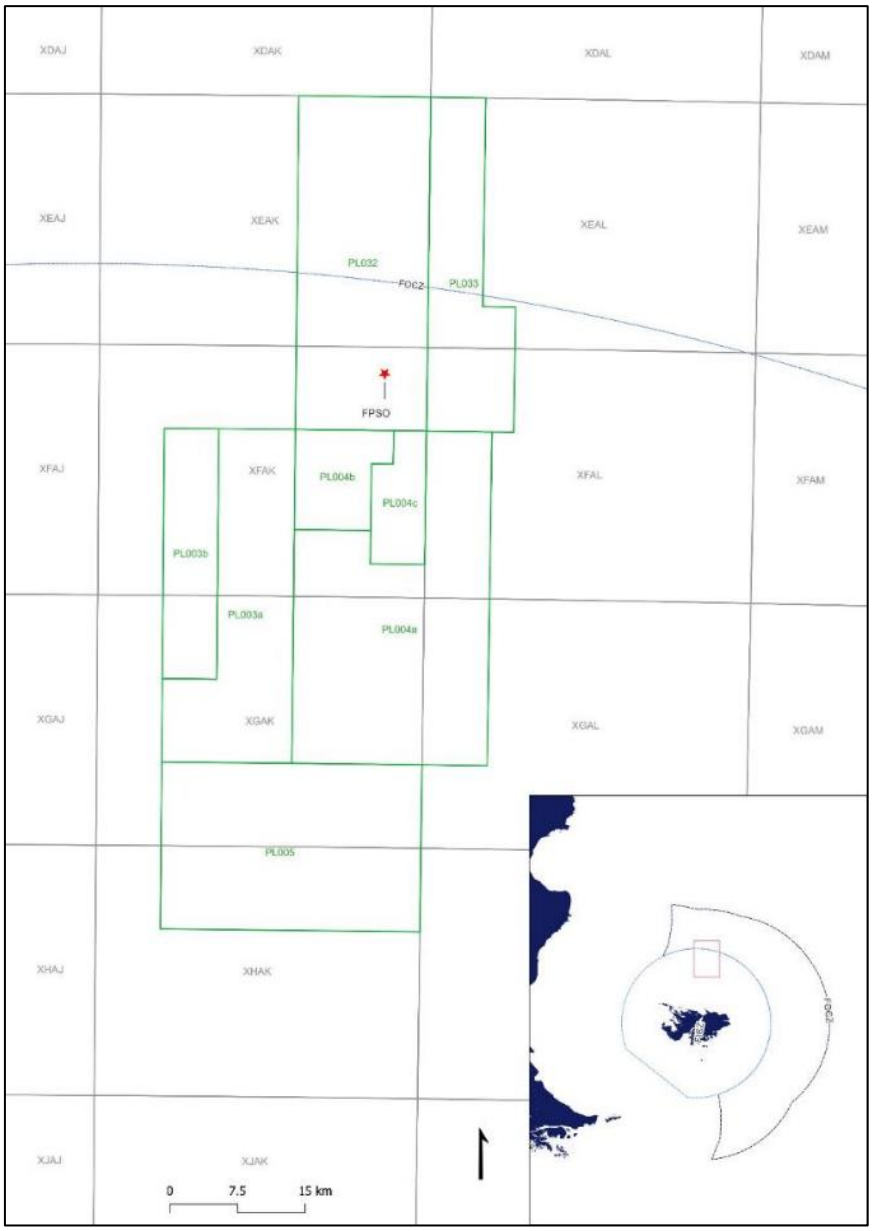

Figure 7-116: Fisheries squares and licences in the Sea Lion Field area

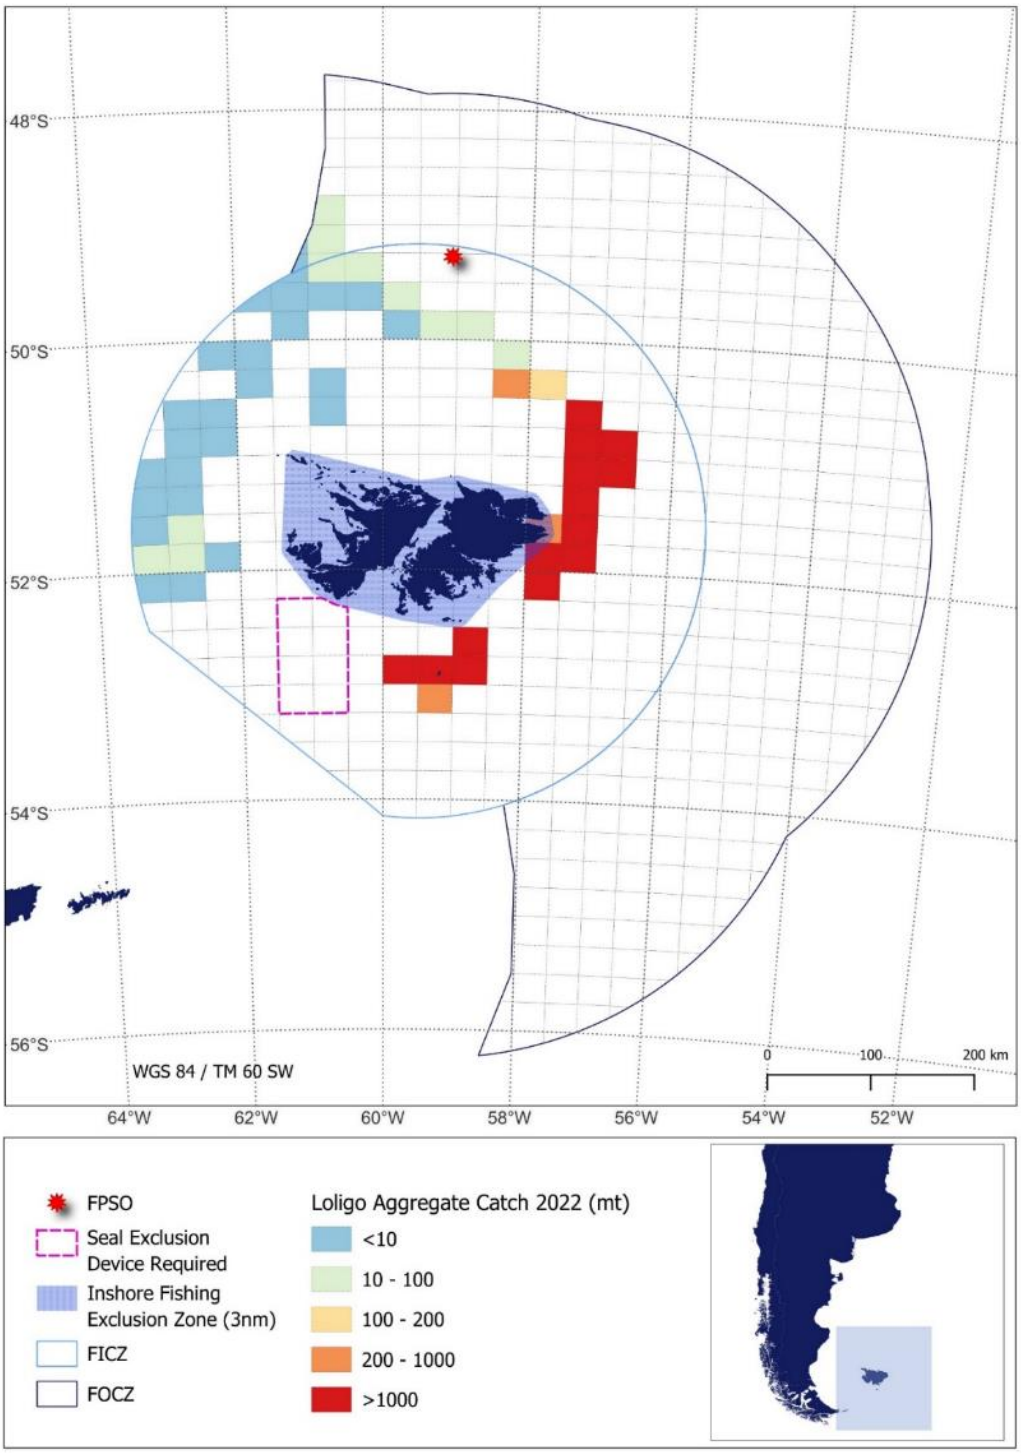

Figure 7-117: *Loligo* catch statistics from 2022 ***(Source: FIG, 2023n)***

7.7.3.2.1.2 Fisheries related activity within Berkeley Sound

Berkeley Sound is used as an anchorage for vessels engaged in the transshipment of fish. Reefer vessels (refrigerated cargo vessels) anchor in the Sound and are visited by fishing vessels to offload their catch. Once full, reefers transport the catch to market. There can also be a number of tanker vessels present within the Sound to bunker vessels with fuel oil.

In a 'normal' fishing year (when *Illex* catches are good) vessel use of Berkeley Sound is highly seasonal, with peak activity between March and June. The different types of vessel vary in size, which is summarised (expressed as vessel length) in Table 7.43. The vessels tend to occupy the area of relatively deep waters in the centre of the Sound. Figure 7-118 below shows vessel positions (both stationary and moving) as derived from AIS data recorded between May 2014 and May 2015. As well as seasonal fluctuation, the degree of activity can vary from year-to-year depending on the amount of fish (squid) caught in any one year. A summary of all vessel use in Berkeley Sound is provided in Section 7.7.3.2.5.

Note: The latest catch data presented in Table 7.41 above confirms that 2014-2015 represent the most significant fishing years in recent times and so have been used as a worst-case benchmark for the assessments herein.

Table 7.43: Summary of size (length) of vessels using Berkeley Sound (May 2014 to May 2015)

Vessel type	Mean length (m)	Standard Deviation	Minimum length (m)	Maximum length (m)
Fishing	62.5	12.1	45	114
Reefer	142.5	15.5	95	195
Tanker	111.5	22.1	98	151

7.7.3.2.2 Tourism service providers and Berkeley Sound

While a few cruise vessels visit Berkeley Sound, many pass the entrance to the Sound *en route* to and from Stanley.

During the cruise ship season many people take time off from their regular work to drive tourists to see wildlife around the Islands. In Camp, tourism accounts for a greater share of income than in Stanley. According to FIG figures, tourism accounts for an estimated 17 % of whole farm income, with the outer islands experiencing a greater share of tourism income at 41 % of the total. A summary of all vessel use in Berkeley Sound is provided in Section 7.7.3.2.5.

7.7.3.2.3 Military uses of Berkeley Sound

There has been a substantial military presence in the Falkland Islands since 1982, which provides air, land, and sea coverage.

There is very limited use of Berkeley Sound by military vessels.

7.7.3.2.4 Other vessels and uses of Berkeley Sound

Research vessels, such as the British Antarctic Survey (BAS) vessel the Sir David Attenborough, often transit through Falklands waters *en route* to South Georgia, Antarctica or other areas within the South Atlantic. It is possible that these vessels, and other commercial shipping, may use Berkeley Sound as an anchorage from time-to-time (see Section 7.7.3.2.5).

All types of vessels may also use Berkeley Sound to shelter during adverse weather.

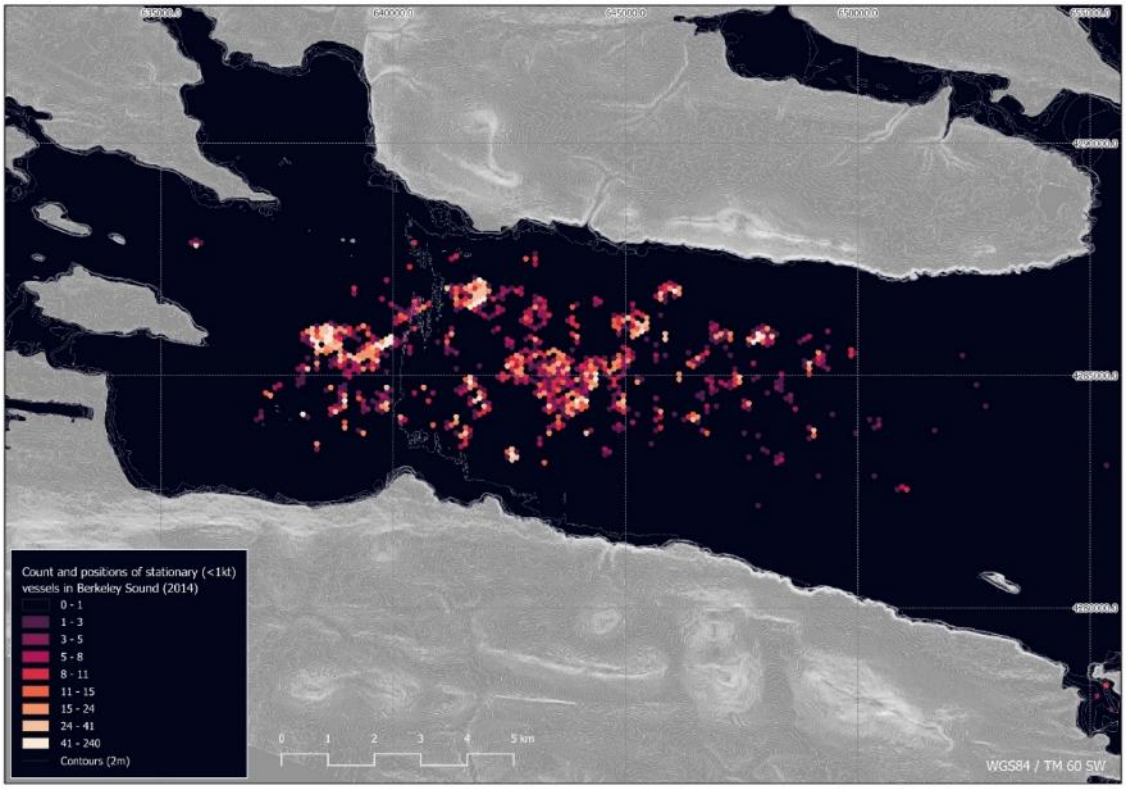

Figure 7-118: Positions of vessels within Berkeley Sound, May 2014 to May 2015

7.7.3.2.5 Summary of vessel numbers and position in Berkeley Sound

A summary of all the above vessel uses in Berkeley Sound for the period 2014 to 2022 is provided in Figure 7-119. The 2014 - 2015 period represents the most significant fishing period in recent times. The positions of vessels for this peak period (2014-2015) are provided in Figure 7-118 and these years have been used as a worst-case benchmark for the baseline and assessments herein.

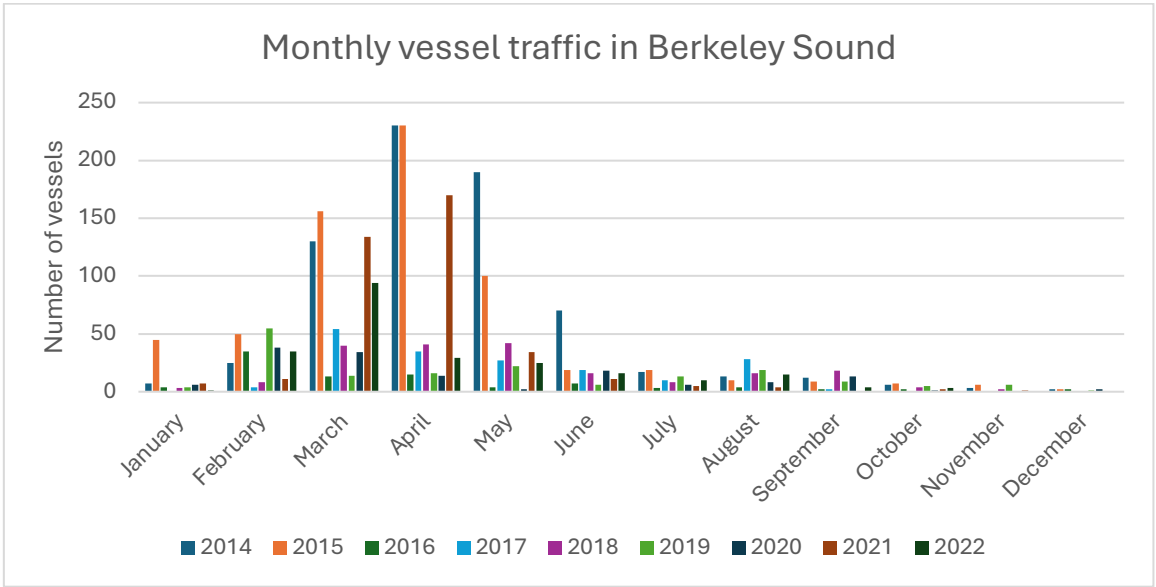

Figure 7-119: Vessel traffic in Berkeley Sound 2014-2022 (FIG Maritime Vessel Visits Data, 2023)

7.7.4 Tangible property

7.7.4.1 Port facilities

The Falkland Islands have port facilities at Mare Harbour and Stanley, including the Falklands Interim Port and Storage System (FIPASS) and the Temporary Dock Facility (TDF).

7.7.4.1.1 Mare Harbour (East Cove Military Port)

Mare Harbour is a deepwater port in Choiseul Sound, East Falklands, operated by the MoD. Mare Harbour is primarily used by the UK Royal Navy vessels patrolling the South Atlantic but also cargo vessels. It is the port facility and depot for MPC and is approximately 36 miles south-west of Stanley by road.

7.7.4.1.2 Stanley Harbour – jetties and FIPASS

Harbour operations in Stanley are currently managed by the Falkland Islands Government Maritime Authority, which sits within the Department of Emergency Services and Island Security (DESIS), with support from other Government Agencies.

There are several jetties within Stanley Harbour:

- East Jetty - 45 m berthing face with approximately 3.7 m of water clearance at its head. This jetty is used by a variety of vessels from privately owned visiting yachts to commercial trawlers up to 75 m in length, and can also be used to land passengers from launches,
- Public Jetty - used only for landing passengers from launches and other small craft. This jetty has approximately 3 m of water clearance at its head,
- The Camber – is located on the opposite side of the Harbour to Stanley but is used as a winter lay-up for charter yachts or trawlers (FIG, 2024a),
- The Temporary Dock facility (TDF) - is situated in the east end of the Harbour and was constructed to support O&G exploration in the NFB (see Section 7.7.4.1.2.1 below), and
- FIPASS (Falklands Interim Port and Storage System) - was constructed in 1984 and consists of flexi-port pontoon structures (Figure 7-120) which, to date, have provided suitable port facilities. FIPASS consists of seven permanently moored barges giving no more than 220 m of berthing face; the north-west barge is now closed (N. Port, *pers. comm.*, 2023). Depth of water clearance ranges from 5.7 - 7 m depending on the berth (FIG, 2023d). FIPASS is managed under contract from FIG by Atlink Ltd. who is responsible for the maintenance and manning of the facility and collect berthing, hard-standing, warehouse and utilities fees and charges on FIG's behalf. At times, there is not enough berthing space at FIPASS to meet demand, which represents the most significant potential conflict between users of the Harbour. Vessels can take bunkers of freshwater and fuel at FIPASS, at a rate of 25 and 35-40 tonnes per hour respectively.

A number of different types of vessel use the facilities in Stanley Harbour and each vessel type has specific requirements. The number of vessels visiting Stanley on a monthly basis is shown in Table 7.44. Descriptions are provided in Section 7.7.4.1.4 below.

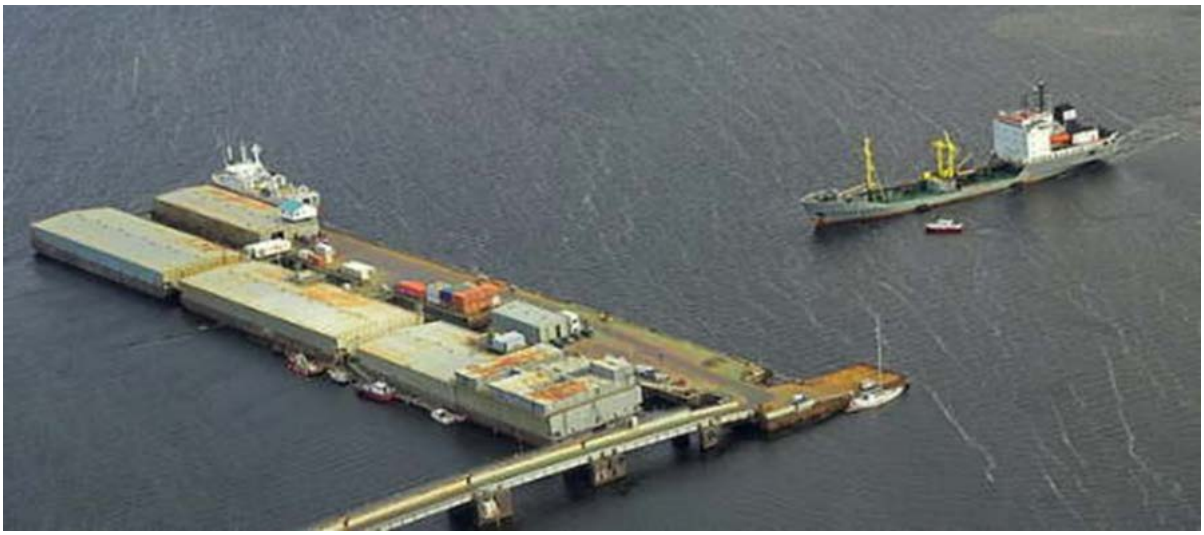

Figure 7-120: FIPASS, ***(Source: FIG, 2023d)***

Table 7.44: Vessels entering Stanley Harbour[1] (during 2014, 2018, 2022[2] and 2023)

[1] The data collated by FIMA records only the final destination of vessels, so if a vessel comes to FIPASS (see Table 7.45), although it will have passed through Stanley Harbour, it is only recorded as visiting FIPASS.
[2] Note 2022 was a COVID year so vessel numbers are lower than would be expected in a normal year.
[3] 2023 data was not available by vessel type but a total for the month is included at the bottom for comparison with other years.
(Source: FIG fisheries department data (FIG, 2015b), Vessel Movements Database (DNR, 2019) and FIMA data (FIMA, 2023; 2024)

7.7.4.1.2.1 Temporary Dock Facility (TDF)

The Temporary Dock Facility (TDF), a floating barge, was installed in 2014 to support the 2015 oil exploration campaign. It is proposed that the TDF will continue to support the activities of Navitas during the Sea Lion Northern Development Area Phase 1 & 2 Development. The initial planning consent for the TDF was granted for three years for exploration and appraisal only. In March 2018, the conditions of the initial planning consent were varied to permit the use of the TDF for the Sea Lion development and production operations. Any upgrades to the TDF will be subject to separate planning applications/consents (Section 5.11.1.1.1).

7.7.4.1.3 Port facilities in Berkeley Sound

Berkeley Sound is a deepwater Harbour used for the transhipment of frozen fish and squid and is a designated port. The Sound is also used for licensed bunkering operations from tankers or reefers. However, only those vessels that have been licensed by Stanley Services Ltd. (SSL) can provide bunkers to other vessels within Falkland Islands territorial waters. The Sound is also regularly used by vessels of all kinds for shelter in adverse weather conditions.

While there are no shore facilities in Berkeley Sound, several companies in Stanley service the Sound (moving people and goods) by harbour launch.

All vessels crossing the reporting line into Berkeley Sound report to Stanley Port Control *via* VHF radio. The Reporting Line stretches between Volunteer Point (51° 31'S; 57° 44'W) and Cape Pembroke (51° 41'S; 57° 43'W). This line forms the outer limit of Berkeley Sound and Port William.

7.7.4.1.4 Vessel visits

7.7.4.1.4.1 Fishing vessels

Fishing vessels are regular visitors to Stanley Harbour throughout the year, where they undergo licence inspections, crew changes and catch transfers. The degree to which Stanley Harbour is utilised by fishing vessels varies considerably between vessel types and target species.

Jiggers visit Stanley Harbour for licence inspections and customs clearance prior to commencing fishing and the number of vessel visits peaks in February. However, most jiggers anchor with very few visits to FIPASS recorded (Table 7.45), (FIG, 2023n).

Trawlers are licensed to target finfish and loligo squid, during two fishing seasons (approximately February to May and August to November) and are regular visits to Stanley Harbour throughout the year. Although fewer trawlers than jiggers are licensed to fish within Falklands waters, trawlers make greater use of the facilities at FIPASS (Table 7.45).

While there is generally only one longliner licensed to fish within Falklands waters at any time, vessels that fish at South Georgia are regular visitors to Stanley Harbour as they all have to undergo catch verification at the end of the fishing season.

Note: 2015 fishing vessel data are presented in Figure 7-118 as it represents a good *Illex* year and correspondingly high vessel numbers.

Table 7.45: Vessel visits to FIPASS[1] (during 2014, 2018, 2022[2] and 2023[3])

Month	Year	Cargo	Cruise ship	Jigger	Longliner	Naval vessel	Oil related	Patrol vessel	Research	Tanker	Trawler	Tug	Yacht	Total

[1] The data, collated by FIMA, records only the final destination of vessels, so if a vessel comes to FIPASS, although it will have passed through Stanley Harbour (see Table 7.44), it is only recorded as visiting FIPASS.
[2] Note 2022 was a COVID year so vessel numbers are lower than would be expected in a normal year.
[3] 2023 data available was given as a monthly total and is included for comparison with other years.
(Source: FIG fisheries department data (FIG, 2015b), Vessel Movements Database (DNR, 2019), FIMA data (FIMA, 2023; 2024 and pers. comm. Atlink, 2024).

7.7.4.1.4.2 Fisheries Patrol Vessels (FPVs)

The Falkland Islands and South Georgia and the South Sandwich Islands Governments' Fishery Patrol Vessels (FPVs) are regular visitors to Stanley Harbour throughout the year and go alongside FIPASS or East Jetty when space is available. The number of FPV visits to FIPASS is variable, as indicated by the following:

- 2014 - 37 visits,
- 2018 - 34 visits, and
- 2022 (COVID year) - 28 visits (Table 7.45).

7.7.4.1.4.3 Cargo vessels

Cargo vessels visit Stanley on a regular basis and require a berth at FIPASS to transfer cargo onshore. In 2014, 37 cargo vessels visited FIPASS. In 2018 cargo vessel visits to FIPASS were slightly less at only 32, and less again in 2022 (COVID year), visiting on 25 occasions (Table 7.45).

7.7.4.1.4.4 Cruise ships

The majority of cruise ships visiting Stanley anchor in the Harbour or Port William, from where they ferry passengers onshore to the Public Jetty or East Jetty in tenders. The vast majority of cruise ship visits occur between October and April. Some of the smaller cruise vessels will go alongside FIPASS. In 2018 there were 31 cruise ships alongside FIPASS reducing to 18 in 2022, due to COVID (Table 7.45).

7.7.4.1.4.5 Reefers

Reefers are refrigerated vessels that transship catch from fishing vessels for delivery to market. They usually anchor in Port William or Berkeley Sound and rarely enter Stanley Harbour.Table 7.44

7.7.4.1.4.6 Tankers

Up to 20 tankers visit FIPASS annually to transfer fuel, with 13 tanker visits to FIPASS in 2022 (COVID year) (Table 7.45). The supply of fuel has to meet demand, if demand increases due to O&G activity the supply will have to increase proportionately.

7.7.4.1.4.7 Yachts

In 2014, 61 yachts came into Stanley Harbour with 71 yachts in 2018. This number had reduced greatly by 2022 due to COVID with only seven yachts entering the harbour. These vessels usually moor at the Public Jetty, the East Jetty or anchor in the Harbour.

7.7.4.1.4.8 Royal Navy vessels

A Royal Naval (River Class) patrol vessel is permanently based in the Falkland Islands, to conduct the South Atlantic Patrol around the Falklands and South Georgia. The HMS Protector (or an equivalent alternative vessel), an Ice Patrol Ship, is on station close to in the waters of Antarctica and the southern hemisphere for 330 days a year (Royal Navy, 2019).

7.7.4.1.4.9 Research vessels

The British Antarctic Survey (BAS) operates three research stations in the Antarctic and two on South Georgia, (BAS, 2023). BAS operates one vessel to support these stations and conduct research at-sea. Throughout the summer season (September/October to May/June) this vessel may come into Berkeley Sound or Port William to resupply, change crew and scientists, but it is not able to come into Stanley Harbour due to insufficient navigable waters (N. Port, *pers. comm.*, 2023).

7.7.4.2 Road network

Until the 1980s, there were only tracks in the Falkland Islands outside of Stanley. By 2008, the road network in the Falkland Islands covered 862 km, with 489 km on East Falkland and 373 km on West Falkland. The road network has increased slightly since 2008, mainly on the west (C. Summers, *pers. comm.*).

However, the majority of the road network remains unpaved, consisting of a consolidated gravel surface with drainage ditches on both sides. The only asphalted roads are those within Stanley, those within the Mount Pleasant Complex (MPC) and the main road between Stanley and MPC.

Though regularly regraded ('ploughed' and rolled), the surface becomes badly potholed and rutted from vehicle wear. A constant programme of maintenance is required to keep the road network in a useable condition.

Over the years the number of vehicles, the weight of vehicles and the number of heavy vehicles has increased significantly having a bearing on the condition of the roads, particularly during winter months.

In April 2010, over a 19 day period, 5,484 vehicles (of which 2 % were Heavy Goods Vehicles (HGVs)) used the road between Stanley and Mount Pleasant. This represents a 170 % increase over the previous 10 years for all vehicles (FIG, 2012a). Although it is the heavier traffic which causes the greatest damage to any road, sealed or unsealed, road usage for all types of vehicles has increased disproportionately for a number of reasons, including:

- Cargoes from the UK now arrive at Mare Harbour and are delivered to Stanley by road,
- Movements to and from New Haven ferry terminal, including a significant increase in stock movements to the Abattoir,
- General increase in Islands wide movements by land rather than sea, and
- Increased localisation of posts for workers at MPC.

Between 2011 and 2015, the FIG Public Works Department (PWD) Roads section deployed pressure activated vehicle loggers at a number of sites to determine the number of vehicle passes as well as the class, weight and speed of the vehicles.

Average daily usage on the MPC road over the three sampled periods (at two locations) averaged 483 vehicle passes / day. The majority of these vehicles were cars, 4x4, minibuses or Light Goods Vehicles (LGV) with these groups accounting for 87.2 % of transit in 2015.

Daily usage on the Airport Road (measured between the Chandlery and Stanley Growers Market Garden), over a single sampled period, averaged at 1,755 vehicle passes / day. Again the majority of vehicles were cars, 4x4s, minibuses or LGVs with these groups accounting for 92.2 % of transit in 2015.

There has not been a detailed road usage survey since 2015. However, FIG (C. Summers, *pers. comm.*)

notes that:

- There has been an increase in the use of the South American Atlantic Service (SAAS) shipping service and therefore there has been an increase in heavy vehicle movements to and from the SAAS yard,
- With increased construction activity in the Stanley area there has been an increase in activity to the Mary Hill spoil dumping area,
- Road transportation of wool is steadily increasing, although numbers are not believed to be particularly significant, and
- The proposed site for the municipal waste transfer facility (Section 7.7.4.5.6) is at the east end of Megabid and will significantly increase the traffic movements in the area.

MPC Road usage has generally increased significantly year on year, however exact recent trends are not certain and road usage may have stabilised.

In 2012, the FIG introduced a Highways Asset Management Plan, which categorises the Islands' road network on the basis of its strategic importance and prioritises maintenance in respect of this (Table 7.46 and Figure 7-121).

Table 7.46: Road classification ***(Source: FIG, 2012a)***

Road Classification	Definition
Class A Road	Primary link road between major national assets
	Greatest traffic use by volume and weight
Class B Road	Link road between all Class A and C roads
	Major tourist destinations
	Major supply route to abattoir
Class C Road	All other roads
MoD Road	Roads linking MoD facilities with the national road network

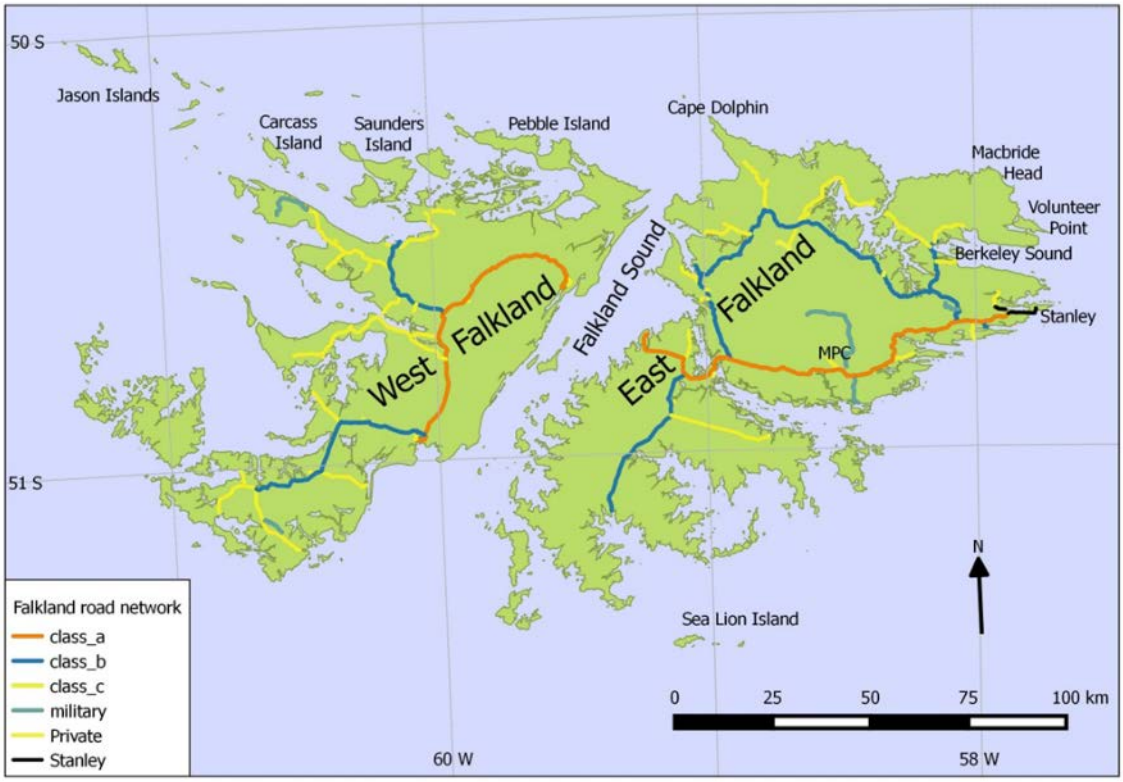

Figure 7-121: Road map of the Falkland Islands, indicating road class

7.7.4.2.1 Roads supporting Berkeley Sound

The settlements and farms at the head of Berkeley Sound are linked to the rest of the Islands by unpaved, gravel roads, as shown in Figure 7-121 above. The land surrounding the remainder of the Sound is only accessible by 4x4 vehicle during the summer months. During the winter, the land is wet and boggy, which increases the risk of becoming stuck in the mud ('bogged'). Access to tracks, such as the one leading to Volunteer Point, is closed to the public during the winter months.

7.7.4.3 Airport and air-links

There are two main paved runways in the Falkland Islands, one at Mount Pleasant International Airport and one at Stanley Airport.

7.7.4.3.1 Mount Pleasant International Airport

The Falkland Islands are currently serviced by two international air-links:

- The MoD air-bridge link to the UK, and

- The LATAM commercial service to Santiago, Chile.

The MoD operates a chartered aircraft between RAF Mount Pleasant and RAF Brize Norton (UK) twice weekly. The current charter service is fulfilled by AirTanker under contract. An agreement with FIG provides for a fixed civilian seat allocation on each flight. At present 31 seats are allocated for civilian use on each flight. In 2018 the average seat utilisation was 20 seats per flight and the number of airbridge flights per annum that were at full capacity was approximately 8-10 flights on both the south and the northbound legs. After the Covid-19 pandemic lowering seat occupancy considerably between 2019 and 2022, numbers are now considered to be back to pre-Covid levels (R. Clark, *pers. comm.*). Average figures should be treated with some caution as there is high seasonality in flight occupancy rates with August and Christmas periods showing the highest demands linked to school holidays. Medical flights are also routinely scheduled with accompanied medical teams for referrals from King Edward Memorial Hospital to the UK NHS for treatment. This may at times reduce capacity on individual flights.

LATAM operates a commercial flight once weekly to Punta Arenas and onwards to Santiago, Chile from where international connections can be made. Once per month the flight makes a brief stop-over in Rio Gallegos, Argentina.

The LATAM service currently utilises an Airbus 320 - 200 with 168 seats (although the plane can be configured for 174 passengers this is not done regularly). Occupancy is variable through the year and ranges from 12 - 100 % seat occupancy with an annual average of 54 % occupancy (2016-2018 data) reducing to an average occupancy of 44 % in 2022-23. For 2022/23 this would provides an average weekly spare capacity of approximately 94 seats (R. King, *pers. comm.*). The peak season is through the summer tourist season between the months of November to March when flights may be fully booked for cruise-vessel passenger exchanges (five flights were fully booked in 2023). A secondary peak occurs during August corresponding with the winter school holidays. This route is increasingly popular with travellers and passenger numbers continue to rise; figures for the duration of 2013 - 2018 showed an annual increase of 7 % but the flight was suspended during the Covid-19 pandemic, returning to normal service in July 2022. Flights can be fully booked, often due to cruise-vessel passenger exchanges and advance provisional block booking of flights.

Some of the key statistical information regarding air links to the Falkland Islands are summarised in Table 7.47 below.

Table 7.47: Summary of flights to and from the Falkland Islands[1]

Statistic	MoD Airbridge	LATAM Airlines (Santiago Route)
Route	Mount Pleasant, Falkland Islands – Brize Norton, UK	Mount Pleasant, Falkland Islands – Punta Arenas, Chile
Aircraft	Airbus A330 variant KC2 Voyager	Airbus 320 - 200
Frequency of flights	Twice per week	Once per week
No. flights per year	104	52
Commercially available seats	31	168
Average Occupancy seats	27 (86 %)	74 (44 %)
No. flights per annum which are at full capacity	8 - 10	5
Peak season	August and Christmas (school holidays)	November – March (cruise vessels and tourism) August (school holidays)
Average spare capacity	9	94

[1] Summary of restricted commercial data provided by FIG in 2018 and 2024 (LATAM) and for 2023 (MoD Airbridge).

7.7.4.3.2 Stanley airport

Stanley Airport has for many years primarily been operated for the domestic inter-island Falkland Islands Government Air Service (FIGAS). It was also used as a heli-base for the 2010-12 and 2015 exploration drilling campaigns. FIGAS currently has a fleet of five Britten-Norman BN2-B Islander aircraft.

7.7.4.4 Importers of supplies / goods to and from the Falkland Islands

The majority of goods are shipped into the Falklands. There are two main routes: direct from the UK or *via* South America.

7.7.4.4.1 Falkland Islands Resupply Service (FIRS)

The Falkland Islands Resupply Service (FIRS) is a service contracted by, and provided to, the Ministry of Defence (MoD), primarily to carry military freight to re-supply MPC. The Ro-Ro container vessel from the UK arrives in the Falklands every 6-12 weeks and operates between Marchwood, Southampton, in UK, and Mare Harbour on the Falkland Islands. This carries commercial freight as well as bringing in some the food imports and other civilian supplies.

7.7.4.4.2 South American Atlantic Service (SAAS)

The South American Atlantic Service (SAAS) also provides a container shipping link between the Falkland Islands and the UK *via* Montevideo, Uruguay.

7.7.4.4.3 Air freight

No specific civilian / private-sector allowance is made for commercial air-freight. Availability of commercial freight is limited by size and weight which is, in turn, limited by the air-frame of the aircraft available. Furthermore, freight capacity is dependent upon passenger numbers and thus spare air-frame load. On high occupancy flights, air freight is not available.

7.7.4.5 Existing resource infrastructure and use

7.7.4.5.1 Accommodation

7.7.4.5.1.1 Existing housing

The 2021 Census (FIG, 2023l) indicates that the overall civilian population of the Falkland Islands has decreased slightly from 3,200 to 3,142 (including those living at MPC) since 2016.

However, Stanley with 2,538 inhabitants, which accounts for 80 % of the total number of residents island-wide (including MPC residents), has shown a population growth of around 3 % since 2016.

The number of households in Stanley continues to grow and it is considered that, overall, there is an ongoing shortage of affordable housing for purchase and rental in Stanley, this is acknowledged as a critical constraint (Regeneris, 2013; Maplecroft, 2019).

The 2021 Census recorded a total of 1,600 resident households, of which, 1,148 (72 %) are located in Stanley (Table 7.48).

In 2021, the majority of houses in Stanley were mortgaged or owned outright (54 %) (Table 7.48). Approximately 40 % of Stanley households were held under rental, while a further 5 % were provided rent free as part of an employment package (FIG Policy Department, *pers. comm*.) (Table 7.48). Currently, only residents with a Permanent Resident Permit (PRP) or full Falkland Islands Status are able to own property in the Falklands. ExCo can grant permission to Non-Permanent Residents (NPR) and work-permit holders, however, most commonly NPR are excluded from owning property. Therefore, NPR form a large part of the rental market, both within FIG housing and the private sector.

In 2012, 87 properties were built in the six years leading up to the census. This number doubled in 2016 to 177 and reflects the increased rate of construction of both public and private housing in recent years (FIG, 2021c). Since then, around 30 new dwellings per year have been developed by FIG (O. Mathers, *pers. comm.* 2023).

Table 7.48: The number and proportion of Stanley households owned outright, owned under mortgage, rented or provided rent free[1]

Household Ownership Class	2006		2012		2016		2021	
	No.	%	No.	%	No.	%	No.	%
Rent Free	57	6	62	6	109	9	65	5
Rental	288	31	322	32	378	32	481	40
Mortgage	270	29	263	26	291	24	268	22
Owned	315	34	355	35	389	33	382	32
Unknown	-	-	-	-	22	2	-	-
Total	**930**	**-**	**1,002**	**-**	**1,189**	**-**	**1,196**	**-**

[1] Data provided by the FIG Policy Department (previously the Policy Unit) (*pers. comm*.). Note that these data cover Stanley housing only.

7.7.4.5.1.2 Future developments and town planning

The Stanley Town Plan (FIG, 2015d) recognises the need to plan for increased housing if future economic development is not to be impeded. The plan, which is based upon Regeneris (2013) projections of need, provides for a target of an additional 450 units over the 17 year duration of the plan from 2013 – 2030. This amounts to a housing target of approximately 26 units per annum.

In order to meet these future demands, the Stanley Town Plan has nominally identified and zoned areas for residential housing. These zones incorporate both FIG land that would be available for phased land release and private land that could be developed through market forces. A total plot capacity of 768 building plots was identified, with 362 plots considered to be potentially viable for development within the duration of the plan. FIG have averaged around 30 new dwellings per annum since 2016 (O. Mathers, *pers comm.*). In addition to residential zoning within the plan, proposals for permanent structures to provide transitory accommodation (e.g., short-term accommodation for offshore workers) would be supported within land identified for light industrial uses.

The development of some sites may be impeded by the location and current capacity of FIG to provide utility services such as water, power and sewage to the site. Nonetheless, the Planning Ordinance 1991 includes provision for the production of Developer Contribution Regulations. This would provide a mechanism to allow developers to fund 3rd party activity on land which is outside the developers' control to address the infrastructure needs or impacts of the Development. This could allow for the fast tracking of development if infrastructure servicing is met by 3rd parties or remunerated for.

7.7.4.5.1.3 Hotels and guest houses

The main hotel in Stanley is the Malvina House Hotel which has 70 rooms, followed by the Waterfront Hotel (six rooms) and Shorty's Motel (six rooms).

Additionally, there are several small Bed & Breakfast establishments in Stanley, and additional hostel style rooms at Lookout Lodge (60 rooms).

7.7.4.5.2 Fresh (potable) water supply

Freshwater in Stanley is a finite resource and, under present operating procedures, water availability and Stanley usage are largely balanced. In order to assess the impact of the additional freshwater requirements of the Phase 1 & 2 Development, it is necessary to quantify the baseline water availability. Therefore, it is necessary to understand:

- Freshwater required by Stanley, and

- Freshwater available to Stanley and the factors which may limit this supply:
  - The number of water catchment sources (i.e., the means of capturing rainwater),
  - Untreated water supply (i.e., how fast is the rainwater carried from the catchment source to the Dairy Paddock Reservoir and for how long in each day),
  - Water treatment (i.e., how fast can the water be treated, and the duration of pumping each day, so it can be supplied to the consumer as needed), and
  - Treated water storage capacities (i.e., where is the treated water held prior to use by the consumer).

7.7.4.5.2.1 Freshwater required by Stanley

Forecasts conducted in 2004 showed that there had been an upward trend in annual water consumption of approximately 3 % per annum over the previous 24 year period from 1980. More recent water forecasts have been difficult to determine due to leaks in the system (Z. Stephenson, *pers. comm.*). However, the year-on-year increase in Stanley consumption has continued into the present with increases of *c.* 2- 3 % p.a. resulting in a baseline maximum annual water use of 335,070 m^3 (i.e., 918 m^3/day) in 2023. Of note, this was a year without the additional demand of oil exploration. Additional use during phases of oil exploration caused spikes in water usage over and above this baseline increase. In 2015 during an oil exploration campaign, a maximum consumption of 346,087 m^3 was recorded, which related to an increase of 23 % upon the previous year of 2014 with no oil exploration. While it is noted from the above that the current basic Stanley water usage levels (2023) have increased almost to the levels of usage during the last exploration campaign (2015), it is clear that oil exploration and production will significantly increase the demand.

7.7.4.5.2.2 Freshwater available to Stanley and the factors which may limit supply

Water sources

Potable water is supplied to Stanley by the FIG Public Works Department water filtration plant.

As shown in Figure 7-122, untreated water (rainwater) is supplied *via* two catchment sources:

- The Moody Brook catchment, and
- The Upper Murrell River catchment which was brought on-line in 2016 and was developed owing to:
  - The increase in residential households in Stanley,
  - Increasing demand (including from new industries e.g., the abattoir, fishing, cruise vessels, and oil exploration activities), and
  - The observed drying of the Falkland Islands climate that limits catchment recharge (FIG, 2008a).

The Murrell catchment area has increased the rainwater catchment for Stanley by over 60 % and will safeguard the continuity of supply. With the commissioning of the Murrell River catchment, supply continuity is no longer considered a limiting factor for current water needs. However, whilst the dual catchments have increased the security of supply they have not increased the volume of supply to Stanley, which is still limited to a single water pipeline with a fixed capacity from the Moody Brook pump station.

Outside of Stanley, the quarry and abattoir are supplied from the Stanley structure through a pump system to augmented pressure. The Mount Pleasant military base operates independently and has a small reservoir and filtration system whilst small camp settlements and farms are served by private groundwater springs without processing.

Untreated water supply (filtration rates and duration) and treatment

Rainfall catchment is pumped from the Moody Brook and the Murrell River catchments to the Dairy Paddock Storage Reservoir (DPR) at a rate of 60 m^3/hr (Figure 7-122) through a single pipeline. Over the current 14.5 hour operating day, this relates to a capacity of 870 m^3/day of water pumping into the DPR which has a capacity of 1,500 m^3.

From the DPR water is processed through the PWD water filtration plant. The water is filtered through clarifiers and treated to ensure it is fit for human consumption. The theoretical maximum filtration rate is 77 m^3/hr. However, this rate cannot be sustained in the long-term as it exceeds the rate at which the DPR fills (60 m^3/hr). Filtration rates that exceed 60 m^3/hr can only be achieved in the short-term if the DPR is used as an additional buffer supply and run down through the filtration plant working day, to be recharged overnight by leaving the catchment water feed running and the DPR to refill unattended. The DPR is an integral component of the Stanley two-day contingency water supply storage and hence draw down of the reservoir is not taken as standard current procedure except in extenuating circumstances of critical demand.

With a total of 870 m^3/day supplied to the DPR over a 14.5 hr day, the water demand during the most recent oil exploration campaign in 2015 passed the supply capacity for the first time and thus required extended pumping times.

In summary, the water availability is affected by the:

- Supply of water from Moody Brook and Murrell River to the DPR (60 m^3/hr),
- Filtration rates at the filtration plant (theoretical maximum of 77 m^3/hr),
- Operational hours of the Moody Brook and Murrell River pumps (usually 14.5 hrs/day, but can be left on overnight to recharge the DPR in extenuating circumstances), and
- Operational hours of the filtration plant which are restricted by staffing and maintenance requirements.

Potable water storage and supply

Following filtration, potable water is pumped to interim storage header tanks to provide a pressure head to the mains system. Two separate systems are utilised:

- Murray Heights Low Level System: Storage of 1,232 m^3 which supplies central ‘old’ Stanley, and harbour frontage to FIPASS and TDF, and
- Sappers Hill High Level System: Storage of 2,874 m^3 which supplies new development areas and the by-pass / airport road. A pressure booster system supplies the abattoir and quarry.

Whilst the tanks can provide some degree of buffer storage, in practice it is not possible to fully draw down the tanks because:

- Excessive draw down of tanks can cause in-line system debris sedimentation, (which does not affect potability, but can lead to discolouration and may cause issues to some consumers), and
- The remit is to maintain two days’ worth of potable water to ensure supply to Stanley at all times.

The two days’ buffer of potable water would be prioritised to Stanley and emergency service usage in the event of shortfalls. In the event of water shortfall, there is a hierarchy of users that would be restricted and ultimately disconnected if required and subject to emergency provision. At present the TDF is classified as of lowest priority and restriction would likely be conducted as follows, TDF, FIPASS, PWD Megabid, and FIGAS, before restrictions were applied to Stanley.

FIG note that with capital funding commitments there will be significant changes to the water provision by 2025/26 (C. Summers, *pers. comm.*).

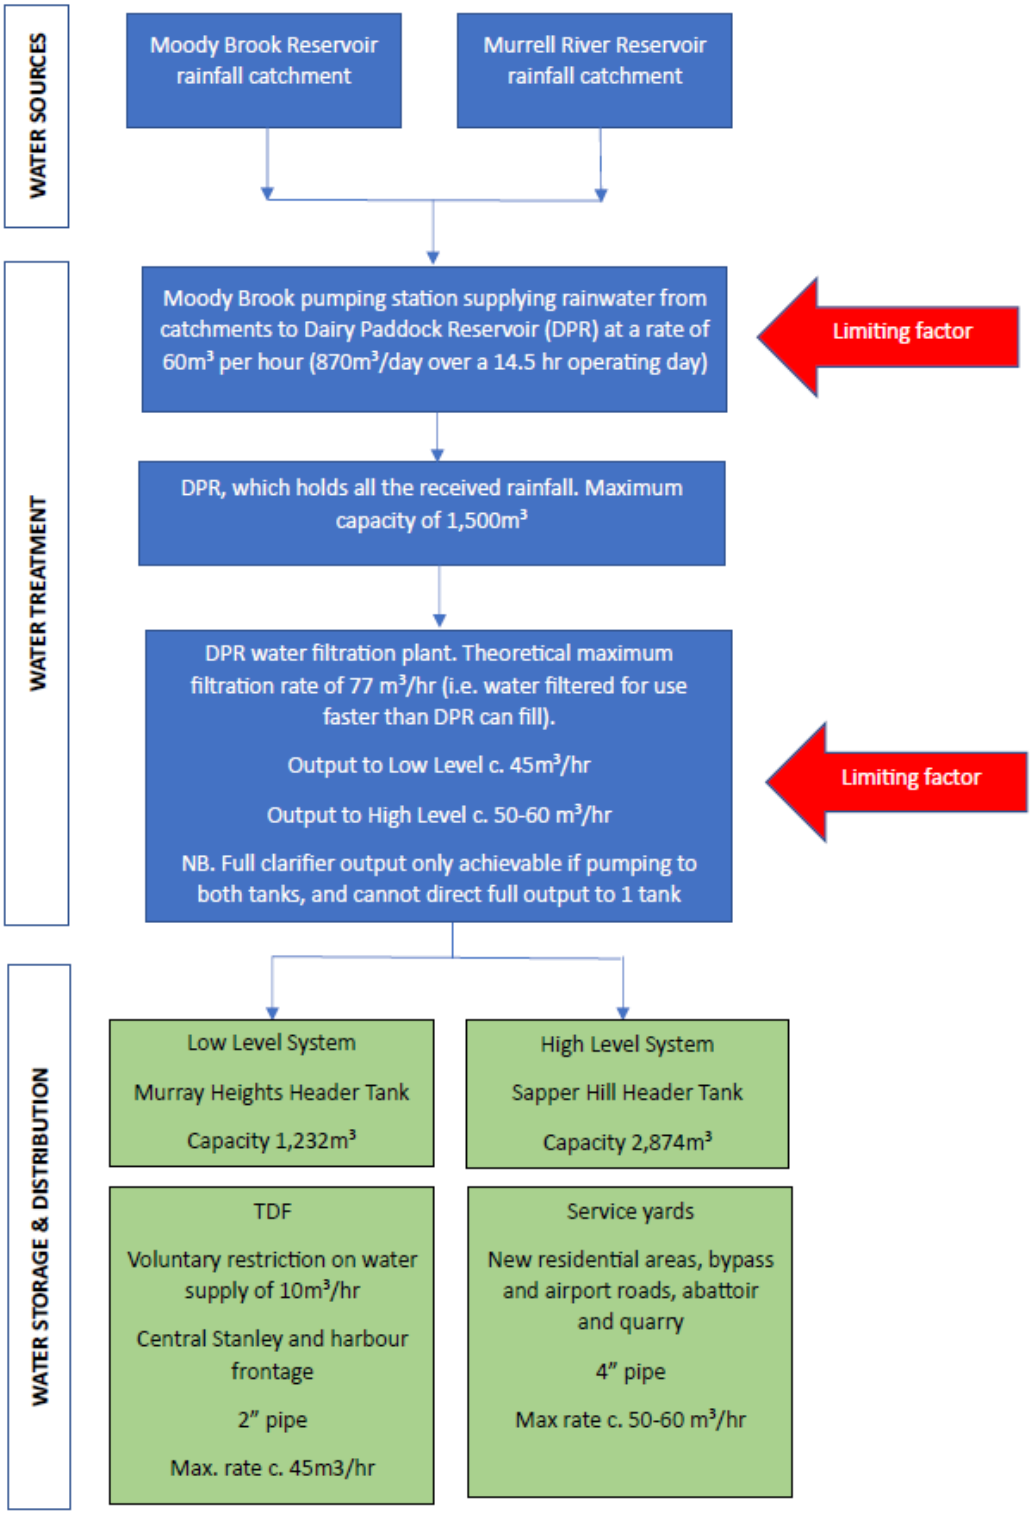

Figure 7-122: The Stanley filtration and water supply system with the limiting capacity of each stage

7.7.4.5.3 Non-potable process water

At present, it is not possible to supply lower quality non-potable water as this would lead to contamination of sections of the potable water supply. In addition, the full capacity of the existing catchment supply pipeline is utilised by the filtration plant excluding the possibility of a take-off from this pipeline.

7.7.4.5.4 Fuel and bunkering

Stanley Services Limited (SSL) was founded in 1987 and operates under an exclusive licence from FIG to provide all domestic fuels and a bunkering service to all vessels within territorial waters (12 nautical miles).

SSL stocks fuel according to demand. The SSL contract with FIG for supply to the local population requires SSL to have three months' worth of supply of each grade of product.

SSL operates a terminal with a capacity of 7,500 m^3 of Marine Gas Oil (MGO) in Stanley and can supply fuel to vessels moored at FIPASS in Stanley (via the ex-pipe alongside the wharf). When there are no O&G vessels operating, SSL only issue minimal amounts to local vessels, several fishing vessels and on occasion to small cruise ships. If there are more vessels operating, the tanks are replenished more regularly. SSL has room in their terminal to build further tank storage if required (L.Yon, *pers. comm.*).

Additionally, bunkering operations can take place in the open sea or in the relative safety of the natural harbour of Berkeley Sound. Together with joint shareholder Lavinia Corporation, SSL provides bunkering coverage to the fishing fleet on the high seas as well as in Berkeley Sound, supplying both MGO and 180 centistokes (cST) Bunker Fuel (i.e., Intermediate Fuel Oil (IFO)). There are two tankers in operation and during the height of the fishing season there are also numerous reefer vessels with large fuel capacities operating on the high seas fishing grounds in the South Atlantic.

With regard to aviation grades of fuel, SSL stocks one grade for the local Islander aircraft and also stocks jet fuel which is generally only supplied to helicopters supporting O&G operations. The SSL terminal in Stanley can stock about five weeks' worth of jet fuel. Jet fuel is replenished from the military base tank farm, 60 kms away by road (L. Yon, *pers. comm.*).

7.7.4.5.5 Electricity

In order to assess the impact of power use by the Phase 1 & 2 Development, it is necessary to understand the baseline electrical capacity to enable comparison between supply and demand. When quantifying the baseline it is necessary to consider the overall amount of power available, as well as the amount available at any given time. Therefore, electrical capacity needs to be considered in terms of the:

- Power required by Stanley:
  - Power consumption (in kiloWatt hours (kWh)) (i.e., the total power used over a unit of time), and
  - Peak power demand (in kiloWatts (kW)) (i.e., the instantaneous power available for use at any given moment in time).
- Power available in Stanley, and
- Future power output.

7.7.4.5.5.1 Power required by Stanley

Current Stanley energy use in 2022/23 amounts to 19,520,590 kWh per annum with an average daily use of 53,481 kWh (Table 7.49). This figure is considered typical of current baseline usage and trends. Within the two year period 2013/14 to 2015/16, i.e., the last time exploration drilling took place in the Falklands, electrical energy use increased from the previous year by 16 %. To be conservative within

the assessment, it is assumed that this increase was a result of the oil exploration activity conducted in 2015. However, as can be seen from Table 7.49, usage figures did not drop back down to pre-exploration figures in subsequent years, remaining at 10 % (2016/17) and 6 % (2017/18) above the 2013/14 figures. In 2021/22 usage was at similar levels to those seen during previous exploration rounds at 15 % above 2013/14 (pre-exploration) figures (J. Greenland, *pers. comm.*). Therefore, it is not entirely possible to accurately determine what the direct and indirect effects of oil exploration were, against a general increase in electrical usage.

The instantaneous power output is limited by the capacity of the generators. Stanley peak power output is currently around 3,200 kW depending upon which of the generators are under-going deep services or are on stand-by. Power generation output must be matched to demand load and sudden peak loading can cause failure or drop out in the system.

7.7.4.5.5.2 Power available in Stanley

Within Stanley, the FIG Power Station is the electrical distribution hub and balances supply from the generators and the Sand Bay wind farm.

Stanley Power Station uses eight in-house diesel generators (seven online as of January 2024) and three high speed sets (a newer type of diesel generator) and supplies over 99 % of the electrical usage within Stanley. The highspeed sets make up the "Interim Power Station" and have been on-line since March/April 2020. They have been contributing roughly 20 % of total generation since that date. Once the new Power Station is operational the intention is for the high-speed sets to either be decommissioned or kept as a form of Standby Power Station (J. Greenland, *pers.comm.*). Outside of Stanley there is no central power grid with settlements and farms serviced by their own independent systems. Mount Pleasant Complex was, until recently, entirely serviced by diesel generators but a wind farm has now been constructed at Mare Harbour to supplement the generators.

The Sand Bay wind farm comprises six turbines and meets, on average, *c.*30 % of demand (C. Summers, *pers. comm.*). This use of a renewable resource has reduced diesel consumption at the Stanley Power Station by approximately 35 – 40 %. However, since this source is reliant on meteorological conditions and output cannot be modified to balance demand, the power needs of Stanley must be considered in the context of the diesel generators alone in order to take a conservative and precautionary approach.

7.7.4.5.5.3 Future power output

It is recognised within capital project planning and the Stanley Town Plan (FIG, 2015d) that the current eight diesel generators are reaching the end of their design life with resultant issues for capacity, reliability and maintenance costs. The three additional high-speed sets are an interim solution and contingency planning is progressing towards a new power station in a new location for the long term. FIG note that with capital funding commitments there will be significant change by 2025/6 (C. Summers *pers. comm.*).

7.7.4.5.6 Waste management infrastructure – Landfill sites

Current waste disposal and recycling facilities in the Falklands are very basic, consisting of:

- Landfill,
- Reuse of glass (as aggregate) and scrap metal, and
- The local collection and recycling of cans and tins, and household batteries batteries (which are collected for recycling in future).

Eliza Cove is a landfill site accepting general waste from Stanley. The site was regarded as being at capacity as long ago as 1997 and was recommended for closure in a study on waste management by Halcrow and Partners. However, in the absence of alternatives, it is still operating.

There are various small landfill sites in Camp and much general waste on farms and the outer islands is burned.

Currently there is no hazardous waste treatment infrastructure on the Islands and such waste streams are stored onshore and shipped in batches to the UK for treatment and disposal.

There is some low-level recycling such as reuse of plastic bags and food containers and FIG has implemented a voluntary code of conduct to charge for single use plastic bags. There is a glass imploder that is operated by the Public Works Department and there are numerous glass recycling bins located around Stanley in which residents can deposit their glass waste. FIG collects used glass from hospitality establishments and crushed glass is used as an infill material for road surfacing. Tins, cans and household batteries are collected within Stanley and recycled in the UK.

FIG developed a Waste Management Strategy in 2018. This strategy includes:

- The separation and collection of tin cans, to be fed into a proposed MoD recycling facility,
- The incineration of all combustible household waste,
- The construction of a waste collection facility to allow the public to dispose of waste which is not placed in kerbside bins, and
- The construction of a joint FIG/MoD landfill site.

Alongside this, FIG is continuing to explore options for waste electrical and electronic items (WEE), large metal waste and hazardous waste. (FIG, 2019b).

There is currently no legislation regarding recycling in the Falkland Islands. However, in line with the planned waste management strategy and associated investment, FIG is committed to development of appropriate legislation (FIG, 2018a). As of January 2024, a consultation was underway to start the development of a Pollution Prevention and Waste Management Policy (*N. Cordeiro, pers. obvs.*)

7.7.4.6 Scenery, wildlife and tourism resources

The role of tourism in the Islands' economy is increasing. Tourist numbers continue to grow, with many attracted by the Islands' pristine environment and its diverse wildlife. Approximately 60,000 tourists visit the Islands by cruise ship each year, and a further 3,500 'land-based' tourists arrive by air annually (FITB, 2022). The total number of cruise ship passengers arriving in the Islands per season (October to April) from 1995/96 to 2022/23 is shown in Figure 7-123. Visitor numbers rose steadily year on year until the 2007/08 and 2008/09 seasons. There was then a decline as a consequence of the global economic turn-down. Visitor numbers have since recovered to slightly more than those achieved prior to the global economic downturn with the peak number of cruise ship visitors to date being achieved in the 2017/18 season. A second dip is seen in visitors due to the Covid-19 pandemic, dropping to as low as zero cruise ship visitors in 2021/22. However, the 2022/23 season saw cruise ship visitor numbers increase again to levels similar to pre-pandemic numbers (N. Cordeiro, *pers. obvs.).*

Many cruise ships will visit locations in the west of the Islands to see wildlife but virtually all vessels will visit Stanley. Within Stanley, there are a number of businesses and individuals that support tourist excursions to locations within driving distance of the city. Many of these sites are important for the wildlife that they support; however, they are also important recreational sites for residents and tourism. Important sites include:

- Surf Bay,
- Gypsy Cove,
- Cape Pembroke,
- Volunteer Point,
- Murrell Farm,
- Kidney Island,
- Long Island, and
- Bluff Cove.

The tourism sector is a large contributor to the Islands economy and in 2018 (the latest figures available) contributed approximately £5.9 m to the annual GDP (FITB, 2022). FIG aims to increase the economic benefits from tourism to the Falkland Islands. A key aspect of the Tourism Development Strategy (TDS) is sustainable development, preserving and protecting the Falkland Islands' character, building on the Islands' abundant wildlife, flora, clean air, open skies, space and remote location, as well as their friendly people and virtually crime-free environment (FITB, 2016).

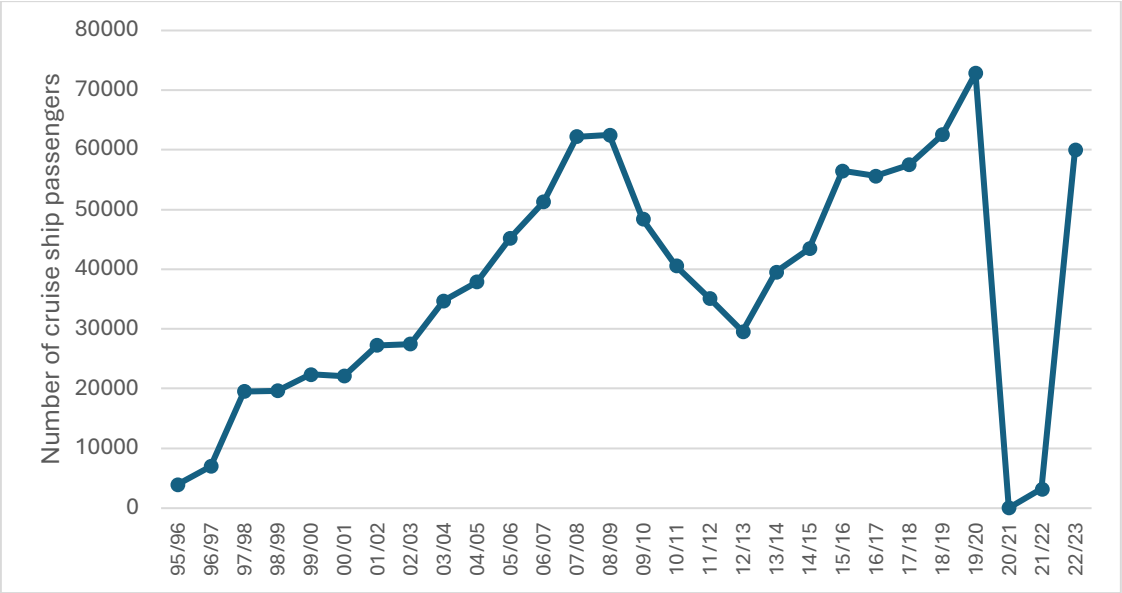

Figure 7-123: Total number of cruise ship visitors per season, from 1995/96 to 2022/2023

7.7.4.6.1 Tourism in Berkeley Sound

Berkeley Sound qualifies as a tourism resource owing to the wildlife and scenery of the area. The Sound already has a seasonally high level of shipping activity, which may impact on the view and perception of wilderness experienced by tourists (Tyler Grange, 2016), although peak vessel and tourist activity have limited overlap. The LTVs will be significantly larger than reefers and fishing vessels and may be present for over a full year and therefore may pose a potentially greater visual impact.

There are a number of sites around Berkeley Sound that are visited by tourists during the summer. Many of these arrive on cruise ships and take over-land day trips from Stanley.

In terms of visitor numbers, the king penguin colony at Volunteer Point is one of the most visited wildlife sites in the Falklands. Additionally, rockhopper penguin colonies on the south side of Berkeley Sound and gentoo penguins at Kidney Cove, both on Murrell Farm land, are popular wildlife attractions. Other tours include trips to Long Island Farm, where visitors can experience life on a Falklands farm.

Tourism away from these sites is at a low level due to access difficulties for independent visitors, although it is possible to hire a 4x4 with a driver, the number of tourists visiting other sites is generally low. However, many sites in Camp are popular with local visitors.

As an alternative to over-land travel, there are also organised visits by harbour launch to Kidney Island to see the wildlife and whale-watching trips to Berkeley Sound.

7.7.4.6.2 Tourism service providers

Tourism is described under Section 7.7.3.2.2.

7.7.4.7 Livestock and agricultural resources

Agriculture was the main economic activity in the Falkland Islands for most of the 20th century and remains an important part of the Islands economy and culture. Its relative importance in terms of GDP has been lower than the fisheries sector in recent years, but it remains the third largest employment sector in the Islands (Plexus Energy, 2012; FIG, 2023l).

Until recently the mainstay of the agricultural sector was wool production. A key constraint is the distance to markets, which makes Falklands' wool relatively expensive. The focus has therefore been

on organic wool and the production of finer wool, which may be sold for a higher price, depending on the market. In an effort to diversify the Camp economy and to help to encourage people to stay in Camp, measures were taken in 2002 to generate additional income from meat export (lamb, mutton and beef), complemented by improved farming practices and pasture improvements (Plexus Energy, 2012).

Most farming activity takes place during the summer months (September to March) and as a result there is much seasonality associated with employment in Camp. This period is also the core tourist season and as such there is competition for labour during the summer months. Contract labour is often used for shearing, fencing or tractor work and is often difficult to source, particularly at peak times of the year (Plexus Energy, 2012).

7.7.4.8 Fisheries resources

Fisheries are described under Section 7.7.3.2.1.

7.7.5 Baseline noise, odour and light levels

7.7.5.1 Stanley

7.7.5.1.1 Noise

Four noise monitoring exercises have been conducted to date in Stanley that provide information on baseline noise levels in the vicinity of the onshore supply base and the TDF. Noise measurements have previously been conducted on behalf of:

- Workboat Services Ltd in March 2013,
- Noble Energy Falklands Ltd in March 2014,
- POEPL in August 2016, and
- POEPL in February 2017.

Locations of the monitoring points are shown in Figure 7-124 and the data collected are summarised in Table 7.50.

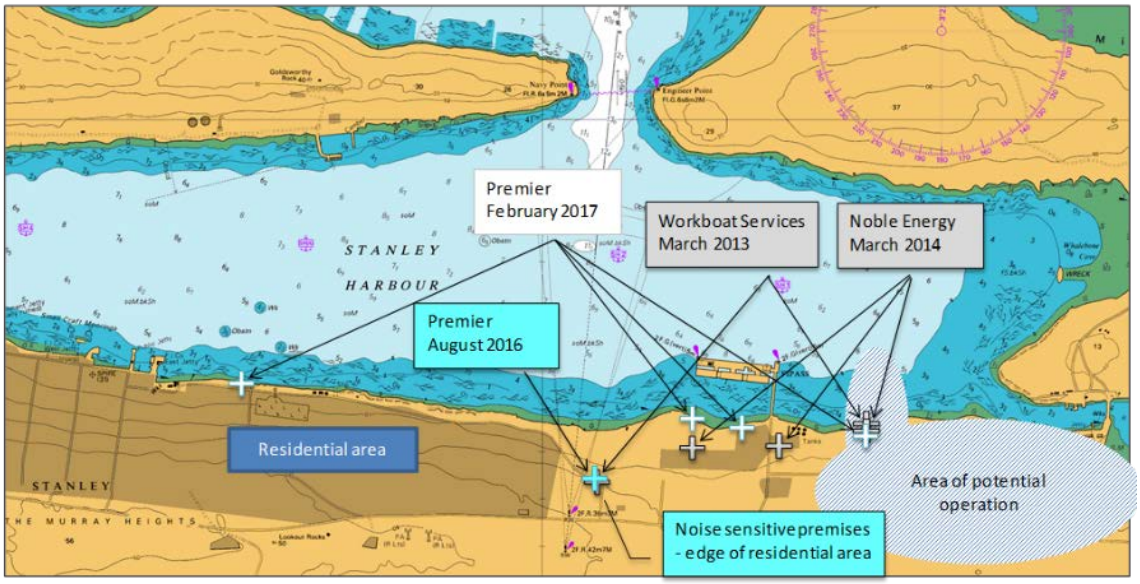

Figure 7-124: Location of noise monitoring points in Stanley

Table 7.50: Summary of the measured noise data

Reference	Description	Time period	LAeq dB [1]	LA90 dB [2]
Workboat Services March 2013	Liberty Lodge	Daytime	45.3	38.9
		Night-time	38.8	35.7
	Coastal Finger Pier	Daytime	43.4	37.7
		Night-time	37.5	34.4
Noble Energy Falklands Ltd March 2014	Stanley Growers	Daily	48.0 - 49.1	Not reported
	TDF	Daily	53.3 - 58.7	Not reported
POEPL, August 2016	Liberty Lodge	Daily	45.3	41.7
POEPL, February 2017	Various, see below	Snapshot	41.8 – 72.5	Not reported

[1] LAeq dB is the average noise level over the measurement period in decibels (dB).
[2] LA90 dB is the noise level exceeded 90 % of the time.

7.7.5.1.1.1 Conclusions from previous surveys

Noble Energy concluded that the levels of noise at premises sensitive to noise (Stanley Growers) from construction and operation activities at the TDF during exploration well campaign were 'negligible' but there was a subsequent complaint from a local resident.

Workboat Services concluded that noise levels from construction and operation of a jetty including the TDF area would be 'negligible' at Liberty Lodge, which lies at the far eastern end of Stanley and is one of the closest occupied properties to the TDF area.

POEPL survey August 2016

Noise monitoring equipment was installed outside in open ground in front of Liberty Lodge, Rowlands Rise in Stanley for 48 hours. The equipment used to undertake the noise survey was:

- Norsonic Nor118 Sound Level Meter (serial number 28248) with all-weather kit,
- GRas 40AS Microphone (serial number 004142), and
- Gras 26AK Preamplifier (serial number 044482).

Noise measurements were undertaken in accordance with current best practice guidance contained within BS7445 and BS4142. The sound level meter was mounted at a height of approximately 1.5 m above ground and was located more than 3.5 m from the nearest building facade or wall to avoid falsely elevated sound levels from reflections. The sound level meter was supplied calibrated (by UKAS accredited laboratories) and was fitted with a windshield at all times, to minimise the effect of wind on the measurements.

The measurement conditions at the monitoring point are shown in Table 7.51 and measured sound levels are shown in Table 7.52.

A frequency spectrum was recorded during this measurement period (covering all 48 hours) and is shown in Figure 7-125. The unmodified sound levels, representing the essential sound energy present, are shown by the red line, but these do not account for human hearing sensitivities, which are instead shown by the blue bars which include the human 'A' weighting[38]. The main frequencies measured contributing to noise perceived by humans (blue bars) are 250 Hz - 1000 Hz. Typically these frequencies are associated with traffic noise (e.g., SINTEF, 2008), although there are many other noise sources that give rise to these frequencies.

[38] An 'A-weighting' is normally applied to sounds measured by instruments in an effort to account for the 'loudness' as it is perceived by the human ear. Essentially, between 500 Hz and 6 kHz the human ear is much more sensitive, but below and above these frequencies the human ear is not particularly sensitive and the 'A-weighting' takes these sensitivities into account.

Although 48 hours is a short window of measurement, the time history (Figure 7-126) shows some potential features of the noise climate that are worthy of note and can be reviewed as further measurements are taken going forwards:

- Sound levels are rarely below 40 dB(A) even at night,
- Quietest periods are between 2300 - 0600,
- There are apparent noise increases relating to diurnal human activity i.e., increases through the morning 0600-0900 and 1500-1730,
- Traffic noise appears to be an important source of noise,
- Wind noise is probably a significant feature of the noise climate, and
- Military jet overflights occur several times per week and add noticeably to overall noise levels despite being of short duration.

Table 7.51: Measurement conditions for baseline sound measurement

Time and date	Location	Weather conditions	Notes
20th August 2016 18:19 to 22nd August 2016 17:39	Liberty Lodge	0-5 °C 1-4 m/s wind Intermittent light snow	Melting snow

Table 7.52: Summary of baseline sound levels at Liberty Lodge

Parameter	Value over 48 hours dB(A)	Value over 1st 24 hours[1] dB(A)	Note
A Leq	49.8	45.3	The 'average' noise level over the measurement period.
A Peak	106.3	-	The maximum noise level recorded at any time (during military jet overflight)
AF Max	95.2	72.3	The maximum noise level (F='fast', averaged over 125 milliseconds)
AF Min	31.9	31.9	The minimum noise level ('F')
AFL 1.0	56.6	-	The noise level exceeded 1 % of the time (F)
AFL 5.0	52.4	-	The noise level exceeded 5 % of the time (F)
AFL10.0	51	-	The noise level exceeded 10 % of the time (F)
AFL50.0	44.9	-	The noise level exceeded 50 % of the time (F)
AFL90.0	41.3	40.5	The noise level exceeded 90 % of the time (F)
AFL95.0	40.5	-	The noise level exceeded 95 % of the time (F)
AFL99.0	38.8	-	The noise level exceeded 99 % of the time (F)
AFL99.8	37	-	The noise level exceeded 99.8 % of the time (F)

[1] The second 24-hours included a period of suspected wind noise so has been discounted. The first 24 hours is considered more representative of overall noise character.

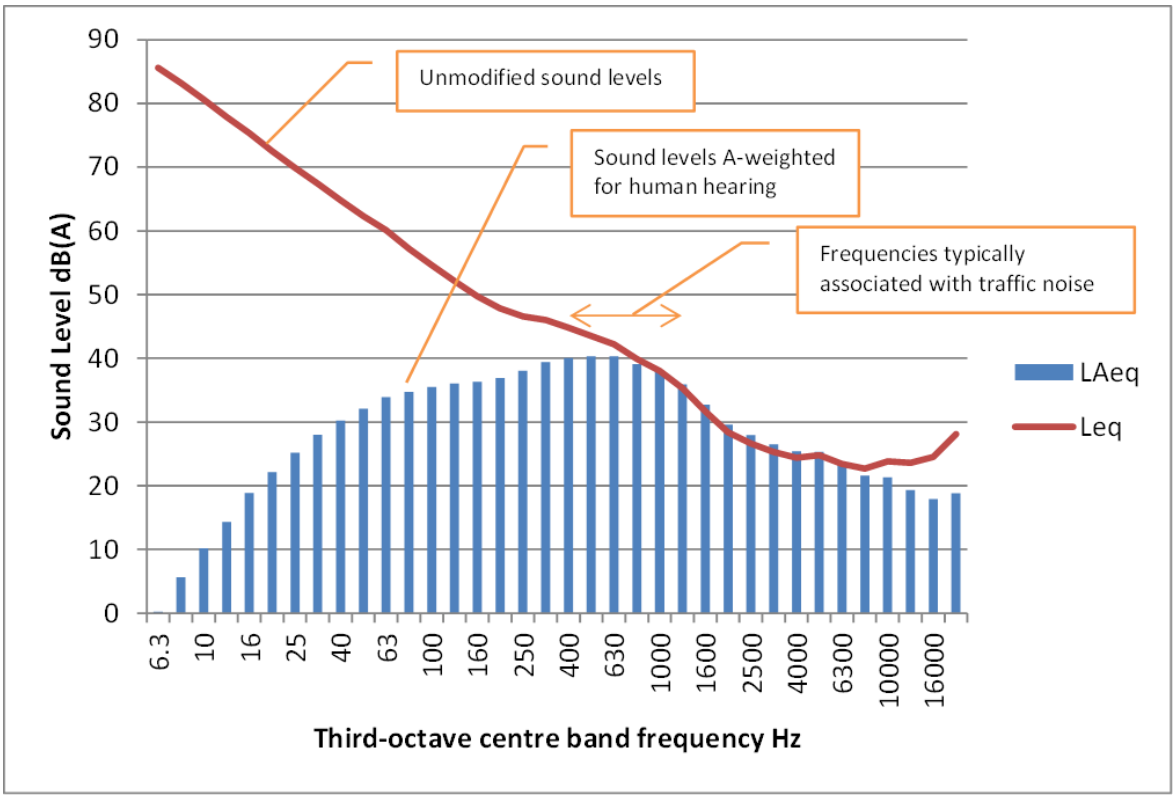

Figure 7-125: Frequency profile for Liberty Lodge sound level measurement

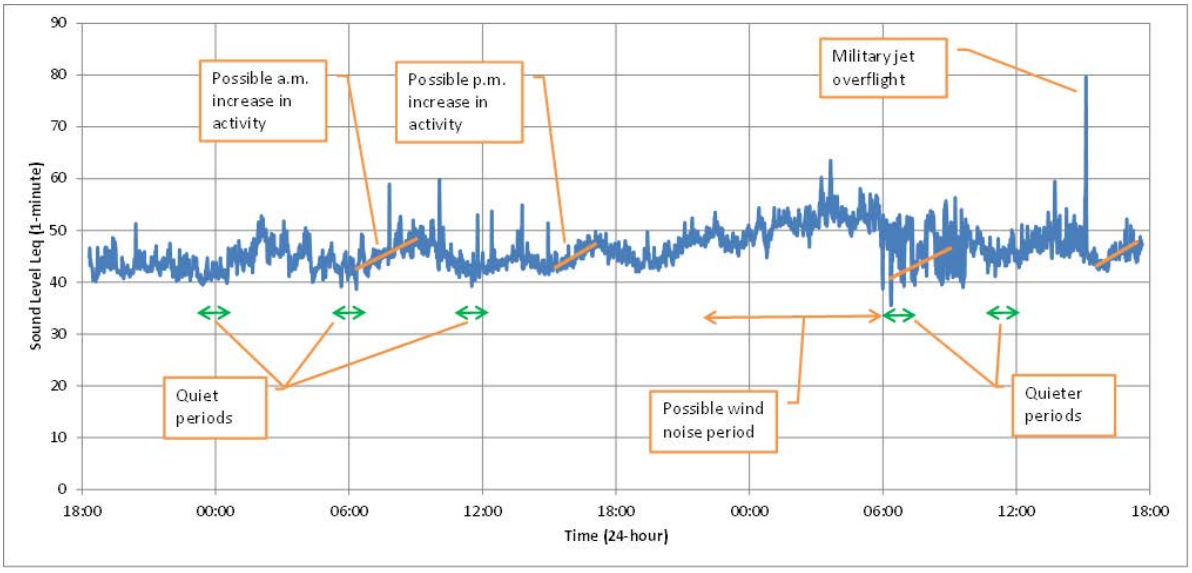

Figure 7-126: Time sequence of noise measurements at Liberty Lodge (1-minute intervals)

POEPL survey February 2017

On 16 February 2017, further baseline noise measurements were taken from several points in and around Stanley. Other sites were associated with the power station, one of the loudest sources of ambient noise, and Moody Brook, at the extreme western end of Stanley Harbour. Snap-shot measurements over a period of 5 – 6 minutes were taken at each point using Mirus Sound Level Meter GA117 s/n 35777, Class 1 microphone, UKAS certified, proprietary windshield. The results are summarised in Table 7.53 (all measurements are 'A' weighted).

On the day, the air temperature was 17 °C, air pressure was 1,004 mbar and wind speed was *c.* 5 m/s (equivalent to *c.* 10 knots). Sources of ambient noise included:

- Several jiggers in the harbour approximately 200 m from the shore, and
- Ongoing refurbishment of FIPASS, which involved grit blasting, compressors and moving plant.

Table 7.53: Summary of baseline sound levels collected in February 2017

Ref	Measurement location	Type	Time	Duration	Leq	Lmax	Lmin	Notes
L11	Ross Road - slipway	Sound level only	13:43	00:06:37	51.3 dB	69.6 dB	47.8 dB	Jigger 1. Passing car.
L12	Ross Road - slipway	SL & 3rd Octave	13:50	00:06:28	60.1 dB	73.2 dB	48.8 dB	Jigger 2 starts (louder).
L13	Ross Road - slipway	SL & 3rd Octave	14:03	00:06:46	56.1 dB	78.4 dB	48.6 dB	Jigger 2. Passing cars.
L14	Ross Road - slipway	Sound level only	14:10	00:05:53	54.9 dB	67.2 dB	47.9 dB	Jigger 2. Ship horn sounding. Passing cars.
L15	FIPASS - Shoreline at west extent of FIPASS pontoons (near Stanley Growers)	Sound level only	14:34	00:06:45	60.0 dB	72.4 dB	47.9 dB	Jigger noise. Grit blasting. Metal deck reverberation. Compressor noise.
L16	FIPASS - Shoreline at west extent of FIPASS pontoons (near Stanley Growers)	SL & 3rd Octave	14:41	00:05:03	61.1 dB	72.8 dB	46.6 dB	
L17	FIPASS - Shoreline opposite gap between two east most pontoons	SL & 3rd Octave	14:55	00:05:14	49.2 dB	54.7 dB	43.0 dB	Jigger noise significantly reduced. Grit blasting. Metal deck reverberation. Compressor noise.

L24	Outside power station	Sound level only	16:40	00:05:03	72.5 dB	75.2 dB	71.1 dB	
L25	Field above power station	Sound level only	16:48	00:05:02	62.9 dB	84.8 dB	45.4 dB	Power station noise. Passing cars
L26	Field above power station	SL & 3rd Octave	16:53	00:05:04	53.6 dB	68.3 dB	44.2 dB	Power station noise. Loud lorry using engine to brake downhill.
L27	Moody Brook	SL & 3rd Octave	17:09	00:05:03	41.8 dB	63.3 dB	29.4 dB	Background noise. Wind picking up 5-10 m/s, potential crackle.
L28	Moody Brook	Sound level only	17:14	00:05:03	44.0 dB	58.1 dB	29.4 dB	

7.7.5.1.2 Odour

No information is currently available on the odour baseline in Stanley. Scoping consultations did not raise it as an ongoing issue, nor was it raised during previous O&G operations.

7.7.5.1.3 Light

Stanley is currently lit at night by streetlights and there are 'operational' lights at night from the industrial end of Stanley (the Gordon Lines area), as well as from FIPASS. Lights can also be seen from vessels in the harbour. The number of vessels depends on the season but is generally highest in January and February, prior to the start of the *Illex* season. During previous O&G operations there were lights at the TDF and supply bases and it was noted during previous scoping consultations that light from the TDF, vessels and yard is noticeable to Stanley residents. A community complaint was also made to POEPL during the 2015 exploration drilling campaign regarding the lighting from vessels moored up in the harbour at night.

The New World Atlas of Artificial Brightness shows that the Falklands are a relatively dark sky area, with the majority of the population living with little very light pollution (CIRES, 2016).

7.7.5.2 Berkeley Sound

7.7.5.2.1 Noise

7.7.5.2.1.1 Long Island Farm - August 2016

In August 2016, POEPL took noise measurements outside Long Island Farm, facing Berkeley Sound, over a period of 30 hours. During this time there was only one vessel in Berkeley Sound (FIMA, 2024, *pers comm*.). Unfortunately, they appear to have been affected by wind. Normally, measurements taken in conditions with winds above 5 m/s are not deemed reliable for noise assessments due to the effect of wind on ambient noise and more specifically the effect of buffeting on the microphone, both effects elevating the noise measurement. More specifically, for assessment or baselining purposes it is recommended to use noise levels derived from measurements taken with appropriate equipment at windspeeds less than 5 m/s. The results are nevertheless shown below. In the absence of wind they would indicate relatively high levels for a rural location, and so are not thought to be reliable. It was not possible to secure another period of quiet weather to re-do the modelling in August 2016; however a further monitoring exercise was undertaken in February 2017 (see below). Table 7.54 shows the measurement conditions for the monitoring. Table 7.55 summaries the measured baseline sound levels.

Table 7.54: Measurement conditions for baseline sound measurement

Time and date	Location	Weather conditions	Notes
23rd August 2016 12:54 to 24th August 2016 19:39	Long Island Farm, Berkeley Sound	1-5 Celsius 2-10 m/s wind No precipitation	Gusting wind, one vessel in Berkeley Sound

Table 7.55: Summary of baseline sound levels at Berkeley Sound

Parameter	Value over 48 hours dB(A)	Note
A Leq	54.3	The 'average' noise level over the measurement period.
AF Max	89.9	The maximum noise level (F='fast', averaged over 125 milliseconds)
AF Min	35	The minimum noise level ('F')
AFL90.0	46.6	The noise level exceeded 90 % of the time (F)

7.7.5.2.1.2 Long Island Farm - February 2017

On 21st February 2017, sound recording equipment was deployed at Long Island (Berkeley Sound) to establish the ambient, background noise level. During this time there were no vessels in Berkeley Sound (FIMA, 2024, *pers comm*.). Following the exercise in 2016, a measurement period was deliberately chosen to measure noise in the absence of strong winds. Although winds were not monitored continuously, they were subjectively very low at the start and end of the measurement (*c.* 0-5 m/s) and no significant changes in weather were noted locally in this time. This reflects conditions when added noise from the proposed project activities may cause the most annoyance. In this area, wind noise is a common and very apparent feature most of the time, and it was difficult to identify a period of more than a few hours when winds were low, and the previous measurement in 2016 was discounted as being wind-influenced (Section 7.7.5.2.1). The results should be read in this context, that they represent unusually 'quiet' conditions and do not reflect long-term averages. Air temperature ranged between 8-14 °C and air pressure 1,002 mbar.

Guidance on how to calculate background noise for assessment purposes was taken from BS4142:2014. Background noise is the 90th percentile of LAeq measurements (i.e., 90 % of measurements are above this) and is considered separately for night-time (11pm - 7am) and daytime (7am - 11pm).

Once established, a comparison against commercial or industrial operating noise can be made to assess the potential impacts on human receptors.

The recorded sound levels are shown in Figure 7-127, from which the following background noise levels (in the absence of significant wind noise) are calculated:

- Daytime LA90, 1 hour 30.8 dBA, and
- Night-time LA90, 15 mins 29.5 dBA.

Generally, daytime noise levels average around 40 dB(A), and night-time background levels average around 30 dB(A) for significant periods. Background (LA90 levels) noise at Long Island Farm was around 10 dBA lower during the daytime and only slightly lower than average at night. Periodic loud noise events were observed lasting 1-2 minutes (Figure 7-127). These were unidentified, but were unlikely to be passing local vehicles given the location of the meter, and would be consistent with passing aircraft.

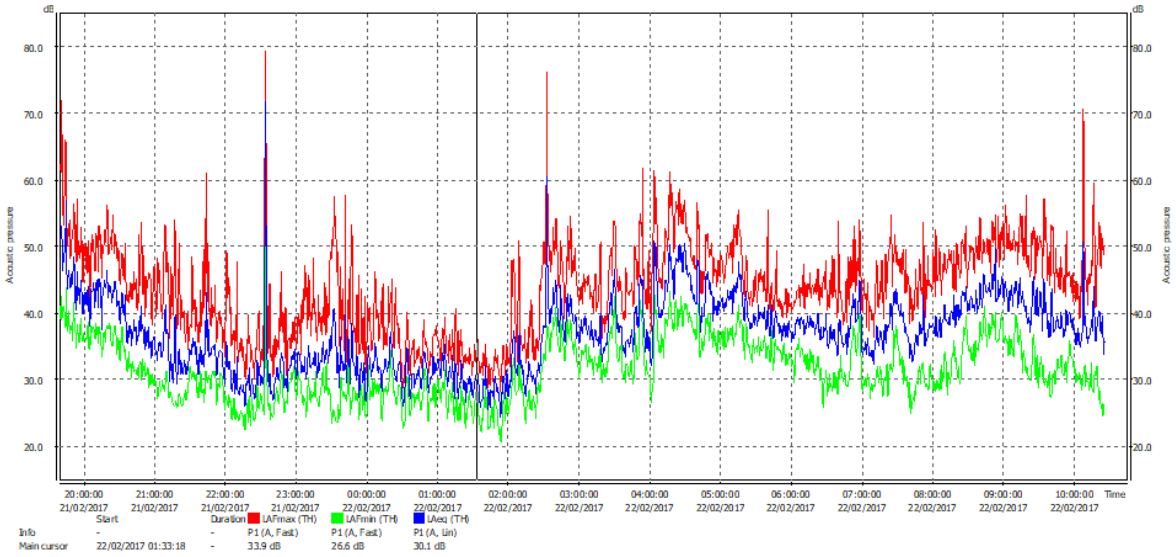

Figure 7-127: Sound pressure levels recorded at Long Island Farm on 21st - 22nd February 2017

7.7.5.2.2 Odour

No information is currently available on the odour baseline in Berkeley Sound. Scoping consultations did not raise it as an ongoing issue.

7.7.5.2.3 Light

Sources of existing anthropogenic light include the jiggers that utilise Berkeley Sound to tranship their catches to reefer vessels and to refuel. Although the full rig of jigging lights is not deployed in Berkeley Sound, there is a considerable amount of light emitted from these vessels, the glow from which can be seen from Stanley (A. Black, *pers. obs.).* In addition to the jiggers, other vessels use Berkeley Sound as an anchorage, primarily for the transshipment of fish catches.

Although vessels can be present in all months of the year, activity peaks between March and June, when more than a dozen vessels can be present, but this varies considerably from year-to-year. Combined, these vessels represent a large source of anthropogenic light. Despite this, The New World Atlas of Artificial Brightness describes the Falklands are a relatively dark sky area, with the majority of the population living with little very light pollution (CIRES, 2016).

7.7.6 Marine archaeology

7.7.6.1 Wrecks in the NFB and Sea Lion Field

The UK Hydrographic Office Wrecksite database indicates that there are 177 shipwrecks recorded within Falkland Islands waters, with records dating from the 1800s to present day (UK Hydrographic Office, 2023). There are nine recorded wrecks within 100 nautical miles radius of the Phase 1 & 2 offshore development site (Table 7.56). The two closest of these wrecks are both located approximately 40 nautical miles from the field (Figure 7-128). There are no recorded wrecks within the immediate vicinity of the Development site.

Table 7.56: Recorded wrecks within 100 miles of the Phase 1 & 2 Development

Wreck	Vessel Type	Latitude	Longitude	Depth (m)	Date
ARA Comodoro Somellera	Argentine patrol boat	49°30'00.2"S	58°30'17.8"W	400	1982

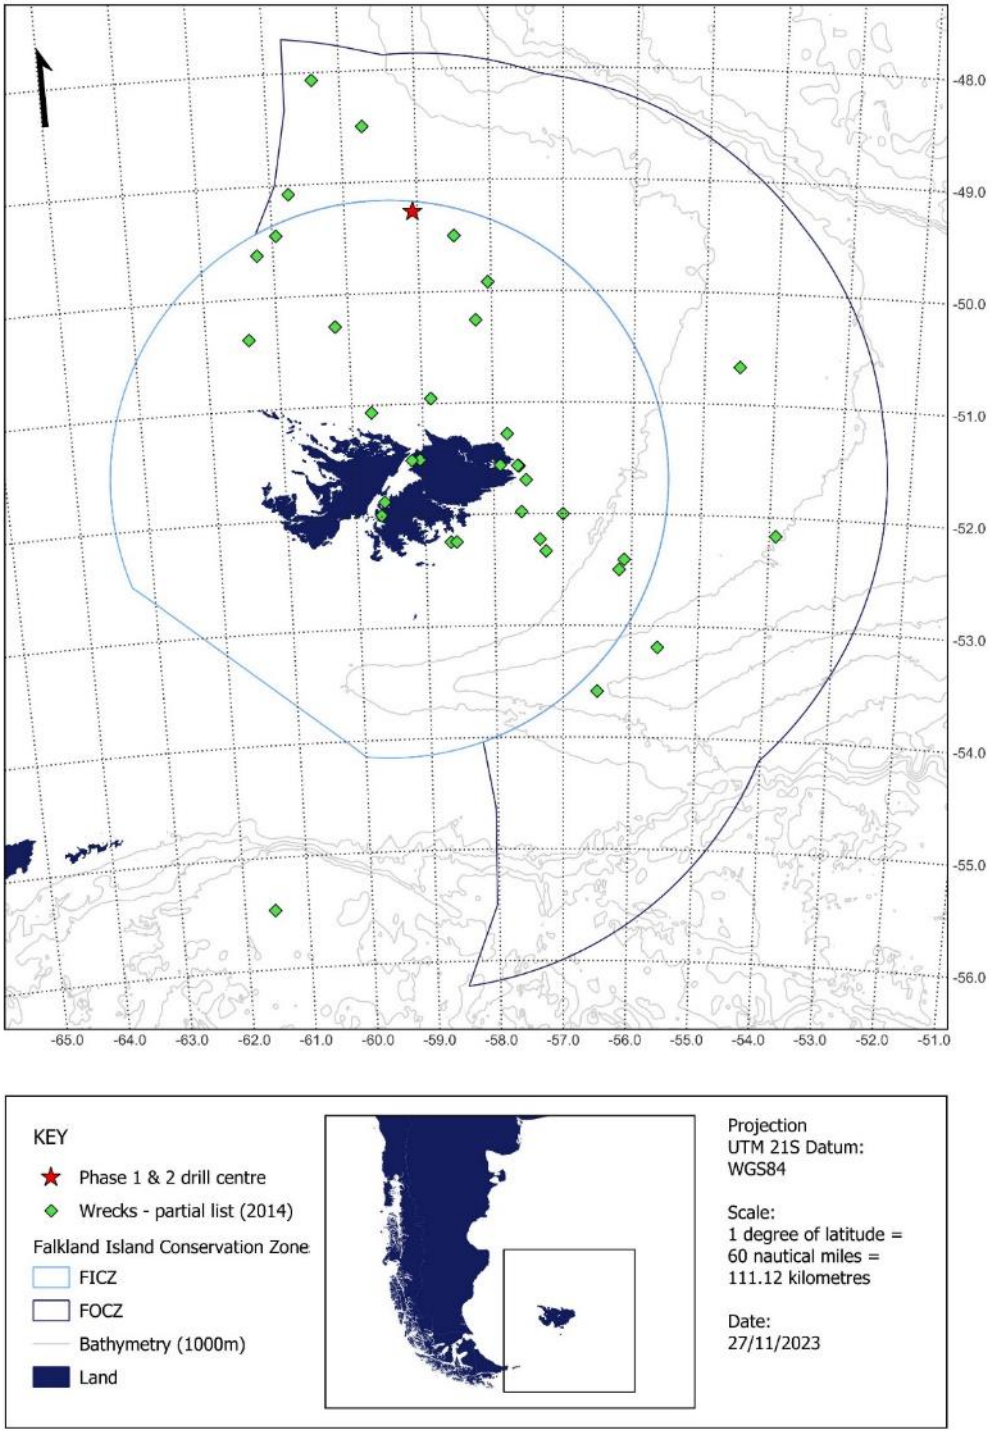

Figure 7-128: Known shipwrecks within the Falklands Continental Shelf

7.7.6.2 Berkeley Sound

7.7.6.2.1 Wrecks

Two wrecks were identified within the survey area Figure 7-129, the trawler Ocean 8 to the north-west and the Blakeney to the south-east. Both wrecks are charted on Admiralty Charts; however, the

charted position of the Blakeney wreck is approximately 1 km due east of the position interpreted from the sonar data. The wreck of the Ocean 8 lies approximately 100 m south-west of the charted position but within the Admiralty buffer.

The wreck Ocean No. 8 was observed within the survey area at 437260E, 4287300N with a shallowest point of 21.5 m surrounded by a seabed of 31 m below CD (Stanley).

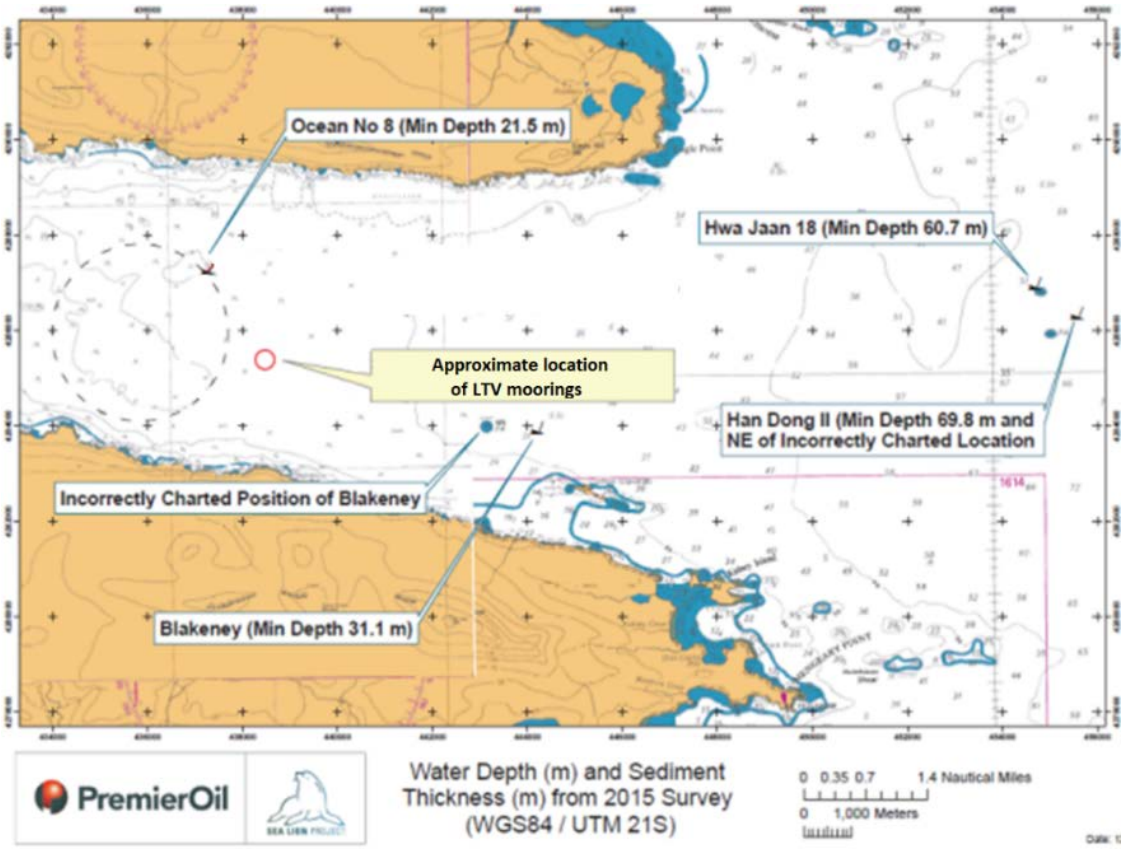

Figure 7-129: The location of wreck sites within Berkeley Sound

7.7.6.2.2 Anchor scars

Reflecting the heavy use of Berkeley Sound as an anchorage, evidence of shipping activity was found throughout the Sound (BSL, 2015a).

The seabed in the sound, especially in the more sheltered western end, is heavily scarred with linear features generated by dragging anchors. A number of anchor scars observed were over 100 m long indicating significant vessel drift, 'anchor drag'. Fan shaped patterns were also observed on the seabed, which are thought to be caused by anchor chains dragging across the surface as a vessel 'swings' on its anchor (BSL, 2015a).

The physical dragging of the anchors disturbs benthic communities, stripping hard surfaces and overturning soft sediments. Seabed imagery indicated the possible presence of the filamentous bacteria *Beggiatoa* sp. within the anchor scars, visible as a white mat on the seabed. This bacteria is generally only found in areas that interface aerobic and anaerobic conditions and is often found in areas of organic enrichment.

7.7.6.2.3 Man-made objects

During a sonar survey in 2015, a total of 1,459 potentially man-made objects were identified within Berkeley Sound (BSL, 2015b). A contact was interpreted as man-made if it had a distinctly linear shape

or shadow and appeared to be of man-made origin, otherwise it was classified as a boulder. Where possible further details were added, however, many targets have been listed at 'debris' if the object could not be further identified.

Many contacts were identified as tyres, piping and lengths of rope, cable or chain which have distinctive forms allowing easy identification. These sorts of debris are typical of an area used by commercial shipping and fishing vessels. Some targets warranted further investigation due to their size and / or proximity to the proposed Berkeley Sound anchorage location. A box shaped object was identified on sonar located at 434699E 4285499N with dimensions of 2.4 m x 2.4 m x 0.7 m (Length x Width x Height). A drop down camera pass was undertaken over the target which showed a metal frame with meshing which looks to be some lost or discarded fishing equipment, possibly a jigger arm (Figure 7-130).

Figure 7-130: Photograph of large man-made object found on the floor of Berkeley Sound (BSL, 2015b)

7.7.6.3 Aviation wrecks and UXO (Unexploded Ordinance)

Previous surveys across the Sea Lion Field and Berkeley Sound have been completed by a range of contractors including but not limited to SAERI, Benthic Solutions, Earth Sciences & Surveying (EGS) and Gardline. The area's marine archaeology is well known and well documented. Further, FIMA (Falkland Islands Maritime Authority) confirms it is not aware of any aviation wrecks or UXO in the area of Sea Lion's proposed activities (S. Barlow, 2024, *pers. comm*.).

7.8 Summary of Key Environmental and Social Sensitivities

7.8.1 Key environmental sensitivities

The key biological sensitivities of the Falkland Islands offshore environment and Berkeley Sound are summarised in Table 7.57 and Table 7.58 respectively. Note that in order to give an overview of the environmental sensitivities, the tables indicate the relative importance of each month, regardless of which particular species, fishery or site is the cause.

Table 7.57: Summary of key environmental sensitivities in the Sea Lion Phase 1 & 2 Development area

Environmental baseline and sensitivity at Sea Lion											
Low[1]				Medium[1]				High[1]			
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Plankton: Plankton comprises of small to microscopic plants (phytoplankton) and animals (zooplankton) that drift in the surface layers of the sea. Phytoplankton require sunlight, like all other plants, to survive, and zooplankton graze upon the phytoplankton or prey on other zooplankton. The oceanic fronts around the Falkland Islands result in nutrient rich waters which create an area of very high phytoplankton productivity immediately to the north of the Islands (and approx. 60 km to the south of the Sea Lion Field). This phytoplankton productivity is seasonal and in turn supports complex communities of zooplankton, which then support complex pelagic (in the water column) and demersal (near the seabed) ecosystems.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine flora: Not applicable to offshore location.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Benthic fauna: Benthic fauna are those animals which live on, or below, the seabed. Overall, benthic fauna around the Sea Lion area is very uniform, with polychaetes (i.e., marine worms) and crustaceans (e.g., crabs) being the two most abundant groups present, followed by molluscs (e.g., clams).											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Fish and shellfish: The convergence of the temperate and sub-Antarctic regions in the Falkland Islands archipelago results in the presence of species belonging to both. The six sub-Antarctic, and seven temperate, fish and squid species found in abundance in Falkland Islands' waters primarily utilise the NFB as feeding grounds, migrating in and out of the area as food availability changes and to follow seasonal spawning migrations. Other species feed in the area as juveniles and move to deeper waters as they mature and become adults. This results in seasonal changes in the fish assemblages across the ecosystem.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Seabirds: Over 70 % of the global population of black-browed albatross breed on the Falkland Islands with a significant proportion of the global populations of gentoo and rockhopper penguins doing the same. The waters surrounding the Falklands also support numerous species that breed elsewhere. Of the species recorded in the Sea Lion area, the Atlantic petrel, grey-headed albatross, and northern royal albatross are all listed as 'Endangered' on the IUCN Red List, and the southern rockhopper penguin, white-chinned petrel, southern royal albatross and the wandering albatross are listed as 'Vulnerable'.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine mammals: Confirmed records indicate that 25 species of cetacean (whales, dolphins and porpoises) occur within Falkland Islands waters and three species of pinniped (seals) breed on the Islands. Many of the cetacean species are rare and inconspicuous and some are only known from stranded animals. Of these 25 cetacean species, two species are listed as 'Endangered' on the IUCN Red List, namely the sei whale and the less common blue whale, two species, the fin and sperm whales, are listed as 'Vulnerable' and the southern right whale is listed as being of regional conservation concern.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Conservation sites: There are no designated marine protected areas in Falkland Islands waters. The Falkland Islands Government (FIG) has identified several areas as proposed Marine Managed Areas, for which a public consultation was held in 2022[2]. Policy work is ongoing (as of March 2024) but it is anticipated the proposed Marine Managed Areas will be designated. Non-statutory Key Biodiversity Areas (KBAs) have also been identified for sei whales and seabirds around the Falkland Islands. On land, a number of Important Bird Areas (IBAs) have been designated. Additionally, a network of National Nature Reserves (NNR) and Important Plant Areas (IPAs) protect many of the most important seabird breeding sites and areas supporting native flora respectively.											

[1] Note that the terms Low, Medium and High in this context provide a guide only as to the general sensitivity / abundance as it is relevant to each receptor. Specific sensitivities of each receptor to each environmental impact are explored in full within the EIS.

[2] Consultation report and scientific evidence to support Marine Managed Areas is available *via* FIG website https://www.falklands.gov.fk/policy/environment/marine-managed-areas-consultation-report.

Table 7.58: Summary of key environmental sensitivities in Berkeley Sound

Environmental baseline and sensitivity in Berkeley Sound											
Low[1]				Medium[1]				High[1]			
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Plankton: Plankton comprises small to microscopic plants (phytoplankton) and animals (zooplankton) that drift in the surface layers of the sea. The most conspicuous component of the inshore zooplankton community is lobster krill, which is an important prey species for higher predators (such as penguins and whales).											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine flora: Marine plants are the major primary producers in the marine environment. The most common species of seaweed within the Falklands are the giant kelp and the tree kelp, which are found around the entire Falklands coastline. Kelp is a habitat forming species and is a very important part of the inshore ecology.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Benthic Fauna: Benthic fauna are those animals which live on, or below, the seabed. Berkeley Sound supports a wide range of benthic habitats (including biogenic and geogenic reefs), each supporting a characteristic range of species. Although none of the species found is rare or protected under any Falkland Islands legislation. Work is ongoing to identify important marine areas, and as such work develops, new designations can be incorporated in the ongoing management of the project *via* the EMMP and the 5-yearly review of the EIS.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Fish and shellfish: The most conspicuous species found inshore off the east coast is loligo squid, which play a key role in the inshore ecology as predator and prey. n addition, loligo support the second largest fishery in the Falklands. Loligo are known to migrate inshore to spawn, although the key spawning sites remain unknown. Periods of 'high sensitivity' reflect the spawning periods of the two loligo cohorts. There are several species of shellfish found within Berkeley Sound that are commercially exploited elsewhere but not currently in the Falklands.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Seabirds: Berkeley Sound encompasses significant breeding populations (>1 % of the national population) of gentoo and rockhopper penguins and a far higher proportion of the national populations of king penguins, sooty shearwaters and white-chinned petrels. In addition to king and gentoo penguins, there are large resident populations of imperial and rock shags and Falklands steamer ducks, which are present year-round. Of the species breeding in Berkeley Sound the white-chinned petrel and southern rockhopper penguin are listed as 'Vulnerable' on the IUCN Red List.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine mammals: Berkeley Sound supports small breeding populations of South American sea lions (Diamond Cove), South American fur seals (Volunteer Rocks) and is likely to have breeding populations of Commerson's and Peale's dolphins. Conspicuous seasonal visitors include sei whales, which are most numerous in the late summer and autumn. Several other species of large whale have been recorded within Berkeley Sound including southern right and Antarctic minke whales. An influx of southern right whales was first *recorded* during the winter of 2017 and seems to have sustained since.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Conservation sites: The entrance to Berkeley Sound is flanked by two National Nature Reserves (Volunteer Point and Cow Bay, and the Kidney Island Group), which are also classed as Important Bird Areas, and a proposed Marine Management Area has also been proposed. Further, the importance of sei and southern right whales in Berkeley Sound and surrounds has resulted in a Key Biodiversity Area and two Important Marine Mammal Areas to be adopted.											

[1] Note that the terms Low, Medium and High in this context provide a guide only as to the general sensitivity / abundance as it is relevant to each receptor. Specific sensitivities of each receptor to each environmental impact are explored in full within the EIS.

7.8.2 Key social sensitivities

The key social sensitivities of the Falkland Islands are summarised in Table 7.59.

Table 7.59: Summary of key social sensitivities in the Sea Lion Phase 1 & 2 Development area

Social baseline and sensitivity											
Low[1]				Medium[1]				High[1]			
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Commercial fisheries: The three most important fisheries within the Falklands Economic Exclusion Zone (EEZ) are the jig fishery for Argentine shortfin squid, Loligo squid and the trawl fishery for Patagonian rock cod, which accounted for 49.5 %, 25.1 % and 5.2 % of the 2013-2022 catches by weight respectively. There is also a fleet of trawlers that operate over the Falklands continental shelf that target a range of finfish species. Currently, the only other fishery in the Falklands EEZ is the longline fishery for Patagonian toothfish, which operates in deeper waters (> 600 m).											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Tangible property and resources: There is a range of onshore infrastructure on the Falkland Islands that will be utilised during the Phase 1 & 2 Development, which could lead to competition for resources with other users of these facilities. The main areas of potential impact include the use of: port facilities, supply routes, airports and airlinks, the road network, accommodation, freshwater and electricity supply. During the austral summer period, accommodation, flight availability and freshwater may all be less available.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Tourism: The majority of tourists visiting the Falkland Islands arrive on cruise ships. Many cruise ships visit locations in the west of the Islands to see wildlife and most vessels visit Stanley. Within Stanley, there are a number of businesses and individuals that support tourist excursions to locations within driving distance of the city. Many of these sites are important for the wildlife that they support; however, they are also important recreational sites for residents.											
Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Marine archaeology: The UK Hydrographic Office Wreck site database indicates that there are 177 wrecks recorded within Falkland Islands waters, with records dating from the 1800's to present day. There are six recorded wrecks within 100 nautical miles of the proposed drilling sites; the closest of these wrecks is located approximately 50 nautical miles from the nearest well site. Two wrecks were identified within the Berkeley Sound survey area: the trawler Ocean 8 to the north-west, and the Blakeney to the south-east.											

[1] Note that the terms Low, Medium and High in this context provide a guide only as to the general sensitivity as it is relevant to each receptor. Specific sensitivities of each receptor to each social impact are explored in full within the EIS.

8.1 Introduction

The impact and risk assessment process provides a framework for assessing the potential environmental and social consequences that may arise from the proposed development based on the information made available during project planning. The purpose of this chapter is to describe the methodology used to identify and assess the environmental aspects and potential impacts and risks resulting from the Sea Lion Northern Development Area Phase 1 & 2 (hereafter referred to as the Phase 1 & 2 Development).

The methodology has been prepared based on the:

- FIG Environmental Impact Assessment Guidance Note (FIG, 2016e),
- Navitas Operating Management System (SEL-REG-OPM-PLN-00001-00), and
- International best practice (IEEM, 2010; Horvath (IAIA), 2013; Morris and Therivel, 2009; Glasson, *et al.,* 2013).

8.2 Overview of the environmental impact and risk assessment process

The International Standard for Environmental Management (ISO14001:2015) defines an environmental impact as 'any change to the environment, whether adverse or beneficial, wholly or partially resulting from a project's environmental aspects'. Environmental aspects refer to the way in which the project activities may interfere with the environment.

Environmental aspects, impacts and risks can be identified by assessing the planned activities that must occur for the project to be successfully completed and by exploring what could happen as a result of these activities. Further, during the course of any project execution, there is a risk that unplanned and accidental events may occur and it is therefore also necessary to consider what could go wrong.

Planned activities give rise to environmental impacts, while unplanned and accidental events pose a risk of environmental impact, if they occur. The risk of environmental impacts resulting from unplanned or accidental events is evaluated by taking the likelihood of the event occurring into consideration.

Therefore, with regard to assessing the Phase 1 & 2 Development:

- Planned activities are subject to an impact assessment only, and
- Unplanned and accidental activities / events are subject to the same impact assessment followed by an assessment of the likelihood that the unplanned or accidental event will actually occur.

Initial assessment of the impacts and risks takes account of key legal compliance requirements, additional industry-standards, controls that are built-in to the basis of design / design philosophies to reduce impacts, and also any input from key stakeholders received during the scoping exercises (Chapter 6). 'Impacts and risks that are initially assessed as 'Low' or 'Very Low' using the base-case mitigations, industry-standard and OMS measures were not prioritised with regard to further project-specific mitigation as extensive additional measures were not considered 'reasonably practicable'. Where an impact or risk is deemed 'significant' (i.e., 'Moderate' or above), alternatives must be considered and project-specific mitigation measures proposed, to eliminate impacts and risks, or reduce them to a level that is 'As Low As is Reasonably Practicable' (ALARP) in line with Navitas' ALARP Procedure (SLN-HSE-RMA-PCD-00001-00). Following identification of project-specific mitigation measures, the 'residual' impact or risk is assessed.

Residual impacts and risks that are assessed as 'Very Low' or 'Low' using the base-case mitigations, industry-standard and OMS measures were not prioritised with regard to further project-specific mitigation as extensive additional measures were not considered 'reasonably practicable'. Where a

residual impact remains 'Moderate' or above, offsetting measures were considered (see Section 8.11). Additionally, throughout the process, the potential for any positive or beneficial impacts is noted.

Further to the assessment of the individual impacts and risks associated with the Phase 1 & 2 Development, the potential for cumulative impacts, which may be caused by the presence of other operations ongoing in the vicinity, are also assessed.

Throughout the whole process, the assessment follows a precautionary approach, taking account of any data gaps and uncertainties. However, upon completion of each assessment, a confidence rating is assigned to the impact and risk rating to inform the reader on the overall level of confidence in each assessment, and to inform the level of monitoring that may be required throughout the life of the operation.

All monitoring requirements will be captured within the Environmental Monitoring and Management Plan (EMMP). Future remedial action may be required where monitoring indicates that an impact is higher than predicted in this EIS and / or where the prescribed regulatory requirements and best practice are considered insufficient. An overview of the EIA process is provided in Figure 8-1 below.

8.3 Aspect, impact and risk identification

Using the project basis of design (Chapter 5), the environmental aspects are determined by walking through the different stages of the Phase 1 & 2 Development and identifying the ways they may impact upon the environment or society (i.e., the human population).

When identifying the environmental and social aspects, impacts and risks, it is important to note that the project activities (e.g., drilling, production, use of vessels etc.) can interact with the environment in many ways.

It is understood that:

- Planned activities with known outputs will inevitably lead to impacts e.g., it is inevitable that there will be some atmospheric emissions and waste,
- Unplanned events may occur which carry the risk of an impact due to, for example:
  - The potential for downtime in equipment e.g., the vapour recovery package, the produced water reinjection unit, and / or
  - The potential for events that are outwith Navitas' control.
- Accidental events may occur which carry the risk of an impact in the event of a loss of control over project activities e.g., oil spills would only result from an accidental or uncontrolled event such as a vessel collision or well blow-out.

Therefore, impacts, and / or the risk of an impact, are associated with planned activities and with unplanned / accidental events.

Environmental and social aspects, impacts and risks are identified during ENVironmental Impact IDentification (ENVIID) workshops. The outcomes of the Sea Lion Northern Development Area Phase 1 & 2 ENVIID are described in Chapter 9.

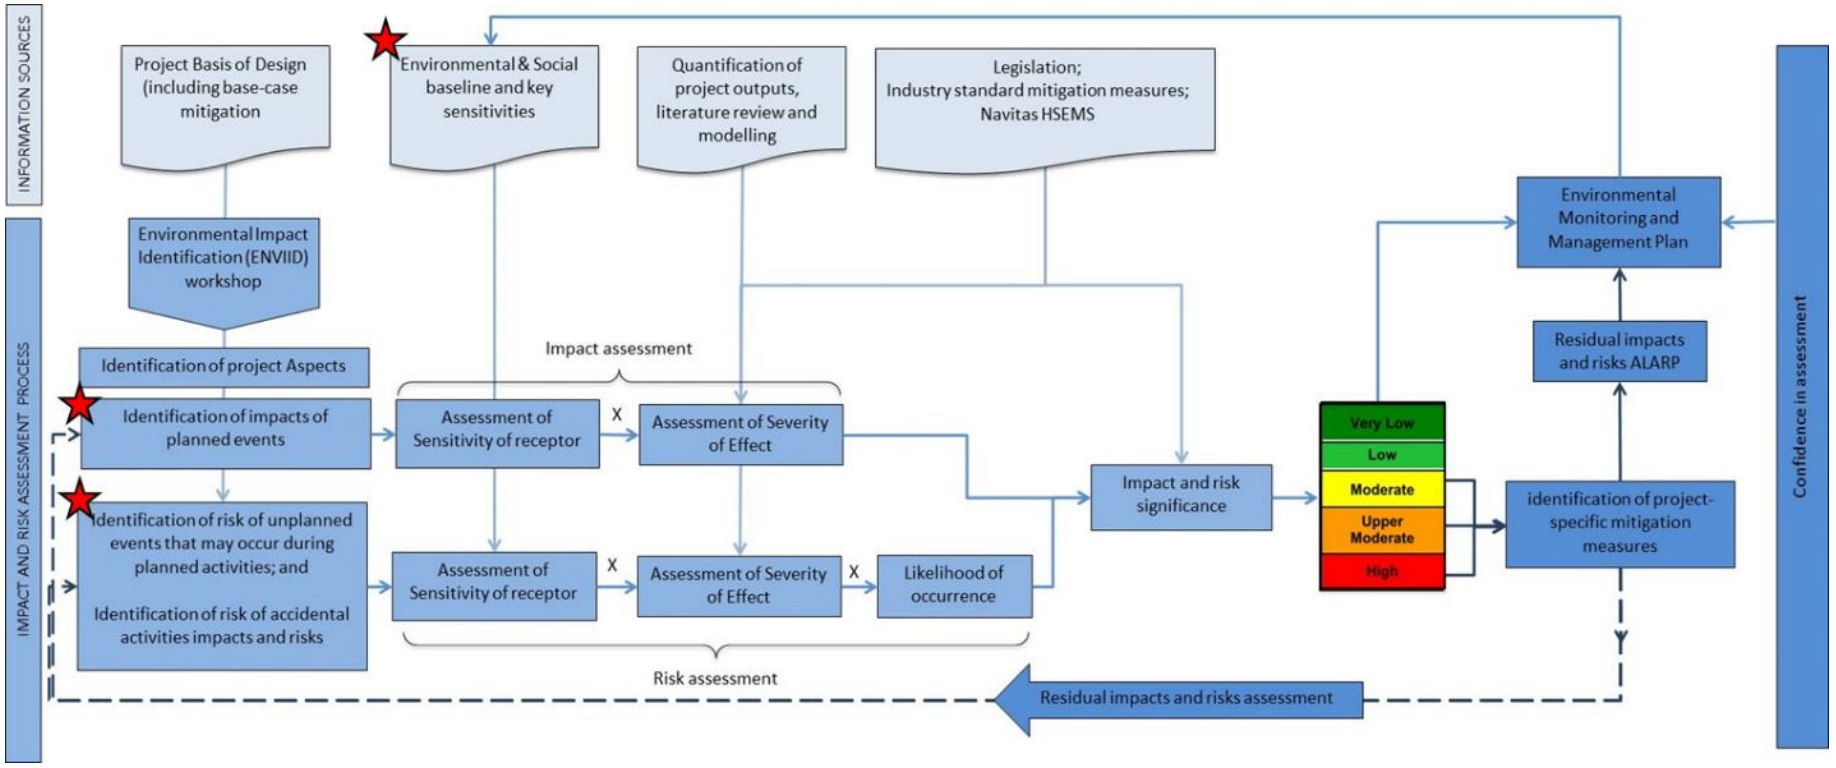

Figure 8-1: Overview of EIA process (Note: the red stars indicate areas informed by the scoping process as described in Chapter 6)

8.4 Environmental baseline and receptor identification

In order to assess the impact or the risk it is necessary to have an understanding of the existing environment and the components within it (i.e., the environmental receptors). Full detail on the environmental and social baseline is provided in Chapter 7.

The term 'environmental receptor' effectively describes the receiving environment which may be impacted by an activity or outcome of the Development (i.e., environmental aspect). Environmental receptors therefore include individuals, species, populations, habitats, the physical environment (locally and globally) and ecological processes. The environmental components or receptors which must be considered in an EIA are defined within Paragraph 4 (2a-k) – Schedule 4 of the FIG Offshore Minerals Ordinance (Section 3.1.7.3.1) and are listed below. Some receptors have been broken down into sub-components to demonstrate how they have been addressed in this EIA.

The sensitivity of the following receptors to environmental impact is described in Section 8.5.2.1 below.

- Human population:
  - Stakeholder and or regulatory concern,
  - Disturbance,
  - Health,
  - Commercial fisheries,
  - Tourism, and
  - Transboundary impacts.
- Flora and Fauna:
  - Benthic (animals living on or in the seabed) and terrestrial ecology,
  - Plankton (plant or animals which live in the water column and drift with the ocean currents),
  - Fish ecology,
  - Seabirds,
  - Marine mammals, and
  - Designated sites (on account of their populations of flora or fauna).
- Soil (including the seabed) (referred to in this EIA as 'Seabed (including soil)'),
- Water quality (including the sea and aquifers under the seabed),
- Air quality (local),
- Climatic factors (global),
- Landscape and seascape,
- Tangible property (e.g., fishing vessels and finite resources such as landfill space, diesel, potable water),
- Architecture and archaeological heritage, and
- The interaction between these factors (in any combination).

8.5 Impact assessment methodology for planned events

This section describes the methodology used for the assessment of environmental impacts arising from planned events.

8.5.1 Environmental Impact Assessment process

The evaluation of impacts follows a structured methodology that systematically:

- Identifies planned project activities and environmental aspects that could lead to an environmental impact (Section 8.3),
- Assesses the sensitivity of the receptor (Section 8.5.2.1),
- Assesses the severity of the effect (Section 8.5.2.2) on the respective receptor/s taking account of statutory and industry-standard safeguards, BAT (Best Available Technology / Techniques) and BEP (Best Environmental Practise) mitigation technologies built-in to the project basis of design (Section 8.7),
- Assesses the initial significance of the impact (Section 8.5.3) of planned activities based on the above,
- Identifies project-specific mitigation measures (Section 8.7) as required to reduce any 'significant' environmental impacts to ALARP,
- Evaluates the residual impact (Section 8.8) taking account of project-specific mitigation measures,
- Evaluates the potential for cumulative impacts and impact interaction (Section 8.9),
- Assesses the degree of confidence (Section 8.10) in the impact assessment, and
- Explores the potential for offsetting significant impacts where possible (Section 8.11).

8.5.2 Assessment of environmental impacts

During the assessment of the sensitivity of receptors and the severity of effect, a precautionary approach is taken.

8.5.2.1 Assessment of sensitivity of receptors

Assessment of the 'sensitivity of the receptor' draws upon the data in the environmental baseline description (Chapter 7) and considers a number of factors (IEEM, 2010; Morris and Therivel, 2009) including, but not limited to:

- The relative importance of the local population size e.g., as a percentage of global / regional population size,
- The conservation status of the habitat or species e.g., does it sit within an IUCN (International Union for Conservation of Nature) threat category,
- Whether the habitat is a designated conservation site,
- The seasonal migrations and abundance of species and populations e.g., whether or not the species or population is likely to be in the relevant area at the time of the proposed activity,
- Species sensitivities e.g., during vulnerable periods of a species' lifecycle, and
- Sensitivity to ecosystem services resulting in changes to species health and ability to survive, including livelihoods and aesthetics or forced behavioural change (migration pattern, livelihoods).

Project-specific guidelines were developed to inform the assessment of receptor sensitivity (Table 8.1). These are based on the criteria for assigning value to ecological features as described in IEEM (2010).

The guide descriptions provided in Table 8.1 are purposefully kept at a high level to afford a degree of flexibility and judgement during the assessment. Details on the rationale behind the allocation of a category e.g., 'Low' is provided in the narrative in the impact assessment chapters. Each descriptor may not be applicable to each receptor and some receptors may be classified within two different

categories. For example, a receptor may have an IUCN status of 'Least Concern' ('Very Low') but may also comprise 1 % of the global population ('Very High') such as the Southern Giant Petrel. In such a case, the worst-case category ('Very High') is applied.

8.5.2.1.1 Sensitivity of global (transboundary) receptors

While most receptors have a sensitivity value based on local conditions, it is acknowledged that emissions have a global impact on climate change which is measured over time (i.e., current day compared to pre-industrial times) rather than by global location. Consequently, the assessment of sensitivity of the atmosphere, or global climate, as a receptor is not included within the sensitivity guidelines in Table 8.1, but is assessed based on the latest IPCC Climate Change 2014 Synthesis Report, Summary for Policy Makers Report.

Within this impact assessment the current sensitivity status of the global receptor, climate, is considered to be 'Very High', based on the following statements from IPCC (2014):

- Human influence on the climate system is clear, and recent anthropogenic emissions of greenhouse gases are the highest in history. Recent climate changes have had widespread impacts on human and natural systems,
- Warming of the climate system is unequivocal, and since the 1950s, many of the observed changes are unprecedented over decades to millennia. The atmosphere and ocean have warmed; the amounts of snow and ice have diminished, and sea level has risen,
- Effects of anthropogenic greenhouse gas emissions have been detected throughout the climate system and are extremely likely to have been the dominant cause of the observed warming since the mid-20th century,
- In recent decades, changes in climate have caused impacts on natural and human systems on all continents and across the oceans. Impacts are due to observed climate change, irrespective of its cause, indicating the sensitivity of natural and human systems to changing climate,
- Continued emission of greenhouse gases will cause further warming and long-lasting changes in all components of the climate system, increasing the likelihood of severe, pervasive and irreversible impacts for people and ecosystems. Limiting climate change would require substantial and sustained reductions in greenhouse gas emissions, which together with adaptation, can limit climate change risks, and
- Many aspects of climate change and associated impacts will continue for centuries, even if anthropogenic emissions of greenhouse gases are stopped. The risks of abrupt or irreversible changes increase as the magnitude of the warming increases.

Table 8.1: Project-specific guidelines for the sensitivity of environmental receptors ***(as adapted from the Navitas OMS (SEL-REG-OPM-PLN-00001-00))***

Level	Category	Environmental receptor sensitivity guide description
5	**Very High**	**Flora and Fauna**[39]: • Population size, of any species present, is of international importance (1 % of global population) and is within the zone of influence of project activity, • Habitat / site is of international value and is protected under international designation (e.g., RAMSAR sites, IBAs during breeding season), • Habitat / site is undesignated but considered to be of international importance (e.g., an IBA that is not formally protected), • A species with IUCN 'Critically Endangered' status has notable presence[40] within the zone of influence of project activity, • Large populations of animals considered under wider threat (e.g., ACAP species) are present within the zone of influence of project activity, and / or • Presence of individuals or species in vulnerable phases of life cycle (e.g., high concentration of synchronous spawning fish) within the zone of influence of project activity. **Seabed (including soil)**[41]**:** Seabed sediment unmodified (e.g., no known demersal fishery). High-grade soil quality, high likelihood of transmitting contaminants to nearby sensitive receptors. **Water quality:** Enclosed water body with no flushing. **Air quality**[42]**:** Very densely populated area within 20 m, very sensitive receptors (e.g., school, hospital), sheltered from winds. **Landscape and seascape:** Location is currently undeveloped, is considered locally an area of beauty, and is 'used or appreciated' by businesses, residents and / or visitors for business promotion and / or recreation e.g., Kidney Island. Includes distinctive, individual or rare features. Placement of objects would conflict with the current use of the area. **Human population:** The receptor has little or no capacity to absorb change without fundamentally altering its present character, or is unacceptable to all stakeholders. **Tangible property:** Resource use has direct or indirect environmental or social impact (e.g., use of diesel, freshwater, landfill space) and resource being used is unsustainable in the short-term (e.g., within five years of commencement of the project). **Architecture and archaeological heritage:** International heritage importance whether designated or not, extremely well preserved.

[39] Adapted from IEEM, 2018.

[40] Notable presence does not refer to a particular number but indicates more than presence of an individual (*i.e.,* greater presence than a rarely occurring 'edge of range' or vagrant species).

[41] Adapted from: https://naturalresources.wales/media/685627/130-soils-and-contamination_190418.pdf.

Level	Category	Environmental receptor sensitivity guide description
4	High	**Flora and Fauna:** • Population size, of any species present, is of regional importance (1 % of biogeographic population) and is within the zone of influence of project activity, • Habitat / site is of national value and is protected under national designation (e.g., fishery closed areas or spawning sites, Falkland red-list habitats), • Habitat / site is undesignated but considered to be of regional importance (as informed by the consultation process), • A species with IUCN 'Endangered' or 'Vulnerable' status has notable presence within the zone of influence of project activity, • Local conservation priority species are present within the zone of influence of project activity (Falklands red-list species), and / or • Presence of individuals or species in vulnerable phases of life cycle (e.g., high concentration of asynchronous spawning fish) within the zone of influence of project activity. **Seabed (including soil):** Seabed sediment experienced previous modification event (e.g., longline fishing effort). Moderate grade soil quality, moderate potential to transmit contaminants to nearby sensitive receptors. **Water quality:** Semi-enclosed water body with limited flushing. **Air quality:** Densely populated area within 20 m exposed to strong winds, moderately populated area within 20 m sheltered from winds. **Landscape and seascape:** Location is partially developed with non-industrial infrastructure e.g., residential settlements or agricultural buildings in camp and may therefore be used for recreational purposes. Distinct landscape character. Placement of objects could conflict with the current use of the area. **Human population:** The receptor has low capacity to absorb change without fundamentally altering its present character, or, unacceptable to the majority of stakeholders. **Tangible property:** Resource use has direct or indirect environmental or social impact (e.g., use of diesel, freshwater, landfill space) and resource being used is unsustainable in the medium term (e.g., between 5 and 30 years of commencement of the project). **Architecture and archaeological heritage:** Regional heritage importance and / or well preserved.

Level	Category	Environmental receptor sensitivity guide description
3	Moderate	**Flora and Fauna:** • Population size, of any species present, is of national importance (1 % of Falkland Islands population) and is within the zone of influence of project activity, • Habitat / site is undesignated but considered to be of national or local importance (as informed by the consultation process), • A species with IUCN 'Near Threatened' status has notable presence within the zone of influence of project activity, and/or • Presence of individuals or species in vulnerable phases of life cycle (e.g., moderate concentration of dispersed spawning fish) within the zone of influence of project activity. **Seabed (including soil):** Seabed sediment subject to infrequent modification (e.g., infrequent demersal trawling). Poor grade soil quality, low potential to transmit contaminants to nearby sensitive receptors. **Water quality:** Semi-enclosed water body with good flushing. **Air quality:** Moderately populated area within 20 m, suburban or edge of town, commercially sensitive land within 20 m, exposed to strong winds. **Landscape and seascape:** Location is used commercially and is developed by local businesses and residential buildings. Some distinct landscape features. Placement of objects would be unlikely to conflict with the current use of the area. **Human population:** The receptor has moderate capacity to absorb change without significantly altering its present character, or, unacceptable to minority of stakeholders. **Tangible property:** Resource use has direct or indirect environmental or social impact (use of diesel, freshwater, landfill space) and resource being used is limited and unsustainable in the medium term (e.g., more than 30 years of commencement of the project). **Architecture and archaeological heritage:** Local heritage importance and / or averagely well preserved.
2	Low	**Flora and Fauna:** • Low numbers of any species of geographical importance present within the zone of influence, • Habitat / site is undesignated and of poor quality, • A species with IUCN 'Least Concern' status has notable presence within the zone of influence of project activity, and/or • Presence of individuals or species out with vulnerable phases of life cycle (e.g., dispersed spawning fish) within the zone of influence of project activity. • Seabed (including soil): Seabed sediment subject to frequent modification (e.g., annual demersal trawling). Very poor grade soil quality, no potential to transmit contaminants to nearby sensitive receptors. **Water quality:** Coastal water body in shallow water. **Air quality:** Sparsely populated area within 20 m exposed to strong winds **Landscape and seascape:** Location is considered an 'industrial hub' and is developed e.g., an industrial estate, a quarry. No distinct landscape features. Area designated for industrial use. **Human population:** The receptor is tolerant of change without detriment to its character, or, unacceptable to a handful of stakeholders. **Tangible property:** Resource use has direct or indirect environmental or social impact (e.g., use of diesel, freshwater, landfill space) but resource being used is not unsustainable. **Architecture and archaeological heritage:** Local heritage interest, site integrity already compromised and value limited by poor preservation.

Level	Category	Environmental receptor sensitivity guide description
1	Very Low	**Flora and Fauna:** • Negligible numbers of any species of geographical importance present within the zone of influence, • Habitat / site is undesignated, of poor quality and / or already degraded, • Species of IUCN 'Least Concern' status notable presence within the zone of influence of project activity, and/or • Presence of individuals or species out with vulnerable phases of life cycle (e.g., highly dispersed asynchronous spawning fish) within the zone of influence of project activity. **Seabed (including soil):** Very poor grade soil quality, no potential to transmit contaminants to nearby sensitive receptors. Seabed sediment highly modified (e.g., multiple demersal trawls per year). **Water quality:** Open ocean conditions. **Air quality:** Unpopulated area exposed to strong winds. **Landscape and seascape:** Location is severely degraded e.g., a waste dump. **Human population:** The receptor is not resistant to change, or, issue is acceptable to all stakeholders. **Tangible property:** Resource use has no direct or indirect environmental or social impact and / or resource being used is unlimited or is created by the Development. **Architecture and archaeological heritage:** No heritage value.

8.5.2.2 Assessment of severity of effect

Assessment of the 'severity of the effect' on the receptor draws on the data in the Development Description and the base-case mitigations (Chapter 5), information gathered in subject-specific literature reviews on the nature of the impact, quantification of the project outputs (where possible) and modelling (where it has been carried out). Taking account of these, the assessment of the severity of effect considers:

- Whether the effect is positive or negative,
- The spatial extent of the effect e.g., the footprint area, or zone of influence, over which the impact occurs,
- The magnitude of the effect e.g., the size or amount of an effect such as the number of seabirds that may be affected,
- The duration of the effect e.g., duration over which the impact is expected to last prior to recovery,
- The timing and frequency of the activity e.g., when the activity will occur and how many times it may be repeated,
- The reversibility of the effect e.g., whether or not recovery from the impact is possible or whether the effect is irreversible and thus permanent, and
- Exposure of the receptor to the effect.

Project-specific guidelines intended to inform the assessment of the severity of the effect on the receptor were adapted from IEEM (2010) and Morris and Therivel (2009) and are presented in Table 8.2.

Table 8.2: Project-specific guidelines for the severity of effect ***(as adapted from the Navitas OMS (SEL-REG-OPM-PLN-00001-00))***

Level	Severity	Environmental severity of effect guide description
5	**Major**	**Flora, Fauna, soil, water quality:** Major effect over large (regional) area. Potential for long-term damage to species / regional population / habitat / ecosystem (recovery period is receptor specific[43]). **Air quality:** Emissions exceed Air Quality Objectives (AQO)[44] by >5 % in locations where receptors are exposed. **Atmospheric emissions (Climatic factors):** Extensive contribution to global emissions, (e.g., when compared to UK annual emissions and current annual Falkland Islands emissions) which will impact upon UK ability to meet current emissions targets and / or future targets. **Landscape and seascape:** Object will be permanently located *in situ* for full Field Life (30 years), is prominent and will be visible from many perspectives, at all times to residents and visitors, potentially imposing upon 'iconic' views. **Human population:** Irreversible effect on livelihood and / or health e.g., permanent damage to fishing grounds, inconvenience of resource use, or very high levels of disturbance to local population, is considered to be a concern to all stakeholders **Tangible property:** Extensive and frequent use of a finite resource throughout lifecycle of project. **Architecture and archaeological heritage:** Major impact on integrity of internationally significant heritage, intrusive, impair appreciation and seriously damage the setting.
4	**Serious**	**Flora, Fauna, soil, water quality:** Serious effect over large but sub-regional area. Serious and long lasting (multi-year) but eventually reversible (recovery period is receptor specific) impact on species / habitat / ecosystem. **Air quality:** Emissions exceed AQO by up to 5 % in locations where receptors are exposed. **Atmospheric emissions (Climatic factors):** Large contribution to global emissions (e.g., when compared to UK annual emissions and current annual Falkland Islands emissions) which could impact upon UK ability to meet current emissions targets and / or future targets. **Landscape and seascape:** Object will be *in situ* for full Field Life (30 years), is quite prominent and will be visible from limited perspectives to residents and visitors e.g., the supply base which blends into the existing context. **Human population:** Long-term effect on livelihood and / or health e.g., seasonal closure of fishing grounds adjacent to the proposed project, inconvenience of resource use, high levels of disturbance to local population, is considered to be a concern to the majority of stakeholders. **Tangible property:** Extensive but infrequent use of a finite resource throughout lifecycle of project. **Architecture and archaeological heritage:** Damaging to regionally or nationally significant heritage assets, adversely affect the setting and appreciation of the assets.
3	**Moderate**	**Flora, Fauna, soil, water quality:** Moderate effect in local area. Temporary and reversible impact on species / habitat / ecosystem (recovery period is receptor specific).

[43] Recovery periods form part of the impact assessment and are discussed, as necessary, in the assessment chapters
[44] As defined by the World Health Organisation, the European Union or the UK as appropriate.

Level	Severity	Environmental severity of effect guide description
		Air quality: Emissions exceed the UK Environment Agency (EA) 'significance' threshold[45] over long- or short-term duration AQO where receptors may be exposed, but do not exceed the actual AQO. **Atmospheric emissions (Climatic factors):** Moderate contribution to global emissions (e.g., when compared to UK annual emissions and current annual Falkland Islands emissions) which will not impact upon UK ability to meet current emissions targets but may in the future as targets are reduced. **Landscape and seascape:** Object will be *in situ* periodically for full Field Life (30 years), will be prominent only when in place and will be visible from limited perspectives to residents and visitors e.g., vessels using port facilities. **Human population:** Medium-term impact on livelihood and / or health e.g., localised temporary closure of fishing grounds, inconvenience of resource use, moderate levels of disturbance to local population, is considered to be a concern to a minority of stakeholders. **Tangible property:** Moderate use of a finite resource throughout lifecycle of project. **Architecture and archaeological heritage:** Compromise the integrity of locally important heritage, be intrusive to the setting and appreciation of the assets.
2	**Minor**	**Flora, Fauna, soil, water quality:** Minor, localised short-term, fully reversible environmental effect once activity ceases. Barely detectable impact on species / habitat / ecosystem. Highly localised. **Air quality:** Emissions exceed the UK Environment Agency (EA) 'screen out' threshold[41] over long- or short-term duration AQO where receptors may be exposed, but do not exceed the 'significance threshold'. **Atmospheric emissions (Climatic factors):** Low contribution to global emissions (e.g., when compared to UK annual emissions and current annual Falkland Islands emissions) but which will not impact upon UK ability to meet current emissions targets and are unlikely to impact upon future targets. **Landscape and seascape:** Object will be in place temporarily and may impact upon the view from close range e.g., unplanned losses of non-biodegradable waste such as plastics. **Human population:** Short term / minor impact on livelihood and / or health, inconvenience of resource use, minor levels of disturbance to local population, is considered to be a concern to a handful of stakeholders **Tangible property:** Minimal use of a finite resource throughout lifecycle of project or moderate use for finite stages of the project. **Architecture and archaeological heritage:** Minor detrimental impact on the context of locally important historic environment.
1	**Slight**	**Flora, Fauna, soil, water quality:** Negligible environmental effect, change not detectable above background variability, rapidly and fully reversible once activity ceases (short-term impact); highly localised effects. No habitat / population effects. **Air quality:** Emissions do not exceed the UK EA 'screen out' threshold[41] over long- or short-term duration AQO at locations where receptors may be exposed. **Atmospheric emissions (Climatic factors):** Negligible contribution to global emissions (e.g., when compared to UK annual emissions and current annual Falkland Islands emissions) with no impact upon UK ability to meet emissions targets in future. **Landscape and seascape:** Object will be in place temporarily and may impact upon the view from close range e.g., unplanned losses of biodegradable waste.

[45] https://www.gov.uk/guidance/air-emissions-risk-assessment-for-your-environmental-permit.

Level	Severity	Environmental severity of effect guide description
		Human population: No impact on livelihood or health, negligible levels of disturbance to local population, or there is considered to be no concern to stakeholders **Tangible property:** No or negligible use of a finite resource for a finite period or throughout the lifecycle of project. **Architecture and archaeological heritage:** Negligible impact on the integrity or setting of the historic environment.

8.5.3 Assessment of impact significance

The significance of an environmental impact is assessed as:

Significance of the **impact** = The **sensitivity** of the receptor to the environmental aspect x The **severity** of the effect on the receptor

The significance of the impact in both the initial and residual assessments, was determined using the impact assessment matrix in Table 8.3, which indicates whether an impact is 'Very Low', 'Low', 'Moderate', 'High' or 'Very High'.

Once the significance has been determined, it is then possible to define whether or not an impact is considered acceptable or otherwise (Table 8.4).

While the significance of an impact is ultimately defined by its category (i.e., 'Very Low', 'Low', 'Moderate', 'Upper Moderate' or 'High'), each category within Table 8.3 is accompanied by an associated score. Note that this score is not on a linear scale and it is not the case that a 'Very High (25)' impact is five times 'worse' than a 'Low (5)' impact. The score simply provides a means of differentiation within the categories in order to inform assessment of what type of mitigation might be most appropriate. For example, where an impact is 'Moderate (5)', a mitigation measure which reduces the severity of effect may be most appropriate. Further, while the mitigation measure may only reduce the severity of effect to such a degree that the overall significance of the impact remains Moderate e.g., from 'Moderate (5)' to 'Moderate (4), the score indicates that improvement has still been achieved (Table 8.3). Definitions and implications of each of the impact significance categories are provided in Table 8.4.

Table 8.3: Environmental impact significance of effect matrix[1]

Impact			Severity of Effect				
			1 Slight	2 Minor	3 Moderate	4 Serious	5 Major
Sensitivity of Receptor	Very high	5	5	10	15	20	25
	High	4	4	8	12	16	20
	Moderate	3	3	6	9	12	15
	Low	2	2	4	6	8	10
	Very low	1	1	2	3	4	5

[1] Dark Green = Very Low, Yellow = Low, Orange = Moderate, Dark Orange = Upper Moderate, Red = High

Table 8.4: Definition and implication of impact significance categories

Impact Significance Level		Impact Significance Definition (planned events)[1]
Unacceptable	High	Action required to eliminate impact *via* project design or to reduce it to an acceptable level *via* additional mitigation measures and controls which aim to minimise consequence where feasible, effective and reasonably practicable. If impact cannot be reduced, the project cannot proceed.
ALARP Region (Impact Tolerable if demonstrably ALARP)	Upper Moderate	Impacts assessed as "Upper moderate" may not be tolerable. Action is required to eliminate or reduce impact *via* project design and / or additional mitigation measures and controls which aim to minimise consequence where feasible, effective and reasonably practicable. Impacts remaining within this category are considered to be within the upper reaches of tolerability and are placed here owing to the combination of a precautionary approach based upon data gaps and / or a lack of further reasonable mitigation options. Where the impact is ALARP[2] and remains within this category, regular reviews (at a minimum of annually) will be held to determine whether the impact can be further reduced based upon the availability of new data and / or new technology. If the impact cannot be further reduced, consideration may also be given to offsetting of the impact (see Section 8.11).
	Moderate	Impacts assessed as "Moderate" require action to identify opportunities for improvement *via* project design, additional mitigation measures and controls which aim to minimise consequence where feasible, effective and reasonably practicable. Where the impact is ALARP and remains within this category, it will be subject to regular ALARP reviews[2] as described above.
	Low	Impacts assessed as low are within the levels of existing natural environmental variability. No project-specific mitigations will be implemented over and above industry-standard measures and controls unless it is stated as a requirement in conditions to EIS approval or Falkland Islands Legislation and / or approved policy. Nonetheless, impacts shall be regularly reviewed to ensure that suitable controls remain in place and shall be subject to continuous improvement where opportunities exist.
Broadly Acceptable	Very Low	Impact barely detectable. No additional actions required beyond industry-standard measures and controls. Nonetheless, impacts shall be periodically reviewed to ensure that suitable controls remain in place and shall be subject to continuous improvement where opportunities exist.
	Beneficial	Has a positive effect.

[1] **Note:** Assessment of the Impact Significance is based on the EIA undertaken to date and detailed in this EIS. Initial views of key stakeholders were sought during the scoping consultation process (Chapter 6). Thereafter, the EIS was updated wherever applicable in response to comments / information received from the previous public consultation. Comments received through the formal communication and consultation process are detailed in Chapter 0.

[2] ALARP Procedure (SLN-HSE-RMA-PCD-00001-00).

8.6 Risk assessment methodology for unplanned and accidental events

This section describes the methodology used for the assessment of environmental risk of unplanned and accidental events.

8.6.1 Environmental risk assessment process

The evaluation of risks follows a similarly structured methodology through systematic:

- Identification of potential unplanned or accidental events that carry the risk of environmental impact,

- Assessment of the significance of the impact (Section 8.5.3) based on the sensitivity of the receptor and the severity of the effect should the unplanned event occur,
- Assessment of the likelihood of the unplanned or accidental event occurring (Section 8.6.2.2) taking account of statutory industry-standard safeguards and BAT / BEP mitigations built-in to the project basis of design (Section 8.7),
- Assessment of the initial significance of the risk (Section 8.6.3) of accidental or unplanned events based on the significance of the impact and the likelihood of the unplanned or accidental event occurring,
- Identification of any project-specific mitigation measures (Section 8.7) as required to reduce 'significant' risks to ALARP by preventing or reducing the likelihood of the event occurring and / or by minimising the consequence should it occur,
- Evaluation of the residual risk significance (Section 8.8) taking account of project-specific mitigation,
- Assessment of the degree of confidence (Section 8.10) in the risk assessment, and
- Explores the potential for offsetting impacts of significant risks where possible (Section 8.11).

8.6.2 Assessment of environmental risks

Risks are evaluated in two steps:

- By assessing the level of environmental impact that could result from the unplanned / accidental event occurring (Section 8.5.2), and
- By assessing the likelihood that the unplanned or accidental event will occur (Table 8.5).

8.6.2.1 Assessment of the potential environmental impact

The significance of an environmental impact that could result from an unplanned / accidental event follows the same methodology as for all impact assessments, see Section 8.5.2 above. The sensitivity of receptor definitions are as outlined in Table 8.1 above, and the severity of effect for unplanned or accidental events are as defined in Table 8.2 above.

8.6.2.2 Assessment of the likelihood of an unplanned or accidental event occurring

The likelihood of the unplanned or accidental event considered two factors as appropriate on a case-by-case basis. These are:

- Whether the unplanned or accidental event has occurred within the industry before and the frequency of occurrence if it has, and / or
- The number of control barriers that might need to be breached for the unplanned or accidental event to occur.

Project-specific guidelines were developed to inform the assessment of the likelihood of occurrence of an unplanned event during the Sea Lion Northern Development Area Phase 1 & 2 Development (Table 8.5). The guidelines have purposefully been kept at a high level to afford a degree of flexibility and details on the rationale behind each assessment are provided in the narrative within the relevant chapters. Where possible, historical frequency of occurrence data will be used to inform the assessment of likelihood and will be described within the respective risk assessment chapters. As with the impact assessment process, a precautionary approach is taken when selecting the likelihood category.

Table 8.5: Project-specific guidelines for assessing the likelihood of an unplanned / accidental event occurring ***(as adapted from the Navitas OMS (SEL-REG-OPM-PLN-00001-00))***

Level	Likelihood	Definition
5	**Very Likely**	Likely to occur more than once per operation e.g., every well or every shutdown, can occur following breach of a minimal number of controls.
4	**Likely**	Likely to occur more than once per applicable time unit, can occur following breach of a minimal number of controls.
3	**Possible**	Likely to occur less than once per applicable time unit and more than once in 10 applicable time units, breach of operational controls would be required e.g., procedural controls.
2	**Unlikely**	Has occurred previously in the industry, however, failure of numerous operational controls would be required e.g., procedural and engineering controls.
1	**Very Unlikely**	Impact almost never observed, few if any events in the industry, failure of nearly all operational controls would be required.

8.6.3 Assessment of risk significance

The significance of the risk is assessed as:

Significance of the **risk**	=	(----------Impact----------) The **sensitivity** of the receptor to the environmental aspect	x	The **severity** of the effect on the receptor	x	The **likelihood** that an unplanned or accidental event will occur

The significance of the risk in both the initial and residual assessments, was determined using the risk assessment matrix in Table 8.6, which indicates whether the significance of the risk is 'Very Low', 'Low', 'Moderate', 'Upper Moderate' or 'High'.

The overall significance of a particular risk is determined according to the highest level of risk associated with the project activity against any one of the receptors. For example, in the event that an oil spill was to occur, the risk might be higher to seabirds than to benthic organisms and is therefore ranked according to the highest assessment (i.e., seabirds).

While the significance of a risk is ultimately defined by this category, each category within Table 8.6 is accompanied by an associated score. As with the assessment of impact significance, (Section 8.5.3) this score provides a means of differentiation within the categories in order to inform assessment of what type of mitigation might be most appropriate. Definitions and implications of each of the risk significance categories are provided in Table 8.7.

Table 8.6: Environmental Risk Assessment matrix[1]

Risk			Likelihood				
			1 Very Unlikely	2 Unlikely	3 Possible	4 Likely	5 Very Likely
Impact	High	5	5	10	15	20	25
	Upper Moderate	4	4	8	12	16	20
	Moderate	3	3	6	9	12	15
	Low	2	2	4	6	8	10
	Very Low	1	1	2	3	4	5

[1] Dark Green = Very Low, Yellow = Low, Orange = Moderate, Dark Orange = Upper Moderate, Red = High

Table 8.7: Definition and implication of risk significance categories

Risk Significance Level		Risk Significance Definition (planned events)
Unacceptable	High	Action required to eliminate risk *via* project design or to reduce it to an acceptable level *via* additional mitigation measures and controls which aim to minimise consequence where feasible, effective and reasonably practicable. If risk cannot be reduced, the project cannot proceed.
ALARP Region (Risk Tolerable if demonstrably ALARP)	Upper Moderate	Risks assessed as "Upper moderate" may not be tolerable. Action is required to eliminate or reduce risk *via* project design and / or additional mitigation measures and controls which aim to minimise consequence and likelihood where feasible, effective and reasonably practicable. Risks remaining within this category are considered to be within the upper reaches of tolerability and are placed here owing to the combination of a precautionary approach based upon data gaps and / or a lack of further reasonable mitigation options. Where the risk is ALARP[2] and remains within this category, regular reviews (at a minimum of annually) will be held to determine whether the risk can be further reduced based upon the availability of new data and / or new technology. If the risk cannot be further reduced, consideration may also be given to offsetting of the risk (see Section 8.11).
	Moderate	Risks assessed as "Moderate" require action to identify opportunities for improvement *via* project design, additional mitigation measures and controls which aim to minimise consequence and likelihood where feasible, effective and reasonably practicable. Where the risk is ALARP and remains within this category, it will be subject to regular ALARP reviews[2] as described above.
	Low	Risks assessed as low are within the levels of existing natural environmental variability. No project-specific mitigations will be implemented over and above industry-standard measures and controls unless it is stated as a requirement in conditions to EIS approval or Falkland Islands Legislation and / or approved policy. Nonetheless, risks shall be regularly reviewed to ensure that suitable controls remain in place and shall be subject to continuous improvement where opportunities exist.
Broadly Acceptable	Very Low	Risk barely detectable. No additional actions required beyond industry-standard measures and controls. Nonetheless, risks shall be periodically reviewed to ensure that suitable controls remain in place and shall be subject to continuous improvement where opportunities exist.

Note: Assessment of the Risk Significance is detailed in this EIS. Initial views of key stakeholders were sought during the scoping consultation process (Chapter 6) and thereafter, the EIS was updated wherever applicable in response to comments / information received from the previous public consultation. Comments received through the formal communication and consultation process are detailed in Chapter 0.
[2] ALARP Procedure (SLN-HSE-RMA-PCD-00001-00).

8.7 Impact and risk mitigation

Mitigation measures aim to avoid, reduce or remedy the predicted significant adverse impacts of an activity (Morris and Therivel, 2009; Glasson, *et al.,* 2013). These different mitigation outcomes are known as the mitigation hierarchy (Glasson, *et al.,* 2013), which focuses on the principal of 'prevention rather than cure'.

Consequently, for planned events, options to avoid and reduce impacts should be considered and implemented before those to remedy the impact. Similarly, for unplanned events, measures to minimise the 'likelihood of occurrence' should be considered first, followed by those to minimise the consequences should the event occur. Further, it is important that mitigation measures are designed with monitoring in mind to ensure that the efficacy of the measures can ultimately be evaluated (Section 8.10.1).

Mitigation measures used in the Sea Lion Northern Development Area Phase 1 & 2 fall into three categories:

- **'Base-case' mitigations** - which refer to the use of BAT / BEP within the project basis of design. These are described in the Development Description (Chapter 5) and are intended to reduce outputs (e.g., emissions) and / or to minimise the likelihood of unplanned events occurring (e.g., the use of inshore exclusion zones, vessel speed restrictions etc.) and thus aim to eliminate (avoid) or reduce impacts. These are factored into the initial impact / risk assessment,
- **Industry-standard mitigations** - which include measures which are not defined by law but are accepted as best practise observed within the O&G industry (and are, therefore, often built-in to the basis of design). These are factored into the initial impact / risk assessment along with legislative requirements, and
- **Project-specific mitigations** - which are additional measures intended to further reduce or remediate significant impacts and / or risks. The need for these is specifically informed by the EIA process when the initial impact assessment indicates that an impact or risk remains significant despite the base-case and industry-standard mitigations.

Ultimately, the aim of all mitigation is to reduce the overall impact or risk associated with an activity to a level that is 'As Low As is Reasonably Practicable' (ALARP), irrespective of whether this is achieved by prevention, reduction and / or remediation (see ALARP Procedure, SLN-HSE-RMA-PCD-00001-00). Very importantly however, 'ALARP' is not synonymous with 'Low' and the concept takes into account the balance between the costs and benefits of a mitigation measure. Here it is recognised that while it may be possible to reduce an impact or risk further, the process of doing so may require excessive time and resource such that it is not considered 'reasonably practicable' in light of the benefits that can be gained.

For the Sea Lion Northern Development Area Phase 1 & 2, and given the concept of ALARP, impacts and risks that were considered to be 'Low' (or below) in the initial assessment were not prioritised with regard to project-specific mitigation as extensive additional measures were not considered 'reasonably practicable'. This said, where project-specific mitigations were immediately available and reasonably practicable, these may be applied even for 'Low' impacts and risks.

However, where impacts were of 'Moderate' significance or above in the initial assessment, it was considered necessary by Navitas to identify and consider project-specific mitigation measures to further drive the impact / risk to a level that is ALARP (SLN-HSE-RMA-PCD-00001-00).

8.8 Residual assessments

The term 'residual impact / risk' refers to the impact / risk that remains once project-specific mitigation measures have been taken into account. As described above, residual assessments were only required for those impacts and risks that were considered to be significant i.e., 'Moderate' or higher significance during the initial assessment.

The residual assessments of impact and risk follow the same process as described above, using the same definitions of sensitivity, severity of effect, likelihood and impact significance but with awareness of the additional mitigation measures which may reduce the severity of effect and / or the likelihood of an unplanned or accidental event occurring.

8.9 Cumulative impact assessment and impact interactions

8.9.1 Cumulative impact

The EIA process initially assesses the impacts / risks to environmental receptors from the proposed operation alone. However, the activities associated with the proposed operations are unlikely to occur in isolation and it is thus important to consider the cumulative impacts also. Cumulative impacts may arise from similar activities being carried out by Navitas, another O&G operator or by another sector at the same time, or in the same space as the proposed development.

Specifically, spatio-temporal cumulative impacts include:

1) Impacts (such as noise, CO_2 emissions, drilling mud) occurring from more than one source and overlapping in space and time. This may result in an increase in the concentrations / level to which the same environmental receptors are exposed (Figure 8-2 below),
2) Impacts (such as noise, CO_2 emissions, drilling mud) occurring from more than one source and occupying adjacent 'spaces' at the same time, or approximately the same time. This may increase the number of organisms directly exposed and thus the extent and proportion of the local or regional population that is exposed (Figure 8-2 below), and / or
3) Impacts (such as noise, CO_2 emissions, drilling mud) from more than one source occupying the same 'space' consecutively or soon after each other. This may increase the duration of exposure for the same receptors and/or the proportion of the local or regional population (Figure 8-2 below).

Importantly, it is not possible to know what activities may be carried out in the future, or to quantify what their impacts / emissions / discharges may be, and therefore it is not possible to assess the cumulative impacts of the proposed Navitas development in combination with future and currently unplanned developments. Therefore, cumulative assessments within this EIA include only those operations that immediately precede the proposed operation and / or will occur simultaneously. Any cumulative impacts of this operation in conjunction with future operations will be assessed in the EIA associated with the future development.

Note that cumulative outputs e.g., emissions, discharges etc. will be quantified where possible. However, most commonly it will not be possible to estimate outputs from other activities and here the cumulative assessment will be in the form of a qualitative narrative.

8.9.2 Impact interaction

Impact interactions include:

1) Different sources of impacts which have known additive or synergistic effects to any of the above, leading to potentially greater negative effects on individuals or ecosystems than would occur if only one type of contaminant were present (Figure 8-2), and/or
2) Different sources of impacts which have known cancelling or ameliorating effects to any of the above, leading to potentially smaller negative effects on individuals or ecosystems than would occur if only one type of contaminant were present (Figure 8-2).

Chapter 13 will consider the impact interactions of the project as a whole. For example, the interaction of impacts of underwater noise on marine mammals in conjunction with the impacts of increased presence of vessels; or the fact that birds attracted to a vessel due to artificial light may be more likely to experience contamination in the event of a spill.

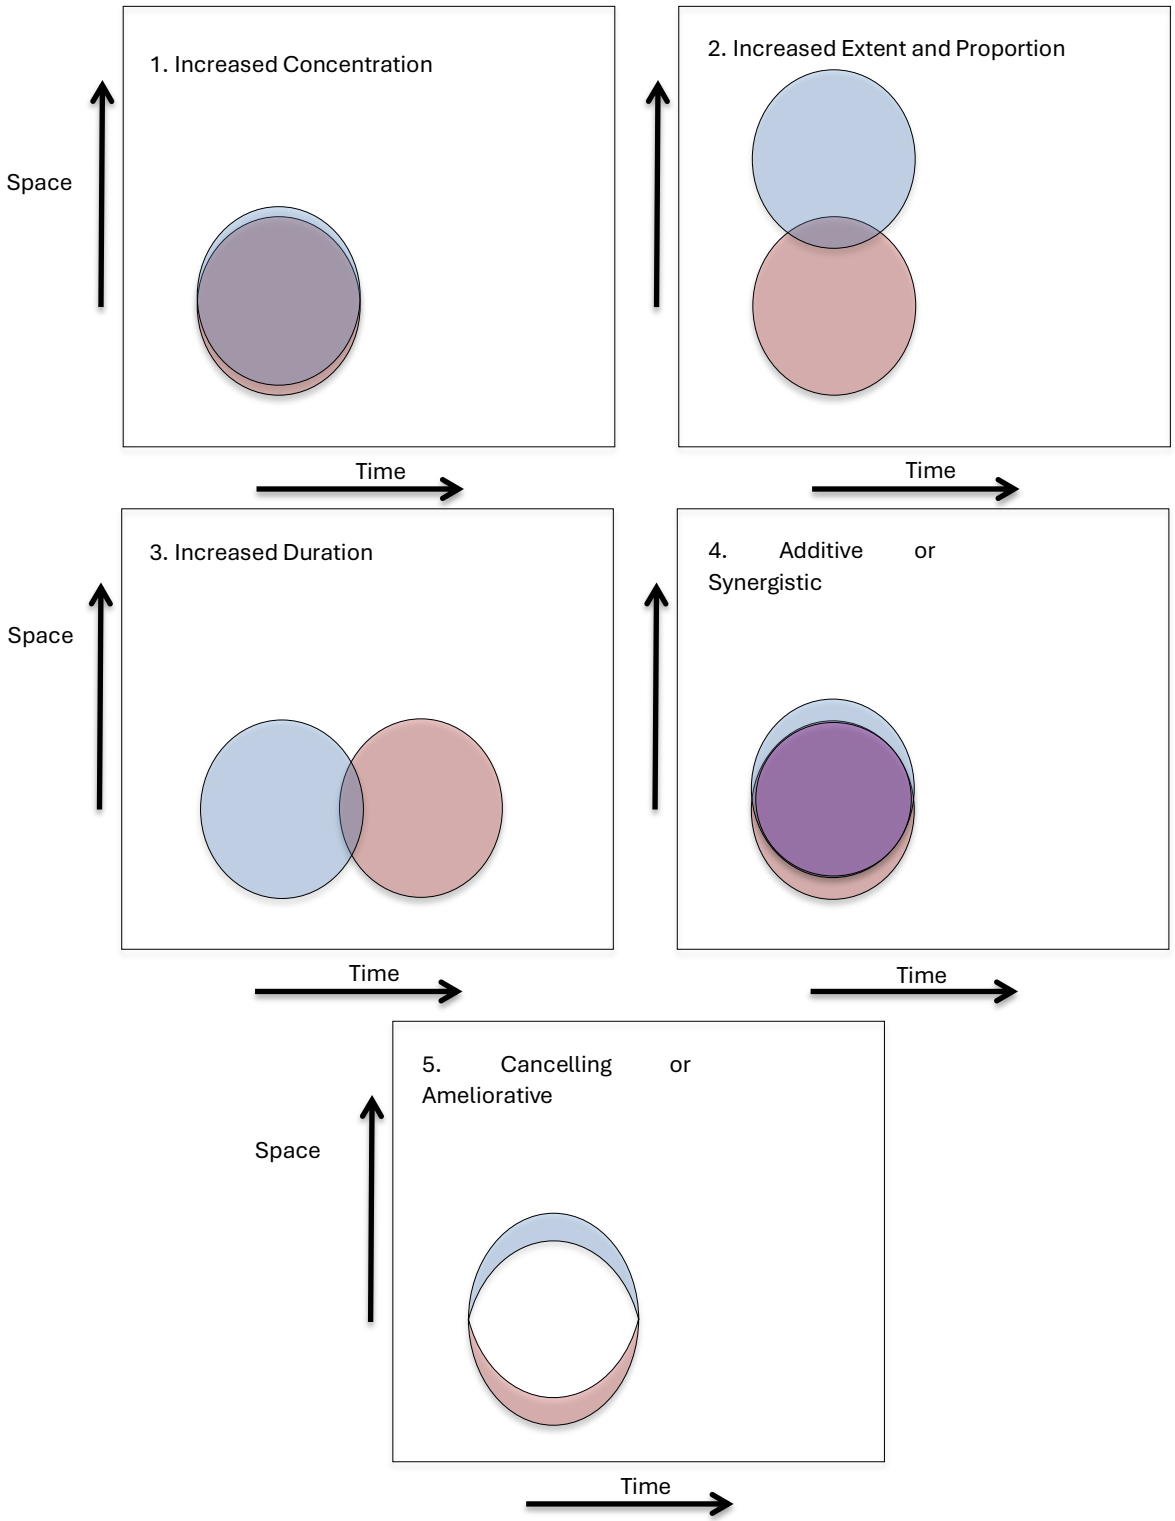

Figure 8-2: Illustrating cumulative impacts and impact interaction on an environmental receptor. Note: Red circle denotes impact from principal Navitas operation, blue circle denotes impact from any other source of impact

8.10 Confidence in the assessment

While a precautionary approach is taken during the impact and risk assessments such that the level of confidence in the data is reflected in the impact / risk significance, it is important to qualify, and indicate, the overall level of confidence in the assessment. The level of confidence in the outcomes of the impact / risk assessment depends upon the degree of uncertainty associated with the basis for the assessment, including:

- The clarity of definition and degree of certainty of project activities,
- The adequacy of available data, knowledge, and understanding about the environmental component / receptor being assessed,
- The number of data gaps,
- The known reliability of the proposed technology,
- The nature of the project-environment interaction, and
- The efficacy of proposed mitigation measures (IAIA, 2013).

Where moderate or greater levels of uncertainty exist, appropriate levels of monitoring may be determined to more fully characterise the impacts / potential risk as part of the on-going Environmental Monitoring and Management Plan (EMMP) (Chapter 15). Where monitoring indicates that the predictions made in the EIA were incorrect such the impact is greater than anticipated, remedial measures may be taken.

The level of confidence in the impact and risk predictions takes into account key characteristics of the impact (e.g., magnitude, extent, reversibility, duration, timing and frequency of effect), and the sensitivity of the receptor (IAIA, 2013). For the purposes of this EIA, the degree of confidence associated with the assessed impact, is evaluated using the qualitative scale: Certain, Probable, Uncertain (IEEM, 2010). Project-specific definitions for these categories have been developed and described in Table 8.8.

Table 8.8: Project-specific definition of the degree of confidence in the impact assessment

Degree of Confidence	Project-specific Definition
Certain	The project activities are clearly defined and are not subject to change. The nature of the impact is well understood from previous projects in terms of the magnitude, extent, reversibility, duration and frequency of the impact. The sensitivity of the receptor is well understood and documented.
Probable	The project activities have been defined although they may be subject to change as the project progresses, a precautionary approach has been taken. The nature of the impact on the environmental receptor is understood, although data gaps exist. The status and sensitivity of the receptor is largely understood, although some data gaps exist. The data gaps are not considered to have the potential to significantly change the outcome of the assessment.
Uncertain	The project activities are poorly defined and are subject to change as the project progresses. The nature of the impact on the environmental receptor is poorly understood and little monitoring data exists from previous projects. The status and sensitivity of the receptor is poorly understood and large data gaps exist.

8.10.1 Monitoring

Where confidence in the assessment is low due to uncertainties concerning the significance of impacts or the efficacy of proposed mitigation measures, monitoring activities should be identified to address these, including, where appropriate, further studies to fill data gaps.

Opportunities for monitoring are identified throughout the impact assessment process. Monitoring activities will be focused on the aspects that are considered to pose an impact of Moderate significance, or those activities that have been highlighted as a particular concern by stakeholders. Monitoring requirements will be recorded in the project-specific EMMP as per the outline provided in Chapter 15.

Monitoring should be carried out when the measuring and recording of tangible variables (e.g., emissions, sediment deposition, property) can:

- Provide feedback on the efficacy of mitigation measures,
- Facilitated improved assessment of the actual impacts resulting from the project activities,
- Enable comparison between the actual impacts and the predicted impacts,
- Provide additional information relating to the nature of the impact where data gaps existed during the EIA,
- Inform future EIAs,
- Provide an early warning system to identify harmful trends in the vicinity of the project activities before it is too late to take remedial action (Glasson, *et al.,* 2013), and
- Enable effective impact auditing.

8.11 Offsetting of impacts

8.11.1 Legislation and Policy

Section 64C of the Offshore Minerals Ordinance states that EISs must contain a description of measures proposed to:

'Eliminate or reduce significant adverse effects…remedy those effects and offset them.'

Appendix 2 to the FIG Hydrocarbons Environmental Impact Assessment Guidance Note (FIG, 2016e) provides offsetting guidance. ExCo paper 124/16 (FIG, 2016d) details FIG's recommendations for further developing offsetting guidance and suggested the establishment of an Environmental Fund.

ExCo paper 124/16 (FIG, 2016d) states that hydrocarbon development should seek meaningful offsetting of any impacts that cannot be avoided or mitigated, specifically in relation to greenhouse gas emissions and biodiversity (FIG, 2016d). The options for offsetting of these impacts include:

- Direct offsetting, i.e., the operator develops local projects to offset, like-for-like, the impacts arising from the Development that cannot be avoided or mitigated,
- Indirect offsetting, i.e., implementing measures that do not directly compensate for the impacts / risks identified, but may provide opportunities to achieve environmental benefits and improve the environment in the longer-term, or
- An environmental fund whereby the operator contributes to a fund with a governance panel to direct, manage and oversee various offsetting projects[46].

The Operator is required to demonstrate how offsetting measures have been considered which may further reduce significant adverse residual impacts identified in the EIS.

Navitas has ambitions for significant future local offsetting programmes, however these need to be informed by feasibility along with empirical data. Navitas will commit to a Carbon and Biodiversity offsetting Fund (see section 8.11.3) that will lay the foundations to inform scaling for island-wide

[46] Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to an environmental trust fund. Consequently, the foregoing dialogue in relation to a Navitas carbon and biodiversity offsetting fund has been superseded.

restoration to achieve carbon and biodiversity benefits. Therefore, the Environmental Carbon and Biodiversity offsetting Fund is a precursor to any offsetting initiative.

The section below details the offsetting options considered by Navitas and the reasons for the approach being proposed.

8.11.2 Review of offsetting options

Following elimination and / or reduction of all the impacts and risks identified for the Phase 1 & 2 Development, Navitas conclude that only tangible significant impacts / risks (i.e., those assessed as 'Moderate' or above), may be offset.

Navitas has reviewed its significant residual impacts / risks, and explored practicable, effective and locally beneficial direct offsetting measures in relation to these, see Section 8.11.2.1. Navitas has also reviewed indirect offsetting, as described in Section 8.11.2.2.

8.11.2.1 Direct offsetting

Direct or 'like-for-like' offsetting means compensating for impacts / risks to the environment at one site through activities that specifically address the nature of the impact in the local area. For example, this might include re-forestation of a nearby area where trees have been cleared for a construction site. For each residual impact / risk assessed as 'Moderate' or above, Navitas has looked for practicable, local, environmentally beneficial and effective opportunities to directly offset them, see Table 8.9 below. However, for each of the significant residual impacts / risks, Navitas has not at this time identified direct 'like-for-like' offsetting that is feasible, effective or reasonably practicable, see Table 8.9. The reasons for this are:

- It has not been possible to sufficiently quantify the impact / risk,
- Navitas has been able to conceive of a suitable project to achieve like-for-like offsetting, and / or
- Navitas has conceived of suitable projects but has not yet been able to determine feasibility, empirically define or formulate the details.

In addition, Navitas conclude it is not possible to offset accidental events where the impact may or may not happen, such as an oil spill. There is the risk of a spill occurring, but it is not possible to state if, when and what the impact of that spill might be, thus the impact is risk assessed in terms of the likelihood of it occurring. The impact itself is very difficult to quantify, and any efforts to remediate an impact that has arisen as the result of a risk, e.g., an oil spill, is considered 'remediation' as opposed to offsetting.

While potential offset initiatives have been identified in relation to atmospheric emissions, it has not been possible at this time for Navitas to determine the feasibility of these projects to confirm and quantify the benefit to the local environment, and that they are practicable for Navitas to implement. As such, while Navitas is committed to offsetting where practicable and to securing a positive environmental legacy, Navitas will not commence direct, like-for-like, offsetting for the residual significant impacts / risks from the Sea Lion Development until such time that identified initiatives have been further developed and proved through and it has been demonstrated that they are practicable and achievable within the Falkland Islands environment[47].

[47] Since the public consultation, Navitas has agreed with FIG that it will make payments to a fund which will support local offsetting projects.

Table 8.9: Significant environmental impacts / risks and direct offsetting[1] options considered

Impact / risk	Section in EIS	Residual impact / risk	Reason for level of impact / risk ranking and uncertainties	Direct Offsetting[1]
Risk of bird strikes due to artificial light	Section 10.1	Moderate	There are a number of uncertainties around the impact of bird strike. Bird strike monitoring carried out by the previous operator during the exploration campaign indicates this has not occurred during offshore operations in the area but occurred on two occasions inshore. There are many other, stronger, sources of light both in the Southern Ocean and inshore that complicate predictions of impact and measures of effectiveness of mitigation, and the assessment is therefore precautionary.	Offsetting is not practicable in this instance as the uncertainty of the impact makes it difficult to quantify and Navitas has not been able to conceive of a realistic and effective direct offset for this impact.
Impact on and behavioural disturbance to marine mammals from underwater noise offshore	Section 10.4	Moderate	Disturbance to marine mammals from continuous[2] noise is assessed as significant largely due to the sensitivity of the receptor.	Identifying a realistic and effective direct offsetting project for this impact has not been possible.
Impacts of drill cuttings discharge on benthos including burial of benthic fauna, modification of habitat, toxicity and oxygen depletion	Section 10.6	Moderate	Burial of benthic fauna is rated as significant in relation to the area of seabed damaged.	In this instance, Navitas could not identify a realistic and effective direct offset for this impact.
Impacts from atmospheric emissions	Section 10.9	Moderate	The impact of emissions directly associated the execution of the Development[3] has been rated as Moderate mainly due to the contribution to global warming and ocean acidification.	There are no emissions trading schemes in the Falklands. Navitas has identified potential carbon offsetting initiatives relating to renewable energy and habitat restoration/carbon sequestration but further research and analyses are required to determine their efficacy and the quantum of potential offset prior to such initiatives being taken forward.

Impact / risk	Section in EIS	Residual impact / risk	Reason for level of impact / risk ranking and uncertainties	Direct Offsetting[1]
Use of regulated landfill for waste disposal	Section 10.10	Moderate	Use of a finite resource: sensitivity of the receptor is considered 'High'	Identifying a realistic and effective direct offsetting project for this impact has not been possible and it has not been possible to accurately quantify the risk.
Risk of injury to marine mammals *via* collision in Berkeley Sound	Section 10.11	Moderate	Inshore operations involving the LTVs and subsea installation vessels are assessed as moderate severity on a precautionary basis given the uncertainty around potential cetacean collisions.	Identifying a realistic and effective direct offsetting project for this impact has not been possible and it has not been possible to accurately quantify the risk.
Risk of introducing marine non-native species from Navitas *ad hoc* freighter vessels	Section 10.12	Moderate	Offsetting is not practicable in this instance as the uncertainty of the impact makes it difficult to quantify.	Navitas has not been able to develop a realistic direct offset for this impact.
Risk of introducing marine non-native species from third-party vessels (i.e., vessels not directly managed by Navitas)		Upper Moderate		
Risk of introducing terrestrial non-native species by marine and air freight	Section 10.13	Upper Moderate		
Accidental releases of oil to sea offshore	Section 12.1	Moderate	Offshore spills, including well blow-out and FPSO inventory loss, are assessed as presenting a significant risk to receptors.	It has not been possible develop a practicable direct offset due to the uncertain impact, particularly as it may not occur during the life of field.
Accidental release of oil to sea inshore	Section 12.2	Moderate		
Accidental spills at-shore	Section 12.3	Moderate	There is a risk of small leaks / spills during day-to-day operations which may present a significant risk to receptors.	

[1] Where direct offsets cannot be identified, indirect offsetting will be undertaken (Section 8.11.2.2).
[2] Please note that no sources of impulsive noise are proposed for use within the Sea Lion Development.
[3] Please note that the emissions associated with combustion of the sold product are included within the emissions chapter (see Section 10.9). However, once sold at the FPSO, it is beyond the ability of Navitas to influence or track the final destination or end use of the product. Consequently no offsets are proposed in relation to emissions from sold product.

8.11.2.2 Indirect offsetting

Indirect offsetting refers to implementing measures that do not directly compensate for the impacts / risks identified above but may provide opportunities to achieve environmental benefits and improve the environment of the Falklands in the longer-term.

Navitas is also committed to exploring indirect offsetting opportunities onshore and offshore in the Falklands Islands. These may include, for example:

- Habitat restoration projects,
- Pest and invasive species eradiation / control and conservation,
- Biodiversity educational initiatives and the research required to inform them.

FIG's offsetting guidance requires proposed offsetting projects to be described in detail (including costs and timelines), to be realistic, practicable and effective, be as quantitative as possible, additional to current projects/schemes or funding sources, and to provide a level of redundancy. Navitas cannot make ad hoc commitments to indirect offsetting projects that are not fully understood, and at this stage it has not been practicable to develop potential indirect offsetting projects to the level of maturity required by the EIA guidance. Given this, as a first step Navitas is working in close collaboration with FIG to initially identify schemes, undertake research as necessary in order to develop local indirect offsetting initiatives for future funding support.

8.11.3 Carbon and Biodiversity Offsetting Fund

Navitas has committed to undertaking operator-led direct and indirect offsetting in the Falkland Islands including the establishment of a carbon and biodiversity offsetting fund which shall undertake Falklands-specific habitat restoration projects. To enable this, in agreement with FIG, Navitas will make contributions to a fund which shall be both proportionate in scale and meaningful in value and impact. Initially the fund will commission research and feasibility studies that lead to pilot offsetting schemes that can be expanded to enable large scale in-Falklands habitat restoration (Carbon sequestration) and biodiversity offsetting. Navitas will monitor opportunities to fund/undertake direct and indirect offsetting throughout Field Life. The Fund will regularly monitor its offsetting initiatives and reporting on its performance.

8.11.4 Conclusion

Navitas is committed to meaningful offsetting of any significant impacts that cannot be avoided or mitigated, specifically in relation to operational greenhouse gas emissions and impacts to the region's biodiversity. Once the Fund is established, which will occur following Final Investment Decision (FID), offsetting projects that benefit the Falkland Islands environment will be identified and prioritised over international schemes. As feasibility of various identified potential direct and indirect offsetting initiatives cannot be confirmed prior to further research, analysis and development, Navitas is not in a position to specify offsetting projects in the detail required by the FIG Offsetting Guidance at the time of issuing this EIS. Given this, Navitas will contribute to a Falklands-specific fund[48] which will initially address and inform the feasibility of large-scale carbon and biodiversity offsetting through commissioned research and investigation. Following this feasibility stage, Navitas will provide further funding to the viable projects identified in order to discharge its offsetting obligation, to work towards achieving carbon neutrality and no net loss to biodiversity and secure a positive environmental legacy. Performance of Navitas' offsetting projects will be monitored and reported on at regular intervals.

[48] Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.

9 ENVIRONMENTAL IMPACT AND RISK IDENTIFICATION AND SCREENING

Table of Contents

9.1 ENVIID workshop 582
9.1.1 ENVIID workshop attendees 582
9.1.2 ENVIID workshop process 583
9.1.2.1 Identification of environmental and social aspects 583
9.1.2.2 Identification of impacts from planned activities 584
9.1.2.3 Identification of risks of unplanned events or accidental activities 585
9.2 ENVIID outcomes - preliminary impact assessment and screening 586

9.1 ENVIID workshop

Having identified the activities associated with the Phase 1 & 2 Development (Chapter 5) and the environmental and social sensitivities specific to the North Falkland Basin, as well as the relevant inshore, onshore and at-shore locations (Chapter 7) it is possible to:

- Identify the environmental and social aspects specific to the project, and
- What the impacts and risks of these may be.

This chapter presents the results of the aspect, impact and risk identification and screening exercises, which were carried out during three ENVironmental Impact IDentification (ENVIID) workshops.

The key objectives of the ENVIIDs were to identify:

- What project activities might interact with the environment and / or the human population, and how (i.e., the aspects, impacts and risks),
- The impacts and risks that could be '**Scoped out**' because of their **Very Low** significance, and
- The impacts and risks that warranted further investigation in the EIA.

Owing to the broad range of activities involved in the Phase 1 & 2 Development, three ENVIIDs were carried out to simplify the process and ensure that all potential impacts / risks were captured. The ENVIIDs were structured to identify impacts and risks in accordance with whether the activities were:

- Offshore,
- Inshore, or
- Onshore / at-shore / logistical.

The ENVIID results are presented in this chapter in accordance with the above location. However, in the remainder of the EIS, the assessment chapters have been grouped by aspect e.g., environmental emissions, discharges etc. to avoid repetition. For example, many activities, regardless of their location, will result in atmospheric emissions and these are assessed in a single chapter to ensure a cumulative assessment of emissions is provided and to avoid repeated explanations of how emissions may impact upon the environment and human population.

Note: as described in Section 5.12, decommissioning of the Phase 1 & 2 Development will be considered a separate project. Therefore, a separate ENVIID will be carried out in support of the EIA that will accompany the decommissioning programme nearer the end of Field Life.

9.1.1 ENVIID workshop attendees

Each workshop was attended by a multidisciplinary team to ensure that all aspects, impacts and risks were considered. The personnel that attended each of the ENVIID workshops were as follows:

- South Atlantic Environmental Research Institute (SAERI) Falklands Ltd. attendees:
  - 4 x Environmental Consultants.
- Operator Attendees:
  - Chief Operating Officer,
  - Development Project Manager,
  - Vice President of Subsea Operations,
  - Falkland Islands Country Manager,
  - Operations Manager,
  - Process and Pipelines Engineer,
  - Logistics Manager,

- Drilling and completions Engineer, and
- Drilling Fluids Engineer.

9.1.2 ENVIID workshop process

During the ENVIID workshops, the team did a 'walk-through' of all the activities that will occur during the Phase 1 & 2 Development.

The ENVIID workshop included identification of the specific activities associated with:

- Offshore operations:
  - Development drilling,
  - Installation of subsea drilling and production facilities and hook-up of production facilities and the Floating Production, Storage and Offloading (FPSO) vessel,
  - Simultaneous drilling and production operations (SIMOPS), and
  - Steady state production.
- Inshore operations:
  - Mooring of two Large Transport Vessels (LTVs) in Berkeley Sound to subsea infrastructure prior to installation, and
  - Manoeuvring of construction vessels as equipment is loaded from the LTV to the construction vessel for transit to the Sea Lion Field.
- Onshore, at-shore and logistical activities required in support of all of the above:
  - Use of the liquid mud plant and dry bulk facility,
  - Use of onshore supply base,
  - Use of port facilities (i.e., 'at-shore'),
  - Use of resources, and
  - Logistical support:
    - Use of vessels, and
    - Use of transportation e.g., fixed-wing flights, helicopters, road transport.

9.1.2.1 Identification of environmental and social aspects

During the 'walk-through' of the Phase 1 & 2 Development activities (Chapter 5), the routes *via* which the planned Phase 1 & 2 activities, and unplanned and accidental events, may interact with the environment and the human population were identified as:

- Environmental aspects:
  - Placement of objects on the seabed,
  - Drill cuttings and mud discharges to sea,
  - Operational discharges to sea,
  - Thermal discharges,
  - Artificial light offshore,
  - Artificial light inshore,
  - Underwater noise offshore,
  - Underwater noise inshore,
  - Atmospheric emissions,
  - Waste:

        - Discharges to sea of grey water, black water, food, drainage and bilge water, and
        - Management of solid wastes.
    - Noise from the use of helicopters,
- Social aspects:
    - Increased vessel use and disturbance to other users of the sea,
    - Competition for resources:
        - Accommodation,
        - Freshwater,
        - Electricity,
        - Road networks, and
        - Airlinks.
    - Disturbance to the human population through:
        - Onshore light,
        - Onshore noise,
        - Odour, and
        - Visual impacts.
- Unplanned / Accidental events:
    - Collisions with marine mammals (including entanglement of cetaceans in mooring apparatus),
    - Introduction of marine and terrestrial non-native species,
    - Vessel collisions offshore,
    - Vessel collisions inshore,
    - Loss of control leading to oil / chemical spill,
    - Small spills contributing to chronic oil pollution, and / or
    - Fuel spill either from bunkering operations or from an accidental event.

The environmental and social aspects relevant to each planned, unplanned and accidental activity / event are summarised in the tables below.

9.1.2.2 Identification of impacts from planned activities

When considering the impact of planned activities associated with the above, the following questions were considered and discussed:

- Will this activity:
    - Require the use of artificial light offshore, inshore, onshore or at-shore?
    - Require the use of helicopters over land?
    - Disturb the seabed or require placement of objects or material on the seabed?
    - Generate underwater noise?
    - Require the discharge of drill cuttings?
    - Require the discharge of liquid to sea e.g., produced water or cooling water?'
    - Require the use and / or discharge of chemicals?
    - Result in the discharge of heat to the environment?
    - Result in the emission of greenhouse gases e.g., *via* fuel combustion, flaring or fugitive emission?

- Result in, or require, the venting of gases?
- Require the use of F-Gases?
- Generate hazardous or non-hazardous solid or liquid waste?
- Require the use of vessels offshore, inshore or in the Falkland Islands' port facilities?
- Require the delivery of cargo to the Islands from overseas?
- Interfere with the activities carried out by other users of the sea?
- Require the use of resources e.g., accommodation, freshwater, electricity, road networks, airports or airlinks to and from the Islands?
- Generate airborne noise inshore, onshore or at-shore?
- Result in odour emissions inshore or onshore?
- Generate exhaust emissions inshore? and / or
- Require the transfer of oil between vessels?

9.1.2.3 Identification of risks associated with unplanned events or accidental activities

To identify the risks, each planned activity was considered and the expertise in the workshop was used to determine:

- What unplanned events could happen as a result of the presence of the operation, malfunction of equipment or loss of control?
- What accidental events could occur?

With regard to the risk of unplanned events therefore, the following questions were asked:

- Could the presence of the operation, malfunction of equipment or loss of control result in:
  - Bird-strikes with vessels?
  - Large dropped objects?
  - Unplanned discharges e.g., of produced water?
  - A release of natural gas?
  - A release of F-gas?
  - The loss of containment of solid or liquid waste to land or sea?
  - The generation of unplanned or unexpected waste quantities?
  - Collision with cetaceans?
  - Entanglement of cetaceans?
  - The introduction of non-native marine or terrestrial species?
  - Collision between vessels?
  - Snagging of subsea infrastructure by trawl fishing gear?
  - Unexpected use of onshore resources?
  - A release of oil offshore via:
    - A well blow-out?
    - A loss of inventory from a vessel, flowline or bunkering hose?
    - The release of small quantities of oil?
  - A release of fuel oil inshore via:
    - A loss of inventory from a vessel due to loss of power, collision or grounding?
    - A loss of inventory from a bunkering / transfer hose?

- A release of fuel oil or chemicals at-shore via:
  - Day-to-day activities at the Temporary Dock Facility?
  - Loss of containment during bulk transfers?

9.2 ENVIID outcomes - preliminary impact assessment and screening

The ENVIID workshop resulted in a detailed list of all planned activities and unplanned and accidental events that could lead to impacts and / or the risk of impacts. A preliminary assessment of their significance was latterly undertaken by the environmental team using the methodology described in Chapter 8. The preliminary assessment was used to determine which of the potential impacts and risks required further investigation in this EIA and which could be '**Scoped out**'.

Specific activities and associated impacts were '**Scoped out**' of further assessment when:

- It was established, with a high degree of confidence during the preliminary assessment, that the significance of the impact of the activity would be '**Very Low'**,
- It was determined that the impact could not occur owing to prevention measures built-in to the Development, and / or
- It was estimated that the impact from a particular source would be sufficiently covered by the assessment of a similar impact or risk of greater magnitude. For example, not every single source of small oil spill was assessed in place of a general assessment of the chronic impact of repeated small releases of oil (Section 12.1).

Aspects and impacts were '**Scoped in**' for a more detailed assessment when:

- Identified impacts and risks had the potential to be of '**Low**' significance, or above,
- Where there was any uncertainty as to the significance of the impact or risk, and / or
- Concern had been expressed by stakeholders during the scoping consultations (Chapter 6).

Table 9.1, Table 9.2 and Table 9.3 provide a summary of the outcomes of the offshore, inshore and onshore ENVIIDs respectively and indicate those aspects, impacts and risks that were '**Scoped out**' and those for which further investigation was considered necessary.

Note: The activities / aspects that were identified as a concern during the informal stakeholder scoping consultation are described and identified in Chapter 6.

Table 9.1: Summary of the outcomes of the *offshore* ENVIID and the preliminary assessment, which was used to determine the environmental and social aspects, impacts and risks that required further investigation in the EIA

Project activities	Environmental Aspects	Planned / Unplanned / Accidental	Receptors which may be impacted by the activities: Benthos	Plankton	Fish / cephalopods	Seabirds	Marine mammals	Designated sites	Seabed and soil	Water quality	Regional[1] air quality	Global atmosphere	Landscape / seascape	Human population / other users	Tangible property	Commercial fisheries	Biosecurity / Biodiversity	Archaeological	Cumulative	Comments
Action required: F = Further assessment required; S = Scoped out of EIA																				
Offshore operations: Subsea installation, drilling, production, offloading of crude from FPSO to CTT																				
Walk-through of planned activities and unplanned events offshore																				
Placement and presence of objects on the seabed e.g., anchors / manifolds	Placement of objects	P	F				F		F	F				F				S	F	**Section 10.3**: Placement of objects on the seabed. **Section 10.11:** Cetacean collisions / Entanglement Impacts to archaeological sites were **Scoped out** as there are no wrecks in the vicinity of the Sea Lion Field and wrecks near Stanley Harbour have been in place for many years with no impact from other vessels.
Presence of hard substrate on seabed following placement of objects	Placement of objects	P	F						F										F	
Large dropped objects	Placement of objects	U	F						F					S	S					
Small dropped objects e.g., a tool	Placement of objects	U	S											S						**Scoped out** during preliminary assessment: Sensitivity of receptor: 'Very Low'; Severity of effect: '**Slight**'

Project activities	Environmental Aspects	Planned / Unplanned / Accidental	Receptors which may be impacted by the activities: Benthos	Plankton	Fish / cephalopods	Seabirds	Marine mammals	Designated sites	Seabed and soil	Water quality	Regional[1] air quality	Global atmosphere	Landscape / seascape	Human population / other users	Tangible property	Commercial fisheries	Biosecurity / Biodiversity	Archaeological	Cumulative	Comments
Offshore operations: Subsea installation, drilling, production, offloading of crude from FPSO to CTT																				
Walk-through of planned activities and unplanned events offshore																				
																				Overall Impact: '**Very Low**' Likelihood: '**Likely**' Overall Risk: '**Low**'
Use and discharge of chemicals during drilling	Drill cuttings and mud	P	F	F	F				F	F									F	**Section 10.6**: Discharge of drill cuttings and mud.
Discharge of drill cuttings to seabed		P	F	F	F				F	F									F	
Use of explosives downhole in the event of stuck-pipe when drilling	Underwater noise generation	P	S	S	S		S													**Scoped out** during preliminary assessment because downhole explosives to relieve stuck-pipe will be used at depths greater than 100 m downhole which means noise levels are largely dissipated by the time they reach the surface of the seabed. Therefore, no receptors are likely to be affected.

Action required:	
F	Further assessment required
S	Scoped out of EIA

Project activities	Environmental Aspects	Planned / Unplanned / Accidental	Receptors which may be impacted by the activities: Benthos	Plankton	Fish / cephalopods	Seabirds	Marine mammals	Designated sites	Seabed and soil	Water quality	Regional[1] air quality	Global atmosphere	Landscape / seascape	Human population / other users	Tangible property	Commercial fisheries	Biosecurity / Biodiversity	Archaeological	Cumulative	Comments
Offshore operations: Subsea installation, drilling, production, offloading of crude from FPSO to CTT																				
Walk-through of planned activities and unplanned events offshore																				
Discharge of iron to the marine environment (e.g., in water-based mud)	Drill cuttings and mud; and Operational discharges	P		S						S										**Scoped out** during preliminary assessment: Sensitivity of receptor: 'Very Low'; Severity of effect: '**Slight**' Overall Impact: '**Very Low**'
Use and discharge of chemicals in produced water during initial production and PWRI unit commissioning	Operational discharges	P	F	F	F	F	F		F	F									F	**Section 10.7**: Operational discharges to sea Discharges associated with the chlorination of seawater were not considered separately as the resulting biocide (sodium hypochlorite) will be discharged with the produced water and are covered by the produced water assessment.
Discharge of oil in produced water during initial production and PWRI unit commissioning	Operational discharges	P	F	F	F	F	F		F	F									F	
PWRI unavailability and discharge of produced water (oil and chemicals) to sea	Operational discharges	U	F	F	F	F	F		F	F									F	
Chlorination of seawater through hypochlorite unit	Operational discharges	P								S										

Action required: F – Further assessment required; S – Scoped out of EIA

Project activities	Environmental Aspects	Planned / Unplanned / Accidental	Receptors which may be impacted by the activities: Benthos	Plankton	Fish / cephalopods	Seabirds	Marine mammals	Designated sites	Seabed and soil	Water quality	Regional[1] air quality	Global atmosphere	Landscape / seascape	Human population / other users	Tangible property	Commercial fisheries	Biosecurity / Biodiversity	Archaeological	Cumulative	Comments
Offshore operations: Subsea installation, drilling, production, offloading of crude from FPSO to CTT																				
Walk-through of planned activities and unplanned events offshore																				
Process upsets and blockages leading discharge of produced water and / or use of more chemicals	Operational discharges	U	F	F	F	F	F		F	F									F	
Subsea discharges of chemicals e.g., pre-commissioning pipeline fluids or hydraulic fluid during valve actuation	Operational discharges	P	F							F									F	
Topside discharge of de-aerated / fresh water	Operational discharges	P		S	S					S										**Scoped out** during preliminary assessment: Sensitivity of receptor: 'Very Low'; Severity of effect: '**Slight**' Overall Impact: '**Very Low**'
Discharge of de-aerated injection water at seabed while flowing until hot	Operational discharges	P	S		S				S											
Sand requiring removal from separator during normal maintenance - oily solids and	Operational discharges	U		S	S					S										**Scoped out** during preliminary assessment: Sensitivity of receptor: 'Very Low';

10.1.1 Introduction

Numerous vessels and offshore installations will be used throughout the three Stages of the Phase 1 & 2 Sea Lion Development, each of which requires the use of artificial light. Further, while there is a zero planned flaring philosophy once into steady state production, there is a contingency within the basis of design to test up to four wells to the Mobile Offshore Drilling Unit (MODU) which would require short-term flaring (Section 5.4.8) and up to 30 days flaring will be required during commissioning of the gas system (Section 5.4.9).

The level of anthropogenic light in the night-time sky has increased dramatically in recent decades and is increasingly becoming an issue relating to impacts on biodiversity (Hölker, *et al.,* 2010). Additionally, light was raised as a concern by stakeholders during consultations in 2014, 2015 and 2016 (Chapter 6). Where light has the potential to adversely effect humans or other animals, this is referred to as 'light pollution' (see Davies, *et al.,* 2014 for review). However, most ecological studies take place during day-light hours and therefore the extent of the ecological consequences of light pollution are only just beginning to be appreciated.

Artificial light and flares can affect the natural behaviour of animals in several ways including disturbance to activity patterns and hormone-regulated processes dictated by the internal clock. A more obvious effect however, is the attraction of animals and seabirds to man-made light sources and their subsequent disorientation. This phenomenon is known as positive phototaxis.

Positive phototaxis is actively exploited to catch species of squid (FAO, 2014), with approximately 63-89 % of the global squid catch being made by light-fishing vessels (jiggers). Equally, it has long been known that seabirds are attracted to lights at-sea (Murphy, 1936), which has also been exploited as a technique for capturing seabirds. There is a growing awareness of the impact that anthropogenic sources of light are having on seabirds (Montevecchi, 2006; Marangoni, *et al.,* 2022), although quantitative studies are few in number (e.g., Rodríguez, *et al.,* 2015b; 2017).

This chapter assesses the potential ecological impacts and risks associated with anthropogenic light arising from the Phase 1 & 2 Development of the Sea Lion Field, which include:

- Attraction of marine life, e.g., plankton, fish and squid, and
- Attraction of seabirds and subsequent collision risk with vessels or flares.

Note: the other impacts associated with vessel use are described elsewhere in this document, as are the social impacts of artificial light on humans, as described in Table 2.2.

10.1.1.1 Relevant legislation

Outside the EIA process for major projects, no legislation is in place in the Falkland Islands to govern the environmental impact of artificial light, although offshore industry guidelines are in place (see Section 10.1.5 below).

While not directly related to the environmental impact of artificial light, it is important to understand during this assessment that mitigation measures will be limited by the need to ensure the use of sufficient lighting for safety reasons. Specifically, offshore installations are required to be illuminated in line with the:

- International Regulations for the Prevention of Collisions at Sea (ColRegs) (Rule 22 and Annex 1).

Lighting of the Floating Production, Storage and Offloading (FPSO) vessel and MODU decks, walkways and process areas will be governed by compliance with occupational safety requirements and process safety requirements. For example, the FPSO design requires that luminance levels for general and

emergency operating conditions shall be in accordance with IEC 61892-2 which follows from compliance with Falkland Islands health and safety legislation for the offshore industry.

Lighting of helicopter landing areas (FPSO, MODU and Commercial Trading Tanker (CTT)) is a requirement of CAP 437 (CAA, 2013).

Offshore flaring (i.e., flaring associated with well testing, well clean-up operations and pressure relief) is regulated in the Falklands by the Department of Mineral Resources (DMR) under the:

- Offshore Mineral Ordinance 1994 (1997 and 2011 Amendments).

10.1.2 Sources of impact and risk

Offshore operations associated with the Development will introduce several sources of artificial light into the offshore waters of the North Falkland Basin (NFB), and in Berkeley Sound, all of which will add to the existing ambient light (Section 10.1.9).

As a worst-case, the Phase 1 & 2 Development sources of artificial light and flaring will include the following:

- Vessels:
  - Within the Sea Lion Field:
    - The MODU,
    - Installation / construction vessels,
    - The FPSO,
    - Supply / support vessels,
    - An Emergency Response and Rescue Vessel (ERRV), and
    - Oil export CTT and Offshore Support Vessel (OSV) used for direct offtake.
  - In transit to inshore locations:
    - *Ad hoc* freighter vessels,
    - Offshore Construction Vessels (OCV),
    - Supply / support vessels, and
    - Large Transport Vessels (LTVs).
  - Within Berkeley Sound:
    - Up to two LTVs in the Sound at any one time, and
    - Subsea Construction Vessel/s during subsea construction.
- Flaring:
  - From the MODU during contingent well clean-up / testing,
  - Permanent flare pilot light on the FPSO,
  - From the FPSO during shut-down and start-up, and
  - In the event of emergency blowdowns

Sources of light on the Phase 1 & 2 vessels will include:

- Navigational lights,
- Illuminated living spaces within all vessels,
- Floodlighting to provide a safe working environment on the decks of ships and MODU,
- Flaring from the MODU during contingent well clean-up and testing,
- Small permanent pilot flare of associated gas from the FPSO, and

- Periodic high-pressure (HP) flaring of gas, only in the event of a blowdown.

The number and type of vessels present at the Sea Lion Development site will vary with the Stage of the Field's development and the activities undertaken (Section 5.11.2). Away from the Development site, support vessels will regularly steam to and from the supply base in Stanley throughout all Stages. Throughout the life of the Development, activities will operate for 24 hours a day and to do this safely, all working areas will have to be well illuminated.

In Stage 1 of the subsea construction campaign, up to four LTVs will be used over a twelve month period. However, the current schedule expects that, during Stage 1, a maximum of two LTVs will be present in Berkeley Sound for a maximum of 13 non-consecutive months. Efforts will be made to avoid competition for sea room during the peak fishing period.

It is expected that Stage 2a only one LTV will be moored for a duration of approximately four months. During Stage 2b, the construction campaign is expected to require an additional three LTVs which would be expected to be on location in Berkley sound for no more than six months. Again, there will be only two LTVs onsite at any one time.

Offshore, direct offtake to the CTT from the FPSO requires the presence of an Offshore Support Vessel (OSV) to manoeuvre and hold the CTT in place during the offtake operation.

10.1.2.1 Navigational lights

Vessels are required to display navigational lights when at-sea. These are relatively small coloured lights (white, red and green) that are of low intensity to avoid glare. Alone, these lights are unlikely to cause impacts or pose any risk (see Poot, *et al.,* 2008).

10.1.2.2 Living spaces

Light can be emitted from living spaces (accommodation, mess rooms etc.) through uncovered portholes and windows on the rig and other vessels (Figure 10-1).

10.1.2.3 Deck lights

Deck lighting is required to provide a safe working environment. These lights are usually very bright floodlights, designed to illuminate a wide area. It is these light sources that are most difficult to manage as they are outside and are essential for safe working practices (Figure 10-1).

10.1.2.4 Flaring

During steady state production from the Phase 1 & 2 Sea Lion Development, there will be no routine flaring of gas with the majority of excess gas being reinjected into the Gas Injection (GI) well (Section 5.8.4.4). However, for safety reasons, there will be a small constant gas fed pilot flare at the end of the flare boom. Periodically, excess gas and hydrocarbons may be burned off by flaring during start-up following process and emergency shutdowns, or during emergency blowdowns.

No flaring is planned during the drilling process as the Open Hole Gravel Pack completion is designed to minimise debris such that clean-up to the MODU will not be required. All wells will be flowed back to the FPSO. However, the contingency is retained to flow / test up to four wells to the MODU (Section 5.4.8). Any flaring would be carried out for one day per well. Further, 30 days flaring will be carried out during the commissioning of the gas system (Section 5.4.9).

a) Lighting arrangement for a representative MODU

b) Lighting arrangement for a representative FPSO

Figure 10-1: Photographs of representative offshore lighting arrangements

10.1.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those environmental receptors upon which the impacts and / or risks of artificial light warranted further investigation (Chapter 9). These include:

- Zooplankton (Section 7.4.1.3),
- Fish and squid offshore and inshore (Section 7.4.4),
- Seabirds offshore and inshore (Section 7.4.5), and
- Marine mammals offshore and inshore (Section 7.4.6).

The offshore marine environment is essentially dark at night, except for moonlight and sources of bioluminescence. The above receptors have evolved to function in accordance with a diurnal cycle where, over any 24-hour period, there are predictable periods of daylight and darkness. The introduction of artificial light during the hours of darkness therefore has the potential to confuse the circadian rhythms (the body clock) followed by the receptors over the 24-hour cycle, leading to impacts on normal behaviour as well as the risk of collision for seabirds.

10.1.4 Characterising and quantifying the impact

When characterising and quantifying the impacts and risks of artificial light it is necessary to consider the:

- Influencing factors,
- The impact of attraction to artificial light and flares, and
- The risk of collision caused by artificial lights and flares.

10.1.4.1 Influencing factors

The potential impact of artificial light from the project's Phase 1 & 2 Development on marine life is influenced by the:

- Number of Phase 1 & 2 light sources and the duration of light exposure,
- Location of light sources,
- Intensity of light,
- Orientation of light,

- Season of activity (and the likely occurrence of receptors), and
- Local weather conditions.

10.1.4.1.1 Number of Phase 1 & 2 light sources and duration of light exposure

The number of light sources and the duration of light exposure during each different stage of the operation is summarised in Table 10.1.

Table 10.1: Number, source and duration of lights during the Phase 1 & 2 Development

Phase 1 & 2 Development Stage		Duration of Stage	Light sources
Offshore			
Phase 1 wells	Stage 1: Mobilisation and installation of materials and equipment, pre-First-Oil drilling by MODU, installation, hook up and commissioning of the FPSO and 'First-Oil'	31 months	Installation vessels, MODU, FPSO, support vessels, oil export vessels and potential flaring
	Stage 2a: SIMOPS with post First-Oil drilling by the MODU and concurrent production operations by the FPSO and oil export	7 months	
	Stage 3: Steady phase production	28 months	FPSO, support vessels and oil export vessels
Phase 2	Stage 2b: SIMOPs SIMOPS with in-fill drilling by the MODU and concurrent production operations by the FPSO and oil export	28 months	Installation vessels, MODU, FPSO, support vessels, oil export vessels and potential flaring
	Stage 3: Steady phase production	325 months (27.1 years)	FPSO, support vessels and oil export vessels
Inshore (Berkeley Sound)			
Phase 1 & 2	Stages 1, 2a & 2b: Anchoring and operation of LTVs	Intermittently for a total of up to 13 months	Up to four separate LTVs with only two anticipated to be *in situ* at any one time, Installation / construction vessels

10.1.4.1.2 Location of light sources

Should initial well clean-up be required to the MODU, flaring will take place from the MODU (Section 5.4.8), whereas intermittent flaring carried out during production (Stage 3) during shutdowns etc. (Section 5.9.4) will take place from the FPSO.

Most of the vessel activity that requires deck lighting will be based offshore at the Sea Lion Field location, which represents a fixed / permanent source of light.

Inshore, up to two LTVs will be temporarily anchored in Berkeley Sound in support of the subsea construction campaign.

Deck lighting will have to be maintained by all vessels to provide a safe working environment.

When in transit to and from inshore waters, light will be limited to navigation lights in accordance with ColRegs (Section 10.1.1.1).

10.1.4.1.3 Intensity of light

Luminous intensity is the amount of light emitted in a given direction and is the most useful measure of 'brightness' with regards to environmental impact. It is measured in candelas, which are a measure of light emission (lumens) per 'solid angle' (steradian). This gives an indication of light intensity received by a receptor. Candelas are used to describe navigation standards for shipping and aviation. There is generally a positive relationship between the power consumption of a light source (in kilowatts) and the amount of light emitted, which is known as 'luminous efficacy' and is measured in 'lumens per watt' (lm/W).

The intensity of light emitted by each vessel will vary depending on activity. At the time of writing the exact identity of the specific vessels involved is unknown; however, some good representative comparisons can be made with vessels operating elsewhere (Figure 10-1 above) and with reference to regulatory requirements.

Marguenie and van de Laar (2004) experimented with the lighting of a gas-production platform (gas production platform L5) in the North Sea to investigate the relationship between light intensity and bird attraction (reported in Poot *et al.,* 2008). By disconnecting different sources of light, they were able to show that bird attraction was influenced by light intensity, although they were more concerned with migratory land birds than seabirds.

For illustrative purposes, Table 10.2 shows the power consumption of different lights on the L5 platform in Danish waters; this can provide a rough guide for light intensity as an increase in power consumption results in an increase in light intensity. It was thought that, at full intensity (30 kW) the light's influence extended 3-5 km from the platform. By way of comparison in the squid fishing industry, each jigger is equipped with lights totalling 300 kW and the fleet may contain up to 100 vessels within Falkland Islands waters.

The lights used on the MODU and large vessels are likely to differ from those on the L5 platform; however, it has been used as an example as information regarding the specific lighting specifications of the MODU or other vessels, are not yet available.

All vessels in the field (including the MODU, FPSO, standby vessel, and supply vessels) will, as a minimum, comply with the Collision at Sea Regulations (ColRegs) requirements for visibility. This requires vessels to maintain lighting that is visible over certain ranges. The lights in vessels of 50 m or more in length must be visible at the following minimum ranges:

- Masthead lights - six miles,
- Sidelights, sternlights and towing lights - three miles, and
- White, red, green or yellow all-round lights - three miles (Figure 10-2).

The intensity of a light visible over six nautical miles will typically be 94 candelas (ColRegs Annex 1).

For helicopter landing, some key requirements of CAA standards for offshore helicopter landing areas (CAP 437) (Section 10.1.1.1) are as follows:

- The periphery of the landing area should be delineated by omni-directional green perimeter lights visible from up to 1.5 nm in good visibility with a minimum intensity of three candelas in the horizontal plane going up to thirty candelas from above,
- The touchdown circle must be yellow light with a minimum intensity of 15 candelas in the horizontal plane up to 60 candelas from above, and
- The green 'H' heliport marking must have a minimum intensity of 10 candelas in the horizontal plane up to 60 candelas from above.

Table 10.2: Examples of the power required by different light sources on gas production platform L5, located in Danish waters in the North Sea

Source	Source power consumption (kW)
Navigational lights (red and green)	0.3
Sodium floodlights of crane	1.5
Helicopter platform	0.16
Landing lights	0.48
Platform total mostly tube lights (400 x 36 W) and sodium floodlights (20 x 400 W)	30

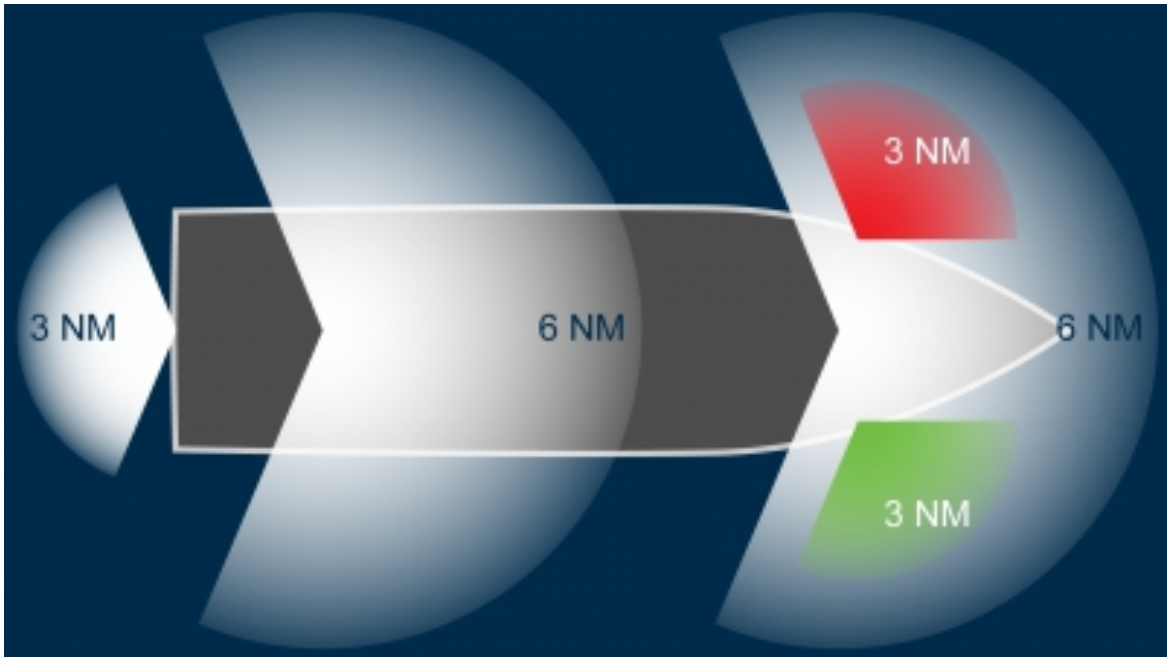

Figure 10-2: Navigational lighting requirements for a vessel over 50 m in length

10.1.4.1.4 Orientation of lights

Some lights, such as navigation lights, are designed to be seen by other vessels and therefore are orientated to face out-board. However, these are usually low intensity lights (Table 10.2 above; ColRegs, 2005). Helicopter platform and landing lights also face outwards, or upwards, to guide incoming aircraft; intensity is required to be highest near the horizontal plane and lowest in the vertical. These are also usually of relatively low intensity (Table 10.2 above).

The highest intensity lights are the deck or crane floodlights, which are generally orientated to illuminate any operational activity being undertaken on the deck of the vessel and surrounding water e.g., during supply boat transfers but can vary in orientation if following a moving load suspended on the crane.

Lights for escape purposes e.g., lifeboat positions must shine overside but their use is limited to actual use of the lifeboats or exercises.

During flaring the flame is emitted from the flare stack, the highest point on the MODU or FPSO (away from any other infrastructure), and would be vertically orientated, with a possible flame height of approximately five metres.

10.1.4.2 Impacts of attraction to artificial light

10.1.4.2.1 Zooplankton, fish and squid

It is well documented that marine zooplankton are attracted to artificial light (Davies, *et al.,* 2014). Aggregations of zooplankton may then attract small fish, which in turn attract larger predatory fish or squid. This effect appears to be more pronounced with static light sources. This principle is very successfully exploited by jigger fishing vessels to catch *Illex* squid (Argentine shortfin squid*, Illex argentinus*; Section 7.7.3.1.1).

Inshore, lobster krill is the 'species' most likely to be attracted to ships' lights that illuminate the water. These animals can form very dense shoals, which can attract predators and even interfere with a ship's ability to work by blocking water intake filters. Other species that may be attracted to ships' lights include squid (in the spawning season), and potentially rock cod, at the beginning of the calendar year through to March (P. Brickle, *pers. obs.*).

Experimental trials to investigate the impacts on abundance and behaviour of fish in response to artificial light indicated that nocturnal lighting created conditions that potentially benefit larger, piscivorous (fish-eating) fish. This outcome was believed to result from both the concentration of prey and the foraging advantage afforded to visual predators (Becker, *et al.,* 2013).

There are relatively few commercially exploitable pelagic (water-column) fish species in the deeper waters of the NFB or inshore waters. Catch statistics indicate that hoki is the most abundant species in the NFB (FIG, 2024b); however, it is likely that unexploited species such as lantern fish (Myctophidae) are also likely to be present. Inshore, species such as Falkland sprat, tessellated rock cod and smelt are known to be present. Section 7.4.4.2 contains further details regarding the distribution of fish in the NFB and inshore waters.

The spread of *Illex* squid catches indicates that there is considerable inter-annual variation in the distribution of this species. However, the distribution of fishing effort in some years indicates that a small proportion of the stock is likely to be near the Sea Lion Field during April and May (Waluda, *et al.,* 2008).

There are numerous other species of squid that are found within Falkland Islands waters. The most numerous of these is likely to be *Onykia ingens* (greater hooked squid), which is widespread at low density throughout the NFB but shows seasonal movement on and off the Shelf (Jackson, *et al.,* 1998; Arkhipkin, *et al.,* 2012b).

Inshore, loligo are very abundant off the east coast of the Islands. This species spawns inshore and the animals migrate into deeper waters (to the edge of the Patagonian Shelf) as they grow before migrating back inshore to spawn as they mature (Section 7.7.3.2.1.1).

Note: Much of the baseline data on fish and squid derives from fisheries surveys with less detail available on non-commercial species. It is accepted that light will also attract other squid and fish species in the area.

10.1.4.2.2 Seabirds

Seabirds take advantage of natural sources of light to find prey and to navigate. Both these essential life functions may be impacted by disorientation from artificial lights and flares. Seabirds may circle an artificial light source for prolonged periods using valuable energy reserves in a process which leads neither to feeding nor effective navigation, and both of which may result in exhaustion (*c.f.* NAM, 2007). Nonetheless, the greater impacts to seabirds result from the risk of collision with the light or flare, or landing on the vessel, both of which are characterised and quantified below in Section 10.1.4.3.1.

10.1.4.2.3 Marine Mammals

Research on the impact of artificial light on marine mammals remains limited. Existing studies, such as Miller and Rice (2023), indicate a lack of evidence supporting direct attraction behaviors of marine mammals to artificial light. This suggests that they are not inherently drawn to artificial light. However, indirect impacts may still occur (Section 10.1.6.3), particularly if marine mammals are attracted to prey species that aggregate around artificial light sources. For example, artificial light inshore may attract prey such as fish and lobster krill (*Grimothea gregaria*, formally *Munida gregaria*) which may in turn attract foraging species like sei whales. Sei whales are known to feed on lobster krill in Falkland Islands waters (Weir, 2022) and changes in prey distribution and abundance could influence their behavior and habitat use. However, there is little information on light attraction to lobster krill.

Therefore, further research is needed to better understand both the direct and indirect impacts of artificial light on marine mammals. Considering their documented sensitivity to other sensory pollutants, such as noise, it is likely that marine mammals respond to multiple stressors across varying gradients. Due to limited data available in the literature on this impact on marine mammals, this issue was not assessed further.

10.1.4.3 Risks associated with artificial light

10.1.4.3.1 Seabird collisions

Globally, there are issues regarding the interaction between birds and anthropogenic light sources. Birds can be impacted directly by a wide range of artificial light sources within marine environments. Of relevance to this assessment, they are often attracted to and collide with offshore hydrocarbon platforms (Ortego, 1978; Hope-Jones, 1980; Tasker, *et al.,* 1986; Baird, 1990; Wiese, *et al.,* 2001; Burke, *et al.,* 2005; NAM, 2007; Ronconi, *et al.,* 2015), as well as commercial fishing vessels and other boats using lights (Dick and Donaldson, 1978; Ryan, 1991; Arcos and Oro, 2002; Black, 2005a; Merkel and Johansen, 2011; Glass and Ryan, 2013).

The receptors can be broadly split into migratory land birds and seabirds. Although there is some seasonal movement of birds between the Falklands and South America, the location of the Sea Lion Field and Berkeley Sound are not regarded to be on the route of migrating land birds (White, *et al.,* 2002) and therefore the potential risk to seabirds is of greatest concern.

Light generated by the O&G industry, and other marine users, has the potential to lead to direct and indirect mortality from:

- The impact of a collision (OSPAR, 2012),
- Incineration in the flare - flaring is the most problematic form of artificial light at-sea, with a high risk of mortality posed to any birds flying too close to the flame (Hope-Jones, 1980; Montevecchi, 2006), and / or
- Loss of feather condition and hypothermia due to contact with the decks of vessels (Black, 2005a; Glass and Ryan, 2013).

Collisions between birds and vessels (known as bird-strikes) are episodic events that, in addition to influencing factors such as the amount and orientation of light (Section 10.1.4.1), are related to a number of other variables including:

- Visibility which can be affected by weather conditions (e.g., reduced visibility due to mist, fog or snow) and moon phase,
- Seabird behaviour (e.g., activity patterns, fledging), and
- Seabird abundance (e.g., large aggregations close to a breeding site)

The number of variables makes the risk of bird-strikes difficult to quantify or predict. Nonetheless, when all of these factors align, hundreds of birds can collide with a vessel on a single night. Although the Sea Lion Field is not located near breeding colonies or areas of notably high seabird density, the impact of lighting has been estimated to extend to 3-5 km around offshore installations (Marquenie, 2007), although it should be noted that this could vary with age / life-stage etc. Therefore, Navitas cannot rule out birds that may be attracted at a much greater distance and there is a risk of episodic bird-strikes throughout the life of the Development.

In contrast, Berkeley Sound contains the largest known colonies of sooty shearwaters and white-chinned petrels in the Falklands and a large number of birds congregate at the entrance to the Sound throughout the breeding season (September to May) (Section 7.4.5.3.2).

10.1.4.3.1.1 Direct and indirect mortality

With regard to the above, some individuals will be killed outright by a collision or contact with a flare, others may be injured, and others still may survive the initial impact.

The likelihood of direct mortality is species-specific and relates to flight style, with species like diving-petrels colliding at great speed being more likely to be killed outright by the impact than larger petrels and shearwaters that have a gentler landing (Glass and Ryan, 2013).

Once on the deck however, petrels, in particular, find it difficult to become airborne as these birds only come to land to breed in burrows and, unlike land birds or gulls, are not well adapted to walking. Therefore, petrels will often seek shelter under gratings, containers etc. This behaviour can potentially lead to indirect impacts in two ways:

- Hypothermia and death caused by contamination of feathers given that the decks of ships can be contaminated with oily, greasy residues and detergents as well as carrying hazards such as save-alls (devices intended to catch waste products and / or prevent losses) (MMS, 2010), and
- Condition loss and / or starvation caused by the time spent hidden away in nooks and crannies where they may stay for prolonged periods.

10.1.4.3.1.2 Seabird behaviour and susceptibility to artificial light and collision

Seabirds of all species can collide with any vessel at-sea whether at night or day. However, not all species are equally susceptible to light induced bird-strike. Diurnal albatrosses and petrels (i.e., active during the daytime) seem less likely to be involved in light induced bird-strikes than birds that are active at night (Wiese, *et al.,* 2001; Black, 2005a). However, fledglings of most species tend to depart from colonies at night and may be more vulnerable at this time (Rodríguez, *et al.,* 2015a). Attraction to artificial lights is particularly strong in small, planktivorous (plankton eating) procellariiform seabirds (i.e., petrels, shearwaters and storm-petrels) that remain active at night (Ryan, 1991; Black, 2005a; Rodríguez, *et al.,* 2017).

It is unclear what exactly attracts birds to light but there are several theories:

- The most susceptible species feed on bioluminescent planktonic organisms that migrate close to the surface at night, and are therefore attracted to light sources (Imber, 1975),
- Light from the moon may be a navigational cue for some species of seabird (Montevecchi, 2006), and
- In the absence of celestial light, on overcast nights, Poot *et al.* (2008) propose that artificial lights interfere with a bird's magnetic compass. It is thought that the magnetic compass is linked to light receptors in the eye that require light of blue wavelengths to function; red light appears to impair this function (Poot *et al.,* 2008).

Whatever the reason, it is clear that small petrels can collide with anthropogenic structures at-sea and die as a consequence (for examples see Ryan, 1991; Wiese, *et al.,* 2001; Black, 2005a; Glass and Ryan, 2013).

It is safe to assume that where artificial light exists at-sea there will be some interaction between vessels and seabirds, which will usually involve small numbers of individuals. However, in conditions of poor visibility (due to fog, snow or rain) the problem is exacerbated, and more individuals are likely to interact with vessels emitting light.

Where artificial light, poor visibility and high seabird numbers coincide, 1,000's of birds may collide with a vessel on a single night (Coleman, *et al*., 2022). While there are no published records, light induced bird collisions with vessels, with varying numbers of birds affected, are a regular occurrence around the Falkland Islands (A. Black, *pers. obs.*), elsewhere in the South Atlantic (Ryan, 1991; Black, 2005a; Glass and Ryan, 2013) and elsewhere in the world (e.g., Wiese, *et al.,* 2001; Merkel, 2010).

10.1.4.3.1.3 Weather conditions and moon phase

Virtually every reported large bird-strike associated with artificial light at-sea is linked to weather conditions (e.g., Ryan, 1991; Black, 2005a; Merkel, 2010; Glass and Ryan, 2013). The probability that snow will fall on any given day (thus reducing visibility) is higher during the winter months than the summer months, so there may be a seasonal component to bird-strike statistics. Fog is generally related to wind direction and in the Falklands is more frequently observed during periods of north or north-easterly winds, which can be experienced at any time.

Additionally, the influence of artificial light appears to be greatest on moonless nights when there is limited ambient natural light (Montevecchi, 2006). The longer nights and poorer weather experienced during the winter months are therefore more conducive to bird-strikes.

10.1.4.3.1.4 Susceptible seabirds and their abundance

Bird-strikes reported by Ryan (1991), Black (2005a) and Glass and Ryan (2013) and observations on vessels in Falkland Islands waters (A. Black, *pers. obs.*) indicate that the most vulnerable species groups in the South Atlantic are; prions, blue petrels, storm-petrels, diving-petrels, gadfly (*Pterodroma*) petrels and shearwaters. Most of these birds are migratory or widely dispersed during the non-breeding season, which results in seasonal patterns of abundance in the region of the Sea Lion Field. These species generally have very large population sizes, are found over extensive ranges and are mostly regarded as being of 'Least Concern' status by IUCN; however, sooty shearwaters are 'Near Threatened' and some of the gadfly petrels (such as Atlantic petrel) are regarded as 'Endangered', due to a restricted breeding distribution and land-based threats.

With regard to abundance, it has been suggested that a mortality rate of >1 % of the natural mortality rate has the potential to have an impact at the population level (OSPAR, 2012). However, this approach can be problematic, not least because it is not possible to determine the size of many / any of the populations of the species most likely to be impacted. The impact of individual mortality is likely to be greater in species that are classified nationally or internationally as 'Declining', 'Threatened' or 'Endangered'. In the NFB at the Sea Lion location, these species include black-browed albatross, white-chinned petrel, sooty shearwater, southern royal albatross, northern royal albatross, Magellanic penguin, grey-headed albatross, wandering albatross, Atlantic petrel and rockhopper penguin (Section 7.4.5.3.2).

Sea Lion Field

Data compiled from at-sea surveys, annual monitoring programs, coastal surveys and tracking data were used to indicate the seasonal abundance of the most susceptible species near the Sea Lion Field (Knipe and Pendoley, 2019). This data indicate that in the NFB, prions were generally the most

numerous 'species' recorded in all months, although they were never encountered in very large numbers (White, *et al.,* 2002; Knipe and Pendoley, 2019).

In addition to prions, small numbers of other potentially vulnerable species, such as blue, Atlantic and Kerguelen petrels may be present during the winter months. For example, Kerguelen petrels have been recorded as striking vessels (Premier, 2015d; Ryan, 1991; A. Black, *pers. obs.*). This species is present, in relatively low numbers, within Falkland Islands waters during the winter months but absent during the summer months (White, *et al.,* 2002; Knipe and Pendoley, 2019).

To characterise the vulnerability of different species, Knipe and Pendoley (2019) undertook a vulnerability assessment of seabirds known to occur, or potentially occur, within the Sea lion Field. The vulnerability assessment was based on the frequency of occurrence of a species and the likelihood of a negative interaction (Knipe and Pendoley, 2019). The vulnerability assessment highlighted that Procellariforms have the highest vulnerability score compared to other seabird sand shorebirds (Table 10.3) (Knipe and Pendoley, 2019). These species include: grey-headed albatross (winter, autumn), northern royal albatross (winter), southern royal albatross (winter, summer, autumn) wandering albatross (spring, summer, autumn), white chinned petrel (all seasons), cape petrel (winter, spring, autumn), Antarctic fulmar (winter, spring, autumn), soft-plumaged petrel (summer autumn), southern giant petrel (all seasons), blue petrel (winter, spring, summer), Wilson's storm petrel (all seasons), grey-backed storm-petrel (all seasons), black-bellied storm-petrel (spring, summer, autumn), prion species (all seasons), great shearwater (summer, autumn), sooty shearwater (spring, summer, autumn), little shearwater (summer, autumn).

Table 10.3. Summary of vulnerability scores for seabirds, shorebirds and terrestrial birds from Knipe and Pendoley (2019)

Species group	Species sub-group	Season	Highest Vulnerability Score	IUCN Red List (range)	Wavelength sensitivity
Seabirds	Procellariforms	Winter	Highest / High	LC – EN	Ultraviolet-blue-green
		Spring	Highest	VU	
		Summer	Highest	VU	
		Autumn	Highest	VU	
	Penguins	Winter	Moderate	LC – VU	Unknown
		Spring	Moderate	LC – VU	
		Summer	Moderate	LC – VU	
		Autumn	Moderate	LC – VU	
Shorebirds	Gills, skuas, sheathbills	Winter	Low	LC	Foraging: Ultraviolet-blue Migration: Red
		Spring	Moderate	LC	
		Summer	Moderate	LC	
		Autumn	Moderate	LC	
	Terns	Winter	Lowest	LC	
		Spring	Lowest	LC	
		Summer	Lowest	LC	
		Autumn	Lowest	LC	
	Waders and waterfowl	Winter	Low	LC	
		Spring	NA	NA	
		Summer	Low	LC	
		Autumn	High	LC	
Terrestrial birds	Passerines and raptors	Winter	Low	LC	Migration: Red
		Spring	Low	LC	
		Summer	Low	LC	
		Autumn	Low	LC	

Berkeley Sound

The waters near Berkeley Sound are numerically dominated by sooty shearwaters during the spring, summer and autumn months. The relative abundance of susceptible species is generally highest during the summer months (Table 10.4), however, the shorter nights and lower likelihood of poor weather conditions at this time act to counter higher seabird numbers.

There is evidence to suggest that fledgling birds on their maiden flight are more susceptible to disorientation by lights than other birds (Troy, *et al.,* 2011; Rodríguez, *et al.,* 2015a) and therefore the sooty shearwater fledging period is likely to be the most critical time. However, the indicative LTV anchorage location is situated approximately 5 - 10 km to the WNW of the breeding colonies (on Cochon and Kidney Islands respectively), so birds will not routinely pass the LTV site *en route* to the colony (Bonnet-Lebrun, *et al*., 2020). The breeding phenology (cyclic and seasonal phenomena) of sooty shearwaters has not been studied in-depth in the Falklands but young birds fledge (depart from the colony) throughout April and early May (Woods, 1988). Sooty shearwater mortality has been

observed on a jigger departing from Berkeley Sound in early May 2014, when six out of 11 birds striking the vessel suffered broken wings or necks and died as a consequence (R. James, *pers. comm.*).

Table 10.4: An example of relative species abundance within approximately 15 nautical miles of the Sea Lion Field and Berkeley Sound (shaded areas indicate relative abundance)

Species	IUCN status	Relative seasonal abundance (see key below)							
		North Falkland Basin				Berkeley Sound			
		Sum	Aut	Win	Spr	Sum	Aut	Win	Spr
Prion species	LC								
Diving-petrel species	LC								
Wilson's storm-petrel	LC								
Grey-backed storm-petrel	LC								
Black-bellied storm-petrel	LC								
Great shearwater	LC								
Sooty shearwater	NT								
Little shearwater	LC								
Soft-plumaged petrel	LC								
Atlantic petrel	EN								
Kerguelen petrel	LC								
Blue petrel	LC

Not recorded	Very Low	Low	Moderate	High

10.1.4.3.1.5 Historical observations of bird-strike associated with O&G in the Falkland Islands

During the 2011 exploration drilling campaign carried out by Rockhopper Exploration plc, in the NFB, observations from the ERRV recorded birds associating with the MODU but did not record any negative interactions (Munro, 2011). Most observations were made from a support vessel some distance from the MODU. In order to be able to detect small petrels at night, observations would ideally be carried out on board the vessel concerned (the MODU in this case); although for reasons of bed space and health and safety this can be difficult. Statistically, significantly more bird association was recorded during the morning than the afternoon and it was suggested that this was due to attraction to lights during the night (Munro, 2011).

During the 2015 exploration campaign in the NFB, Navitas (then POEPL) developed and implemented a Bird-Strike Management Plan (BSMP) in accordance with the Bird-Strike Management Standard (Premier, 2015b) to monitor, record, report and mitigate (if required) bird strikes on the MODU and associated vessels (Table 10.5). During this campaign, there were no reports from the MODU but there were five records from the supply vessels (Table 10.5). All of these incidents were reported from supply vessels and at least three of the incidents were reported as having occurred in Stanley Harbour.

Given all that is described above, it is not possible to estimate the number of birds at risk from light induced bird-strikes during the life of the Phase 1 & 2 Development. However, from experience gained on vessels that operate in South Atlantic waters (Ryan, 1991; Black, 2005a; Glass and Ryan, 2013; A. Black, *pers. obs.*) and on O&G platforms elsewhere (Hope-Jones, 1980; Tasker, *et al.,* 1986; Wiese, *et al.,* 2001), it is considered likely that some birds will collide with vessels involved with the Development.

Table 10.5: Bird-strikes reported during the 2015 Exploration Drilling Campaign

Date	Species	Number	Weather	Location	Outcome
30th April	Sooty shearwater	1	Overcast / foggy	TDF	Injured
1st May	Sooty shearwater	1	Overcast / foggy	TDF	Injured
13th June	Kerguelen petrel	1	Occasional snow	52° 09' S, 55° 42' W	Released OK
14th June	Grey-backed storm-petrel	1	Not recorded	Not recorded	Oiled
31st August	Snipe	1	Clear	Stanley Harbour	Dead

10.1.5 Industry standard mitigations

Good working practice and design will help to limit the amount of light pollution and reduce the risk of bird-strikes. However, as light is required to maintain a safe working environment, it is not possible to eliminate all sources of light (black-out) as compliance with the ColRegs (Section 10.1.1.1) must be maintained.

Nonetheless, the Convention for the Protection of the Marine Environment of the North-East Atlantic (the 'OSPAR Convention') has published the following guidelines based on discussions at the 2012 OSPAR Workshop aimed at reducing potential lighting impacts on migrating birds and seabirds:

- Guidelines to reduce the impact of offshore installations lighting on birds in the OSPAR maritime area (OSPAR Agreement 2015-08).

These guidelines recommend:

- Assessment of light sources:
  - All lighting equipment on offshore installations potentially emitting light outside the physical boundary of an installation should be assessed to determine whether the light is essential for safety reasons and whether there is the potential for reducing external emissions. As part of this process, photographs taken in the dark from outside the offshore installations can be used to detect significant light sources, including stray and spurious light sources, emitting light to the surrounding environment.
- Reduction of light emissions:
  - The lighting on offshore installations should be reduced to a minimum compatible with safe operations whenever, and wherever, possible. This includes the use of black out blinds, minimising the number of lights and the intensity of the lights and / or adapting the spectrum of the lights to bird-friendly lighting systems,
  - Unnecessary light sources should be removed, as far as possible,
  - In areas where lighting is not a continuous requirement, light sources should be automatically or manually controlled through the process control system. Normally unmanned platforms should have switches installed and during unmanned periods lights should be switched off apart from lighting requirement to comply with national and international regulations on aviation and shipping navigation, and
  - Where the use of automatic or manual light controls is impractical, the installation of light barriers (shielding) should be considered. This could be used, for example, in areas external to living quarters in order to ensure that adequate lighting is available on external steps but there are limited emissions outside the structure.
- Optimum alignment and light shields:

- Light sources should, if possible and consistent with safe working practices, be positioned in places where emissions to the surrounding environment can be minimised. Additional shielding should also be installed, where practicable.

There are no industry-standard mitigations available with regard to light associated with flaring during initial well clean-up / testing from the MODU in terms of reduction of light impacts. During production, flaring will be minimised and the base-case is for all excess gas to either be used as fuel on the FPSO or to be re-injected into the reservoir (Sections 5.8.3.3 and 5.8.5.9).

10.1.6 Impact and risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. The assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes is tabulated in Section 10.1.12, which shows the worst-case impact / risk for each activity and receptor.

10.1.6.1 Impact assessment of attraction to offshore artificial light

10.1.6.1.1 Attraction of marine life (zooplankton, fish and squid)

Any impact of the project's Phase 1 & 2 Development on zooplankton, fish and squid is expected to be very small and localised. Vessels in transit should only be displaying navigation lights, which are of low light intensity (Section 10.1.4.1.3). Additionally, relatively slow-moving plankton, fish and squid would be unable to maintain position alongside a moving vessel. Therefore, the impact on this group of receptors is likely to be greatest around the MODU, FPSO and stationary vessels; where the surface of the water may be illuminated. These animals may be attracted to the lights of the vessels but there is nothing to suggest that this should be regarded as a significant impact on these organisms, although there could be some indirect impacts. For example, squid and fish may be attracted to the vessels to feed on zooplankton and may in turn be an easier target for larger squid, fish, seabirds or marine mammals. Nonetheless, given that there is likely to be 'negligible numbers of any species of geographical importance' (as per the methodology described in Chapter 8) present within the zone of influence, the sensitivity of this receptor group is considered to be '**Very Low**'.

It is anticipated that the impact on zooplankton, fish and squid will be very localised (in the immediate vicinity of the vessels) and any impacts resulting from changing predation patterns will 'not be detectable above background variability' and / or will be 'reversible once activity ceases'. Therefore, the severity of the impact is assessed as '**Slight**'.

Therefore, the overall significance of the impact of artificial light on zooplankton, fish and squid is assessed as '**Very Low (1)**'.

10.1.6.1.2 Attraction of seabirds in the Sea Lion Field

As indicated in Section 10.1.4.3.1.4, not all seabirds are susceptible to the impacts and risks associated with artificial light and flares. The available survey data indicate that there will be a low number of individuals of all of the potentially susceptible species present within the zone of influence of the Development (Section 10.1.4.3.1.4, Table 7.17 and Table 7.23) Although accurate population estimates are not available for all species, the biogeographical populations are known to be very large. Therefore, it is anticipated that the assemblage of birds within the zone of influence of the Development, at any given time, will not be of geographical importance (i.e., <1 % of the local population). As shown in Table 10.4 above, the majority of species that are typically impacted in the south-west Atlantic have an IUCN status of 'Least Concern'. Atlantic petrels (IUCN 'Endangered') are occasionally sighted in the

NFB but they are not considered to be a notable presence within the zone of influence of the Development. Therefore, the sensitivity of the receptor is considered to be '**Low**'.

In the absence of collision, mortality after contact with a flare or oiling of feathers (Section 10.1.4.3.1.1), the severity of effect on seabirds from simple attraction to artificial lights or flares is expected to be low. Seabirds may be distracted from natural feeding behaviour, or may expend energy flying in circles around the vessel (Burger, *et al.*, 2019). This has the potential to affect the body condition of the birds, particularly during migratory movements. However, if the impact is short-lived (a matter of hours), and there is no contact between the birds and the vessel, the long-term consequences are anticipated to be low. Therefore, the severity of effect of distraction by artificial light or flares (i.e., with no resultant contact with the vessel) to seabirds is considered to be '**Slight**'.

The overall significance of the impact of distraction of seabirds by artificial light or flares (i.e., the birds do not come into contact with the vessel or flare) is assessed as '**Very Low (2)**'. However, the distance from which birds are attracted to light remains unclear and the impact could be higher, if light detection is further than commonly reported (5-15 km) (e.g., Rodríguez, *et al.,* 2014).

Please also see Section 10.1.6.2 below which assesses the impacts where contact with the vessel is made.

10.1.6.1.3 Attraction of seabirds in Berkeley Sound

As indicated in Section 10.1.4.3.1.4, not all seabirds are susceptible to the impacts and risks associated with artificial light. Within Berkeley Sound, sooty shearwater is the species of greatest concern, although other species, such as, great shearwater, common diving-petrel, Wilson's and grey-backed storm-petrel are also thought to breed on Kidney Island and are present in the waters adjacent to the Sound. The colony of the IUCN 'Near Threatened' sooty shearwaters on Kidney Island is situated approximately 10 km from the indicative LTV anchorage location and during the Phase 1 & 2 Development, the LTVs will be present for short durations only, with a maximum duration of 13 months in total between Stages 1 and 3 of the Development (Section 5.5.1). The IUCN status indicates that the sensitivity of the sooty shearwater as a receptor is 'Moderate'. However, Kidney Island is the largest of the known colonies in the Falkland Islands and represents a significant proportion of the biogeographic population (i.e., >1 % of the South Atlantic population[49]). Although the shearwaters are only present for part of the year (September to May) and this may or may not overlap with the presence of the LTVs, the worst-case sensitivity of the receptor is considered to be '**High**'[ibid].

In the absence of collision or oiling of feathers (Section 10.1.4.3.1.1), the severity of effect on seabirds from simple attraction to artificial lights is expected to be minimal. Although sooty shearwaters do feed inshore, these birds gather in large numbers at the entrance to Berkeley Sound late in the day (between September and May) but do not return ashore to visit nest burrows until dusk. Experience from elsewhere in the world, suggests that lights do not prevent adult shearwaters from returning to their colonies and impact on fledglings is of greater concern (Rodriguez, *et al.,* 2015a & b). Therefore, the severity of effect of distraction by artificial light (i.e., with no resultant contact with the vessel) to seabirds is considered to be '**Slight**'.

Overall the significance of the impact of distraction of seabirds by artificial light (i.e., the birds do not come into contact with the vessel) is assessed as '**Low (4)**' [ibid].

[49] **Post-consultation update (July 2025):** Table 7.23 in Section 7.4.5.3.3 above has been updated showing that the Falkland Islands population of sooty shearwaters is now considered to be 3.2 % of the global population (BirdLife International, 2025). As such, according to the methodology Section 8.5.2.1, the sensitivity of the receptor would now be considered '**Very High**'. However, the overall impact category remains the same, changing from '**Low (4)**' to '**Low (5)**'.

Please also see Section 10.1.6.2 below which assesses the impacts where contact with the vessel is made.

10.1.6.2 Risk assessment of artificial light use

Given the number of variables that influence the potential for bird-strikes it is challenging to assess the risk of bird strikes with the Phase 1 & 2 vessels (Section 10.1.4.1). It can be stated however, that collision with a vessel or installation, and then landing on a deck, may result in injury to a wild bird that is likely to have implications for the survival of the individuals concerned (Section 10.1.4.3.1). Additionally, collision with a flare may result in mortality (Section 10.1.4.3.1.1).

10.1.6.2.1 Risk of small scale seabird strikes in the Sea Lion Field

The sensitivity of the receptors in the Sea Lion Field is as described above in Section 10.1.6.1.2. Therefore, the sensitivity of the seabird receptors impacted by artificial light has been assessed as '**Low**'.

Where a single bird-strike occurs, the effect is localised and it is unlikely that any impact will be detectable above background variability and therefore will not pose a threat to the populations of the species involved. Although birds may be killed, which is clearly undesirable, the severity of effect of artificial light at this scale is considered to be '**Slight**'.

The overall significance of the impact of small-scale seabird strikes in response to artificial light and flares is considered to be '**Very Low (2)**'.

With regard to the likelihood of a single bird-strike event occurring, observations on other vessels operating within Falkland Islands waters indicate that these small-scale events occur on a regular basis. Although the results of observations during the 2015 exploration drilling campaign suggest that these events occur less frequently, small scale bird-strike events, concerning low numbers of birds, are likely to occur on multiple occasions per year. Therefore, the likelihood of a single bird-strike is considered to be '**Likely**'.

The overall significance of the risk of single bird-strike events is therefore considered to be '**Low (4)**'.

10.1.6.2.2 Risk of multiple (large scale) seabird strikes in the Sea Lion Field

The sensitivity of the receptors in the Sea Lion Field is as described above in Section 10.1.6.1.2. Therefore, the sensitivity of the seabird receptors impacted by artificial light and flares has been assessed as '**Low**'.

Multiple bird strike events can result in hundreds of bird mortalities in a single night, however, these events usually occur close to land (i.e., breeding sites) where some birds congregate at dusk. The Sea Lion Development is 220 km offshore, in an area that supports relatively low seabird densities throughout the year, and therefore it is not considered likely that multiple bird strikes will occur on a regular basis. While, like all seabirds, the susceptible species are relatively long-lived, reproduce slowly and have low natural adult mortality rates, the biogeographic populations of the most susceptible species are very large (millions of individuals) and so it is not anticipated that the impact of light induced bird-strikes from the Sea Lion Development will affect the local populations. Losses at this scale however, may add cumulatively to mortality caused by other sources of anthropogenic light. Additionally, concern regarding this issue was expressed by stakeholders during scoping (Chapter 6) and has been raised as an issue within the Falkland Islands' Offshore Hydrocarbons Environmental Forum (FIOHEF, 2013). Therefore, there is a need to identify opportunities for improvement through mitigation and controls, and to consult with project stakeholders. On balance, the severity of effect of multiple seabird strikes caused by artificial light or flares is considered to be '**Moderate**'.

The overall significance of the impact of multiple seabird strikes in response to artificial light or flares is considered to be '**Moderate (6)**'.

With regard to the likelihood of a multiple bird-strike event occurring, such a strike is likely to occur less than once per year but more than once in 10 years. Therefore, the likelihood of a multiple bird-strike is considered to be '**Possible**'.

Therefore, the overall significance of the risk of multiple bird-strike events is considered to be '**Moderate (9)**'.

10.1.6.2.3 Risk of small-scale seabird strikes in Berkeley Sound

The sensitivity of the receptors in Berkeley Sound is as described above in Section 10.1.6.1.3. Therefore, the sensitivity of the seabird receptors is considered to be '**High**'[50].

Where a single bird-strike occurs, the effect is localised and it is unlikely that any impact will be detectable above background variability (considering the area is already subject to a high degree of light pollution from fishing vessels), and will not pose a threat to the populations of the species involved. The LTVs will only be present within Berkeley Sound for a limited amount of time (i.e., for up to twelve months) (Section 10.1.2). Therefore, the severity of effect of artificial light and losses of this scale is considered to be '**Slight**'.

The overall significance of the impact of single seabird strikes in response to artificial light is considered to be '**Low (4)**'.

With regard to the likelihood of a single bird-strike event occurring, observations on other vessels operating within Berkeley Sound indicate that these small scale events occur on a regular basis. Therefore, the likelihood of a single bird-strike is considered to be '**Likely**'.

Therefore, the overall significance of the risk of single bird-strike events is assessed as '**Moderate (8)**'[ibid].

10.1.6.2.4 Risk of multiple seabird strikes in Berkeley Sound

The sensitivity of the receptors in Berkeley Sound is as described above in Section 10.1.6.1.3. Therefore, the sensitivity of the seabird receptors is considered to be '**High**'[51].

Multiple bird strike events can result in hundreds of bird mortalities in a single night, these events usually occur close to land (i.e., breeding sites) where birds congregate at dusk. However, the situation in Berkeley Sound is unusual in that the indicative LTV anchorage location is situated approximately 10 km inshore of the breeding colony, so birds will not routinely pass the site *en route* to the colony. This is significant as multiple seabird strikes are closely linked to weather conditions (Section 10.1.4.3.1.3) and are more likely to occur when visibility is reduced due to fog or snow. However, under these conditions, the deck lights of vessels may not be visible at a range of 10 km such that the zone of influence is effectively reduced. The severity of the impact would be higher for vessels entering or departing from the Sound, which would pass close to the colony on Kidney Island.

---

[50] **Post-consultation update (July 2025):** Table 7.23 in Section 7.4.5.3.3 above has been updated showing that the Falkland Islands population of sooty shearwaters is now considered to be 3.2 % of the global population (BirdLife International, 2025). As such, according to the methodology Section 8.5.2.1, the sensitivity of the receptor would now be considered '**Very High**'. However, the overall impact category remains the same, changing from '**Low (4)**' to '**Low (5)**'. The risk category of '**Moderate (8)**' remains unchanged.

[51] Post-consultation update (July 2025): Table 7.23 in Section 7.4.5.3.3 above has been updated such that the Falkland Islands population of sooty shearwaters is now considered to be 3.2 % of the global population (BirdLife International, 2025). As such, according to the methodology Section 8.5.2.1, the sensitivity of the receptor would now be considered '**Very High**'. However, the overall impact category remains the same, changing from '**Moderate (8)**' to '**Moderate (10)**'. The risk category of '**Moderate (9)**' remains unchanged.

The greatest impact is likely to affect fledglings, which seem to be more susceptible to disorientation by artificial light than adults regardless of weather conditions. Fledging is a once in a lifetime event that occurs over a period of several weeks for the entire population (during April and May). However, the overlap between LTV activity, and fledging is expected to be limited with the maximum duration of LTV presence being 13 months in total (Section 5.5.1).

Berkeley Sound has been the focus of shipping activity for many years. There is considerable light pollution in the area (Section 10.1.9.2), primarily from vessels engaged in transhipment, although this can vary considerably from year-to-year depending on squid (*Illex*) catches. Nonetheless, while there are records of bird-strikes in Berkeley Sound at this time (R. James, *pers. comm.*), the issue has not been investigated in great detail and the population of sooty shearwaters on Kidney has apparently increased (Woods and Woods, 1997; Clark, *et al.,* 2019).

Therefore, the current impact is not thought to be a threat to the population of sooty shearwaters and therefore the severity of the effect of the additional light from LTVs is considered to be '**Minor**'.

The overall significance of the impact of multiple seabird strikes in response to artificial light from Inshore vessels is considered to be '**Moderate (8)**'[ibid].

The LTVs will be present in the Sound for a combined period of up to 13 months for all LTVs. Nonetheless, it is likely that more than one multiple bird-strike may occur during this intermittent period and therefore the likelihood of a multiple bird-strike is considered to be '**Possible**'.

The overall significance of the risk of multiple bird-strike events is therefore considered to be '**Moderate (9)**' [ibid].

10.1.6.3 Indirect impacts and impact interactions

Other marine life may be indirectly impacted by artificial light and flares if it is attracted to food sources clustering beneath vessels. For example, where marine mammals are attracted to food sources which were initially attracted by the light, this may render marine mammals more vulnerable to underwater noise. Equally, diurnal birds may be attracted to additional food sources and, once attracted there is the risk of these birds colliding with the structure, flare or becoming contaminated from any minor oil spills.

Further, 'additive or synergistic' impact interactions (Section 8.9) may occur where attraction of marine life and seabirds to artificial light or flares then increases the likelihood of other impacts, such as those associated with underwater noise (Sections 10.4 and 10.5), operational discharges (Section 10.7) or accidental spills (Chapter 12). An overview of the potential for impact interactions is provided in Chapter 13.

10.1.7 Project-specific mitigation

It is best practice to minimise any impacts to the marine environment and the amount of light spilling horizontally into the environment will be minimised where practical and possible.

10.1.7.1 Reducing light pollution

During the FPSO FEED process, the number of lights and light levels on the FPSO topsides, and other external areas, will be reviewed. The minimum and maximum luminance levels for general and emergency operating conditions shall be in accordance with IEC 61892-2'. OSPAR Agreement 2015/08 (Section 10.1.5) will also be followed in the Best Practical Environmental Option (BPEO) process during FPSO design.

Likewise, during the direct offtake the decks and water around vessels will be illuminated to provide a safe working environment and to facilitate monitoring of spills, leaks or other potential hazards.

Nonetheless, Navitas recognise there is a driver to minimise light pollution from all project vessels particularly in the South Atlantic region, to limit the incidence of bird strikes. A summary of the design and auditing procedures associated with the project vessels is provide in Table 10.6. However, while lighting will be minimised from a cost / maintenance perspective, there is limited opportunity to implement additional measures specifically designed to reduce the risk of bird strike.

Shielding of light is a possible method of limiting the intensity of light emissions in certain directions but, if done without proper thought or analysis, it can actually increase overall light emissions. For example, applying shielding after lighting has been designed can increase the illumination of the work area, whereas if it is applied as part of the lighting design it can reduce the required output of the lighting units. Intelligent shielding at the design stage can reduce attraction of birds to lighted structures and significantly reduce associated mortality (MMS, 2010). Lights can also be designed to minimise upward emissions where these are not required.

As shown in Figure 10-3 the issue of bird-strikes is recognised by the cruise ship industry in the Southern Ocean and the International Association of Antarctic Tour Operators (IAATO) has guidelines for their vessels, which have been adopted by other operators in the region. Some of these measures are practical for use on the FPSO, supply and installation vessels, the ERRV and the MODU. These include:

- Dousing of deck lighting on supply vessels when not in use, necessity and emergencies notwithstanding, and
- Dousing of helideck landing lights when not in use and at night, if this is permissible (e.g., helidecks may need to be kept available to third-party aircraft in distress).

Elsewhere in the South Atlantic, the issue of bird-strikes on fishing vessels operating around Tristan da Cunha has been managed through a strike policy of blacking-out at night (Glass and Ryan, 2013). However, this is clearly not feasible in an industry that operates 24 hours a day.

As far as possible without increasing safety risks, it should be an aim to coincide planned flaring, such as flaring during initial well clean-ups / testing (contingency only) and blowdowns in preparation for periods of maintenance during Stage 3, with daylight hours. This intent will be carried forward into the flaring policy in the FPSO operating procedures. Further mitigation measures (e.g., the use of different light spectra and the use of a ballistic flare ignition system to negate the need for a pilot light) will be explored in the FEED process with Reliability, Availability and Maintenance (RAM) studies conducted for viable options. Ongoing monitoring during the operation will serve to validate the impact assessment and adjust the use of mitigation measures as necessary. Monitoring of light-related impacts forms a part of the EMMP (Chapter 15) and further mitigation will be discussed should adverse impacts be identified.

Table 10.6: The design and auditing procedures associated with lighting on project vessels

Vessel	Design / auditing procedure
FPSO	Overall, the design intent will be to ensure the right level of light coverage to extend to the edges of structures (where there are often walkways and escape routes). Attempting to shield individual lights onto focused areas will likely lead to neighbouring areas not meeting the specified minimum values and hence, additional lights would be required, which may ultimately serve to increase the overall level of light pollution. Application of OSPAR 2012.
MODU	The MODU will undergo a strict regime of acceptance audits in line with Navitas' rig acceptance processes. Part of these audits, albeit primarily for safety, will include a lighting survey which may identify unwanted light emissions and recommend practical shielding and operational practices to minimise unwanted light taking account of safety and operational requirements (application of OSPAR, 2012). The outputs of this survey will be incorporated

Vessel	Design / auditing procedure
	into the Master Corrective Actions Register for the rig along with all other HSE actions. Crew inductions will include information about the risks of unnecessary light alongside other HSE priorities. The BSMP will feed back into ongoing operational adjustments and incident resolution.
Contracted third-party vessels	Navitas has limited control over third-party vessels; nevertheless the importance of minimising light will be communicated to contractors tendering for the work and they will be asked to make a statement on their proposals to minimise unwanted light as part of their tender evaluation. Ongoing operational reviews and crew inductions will include information about the risks of unnecessary light. Navitas vessels representatives will be responsible for ensuring bird-strikes are recorded and incidents resolved satisfactorily.
CTT	Site-specific HSE priorities including unwanted lighting will be communicated to incoming CTTs and all vessels hired by Navitas. Support vessels will communicate directly with any vessel that appears to be emitting unnecessary light to minimise sources.

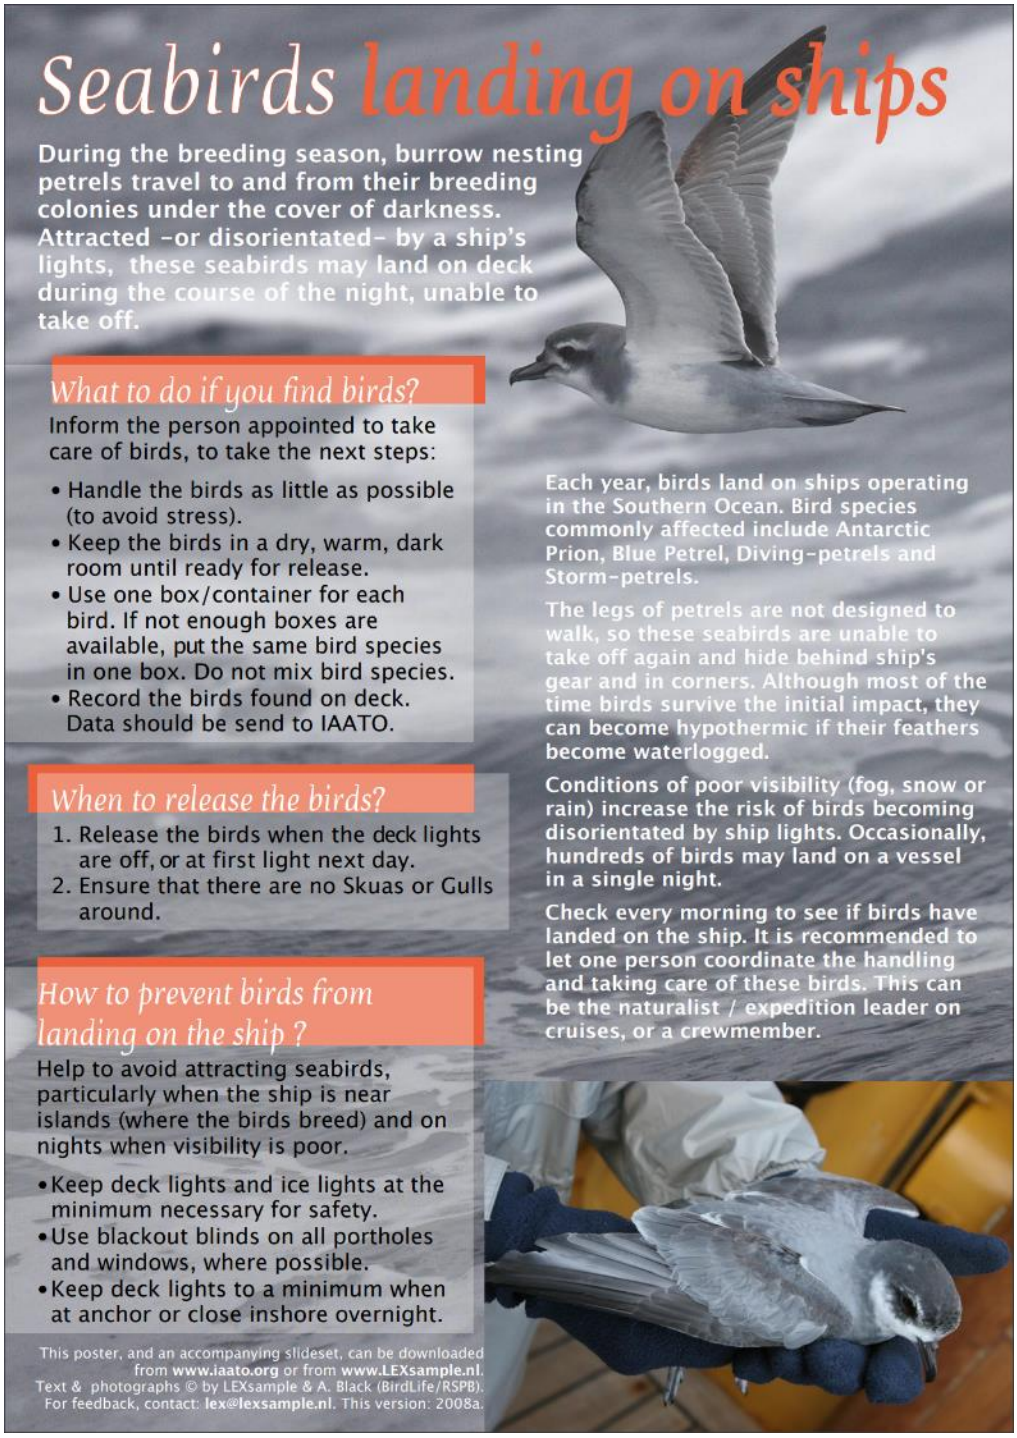

Figure 10-3: Example of an educational poster for the management of birds on deck ***(Source: www.LEXsample.nl)***

10.1.8 Residual impact assessment

The impacts on zooplankton, invertebrates, fish and seabirds associated with artificial light offshore are considered to be of '**Very Low**' or '**Low**' significance such that no mitigation measures are considered necessary.

However, the risks of large-scale seabird collisions in offshore waters of the NFB and both small and large-scale seabird collisions in Berkeley Sound are '**Moderate**'. While numerous mitigation options exist that may be incorporated into the design of vessels, until further investigation during the FEED process, with associated RAM studies, has been conducted to indicate that these are effective, the risk of collisions must remain the same as described above[52].

10.1.9 Cumulative impacts

Under natural conditions, the only sources of light at-sea are moonlight, starlight and bioluminescence. In addition to the artificial lights from the Phase 1 & 2 Development, there are currently several other sources of anthropogenic light in the wider area of the NFB and in Berkeley Sound which can lead to cumulative impacts from increased 'concentration' and increased 'extent and proportion' (Section 8.9.1).

10.1.9.1 Sea Lion Field

The most significant source of artificial light in the south-west Atlantic is the *Illex* (Argentine shortfin squid) jigging fleet (Table 10.7; Figure 10-4 and Figure 10-5). Numbers of jiggers fishing in the Falklands EEZ varied until about 2011 when numbers of licenced vessels plateaued at between 99-109 vessels (FIG, 2024b). The distribution of these vessels can be followed *via* satellite images (Rodhouse, *et al.,* 2001; Waluda, *et al.,* 2008), which have been used to quantify fishing effort. The presence of Argentine shortfin squid, and the vessels that fish for them, within Falklands waters is seasonal and the licence period extends from February to June (FIG, 2014a). Therefore, jigger fishing vessels represent a seasonal high intensity source of anthropogenic light in the NFB (Table 10.7).

A small number of jiggers have FIFD (Falkland Islands Fisheries Department) observers deployed on board every year, which has provided some evidence of interactions between these vessels and seabirds inshore. For a short period, dedicated seabird observers were deployed on jiggers to assess the degree of seabird bycatch on these vessels. Although the focus of these observations was interactions between seabirds and fishing gear, there was no evidence to suggest that these vessels had a significant bird-strike problem (Wolfaardt, *et al.,* 2010). It is not clear why bird-strikes are not a more significant issue on jigger vessels. It could be that the lights are so bright that birds are able to see the superstructure of the vessels and therefore avoid collisions; however, this remains unproven. Some jiggers (especially Korean vessels) use lights that are tinted green. Studies in the North Sea (Poot, *et al.,* 2008) have shown that the wavelength of light emitted influences the behaviour of birds. However, many jiggers appear to use white light so this would not mitigate the fleet as a whole.

The additional light of the MODU and supporting vessels will add to light emitted by other vessels in the NFB and therefore adds to the extent of artificial light and proportion of seabird populations exposed to artificial light in the NFB. However, it is not anticipated that this will constitute a significant cumulative effect due to the overwhelming influence of the jigging fleet. Nonetheless, the Sea Lion Development vessels will be operating year-round, whereas the presence of fishing vessels is seasonal. Additionally, the effect of artificial light attracting birds to the Development site may expose these birds to other impacts, such as accidental spills, that they would otherwise not be exposed to, although it is noted that accidental spills are not solely related to O&G operations.

10.1.9.2 Berkeley Sound

Places of human settlement and industry ashore represent permanent sources of light pollution. In the Falklands, these are primarily associated with the two major population centres, Stanley and Mount

[52] **Post-consultation note (July 2025):** The residual impact assessment does not take account of measures that may be written into the vessel ASOGs as described in Section 5.5.1 above regarding entrance routes into Berkeley Sound and avoidance time windows. These will be determined in consultation with relevant stakeholders prior to operations.

Pleasant Complex (MPC). Additionally, Berkeley Sound is used as an anchorage for the trans-shipment of fish and is also a significance seasonal source of light pollution.

Sources of existing anthropogenic light within Berkeley Sound are summarised in Table 10.7. Notably, the jiggers described above utilise Berkeley Sound to tranship their catches to refrigerated cargo ships known as 'reefer' vessels and to refuel. Although the full rig of jigging lights are not deployed in Berkeley Sound, there is a considerable amount of light emitted from these vessels, the glow from which can be seen from Stanley (A. Black, *pers. obs.*) and can also be seen from space, resembling a small town (Figure 10-6). It is noted that 2007 (see Figure 10-5 and Figure 10-6) was a busy year for jiggers and this year was chosen to illustrate the magnitude of artificial light sources already in the south Atlantic, to which Navitas will make a relatively minor contribution.

In addition to the jiggers, other vessels use Berkeley Sound as an anchorage, primarily for the transshipment of fish catches.

Although vessels can be present in all months of the year, activity peaks between March and June when tens of vessels can be present. Combined, these vessels represent a large source of anthropogenic light. The inshore LTVs will add to this with varying degrees of significance depending on timing / season. The period of greatest conservation concern is linked to the sooty shearwater fledging, which occurs in April and early May.

At other times of the year, there may be very few vessels using Berkeley Sound and therefore the LTVs will add considerably to the ambient level of light pollution but these are likely to be periods when very few susceptible receptors are present.

The data presented in Figure 10-5 and Figure 10-6 are a composite of the data collected over the period of a year (2007 in this case) to display the average light intensity. Vessel activity within Berkeley Sound is highly seasonal and therefore the light intensity within the Sound during the period of peak vessel activity (March to May) will be considerably higher than illustrated (for example, the value for a light only detected half the time is discounted by 50 %).

Table 10.7: Other sources of artificial light in the NFB and Berkeley Sound

Source	Light source	Seasonality / frequency	Description
NFB			
Coasters / Freighters / Tankers	Navigation lights and Accommodation lights.	Year round	Several shipping routes pass close to the Sea Lion Field (see Section 11.1)
Finfish trawl fleet	Navigation lights, Accommodation lights and Deck lights.	During two fishing seasons (Feb to May and Aug to Nov)	Operates along the edge of the continental slope (200 m depth contour) approximately 50 km to the south and west of the Sea Lion Field (Section 7.7.3.1.1.1). Although these vessels often stop fishing at night, deck lighting may remain on throughout the night.
Illex jigging fleet	Navigation lights, Accommodation lights, Deck lights and Squid jigging lights.	Between February and June	Operates over the continental shelf to the south and west of the Sea Lion Field. These vessels use powerful arrays of lights (up to 150 bulbs totaling 300 kW per vessel) to attract squid to jigging lures. The size of the jigger fleet and distribution of fishing effort are related to squid abundance, which can vary considerably from year-to-year.
Berkeley Sound			
Reefers	Navigation lights, Accommodation lights and Deck lights.	Peak activity during the *Illex* season (March to June)	The number of reefers varies considerably from year-to-year and is closely linked to the amount of *Illex* squid caught each year.
Finfish trawl fleet	Navigation lights, Accommodation lights and Deck lights.	During two fishing seasons (Feb to May and Aug to Nov)	Trawlers are licensed to fish in two seasons and can be present in small numbers in most months of the year. However, due to the generally small catch these vessels visit Berkeley Sound far less frequently than jiggers
Illex jigging fleet	Navigation lights, Accommodation lights, Deck lights and Squid jigging lights.	Between February and June	During periods of good fishing, each jigger in a fleet of approximately 100 vessels, may visit Berkeley Sound on a weekly basis. However, catches show very high inter-annual variation (Section 7.7.3.2.1). Jiggers tend to use 4-6 of the fishing lights to illuminate the deck when transhipping.
Fueling vessels	Navigation lights, Accommodation lights and Deck lights	Year round	Vessels bunkering fuel

10.1.10 Confidence

While the approximate timing and type of vessels used during the Phase 1 & 2 Development of the Sea Lion Field is known, the intensity and orientation of lights on the FPSO, MODU, and other vessels are not yet quantifiable, and representative, analogous examples have been used in this assessment. Additionally, there is the potential that flaring may be undertaken during up to four well tests (contingency only) over four days and will also be required periodically during process and emergency shutdowns, and in the event of emergency blowdowns.

The nature of the impact on the environmental receptor is understood, however, the scale of the potential impacts and risks are difficult to predict due to their episodic nature; this is acknowledged as a data gap. Some monitoring data exist from previous Falklands campaigns, although these were short-term and did not directly record a significant issue with bird-strikes. While some specific survey data exist for seabirds in the wider NFB and the area around the Sea Lion Field, these data are limited to very short time points and lack good spatial coverage over several years that would take into account the temporal and spatial variability of such mobile species. Therefore, although it can be assumed that some birds may be killed as a result of bird-strikes, it is not possible to predict the potential impact in quantitative terms.

The use of deck lighting, occurrence of potentially susceptible species (albeit in low numbers offshore) and the likelihood of poor weather conditions (reduced visibility) combined suggest that some incidents of bird-strike are likely to occur throughout the life of the Development. Navitas' BSMP will help to determine the accuracy of this assessment and inform future management plans. The initial focus of the BSMP is monitoring, but also includes awareness training for workers on the MODU and other vessels. The information collected should help to better assess whether bird-strikes associated with the O&G industry are an issue in the Falklands and prompt additional mitigation, if required.

With the available data, the level of confidence in the impact predictions (in terms of the nature of the impact and its level of significance) is considered to be '**Probable**'. Additionally, the data gaps are not considered to have the potential to significantly change the outcome of the assessment.

10.1.10.1 Monitoring required

As during the 2015 exploration drilling campaign, Navitas will develop and implement a BSMP, which describes the processes required to monitor, record and report seabird interactions during the Development.

The Bird Collision Observation Form will be submitted to FIG on a monthly basis (at a minimum) and the contributing factors for the events that result in bird-strikes will be reviewed. If it is determined that any bird-strike events have similar contributing factors, or a trend is identified, the most appropriate mitigation measure will be identified and implemented.

Opportunistic observations of rare events have highlighted the potentially deleterious nature of bird-vessel interactions (e.g., Ryan, 1991; Black, 2005a) and observations were made of bird-strikes during the previous exploration campaign. However, systematic observations by trained independent observers would provide more valuable data towards better understanding of bird / vessel interactions.

Offshore, Navitas will use independent Seabird and Marine Mammal Observers (SMMOs) on support vessels and investigate the possibility of a collaborative survey with FIFD, potentially using the fisheries patrol vessel as a platform. A seabird distribution monitoring programme will be developed over several years with an understanding of ongoing work and in collaboration with FIFD, if possible. This will cover the offshore area, transit zones and targeted onshore colonies. Dedicated seabird observers will be deployed offshore during any initial well test and commissioning flaring to quantify any impacts.

The practicalities of adopting the OSPAR green lighting strategy will be investigated during the project FEED phase as a potential additional mitigation against bird-strikes. Navitas will also investigate a pilot-free flare design using an automated ignition system.

Detailed monitoring requirements have been established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline of the EMMP is provided in Chapter 15).

10.1.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

10.1.12 Findings summary

Table 10.8: Summary of the impacts and risks associated with artificial light offshore and inshore arising from the Phase 1 & 2 Sea Lion Development

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control

10.2.12 Findings summary 657

10.2.1 Introduction

There is the potential for aircraft noise to impact upon colonies of penguins and seals (Hughes, *et al.,* 2008) and also to impact upon livestock and the human population. Concern over such impacts was raised by stakeholders during the scoping consultation (Chapter 6).

This chapter investigates the potential for disturbance to penguins and other wildlife caused by the use of helicopters during the transport of personnel to and from the offshore Sea Lion Field. The potential for social impacts and disturbance to livestock and the human population from helicopter noise and other sources of noise is described in Section 11.9.

Note: the other impacts associated with helicopter use e.g., atmospheric emissions, are described elsewhere in this document, as described in Table 2.2.

10.2.1.1 Relevant legislation

There are numerous pieces of International and Overseas Territory legislation in place to govern air safety which are out with the scope of this EIA which is only concerned with environmental and social impact and risk.

Aviation activities within the Falklands specifically are overseen by Falkland Islands Civil Aviation Department (FICAD). Their work is principally governed by the following:

- Air Navigation (Overseas Territories) Order (AN(OT)O) (2013), and
- International Conventions and Standards ('Rules of the Air').

While no legislation is in place specifically with regards to the environmental impacts of disturbance, guidelines have been developed in the Falklands, and elsewhere, to minimise the impact due to concerns over disturbance to wildlife and livestock from low flying aircraft. Detail on these guidelines is provided in Section 10.2.5 below under Industry-Standard mitigations.

10.2.2 Sources of impact and risk

During the Phase 1 & 2 Development the use of helicopters will be required:

- To carry personnel and / or equipment to and from the Mobile Offshore Drilling Unit (MODU) in Stages 1, 2a & 2b and the Floating Production, Storage and Offloading (FPSO) vessel throughout the project life,
- To carry personnel and / or equipment to and from the FPSO in Stages 2a, 2b & 3,
- To carry a Falklands marine berthing crew to and from the purchaser's Conventional Trading Tanker (CTT) prior to each direct offtake operation, and
- For Search and Rescue (SAR) exercises and test flights.

10.2.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify the specific receptors upon which the impacts and / or risks associated with helicopter use warranted further investigation (Chapter 9). The specific receptors that may be impacted include:

- Seabirds (Section 7.4.5), and
- Marine mammals (seals) (Section 7.4.6).

While cetaceans at or near the surface may experience brief exposure to helicopter overflight noise, such events are typically transient due to the rapid transit of helicopters and their operational altitudes, which exceed 3,400 feet except during take-off and landing. Given that cetaceans generally spend limited time at the surface—particularly in comparison to hauled-out seals or seabird colonies—any disturbance is expected to be minimal. Consequently, helicopter noise is not considered a

significant factor in this assessment. All Sea Lion helicopter operations will be conducted in accordance with the FILFH Guidelines and so the potential impact of helicopter noise on cetaceans is not assessed.

In the Falklands, the most vulnerable receptors are breeding and moulting penguins; a number of species of which will be present on land throughout the year. Similarly, seals haul-out regularly throughout the year on the Falkland Islands to rest and breed.

10.2.4 Characterising and quantifying the impact

In order to characterise the quantify the impact of noise from helicopters, it is necessary to:

- Understand the nature of the impact to seabirds (specifically penguins) and seals, and
- To quantify the number and routes of flights to determine the levels of exposure to noise disturbance.

10.2.4.1 Nature of potential impact to wildlife

Aircraft are increasingly used to support research and other operations in remote environments, such as the Arctic and Antarctic. Although there has been little dedicated research into the effects of disturbance on wildlife, with most evidence coming from opportunistic observations, there is a strong suggestion that low flying aircraft result in both behavioural and physiological changes in penguins and seals (Culik *et al.,* 1990; Cooper *et al.,* 1994; Southwell, 2005).

10.2.4.1.1 Seabirds

Numerous bird species could be disturbed by low flying aircraft. This includes, for example, shorebirds, where disturbance can lead to a flight response, which has an energetic cost, including a loss in foraging time and potentially foraging habitat (Derose-Wilson, *et al.,* 2015; Linssen *et al.,* 2019; van der Kolk, *et al.,* 2020). Nevertheless, the focus of this section is on seabirds and specifically, penguins. This is because of the known overlap between penguin colonies and the proposed helicopter flight paths (see Figure 10.7) and a comparatively poor understanding of the distribution and breeding density of shorebirds. In addition, several seabird colonies in the area of helicopter operations are mixed breeding colonies of Rockhopper penguins and Imperial Shags. Little information exists on low flying aircraft and impacts on shags. However, the impacts reported for penguins (as described below), are likely to be relevant to shags.

Low flying aircraft may invoke particularly strong behavioural responses in penguins, which could lead to trampling of adults, chicks and eggs, and / or the loss of exposed eggs and chicks to predators. Indeed, one well publicised (though unverified) incident of mass mortality of approximately 7,000 king penguins on Macquarie Island was linked to panic caused by the over-flight of a C-130 Hercules aircraft (Rounsevell and Binns, 1991; Cooper, *et al.,* 1994). While a few studies have already linked helicopter activity with local population declines (Thomson, 1977; Wilson, *et al.,* 1990), incidents such as that on Macquarie Island have led to more dedicated research.

The most comprehensive study of the impacts of aircraft noise on penguins was carried out by Hughes *et al.* (2008) at a king penguin colony on South Georgia. This study aimed to quantify the short-term effects of helicopter overflights, with emphasis on:

- The relative effects of different overflight altitudes on behaviour,
- Whether noise levels are associated with specific levels of disturbance, and
- Whether penguin responses change with repeated overflights.

Although no mortality was recorded, the results of the study found significant changes in penguin behaviour during all overflights (at altitudes between 230 and 1,768 m). Differences in behavioural response were recorded between incubating and non-incubating birds with birds sitting on eggs

tending to remain in place and non-incubators moving away from the approaching helicopter. Pre-overflight behaviour resumed within 15 minutes of the aircraft passing overhead and no chicks or eggs were taken by predators as a consequence of the behavioural response to the overflights.

In terms of the specific cause of the impact, no relationship was observed between helicopter noise level and penguin behavioural response in this study. Although the sound of the helicopter is likely to be an important factor, it is understood that the visual disturbance is the greater contributor to the changes in the penguins' behaviour. As a helicopter approaches, the colony becomes silent and penguins, and other birds, look upwards and follow the aircraft as it passes (A. Black, *pers. obs.*). Cooper *et al.* (1994) suggested that penguins react to the visual appearance and size of the helicopter as they would do a natural aerial predator, such as a skua or gull. However, as the study of Hughes *et al.* (2008) progressed, the penguins exhibited a reduced behavioural response to overflights suggesting a degree of habituation to aircraft.

In conclusion, to minimise disturbance to king penguins, Hughes *et al.* (2008) recommended a precautionary approach and suggested that overflights occur at the maximum altitude that is operationally practical, or preferably, that colonies are avoided altogether.

With regard to physiological impacts, a number of studies have investigated the relationship between behavioural response and physiological stress in penguins (for example, Ellenberg, *et al.,* 2006; Ellenberg, *et al.,* 2007). The results indicate that even in the absence of a behavioural response, in incubating birds for example, the animal is still subjected to stress as is evidenced by changes in physiological indicators, such as heart rate, and increased body temperature (Sladen, *et al.,* 1966; Regel and Pütz, 1997). Therefore, the fact that incubating birds did not move from their nest sites does not necessarily indicate the absence of an impact from helicopter overflights. Breeding and other activities, such as moulting, all have associated energy costs and disturbances from helicopter overflights that cause animals to move, or induce a physiological stress response at this time would incur an additional burden in terms of energetic cost. Such physiological stress has been linked to reduced breeding success in penguins and other seabirds (Regel and Pütz, 1997). Moulting penguins fast for about a month and during this time birds lose over 40 % of their body weight (Williams, *et al.,* 1992) such that additional energy expenditure could lead to starvation or have chronic impacts on the survival of individuals (Regel and Pütz, 1997).

10.2.4.1.2 Seals

Seals haul-out throughout the year to rest and to aid thermoregulation and digestion, and therefore this behaviour is an essential part of the animal's routine. If disturbed while on land, seals will usually depart for the water thus escaping the perceived threat. If seals are continually disturbed, the physical exertion and energy expended to haul-out repeatedly, combined with inefficient digestion of food, could disturb the balance of the animal's energy budget and have chronic impacts on survival and reproduction.

Although seen onshore throughout the year, the most sensitive period for these animals is the breeding season. Fur seals and sea lions display complex territorial or harem behaviour, which helps to maintain the genetic fitness of the population. Continual disturbance could interfere with the breeding behaviour of these animals leading to unforeseen consequences for population fitness (French, *et al.,* 2011). Additionally, young animals can become separated from their mothers and therefore from their source of food.

There has been some dedicated research to investigate the impact of disturbance to lactating southern elephant seals. Arnbom *et al.* (1997) found that lactating bouts were shorter in stressful environments, which resulted in pups with lower weaning weights than found in undisturbed pups. Given that

elephant seal pup weight at weaning is directly related to its chances of survival in its first year (McMahon, *et al.,* 2000) there is a direct link between disturbance and pup survival rate.

As a worst-case, it is apparent that some responses of seals to disturbance can be associated with reduced survival and reproduction. However, other less severe responses, such as increased alertness, can be temporary and have little or no impacts on fitness. As with seabirds, the degree of response is linked to the proximity of the aircraft to the animal (Southall, 2005).

10.2.4.2 Quantifying the impact of helicopter disturbance on wildlife

When quantifying the potential impacts of helicopter disturbance on wildlife, it is necessary to consider the following:

- The proposed helicopter activity during the Development,
- Helicopter noise levels,
- The distribution of helicopter-sensitive wildlife, and
- The overlap between helicopter flight paths and seal, sealion and penguin distribution.

10.2.4.2.1 Proposed helicopter activity during the Phase 1 & 2 Sea Lion Development

As detailed in the project description (Section 5.11.3), helicopter flights will occur most frequently during Stage 2a & 2b of the Development when routine flights to the MODU and FPSO may occur up to ten times per fortnight and there are regular flights to coincide with the offtake operation, along with SAR test flights and exercises.

It is likely that crews arriving at Mount Pleasant Airport (MPN) on the fixed-wing flight will be transported by road to Stanley airport, where the helicopters are based, prior to being taken offshore. However, in some instances, the helicopters may collect crews directly from MPN before transporting them offshore, and crews returning would be taken directly to MPN. At the time of writing, it is possible that the SAR aircraft may be based at MPN rather than at Stanley Airport and that the test flights will be conducted in the vicinity of MPN. A summary of the estimated number of helicopter flights that will occur is provided in Table 10.9.

Details on the proposed flight paths are provided in Section 10.2.4.2.4 below.

Table 10.9: Number of helicopter flights during the Phase 1 & 2 Development

Helicopter activity[1]	Stage 1 (31 months, 942 days)		Stage 2a & b (35 months, 1,064 days)		Stage 3 (325 months, *c.* 27 years)	
	Frequency of flights	Number of flights[1]	Frequency of flights	Number of flights[1]	Frequency of flights	Number of flights[1]
Crew change to MODU	10 / fortnight	670	10 / fortnight	750	-	-
Crew change to FPSO					2 / week	2,795
Berthing crew transfer to CTT	n/a	n/a	Per direct offtake (average every 10 days)	106	Per direct offtake (average of 36 / year over Field Life)	972
SAR training	6.7 / month[2]	208	6.7 / month[2]	235	6.7 / month[2]	2,178
Total number of	**-**	**878**	**-**	**1091**	**-**	**5,945**

Helicopter activity[1]	Stage 1 (31 months, 942 days)		Stage 2a & b (35 months, 1,064 days)		Stage 3 (325 months, *c.* 27 years)	
	Frequency of flights	Number of flights[1]	Frequency of flights	Number of flights[1]	Frequency of flights	Number of flights[1]
flights per Stage						
Total	7,914					

[1] Based on an average of 30.4 days per month, and an average of 4.3 weeks per month.
[2] Based upon 20 hours flying per month at 3 hours per trip.

10.2.4.2.2 Helicopter noise levels

The noise received by a receptor on the ground is related to a helicopter's altitude and prevailing weather conditions at the time. Disturbance to wildlife is not purely due to noise (as explained in Section 10.2.4.1 above) but is an important contributor to disturbance. Note that there are no sound level thresholds for disturbance in terrestrial wildlife (or marine animals when on land) and research indicates that there is no direct relationship between noise level and behavioural response (Hughes *et al.,* 2008).

While helicopters are widely used in the O&G industry, there are few data available regarding the sound level generated in-flight. Sound levels are measured in decibels (dB), which is a logarithmic scale and, in effect, an increase in sound level of 10 dB is equivalent to a doubling in the perceived sound level.

The noise experienced on the ground will be directly related to the distance between the helicopter and the receptor. One study, looking at the impact on human health, reported sound levels of 110-115 dB as passengers boarded an idling Sikorsky S92 aircraft (Ognedal, 2012). The same helicopter would be considerably louder when in-flight. BMT (2005) contains measurements of a Eurocopter EC155 B1, a type of helicopter commonly used for O&G shuttle purposes, and reports 88.9 dB at a horizontal distance of 150 m with an overflight at 150 m height (a straight line distance of 212 m). By applying a simple ISO9613-2 attenuation calculation to the scenario, it is likely that the source level was around 144 dB (sound power level) which approximates to 133 dB sound pressure level at 1 m for a spherically spreading source. This allows the sound pressure level at other distances to be estimated. A similar calculation has been undertaken for two other common types of helicopter: Super Puma EC225 and a Sikorsky S-92 (Norske Olje & Gass, 2014). The anticipated levels of sound experienced at different distances from the source are shown in Table 10.10 along with noise levels of actual recordings of flights in the Falkland Islands and day-to-day activities for comparison.

It is important to note however, that environmental factors, especially wind, will influence the propagation of sound and far more sophisticated models would be required to accurately predict the noise level experienced by different receptors at any given point under a range of environmental conditions. Therefore, the values given here should be regarded as a rough guide to sound perceived under still conditions.

Table 10.10: Sound level from helicopter and flight activity experienced at ground level *(adapted from Norske Olje and Gass, 2014; BMT, 2005)*

Activity	Maximum sound level at distance from sound source (dB(A))[1]			
	Equivalent at 1 m	Approx. 100 m	600 m	3,500 m
Super Puma[2] EC225 (idling)	>114	-	*c.* 68	*c.* 43
Sikorsky S92 (idling)	>110	-	*c.* 54	*c.* 39
EC155 (overflight)	133	-	77	48
Sikorsky S61[2] taking off (recorded at MPN)	-	145	-	-
FIGAS Britten-Norman Islander (recorded at Stanley Airport)	-	148	-	-
Comparison with typical noise levels experienced by the public[3]	Chainsaw (120 dB)	-	Conversation (60 dB) Small penguin colony (65 – 69 dB)	Street in the evening (41 dB)

[1] An 'A-weighting' is normally applied to sounds measured by instruments in an effort to account for the 'loudness' as it is perceived by the human ear. Essentially, between 500 Hz and 6 kHz the human ear is much more sensitive, but below and above these frequencies the human ear is not particularly sensitive and the 'A-weighting' takes these sensitivities into account.
[2] Superpumas and S-61s are no longer used in the O&G industry.
[3] After NoMEPorts, 2008.

10.2.4.2.3 The distribution of helicopter-sensitive receptors

The wildlife receptors likely to be most vulnerable to helicopter noise are mostly coastal in distribution. Wildlife colonies of note in the north of East Falkland include:

- The king penguin colony at Volunteer Point. The unusual breeding strategy of this species means that breeding birds will be present year-round, as it takes over a year to raise a chick. This colony supports virtually the entire Falklands' breeding population of this species.
- Gentoo penguins breed between October and February on the coasts of northern East Falkland (e.g., at Seal Bay), but also return to shore to rest at other times throughout the year when they may congregate away from breeding colonies. The number of breeding birds on the coasts of northern East Falkland is approximately 23 % of the Islands' population (Baylis, 2012).
- Magellanic and rockhopper penguins will be on land between September and April while they moult and breed and are at-sea between May and August. When breeding, Magellanic penguins are dispersed around much of the coastline and there are no population estimates although there are colonies at Seal Bay. Rockhopper penguins are relatively uncommon in the north of East Falkland, which supports approximately 2.3 % of the Islands' population.
- There are several small southern giant petrel colonies in the north of East Falkland, at Black Point (Volunteer Lagoon) and Rincon Grande. Generally, the birds return to colonies in September but do not lay until late October with the chicks fledging in late March.
- Eddystone and Volunteer Rocks are used by South American fur seals which favour the seclusion of isolated offshore rocks / small islands (Cárdenas-Alayza, *et al.*, 2016). Fur seals are at their most vulnerable during the pupping, which takes place between October and December.

- There are several locations on the north coast of East Falkland where South American sea lions breed or haul-out (including Diamond Cove, Big Shag Island and Cape Bougainville). Sea lions pup during December and January and are likely to be more susceptible to impacts associated with disturbance at this time.

A visual summary of the above, showing the temporal distribution of colonies on the north coast of East Falkland is provided in Table 10.11, which indicates that colonies of penguins and seals will be present year-round and most predominantly in the austral summer when breeding and moulting occur.

It is likely that other species of seabird and seals would also be disturbed by helicopter over flights (for example, shorebirds Dorose-Wilson *et al.,* 2015, van der Kolk *et al.,* 2020). In the Falkland Islands, areas with notably high wildlife significance are designated as National Nature Reserves (NNRs) (e.g., Volunteer Point), Important Bird Areas (IBAs) (e.g., Kidney and Cochon Islands, Volunteer Point, Seal Bay and Cow Bay and Cape Dolphin) or Ramsar sites (e.g., Bertha's Beach) (Section 7.5.2).

Table 10.11: Temporal distribution of colonies and / or haul outs on and around the northern coast of East Falkland

Species	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
King penguins	Breeding at Volunteer Point											
Gentoo penguins	Breeding			Occasional return to shore to rest						Breeding		
Magellanic / rockhopper penguins	Breeding and moulting				-	-	-	-	Breeding and moulting			
Southern giant petrel	Breeding			-	-	-	-	-	Return to shore for breeding			
South American fur seals	Haul-out throughout year									Pupping		
South American sea lions	Pupping		Haul-out throughout year									pupping

10.2.4.2.4 Overlap between helicopter flight paths and wildlife aggregations

Figure 10.7 below shows the spatial distribution of sensitive environmental receptors and community settlements in the north of East Falkland alongside the expected flight paths associated with the Development.

10.2.4.2.4.1 Flights to the Sea Lion Field

Direct flightpaths between the two main heliports and the Sea Lion Field are indicated by the arrows in Figure 10.7. The flightpath from Stanley Airport to the Sea Lion Field is on a bearing of 340° (I. Ewen, *pers. comm.*).

Flights from MPN directly to the Sea Lion Field will pass close to gentoo breeding colonies on the north coast but this area is not designated as an NNR, IBA or Ramsar site (Figure 10.7).

Helicopters flying between Stanley and the Phase 1 & 2 Development would pass approximately 5.5 km to the west of the king penguin colony at the Volunteer Point NNR / IBA and directly over Seal Bay on the north coast of East Falkland. Seal Bay is designated an IBA due to the populations of breeding rockhopper, gentoo and Magellanic penguins and sooty shearwaters (Section 7.5.2.3.1). Additionally, there are a number of small rockhopper penguin colonies in Berkeley Sound, which are undesignated.

10.2.4.2.4.2 Flights to the CTT

During the direct offtake operation of crude from the FPSO to the CTT, a berthing crew will be transported from Stanley Airport by helicopter to the CTT at an offshore location close to the Sea Lion Field.

Flight paths out to the CTT will generally be similar to those going out to the FPSO but may range slightly further east or west depending on from which direction the CTT is arriving at the field. It is not possible to predict their exact routes at the time of writing but all flights out to the CTT (as with all Sea Lion helicopter flights around the Islands) will comply with the Falkland Islands Low Flying Handbook (FILFH, 2024).

10.2.4.2.4.3 SAR Test Flights

SAR test flights may occur from MPN or from Stanley Airport, as occurred during the 2015 exploration campaign.

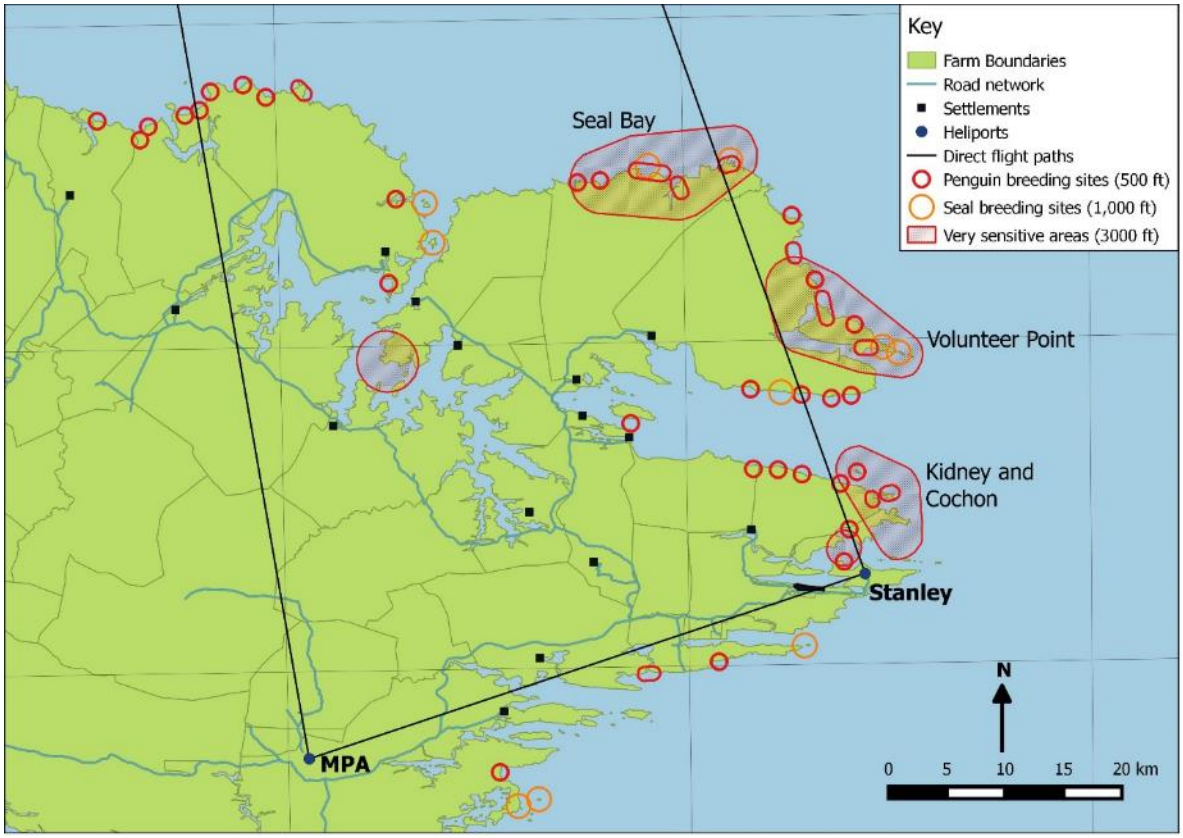

Figure 10.7: The distribution of sensitive wildlife receptors and settlements in relation to the most direct helicopter flightpaths

Note: penguin colonies at Kidney and Cochon islands, Berkeley Sound and Cape Bougainville contained mixed colonies of Rockhopper penguins and Imperial Shags.
Note: the arrows heading out to sea ultimately converge at the Sea Lion Field 220 km offshore.
Note: the sensitive areas shown in Figure 10.7 are taken from the Ministry of Defence's Falkland Islands Range and Avoidance Areas (5-GSGS) map (MoD, 2014).

10.2.5 Industry standard mitigations

While no industry-standard mitigations exist for the O&G industry specifically, guidelines have been developed in the Falklands, and elsewhere, to minimise the environmental impacts of disturbance from helicopters. These include:

- The Ministry of Defence's (MoD's) Falkland Islands Range and Avoidance Areas (5-GSGS) map (MoD, 2014),
- The Falkland Islands Low Flying Handbook (FILFH, 2024), and
- South Georgia Low Flight Avoidance Map (GSGSSI, 2009).

The simplest and most effective way to mitigate the effects of disturbance from helicopter overflights is to route helicopters away from colonies of penguins, other seabirds and seals. Following the example set by the MoD (MoD, 2014) and on other islands such as South Georgia, impact reduction methods (e.g., flight avoidance maps) can be used, which generally have a history of successful use and acceptance.

In addition to guidance on the avoidance of bird activity with regard to flight safety etc., the key avoidance areas are marked on the FILFH avoidance maps. Specifically, the FILFH (2024) lists the following guidance:

- Sensitive areas with increased risk of birdstrike - not to be over flown by any aircraft below 3,000 ft unless landing or taking off. Full details are provided on the Falkland Island Range and Avoidance Areas, GSGS 5563, Ed 5/6,
- National Nature Reserves - to be avoided by 1,000 ft above ground level (AGL) vertically and 0.25 nm laterally unless otherwise specified. See Falkland Island Range and Avoidance Areas, GSGS 5563, Ed 5/6 for more details,
- Sensitive breeding sites - to be avoided by 1,000 ft AGL vertically and 0.25 nm laterally unless otherwise specified. See Falkland Island Range and Avoidance Areas, GSGS 5563, Ed 5/6 for more details, and
- Penguin and Seal Avoids - areas listed as 'known sensitive breeding sites of penguins or seals' are not to be over flown by any aircraft below 1,000 ft AGL. See Falkland Island Range and Avoidance Areas, GSGS 5563, Ed 5/6 for more details.

Importantly, according to the FILFH (2024), the source data for the 'avoid areas' above is unknown. Both the Falkland Islands Director of Civil Aviation and Environmental Departments have been consulted but they do not have a record of the origin. Until a full review can be completed, the GSGS 5563 is to be used as the source document.

In addition to the restricted areas identified on the MoD map and the guidance in FILFH (2024), the following additional recommendations are made in the GSGSSI (2009):

- When following the coastline, maintain a vertical separation distance of 600 m and a horizontal separation of about 500 m from the coastline where possible,
- Cross coasts at right angles and above an altitude of 600 m where possible,
- Never hover or make repeated passes over wildlife concentrations or fly lower than necessary, and
- At all times, the number of animals exposed to disturbance will be reduced to as low as reasonably practical taking account of safety, weather conditions etc.

As the above is considered standard practice within the Falklands, Navitas will develop an approved project-specific flight plan, which should be sufficient to mitigate the impact of helicopter disturbance on wildlife. Navitas will use the flight avoidance map as the basis for flight planning, following the Falkland Islands Low Flying Handbook Guidance (FILFH, 2024). All helicopter pilots will:

- Be briefed on flight avoidance protocols for sensitive areas prior to flying,
- Sign a document indicting that that the FILFH (2024) has been read and understood,

- Be accompanied by a pilot experienced in the area on their first flight, and
- Be issued with an approved flight path.

The above mitigation measures are taken into account during the initial impact assessment described below.

10.2.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

A summary of the impact assessment outcomes for this Development is tabulated in Section 10.2.12, which shows the worst-case impact for each activity.

10.2.6.1 Disturbance to wildlife

Of all the helicopter-sensitive wildlife described, the species of greatest concern is the king penguin as these birds breed year-round onshore, and virtually the entire Falklands' population is in one location at the Volunteer Point NNR / IBA (Section 10.2.4.2.3). As well as passing *cc.* 5.5 km away from the Volunteer Point IBA, direct flight lines from Stanley to the Sea Lion Field would also pass directly over, or close to, a number of small rockhopper penguin colonies at Seal Bay (Figure 10.7). Further, other undesignated but significant penguin colonies and are on (or close to) the direct flight paths between the Sea Lion Field and the Stanley and MPN heliports (Figure 10.7). The national importance of these areas and the species they support means that the sensitivity of the receptors could be considered to be 'Very High'. However, as a flight plan will be in place, in line with the FILFH (Section 10.2.5), the exposure time and the frequency / level of exposure that these colonies will experience is greatly reduced. As the colonies will not actually be exposed to the helicopter noise, the sensitivity of the receptor to the impact of helicopter noise can be considered to be '**Low**'.

The impact of a single helicopter overflight on any population of penguins is likely to be short-term and rapidly reversible. However, the combined impact of numerous (potentially daily) disturbances could have serious implications for the survival of moulting birds or chicks. If this were to continue over a number of years, it could result in a reduction in the local populations or redistribution of known colonies (Section 10.2.4.1.1). Nonetheless, as the FILFH compliant flight plan will prevent such chronic exposure, the severity of effect of helicopter over-flights is considered to be '**Minor**'.

Therefore, the overall significance of the impact of helicopter disturbance on wildlife is considered to be '**Low (4**)'.

10.2.7 Project-specific mitigation

As the impact is considered to be '**Low (4)**', there is no need to consider any additional project-specific mitigation measures.

10.2.8 Residual impact assessment

No residual assessment was carried out as the initial impact was considered to be '**Low (4)**' owing to the use of the FILFH compliant flight plan.

10.2.9 Cumulative effects

Low flying aircraft are a common sight around the Falkland Islands and therefore there is the potential for cumulative impacts in the form of increased 'concentration', 'extent and proportion' and 'duration' (Section 8.9.1).

The Government Air Service (FIGAS) operates a small fleet of Britten-Norman Islander fixed-wing aircraft that transport passengers and small quantities of freight around the Islands, most of which

have an airstrip. Additionally, there are a number of military fixed-wing aircraft (from Typhoon jets to A400N Atlas) that regularly practice low-level flying around the Islands.

In addition to the Navitas helicopters, there are a number of helicopters based at MPN that are used for SAR and transporting military personnel and cargo around the Islands. Additionally, helicopters fly visitors to some of the offshore islands that support concentrations of wildlife and occasionally overfly Stanley. SAR helicopters occasionally undertake exercises in Stanley Harbour and deliver patients to the King Edwards Memorial Hospital (KEMH), landing on the school's football pitch.

In recognition of the threat posed by low-flying aircraft to wildlife, and also the risk of bird strikes and damage to aircraft, all flights within the Falkland Islands adhere to the MoD flight avoidance map (MoD, 2014). Although, notably, MoD aircraft may breach the guidelines if operationally necessary.

Under normal operating conditions, helicopter activity during the Phase 1 & 2 Development will follow the project-specific flight plan (Section 10.2.5) and will have no need to land anywhere other than Stanley airport or MPN. Therefore, with the impact considered to be '**Low**', the Development should not result in any additional impact on wildlife.

10.2.10 Confidence

The project activities are clearly defined in terms of the:

- Start and end points of flights,
- Frequency of flights, and
- Adherence to project-specific flight plans.

Equally, the locations of vulnerable receptors are known. While the long-term consequences of the impact of noise on wildlife are not fully understood, the application of the Falkland Islands Low Flying Handbook and associated guidance will take account of tried and tested mitigation measures such that the confidence in the assessment is considered to be '**Certain**'.

10.2.10.1 Monitoring required

No specific monitoring over and above any legal requirements, or those indicated in Navitas' corporate standards have currently been identified. However, monitoring requirements were recorded during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline EMMP is provided in Chapter 15.

10.2.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

10.2.12 Findings summary

Table 10.12: Summary of the assessment of impacts to wildlife associated with helicopter disturbance during the Phase 1 & 2 Sea Lion Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance a		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Helicopter use	Disturbance to wildlife	Behavioural and physiological stress reactions to helicopter over-flights, leading to trampling, increased vulnerability to predation, increased energy demands and possible reduced breeding success	Planned	1, 2a, 2b & 3	Low	Minor	n/a	**Low (4)**	**n/a**	**Certain**	**Industry-standard:** Use of project-specific flight plan in line with the flight avoidance map as the basis for flight planning, following the Falkland Islands Low Flying Handbook Guidance (FILFH, 2024). **Project-specific:** None

10.3.1 Introduction

The Phase 1 & 2 Development will require the short-term and long-term placement of objects on the seabed at the offshore location as well as the use of temporary anchors in Berkeley Sound. Both the installation and removal of subsea structures can cause disturbance to the seabed, potentially affecting the benthos and habitats. Additionally, the introduction of hard substrates to the seabed may present the opportunity for marine growth and for 'artificial reefs' to form.

This chapter assesses the potential impacts associated with the installation and presence of structures and the removal of temporary structures, as well the risk associated with accidentally dropped objects.

All long-term structures will be installed in anticipation of full removal at the time of decommissioning (Section 5.12) and the impacts of removing these will be assessed in a dedicated EIA in support of the Decommissioning Programme (Section 5.12.1).

Note: the impacts to other users of the sea from the placement of objects on the seabed are assessed elsewhere in the document as described in Table 2.2.

Note: the potential for impacts to marine mammals and entanglement with seabed infrastructure (i.e. mooring lines etc.) is assessed in Section 10.11.

10.3.1.1 Relevant legislation

Currently there is no legislation enacted in the Falkland Islands which governs the placement (or removal) of objects on the seabed or any associated disturbance of the seabed.

However, UK Legislation which may be relevant from the environmental perspective are the:

- Petroleum Act 1998.
- Offshore Petroleum Production and Pipelines (Assessment of Environmental Effects) Regulations 1999 (and all associated amendments).
- Offshore Marine Conservation Regulations (Natural Habitats, &c) 2007 (as amended) (which implement the Habitats Directive).
- The Marine and Coastal Access Act 2009 and The Marine (Scotland) Act 2010, which introduced the requirement for marine licences for objects placed on the seabed and for disturbance of the seabed (normally applies to objects not directly related to drilling, production or pipelines).
- Energy Act 2008 (Part 4A) which covers navigational issues and the consent to locate.

10.3.2 Sources of impact and risk

The following chapter assesses the impacts of the offshore and inshore seabed disturbance which will result from the Sea Lion Phase 1 & 2 Development. As described in Section 2.1.1, the Sea Lion Development offshore subsea layout and location of wells has been optimised and the sources of offshore seabed disturbance include:

- Offshore:
  - Mooring systems:
    - The repeated installation and removal of the temporary Mobile Offshore Drilling Unit (MODU) mooring system, and
    - Installation of the long-term Floating Production, Storage and Offloading (FPSO) mooring system (in place for Field Life).
  - Installation of well infrastructure:
    - Conductors, and

        - Wellheads for drilling (with Blow Out Preventors (BOPs) and X-mas trees placed on top of the wellhead during drilling and production respectively).
    - The Subsea Production System (SPS) and Subsea Umbilicals, Risers and Flowlines (SURF):
        - Manifolds,
        - Production, water injection, gas injection and diesel service flowlines / risers,
        - Flexible jumpers and flying leads,
        - Umbilicals,
        - Sandbags and gravel bags used as markers and construction aids, and
        - Temporary deposits e.g., clump weights for installation of equipment and for downlines for hydrotesting.
    - Survey equipment, transponders and sampling equipment.
    - Accidentally dropped large objects e.g., subsea infrastructure during installation.
- Inshore impacts will relate to the:
    - Use of temporary anchors by up to two Large Transport Vessels (LTVs) anchored in Berkeley Sound at any one time.

Note: the MODU will either be moored by anchors or by pre-installed suction anchors. The exact number of anchors used will not be known until the rig is selected, it is assumed for the purposes of assessment that approximately ten anchors will be used with different lengths of chain required in order for the rig to maintain position.

Note: smaller dropped objects such as tools etc. are considered to have negligible impact to the seabed and were scoped out as indicated in Chapter 9. The risks associated with large potential dropped objects are assessed below.

10.3.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts and risks of seabed disturbance warranted further investigation (Chapter 9). These include:

- Benthic fauna and habitats at the Sea Lion Field (Section 7.4.3.2) (as impacted directly and by impacts to seabed and water quality), and
- Benthic fauna and habitats in Berkeley Sound (Section 7.4.3.3), (as impacted directly and by impacts to seabed and water quality).

Note: impacts to sites of archaeological interest were scoped out during the ENVIID (Chapter 9) as there are no known shipwrecks in the vicinity of the Phase 1 & 2 Development locations (Section 7.7.6). In Berkeley Sound, the location of the LTVs and associated anchors has been chosen to avoid known wrecks, the location of which has been confirmed through sidescan and multibeam sonar survey (BSL, 2015a).

Note: based upon the historical drilling locations, no previous WBM cuttings piles are expected to be disturbed by MODU / FPSO anchor chains.

10.3.4 Characterising and quantifying the impact

When characterising and quantifying the potential impacts and risks associated with placing and removing objects on the seabed it is necessary to consider the:

- Nature of the impact from the installation and presence of objects on the seabed,
- Potential impacts at the Phase 1 & 2 Development locations including:

- Fauna and habitats in the Sea Lion Field, and
- Fauna and habitats Berkeley Sound.

- Quantification of the subsea infrastructure including the dimensions and footprint of the:
  - FPSO and MODU mooring systems,
  - Well infrastructure, SPS, SURF and temporary deposits, and
  - Temporary inshore anchors used by the LTVs during the early construction stages.
- Risk of large dropped objects and associated impacts on benthic fauna.

10.3.4.1 Nature of the impact from installation, presence and removal of structures

Placement and / or removal of objects on the seabed may directly and / or indirectly impact upon:

- Benthic fauna (as impacted directly and by impacts to seabed and water quality), and
- Biodiversity *via* habitat modification and marine growth.

10.3.4.1.1 Impacts to benthic fauna (and seabed and water quality)

Benthic fauna are primarily impacted by:

- Direct crushing of sessile or sedentary organisms, and
- Indirect smothering of organisms with re-settling suspended sediments.

Direct impacts include the crushing of sessile or sedentary organisms which cannot move away. These effects will be immediate, very localised and will affect the area directly covered by the structure, and possibly the immediate vicinity in which the activity occurs. During installation processes however, seabed sediments will be stirred up and become suspended, which can lead to indirect impacts.

While larger, more mobile animals, such as crabs, fish, shrimps and prawns may be able to avoid these impacts, the suspension of sediment into the water column can cause clogging, smothering or abrasion of sensitive feeding and respiratory apparatus in sedentary or slow moving organisms (Nicholls, *et al.,* 2003). These impacts are of greatest concern for filter feeders such as the saltwater clams (*Thyasira* spp.) found at the offshore Development site.

One study (Carlmark, 1971) involved laboratory testing of objects falling into sediments in test conditions and contains notes on the behaviour of the sediments on impact. Overwhelmingly, there was displacement of solids either side of the impact and an elevated 'lip' forming to the impact depression, but very little material was visibly ejected into the water column.

However, and importantly, the degree of the impact upon filter feeders depends upon the duration of exposure to suspended sediments. For instance, experiments have shown that the filter feeding scallop *Pecten novaezelandiae* was unaffected by exposure to 250 mg/l of sediment in suspension for a single week, but decreased growth was observed in individuals exposed to lower density suspensions for periods longer than one week (Nicholls, *et al.,* 2003).

10.3.4.1.2 Impacts to biodiversity from habitat modification and marine growth

Habitat modification can result from the placement of hard substrates on the seabed and can have direct and indirect impacts on biodiversity as follows:

- The anthropogenic installation of new habitat in an area leading indirectly to:
  - The settlement and growth of native marine fauna not otherwise present in the immediate area,
  - Provision of a ‘stepping-stone’ for species with only moderate dispersal abilities (BAS, 2014), and

- The establishment of non-native species.
- Direct damage to existing habitats.

10.3.4.1.2.1 Anthropogenic installation of new habitats

When hard substrates are placed on the seabed in an area where such materials are naturally sparse, there is the potential that these structures may become colonised by species which prefer hard substrates and would not ordinarily be in the area. Further, such habitats may enable the spread of species with moderate dispersal abilities by providing 'stepping-stones' which create interconnectivity with other regions (BAS, 2014).

It is observed that installations in the North Sea are predictably colonised with numerous epifauna groups which wouldn't otherwise be present in the area (OSPAR, 2009a). For example, seaweeds, mussels, anemones, sponges, hydroids and cold-water corals are frequently recorded on Oil and Gas (O&G) structures (e.g., jackets, risers and seabed infrastructure) (Coolen *et al.,* 2015). A very specific example of the settlement of fauna which is otherwise not found in an area is the presence of the cold-water coral *Lophelia pertusa*[53] in the North Sea. This species was most frequently reported on the shelf-edge and the offshore banks of the north-east Atlantic (Roberts, 2002) and is now found in the North Sea where it had not previously been recorded (Gass and Roberts, 2006). Importantly, these colonised 'habitats' can then attract more mobile fauna which are attracted by the shelter and food source provided.

While the likelihood of colonisation, and the composition of marine growth on a particular structure depends on a variety of factors (such as water temperature, water depth, wave action, the indigenous and / or non-native species present in the area and the season in which the structure was installed (Fortreath, *et al.,* 1982; OGUK[54], 2011)), it is generally recognised that the presence of marine growth on artificial hard substrates can impact upon biodiversity and species abundance in an area.

Indeed, in order to better understand the extent to which artificial substrates associated with the O&G industry affect biodiversity, and to examine the impact of habitat creation by O&G activities in the North Sea in general, OEUK[1] launched a scientifically led and long-term environmental Joint Industry Project to assess the 'INfluence of man-made Structures In The Ecosystem' (INSITE). The INSITE Programme was launched in 2014, with the aim of providing stakeholders with the independent scientific evidence-base needed to better understand the influence of man-made structures on the ecosystem of the North Sea. The INSITE programme is currently funded by the Natural Environment Research Council (NERC) and the Centre for Environment, Fisheries and Aquaculture Science (Cefas), and is sponsored by an industry partnership of North Sea asset operators (UKRI, 2022).

While it is debatable as to whether the impact of 'artificial reefs' is positive, negative or negligible in the immediate location, there may be the potential for broader reaching negative effects. For example, based on laboratory work, Holst and Jarms (2007) suggest that one reason for a worldwide increase in mass occurrences of Scyphozoan jellyfish may be due to increases in artificial substrates and marine litter in coastal and offshore regions, which provide increased settlement opportunities for larval stages. Although the cause is unlikely to be directly related to artificial substrates or litter, jellyfish blooms are already experienced in Falklands waters, with peaks in jellyfish catch approximately every ten years and long-term trend of growing catches (J. Pompert, *pers. comm.*).

With regard to non-native species, there is the potential for the creation of new habitats to enable such species to settle and become established. The potential for this may be enhanced where the

[53] *Lophelia pertusa* is now known as *Desmophyllum pertusum*. This change is based on molecular evidence although there remains some uncertainty about the change which may be reversed following further investigation.
[54] Oil and Gas UK (OGUK) is now known as Offshore Energies UK (OEUK).

surfaces of the artificial 'habitat' are heated, which may increase the range of species able to survive in the region, growth rates and maturation times (BAS, 2014). An overview of the potential for such impact interactions (i.e., the combined effect of species introduction and artificial habitat provision) is provided in Chapter 13.

10.3.4.1.2.2 Damage to existing habitats

Damage to existing habitats can result directly from the placement of objects on the seabed. The significance of such damage will depend upon the extent of the damage, the importance of the habitat with regard to its ecological value and whether or not the habitat is ubiquitous, rare or isolated. Detail on the habitats of the Sea Lion Field and the LTV locations in Berkeley Sound are provided below.

10.3.4.2 Potential impacts at the Phase 1 & 2 Development locations

10.3.4.2.1 Impacts in the Sea Lion Field

10.3.4.2.1.1 Existing habitats and fauna

The sediment at the Sea Lion site is classed as medium to coarse silt with a high percentage of fine material (61-80 %) (Section 7.3.7.1.1) which is likely to become suspended during the installation processes with the potential to impact the fauna present.

With regard to fauna present, an 'area-wide' seabed survey of the Sea Lion development area was carried out in 2012 (Gardline, 2013a & b), and several surveys were carried out in support of the 2015 exploration drilling campaign (Section 7.2.2). These surveys indicated that the benthic communities in the area were:

- Typical of the sediment type and were rich in species assemblages, diversity and abundance (Gardline, 2013a & b), and
- Relatively homogeneous throughout the surveyed area (Section 7.3.7.1.1).

Nonetheless, hard substrates do occur in the North Falklands Basin (NFB) and these areas have been colonised. For example, about 40 km to the south of the Sea Lion Field, in the region of the Isobel Deep well, seabed photography revealed the presence of hard substrates in the form of clay outcrops, boulders and drop-stones associated with glacial and iceberg groundings (Premier, 2014c). Assessment of the epifaunal assemblages within these habitats, confirmed the presence of a relatively well populated community of species. Brittlestars, sea urchins, starfish, hard and soft corals, bryozoans, hydroids, ascidians and anemones were frequently encountered. In turn, this colonisation has led to the presence of demersal fish (notably Notothenidae spp.), pelagic fish and cephalopods. An example of the growth found on erratic glacial rocks is shown in Figure 10-8.

Figure 10-8: Example of marine growth on seabed boulder in the Isobel Deep area of the NFB
(Source: MG3, 2015)

10.3.4.2.1.2 Habitats of importance

There is a low likelihood of there being habitats in the region of the Sea Lion Field that are equivalent to those of conservation significance in the UK as defined by the Offshore Marine Conservation of Habitats Regulations (Section 7.4.3.2.2). Although some indicator taxa of important habitats are predicted to be present (≥50 % probability), these are likely to occur in low densities and not in aggregations as would typically contribute to the definition of important habitats. Predicted habitats are found widely in areas adjacent to the license area, and as such any potential impacts within the license area are not likely to impact the health of the local population.

10.3.4.2.1.3 Anticipated marine growth

With regard to marine growth opportunities, in the upper water column, colonisation by seaweeds and mussels may occur quite quickly on the upper lengths of risers and FPSO anchors chains as is observed in similar latitudes. At depths of approximately 450 m however, it is likely that colonisation and growth on the subsea infrastructure will be slower.

In order to obtain a firmer estimate of marine growth potential, British Antarctic Survey (BAS) were commissioned by POEPL to estimate the type of marine growth that could occur in the Sea Lion Field (BAS, 2014).

Existing oceanographic data and models suggest predominant currents at the location of the proposed Sea Lion Development come from East Falkland and north of Tierra del Fuego with the current speed generally being less than 15 cm/s (Section 7.3.3). Following biofilm development in the initial weeks of deployment, *Ectocarpus* and *Enteromorpha* algae, tubicolous polychaete worms and acorn barnacles

are likely to establish. These will be followed by a complex succession of fouling types. Ultimately, barnacles, oysters or mussels (probably the latter) are likely to dominate.

The study indicated that, by far, most growth should occur in the top 40 m, as is seen in the North Sea. However, thicknesses of marine growth are predicted to be less, overall, than that seen the North Sea, and comparative estimates are shown in Table 10.13. The most unpredictable element with regard to marine growth, is the chance establishment of the occasional giant kelp.

Elsewhere, seaweeds have been shown to grow on oil structures, particularly in shallow, well-lit areas where conditions support their attachment and growth. Such structures provide a hard substrate that facilitates the settlement of marine organisms, including macroalgae (Foster and Willan, 1979; Ponti, *et al.,* 2015). While this growth can alter local biodiversity, excessive biofouling by seaweeds and other sessile organisms can also pose operational challenges, such as increased structural load, hydrodynamic drag, and maintenance costs (Perkol-Finkel and Benayahu, 2007). To mitigate these effects, operators use various biofouling management strategies, including anti-fouling coatings (Section 5.8.3.1). These mitigation measures help maintain the structural integrity and functionality of offshore oil installations while minimising environmental impacts.

The roughness of fouling growth is generally expected to peak at 2-6 cm in the top 20 m depth within 3-9 years (BAS, 2014).

In the event that marine growth on risers / anchor chains exceeds safety parameters with regard to structural integrity, the marine growth will be mechanically cleaned off to sea. This process will destroy all native, and any non-native, marine growth and the organic matter will fall to the seabed as natural detritus.

Table 10.13: Summary of terminal marine growth estimates in the UK versus Sea Lion (BAS, 2014)

Area	Depth	Type of growth		
		Hard (m)	Soft (m)	Algae / kelps (m)
UK	0 - 15 m	0.2	0.07	3
	15 - 30 m	0.2	0.3	Unknown
	30 m to seabed	0.01	0.3	No growth
Sea Lion	0 - 15 m	0.15	0.1	Unknown
	15 - 30 m	0.12	0.1	Unknown
	30 m to seabed	0.04	0.01	No growth

10.3.4.2.2 Impacts in Berkeley Sound

The area that may be affected in Berkeley Sound is limited to the location of the LTVs' anchor site (Section 5.5.1).

The following sections describe what is known of the species and habitats in the area.

10.3.4.2.2.1 Existing habitats and fauna

Full detail on the flora, fauna and habitats of Berkeley Sound are provided in Section 7.4 of the Environmental Baseline chapter. The following section provides a summary of the results of surveys which were carried out for the project.

Within the Sound, the dominant sediment type was slightly gravelly sand. Finer sediments occurred more in the inner bays to the west with sediments generally becoming coarser toward the east end. The nearest sampling station to the proposed LTV anchorage was found to contain slightly gravelly sand with some hard substrates located approximately 4 km to the west.

The flora and fauna throughout Berkeley Sound is highly variable in terms of species abundance, richness and composition, as would be expected given the highly variable nature of the sediment and

the large scale of survey area. Samples taken nearest to the identified potential LTV anchorage indicated comparatively average species richness with low abundance but high diversity.

Overall, the habitats found within Berkeley Sound are widespread and the seabed is scarred from historic and ongoing ship anchoring.

10.3.4.2.2.2 Habitats of importance

As is detailed in Section 7.4.3.3.3, a number of habitats were identified within the surveyed area of Berkeley Sound that could potentially qualify as those of conservation significance under the UK's Offshore Marine Conservation Regulations 2010 (which implements the EU Habitats Directive). One of these locations (BS_ENV_42), primarily a rock face and cobbles habitat, was found to carry the mottled sea star, *Glabraster antarctica*, amongst the coralline algae encrusted bedrock exposures. This species is described as 'a primarily Antarctic and Sub-Antarctic species only rarely seen inshore in the Falklands' by SMSG (Neely and Brickle, 2013). BS_ENV_42 is near the coast, south of the LTV anchoring locations that are 1.2 nm from the coast (Figure 5-5 above). Other survey locations closest to the proposed LTV sites (namely BS_ENV_31 and 40, Section 7.4.3.3.3) did not indicate habitats of conservation significance.

10.3.4.2.2.3 Anticipated marine growth

As described above, Berkeley Sound contains varied habitats, and hard substrates are already found in the area. As such, marine growth on LTV anchors is likely to be typical of fauna and flora already in the area. However, as the anchors are temporary, marine grown on introduced hard substrates in Berkeley Sound is not considered further.

Nonetheless, the potential for the LTV anchors to provide an added, albeit temporary, hard substrate for the settlement of any non-native species which may be introduced by biofouling on the LTVs is considered in Section 10.12.

10.3.4.3 Quantification of the subsea infrastructure

10.3.4.3.1 FPSO and MODU mooring systems

During Stage 1 of the Development, the MODU will be in position to drill, and during Stages 2a & 2b, both the MODU and the FPSO will be in the field, carrying out simultaneous operations (SIMOPS). An example of the anticipated FPSO anchor array is shown in Figure 10-9. It is expected that the greatest disturbance to the seabed will result from the installation of the mooring systems.

For the purpose of this EIA, a ten anchor spread has been assessed for the MODU using '15T Stevpris MK6 anchors' and it is anticipated that 300 m of chain will be laid upon the seabed for each anchor (Table 10.14). Of note, when in position over a given DC, the MODU will be able to move between wells (Section 5.4.3.1). However, anchor lay and anchor lift will be required for each move to another DC. Therefore, according to the DC locations and drilling schedule (Section 5.4.2), over the course of Stages 1, 2a & 2b, a total of 20 anchor lays / lifts has been assumed (note that this is 20 lift / lay events over the DC's, not 20 different locations). As a result, the total area disturbed by the MODU mooring system throughout the Phase 1 & 2 drilling campaign is estimated at 0.66 km^2 (Table 10.14).

The mooring system for the FPSO will be installed toward the end of Stage 1 and will remain in place for the duration of the Field Life. The mooring system will comprise 12 suction-piled anchors distributed in clusters of four. Each cylindrical anchor will be six metres in diameter. The installation aids will protrude from the top of the suction anchors by approximately one to two metres.

The area that may be disturbed during the installation of the FPSO mooring system is estimated to be 0.095 km^2 while the long-term footprint of the mooring system is 0.0016 km^2 (Table 10.14).

The total area of seabed disturbance anticipated from the deployment of anchors / moorings for the MODU and FPSO combined is 0.75 km^2 with a long-term footprint of 0.0016 km^2 (Table 10.14).

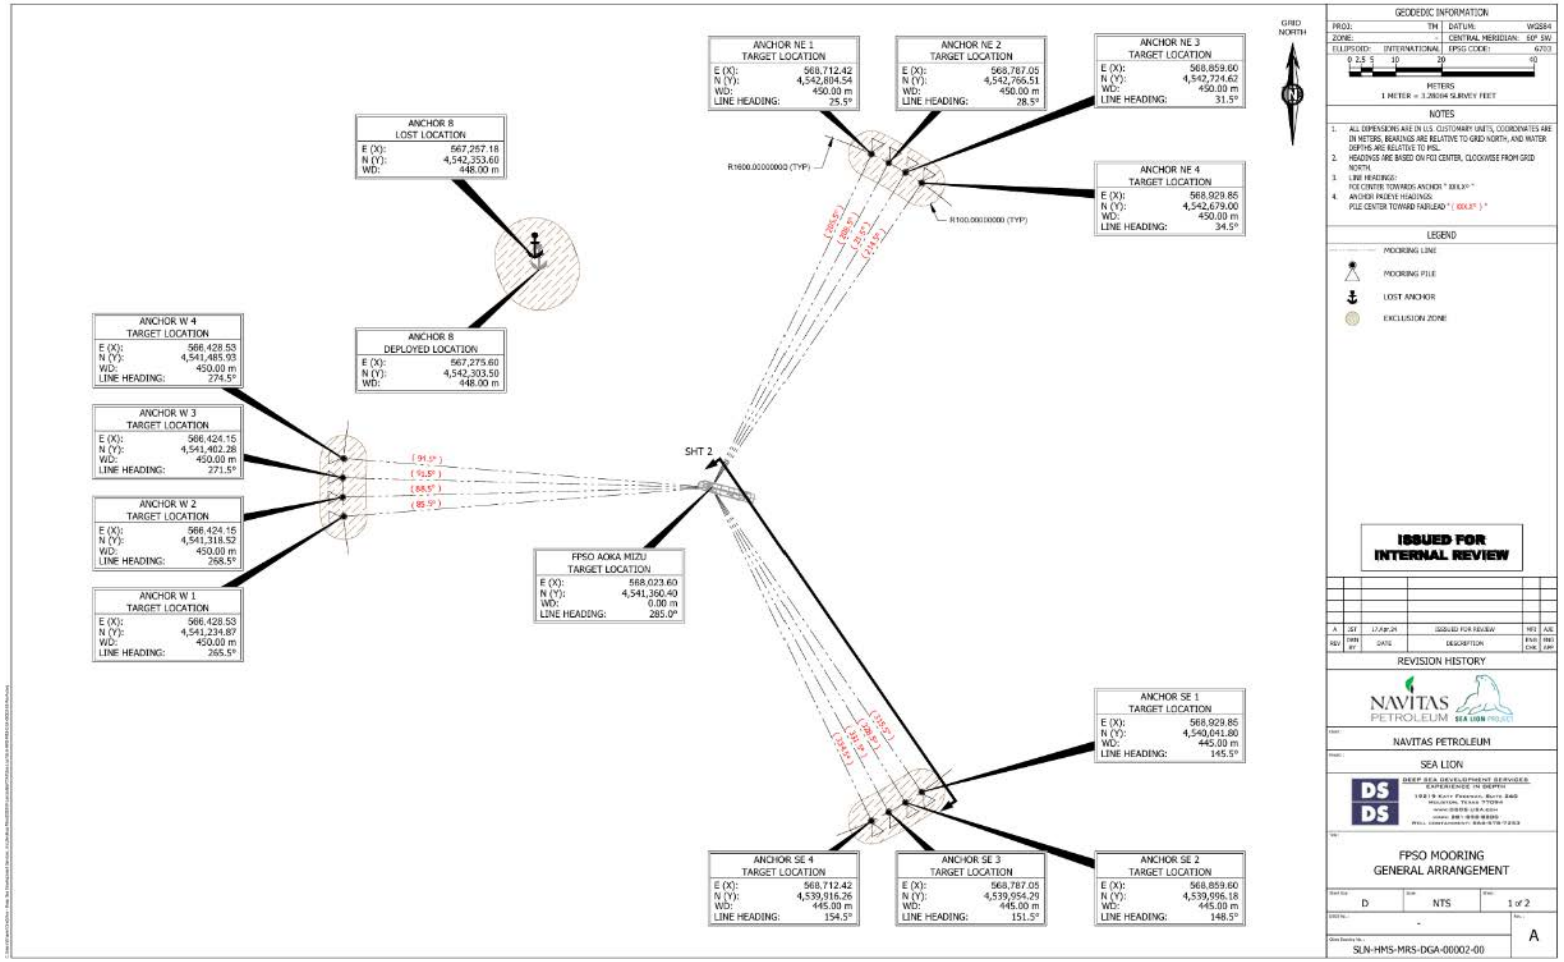

Figure 10-9: Layout of long-term FPSO anchors

Table 10.14: Dimensions[1] and footprints of the FPSO and MODU anchor layouts

Installation	Structure	Quantity	Dimensions			Worst-case assumptions	Temporary seabed disturbance (m^2)	Permanent footprint (m^2)
			Outer diameter (m)	Length (m)	Width (m)			
MODU (temporary[2])	Anchor chains	10	n/a	1,371	0.08	300 m in contact with seabed and impact corridor width 10 m	30,000	n/a
	15 tonne Stevpris MK6 Anchors	10	6	6.7	6	Disturbance zone of 300 m^2 per anchor	3,000	n/a
	Total area of disturbance for each MODU placement						**33,000**	**n/a**
	Total for all MODU anchor placements and removals (10 anchor placements and 10 anchor removal events over the three DC locations (not 20 different locations))						**660,000**	**n/a**
							0.66 km^2	**n/a**
FPSO (Permanent[3])	Anchor chains	12	n/a	1,537	0.132	780 m in contact with seabed and impact corridor width 10 m	93,600	1,236
	Cylindrical suction anchors	12	6	n/a	n/a	Disturbance zone of 100 m^2 per anchor	1,200	339.3
	Total FPSO						94,800	1,575
							0.095 km^2	**0.0016 km^2**
Total FPSO and MODU disturbance							754,800	1,575
							0.75 km^2	**0.0016 km^2**

[1] Areas for unconventional shapes are calculated by assuming an oblong / square according to the longest dimensions as a worst-case.
[2] The MODU will be *in situ* for a total of 66 months during Stages 1 and 2 (a & b) of the Development.
[3] The FPSO moorings will be installed in Stage 1 and will be in place for the life of the field.

10.3.4.3.2 Well infrastructure, SPS and SURF

The dimensions of the well infrastructure, SPS, SURF and associated supports are summarised in Table 10.15, as are the assumptions made with regard to the area impacted. The SURF will be installed directly on the seabed and no mechanical trenching or burial will be required for the permanent infrastructure, although sand and gravel bags may be used for support and placement.

Further, temporary deposits will include items such as clump weights, ROV tooling baskets, tethers etc. and wet storage areas may also be required to store jumpers, umbilicals, anchor wires etc. prior to installation (Section 5.5.3.3). An overall 10 % allowance is added for deposits, wet storage and for other construction-related deposits such as sandbags (Table 10.15). As described in Section 5.5.3.3, this allowance is considered highly precautionary and is used in the absence of specific details on the definite number of temporary and permanent deposits.

Including allowance for the above, the total seabed disturbance from the well infrastructure, SPS and SURF installation is estimated to be 0.143 km^2. The long-term (until decommissioning) footprint is estimated to be 0.024 km^2.

Table 10.15: Estimated dimensions of subsea equipment and temporary deposits

Equipment	Quantity	Dimensions			Worst-case assumption	Temporary seabed disturbance (m^2)	Permanent footprint (m^2)
		Outer diameter (m)	Length (m)	Width (m)

10.3.4.3.3 Inshore LTV anchors

Over the duration of Stages 1, 2a & 2b, up to four different temporary LTVs will be used as floating storage barges however, only two are anticipated to be anchored within Berkeley Sound at any one time.

The dimensions of the anchoring systems used are summarised in Table 10.16, as are the assumptions made with regard to the seabed area impacted. The assumptions are based on the worst-case disturbance that could be caused during installation and / or use e.g., anchor placement and disturbance as the vessels weathervane around the anchors.

The overall seabed disturbance is estimated at 0.06 km^2 which amounts to about 0.12 % of the total area of Berkeley Sound (Table 10.16).

Table 10.16: Estimated dimensions of inshore LTV anchoring

Installation	Structure	Quantity	Dimensions		Worst-case assumptions	Seabed disturbance (m^2)	Permanent footprint (m^2)
			Length (m)	Width (m)			
Up to two LTVs *in situ* at any time	Anchor chains	2 (1 per vessel)	100	0.08	75 m of disturbance to seabed in circular band around the vessel	58,905[1]	n/a
	Drag embedment anchors	2 (1 per vessel)	5	4	Disturbance zone of 300 m^2 per anchor	600	n/a
Overall total						**59,505**	**n/a**
						0.06 km^2	**n/a**

[1] This was calculated as the difference between a 200 m diameter circle (based on the vessel weathervaning on a 100 m anchor chain) and 50 m diameter circle (namely the centre point where the 25 % of the chain length does not contact the seabed).

10.3.4.4 Risk of dropped objects

Throughout the entire Phase 1 & 2 Development there is the potential for subsea infrastructure to be accidentally dropped during the installation process.

In the event that a large object is dropped, the nature of the impacts will be the same as for intentionally placed objects, *via* direct crushing of benthic fauna and suspension of sediments (Section 10.3.4.1.1). However, owing to the uncontrolled nature of a dropped object it is possible that such an event could lead to substantial suspension of sediment and the associated impacts.

Equally, there is the potential that subsea infrastructure already in place could be damaged leading to spills or leaks. The environmental impact of oil leaks and spills is assessed in Chapter 12.

10.3.5 Industry standard mitigations

10.3.5.1 Seabed disturbance

Over and above an EIA of potential effects, there are few industry-standard mitigation requirements with regard to the disturbance of the seabed from the placement of objects. Those that do exist, e.g., the use of chain mats deployed from bottom-trawl fishing vessels in the North Sea to flatten the profile

of raised clay berms (and thus reduce the future risk to fishermen), do not apply in the Sea Lion location as the lines are not being trenched or buried, nor is the sediment comprised of clay.

However, during all vessel anchoring, preparation and management activities, good operational practices, e.g., optimal tensioning of anchor chains, will be used to minimise anchor scouring and damage to the seabed.

10.3.5.2 Marine growth on hard substrates

In the North Sea, the composition of marine growth and the depth of each marine growth layer (e.g., seaweed, mussels etc.) is periodically surveyed and the growth is removed if the structural integrity of the asset is compromised by the added weight of marine growth. This applies less for an FPSO than for fixed structures. However, if the FPSO risers become fouled to a point where they fall out of design safety parameters, the marine growth may be cleaned off into the sea. The FPSO will be treated with antifoulants to minimise the potential for growth. However, seabed surveys / inspections throughout the Development will inform the level of growth on the seabed structures and mooring systems.

10.3.5.3 Dropped objects

Good oilfield practice will be observed such that all dropped objects will be reported to FIG and retrieved, where possible, as soon as is reasonably practicable. Any remaining debris will be retrieved in the decommissioning process and checked with a seabed clearance survey.

10.3.6 Impact and risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall impact of planned activities. The assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes is provided in Section 10.3.12, which shows the worst-case impact / risk for each activity and receptor.

10.3.6.1 Impact assessment of disturbance to the seabed

10.3.6.1.1 Sea Lion Field

10.3.6.1.1.1 Disturbance to fauna and existing habitats

It is assumed at this time that the benthic species diversity and abundance in the area of the Drill Centres (DCs) will be similar to that recorded in the previous benthic surveys across the Sea Lion Field area and that the benthic communities are typical of the area (Section 7.4.3.2).

The area likely to be disturbed during the installation of subsea infrastructure is relatively small (Section 10.3.4.3) as, with the exception of the conductor pipes, the equipment is laid directly onto the seabed without the need for trenching or burial operations. Furthermore, the seabed area is likely to contain 'negligible numbers of any species of geographical importance' and no habitats have been identified that would be equivalent to designated sites under UK legislation (Section 10.3.4.2.1.2). Should any species or habitats which are of ecological importance be identified in site-specific surveys, the zone of influence remains sufficiently small such that the sensitivity of the receptor is considered to be '**Very Low'**.

While direct impacts will be fatal to a small number of individuals, the combined area likely to be impacted by direct crushing or smothering is small. Similarly, the suspension of sediments following one-off installation processes will be very short-lived and therefore unlikely to result in any impact (Section 10.3.4.1.1). Therefore, any changes will be barely detectable above background variability. At the population level, any impacts will be fully reversible once the installation activity ceases and therefore the severity of effect is considered to be '**Slight**'.

The overall significance of impact is considered to be '**Very Low (1)**'.

10.3.6.1.1.2 Habitat modification and marine growth

Assessing the 'sensitivity of the receptor' and 'severity of effect' of marine growth on hard substrates is a challenge as the impact of 'artificial reefs' on biodiversity may be considered positive or negative (Section 10.3.4.1.2.1). However, for the purposes of this assessment, it assumed that any anthropogenic contribution to the environment is 'negative'.

The main receptors that may be impacted by marine growth are flora and fauna. The biodiversity of the local area may be affected should any species not common to the area be able to settle. The broader region may be affected should such species use the substrate as a stepping-stone (Section 10.3.4.1.2). However, species diversity and abundance in the NFB is relatively uniform, and the species are not considered to be of geographical or conservation importance (Section 10.3.4.2.1.1). Therefore, the sensitivity of the receptors in the existing Sea Lion baseline is estimated to be '**Very Low**'.

There are not believed to be any habitats of particular ecological importance that could be damaged in the Sea Lion Field (Section 10.3.4.2.1.2). However, given the homogenous nature of the seabed and sediments at the Sea Lion Field, and the relative absence of hard substrates in the region, the installation of infrastructure will effectively create a new habitat in the area. The small surface area of the artificial substrate and the isolated location indicate that the colonisation of seabed infrastructure will be slow. Although, as is shown in Section 10.3.4.2.1.3 above, it is likely that the hard substrate will become colonised and this change to the benthic community in the area will be detectable against the background environment. Nonetheless, this impact will be very localised and reversible once the infrastructure is removed such that, on balance, the severity of effect is considered to be '**Moderate**'.

The overall significance of impact is assessed as '**Low (3)**'.

10.3.6.1.2 Berkeley Sound

Given the temporary nature of the LTV anchorages, the long-term impact of habitat modification and marine growth is not considered.

10.3.6.1.2.1 Disturbance to fauna and existing habitats

Berkeley Sound supports a wide range of habitat types and benthic species. Most of these are widespread and commonly found elsewhere in the Falklands archipelago. However, the mottled sea star which was found at the BS_ENV_42 location is considered to be rare in inshore waters (Section 7.4.3.3.3). Further, the identification of habitats that could potentially qualify as geogenic reefs, also at BS_ENV_42, indicates that a precautionary approach should be taken. Given that these habitats are 'currently undesignated but could be of local importance', the sensitivity of the receptors to damage / crushing / smothering is, on balance, considered to be '**Moderate**'.

The area that will be disturbed by the anchored LTVs is very small (Section 10.3.4.3.3) and is likely to be in a part of the Sound that has frequently been subject to numerous anchor placements before (as indicated at BS_ENV_31, Section 7.4.3.3.3), as has much of Berkeley Sound. While the previous scarring of the area does not directly affect this assessment, it does indicate that the disturbance caused by the use of anchors is unlikely to stand out over and above the existing baseline and therefore, the severity of effect is considered to be '**Slight**'.

The overall significance of impact is assessed as '**Very Low (3)**'.

10.3.6.2 Risk assessment of unplanned and accidental events

10.3.6.2.1 Risk of dropped objects

Given that dropped objects would be an unplanned event, it is not possible to predict what might fall or what the extent of any impacts may be. Although a dropped object may result in the suspension of

sediment, even if a large object was dropped, a relatively small area would be affected. It is likely that negligible numbers of any species of geographical importance will be present within the zone of influence and therefore the sensitivity of the receptor is considered to be '**Very Low**'.

Equally, the duration of sediment suspension will be very short such that the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of impact is assessed as '**Very Low (1)**'.

With regard to the likelihood of objects being dropped, over a period of 37 years (1970 - 2007), only one dropped object was recorded worldwide from units ranging from FPSOs to semi-submersibles (OGP, 2010b). This amounts to a frequency of 0.027 incidents per year. According to the OGP (2010b) on mechanical lifting failures, the probability of a dropped object from a mobile unit is 0.0000014 per lift. Given the ongoing developments that have occurred in the industry since 2007 with regard to improvements in safety, the loss of a larger object during the installation process would require the failure of numerous engineering and procedural controls and therefore the likelihood of occurrence is considered to be '**Unlikely**'.

Therefore, the overall risk associated with disturbance to the seabed from dropped objects considered to be '**Very Low (2)**'.

10.3.7 Project-specific mitigation

The impacts and risks are considered to be '**Low**' or '**Very Low**' such that there is no need for any further project-specific mitigation measures.

Note: please see also the mitigation measures described in Section 10.12 with regard to the introduction / spread of non-native marine species.

10.3.8 Residual impacts and risks

Not applicable.

10.3.9 Cumulative impact

10.3.9.1 Sea Lion Field

Given the absence of any other O&G activities in the NFB, there is no potential for cumulative effects at this time, or for the interconnectivity of 'created habitats'. In the event of future O&G activity however, the potential for cumulative effects and interconnectivity with regard to the potential 'stepping-stone' effect of marine growth (BAS, 2014) would need to be re-examined in the EIA carried out by future operators. Note that fisheries within the Sealion field have not been considered as a factor that could influence cumulative impacts on seabed disturbance of the project. The impacts to fisheries are considered in Section 11.1.

10.3.9.2 Berkeley Sound

Scarring on the seabed in Berkeley Sound is widespread and extensive owing to the extent of historical and ongoing vessel activity and anchoring (Section 7.7.6.2). While the LTVs will anchor during the initial construction phase, and will weathervane around the anchors, this will occur in one location causing damage to only a very small area. Therefore, the LTV anchors are not expected to make a significant contribution to cumulative impacts on biodiversity.

10.3.10 Confidence

The uncertainties within this assessment include:

- Confirmation on which MODU anchor array will be used,

- The absence of site-specific offshore benthic surveys and detail on the diversity and abundance of benthic fauna around the DCs and the GPI well(s),
- Final location of the LTV anchorages, and
- The absence of samples at the specific LTV anchoring locations.

The use of a different MODU anchor array is not considered to affect the impact assessment because of the contingencies included in the calculations.

While the wider survey of the Sea Lion Development area has provided sufficient information on which to base the current assessment, the specific benthic habitats and fauna at the Sea Lion location have not yet been surveyed and this is acknowledged as a data gap.

Beyond the above, the subsea infrastructure requirements are well understood and the data used for the assessment assume the worst-case with regard to equipment dimensions and the local environment. Overall, the confidence in the seabed disturbance and marine growth assessments is '**Probable**'.

10.3.10.1 Monitoring required

As noted in, seabed surveys will be required prior to, and throughout, the Development for numerous reasons and will be used to:

- Further inform the environmental baseline,
- Enable validation of this EIA in future years, and
- Assess any needs for remediation.

Detailed monitoring requirements have been established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline EMMP is provided in Chapter 15.

10.3.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

10.3.12 Findings summary

Table 10.17: Summary of the impact and risk assessment for the placement and removal of objects on the seabed

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance a		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Placement of objects on the seabed	Installation of MODU / FPSO mooring systems, SPS and SURF at Sea Lion Field	Disturbance to the seabed, water and sediment quality, benthic fauna and habitats offshore	Planned	1	Very Low	Slight	n/a	**Very Low (1)**	**n/a**	**Probable**	**Industry-standard:** Good operational practices. Marine growth removal. Seabed surveys / inspections. **Project-specific:** None proposed.
		Habitat modification and marine growth	Planned	1, 2 & 3	Very Low	Moderate	n/a	**Low (3)**	**n/a**	**Probable**	
	Anchoring of the LTVs, in Berkeley Sound for a combined period of up to 13 months for the complete subsea campaign	Disturbance to the seabed, water and sediment quality, benthic fauna and habitats	Planned	1 & 2	Moderate	Slight	n/a	**Very Low (3)**	**n/a**	**Probable**	
Dropped objects	Loss of equipment or infrastructure to the seabed	Disturbance to the seabed, water and sediment quality, and benthic fauna	Unplanned	1, 2 & 3	Very Low	Slight	Unlikely	**Very Low (2)**	**n/a**	**Probable**	**Industry-standard:** Reporting and retrieval of dropped objects **Project-specific:** None proposed.

[1] See Chapter 8 for definitions of sensitivity, severity, likelihood and significance.

10.4.1 Introduction

Underwater noise will be generated in the Sea Lion Field throughout the Development and will result from the use of vessels.

The properties of sound in water (range and speed of travel) are exploited by many marine animals as a means of communication, navigation and detecting prey or predators. Sound travels at approximately 1,500 m/s in water (about five times faster than in air) and low frequency sound can propagate over hundreds to thousands of kilometres, although the effective range of most biological functions is tens of kilometres. Human-made (anthropogenic) noise in the marine environment can interfere with these processes and is recognised as having the potential to cause harm to marine animals. Consequently, underwater noise is regarded as a form of pollution.

The sources of underwater noise generated by the Oil and Gas (O&G) industry are well documented (e.g., Wartzok, *et al.,* 2004; Gordon, *et al.,* 2004; Southall, *et al.,* 2007 and 2019; OSPAR, 2009b; NOAA, 2018). However, despite the growing volume of research this remains an area with many uncertainties, largely due to the difficulties of observing and measuring the impact of noise on animals in the marine environment. Therefore, a precautionary approach is required during any impact assessment.

This chapter provides an assessment of the potential impacts of underwater noise generated during the offshore components of the Phase 1 & 2 Sea Lion Development. When assessing the impact of sound on any animal, it is necessary to compare the sounds being made with the thresholds above which the animal may experience injury or may exhibit behavioural reactions to disturbance. It is also necessary to consider how close the animal needs to be to the source of the noise for it to experience the sound at levels above the injury and disturbance thresholds. Therefore, to inform the assessment, Genesis Oil and Gas Consultants Limited (Genesis, 2024a & b) have been commissioned to conduct underwater noise modelling to identify and characterise the sources of underwater noise that will be generated during the Phase 1 & 2 Development, and their potential impacts.

The impact of underwater noise from any vessels used inshore (i.e., LTVs in support of the subsea construction campaign) is assessed in Section 10.5.

Note: the other impacts associated with vessel use are described elsewhere in this document, as described in Table 2.2.

10.4.1.1 Relevant legislation

The following legislation is relevant to the management of underwater noise:

- European legislation:
  - EC Habitats Directive (Council Directive 92/43/EEC on the Conservation of natural habitats and of wild fauna and flora).
  - EU Marine Strategy Framework Directive (Council Directive 2008/56/EC).
- UK legislation:
  - The Conservation of Offshore Marine Habitats and Species Regulations 2017 - and the potential need for a Disturbance Licence.
  - Conservation (Natural Habitats) Regulations 1994 listing of all European Protected Species (EPS).
- Falkland Islands legislation:
  - Marine Mammals Protection Ordinance 1992.
  - Conservation of Wildlife and Nature Ordinance 1999.

- Fisheries (Conservation and Management) Ordinance 2005.

The following guidelines are relevant to the management of underwater noise:

- International Maritime Organisation, MEPC.1/Circ.833 Guidelines for the Reduction of Underwater Noise from Commercial Shipping to Address Adverse Impacts on Marine Life, 7th April 2014,
- Convention on the Conservation of Migratory Species of Wild Animals (CMS), Best Available Technology (BAT) and Best Environmental Practice (BEP) for Mitigating Three Noise Sources: Shipping, Seismic Airgun Surveys, and Pile Driving - Technical Series No. 46, 2023,
- Falklands Conservation Cetacean Code of Conduct for the Falkland Islands, 2020,
- The Falkland Islands Species Action Plans (SAP) for Cetaceans, and Seals and Sea Lions. **Note:** the 2008 SAPs (FIG, 2008b & 2008d) expired in 2018 and a new version is currently in draft and will highlight the need to:
  - Assess and manage acoustic disturbance – including the application of appropriate licence conditions under the Offshore Minerals Ordinance (or relevant proposed replacement legislation), and
  - Assess and manage physical disturbances from development activities such as aquaculture, O&G exploration and extraction industries with the application of environmental impact assessments where appropriate.
- The Sei Whale Conservation Management Plan (2024).

10.4.1.1.1 Offences against marine mammals

The Falkland Islands' Marine Mammals Ordinance 1992 states that it is an offence to:

- Intentionally take, wound, or kill any marine mammal in Falkland Islands waters.

However, what constitutes a 'wound' is not clearly defined. Therefore, following the definitions used by the EC Habitats Directive, injury to a marine mammal (assumed to be analogous to wounding) is assumed to include:

- The creation of a 'Permanent Threshold Shift (PTS)' in hearing.

Further the Ordinance does not cover disturbance to marine mammals. Therefore, again, the EC Habitats Directive guidelines are followed in this assessment whereby it is an offence to intentionally or deliberately disturb any marine mammal in a way which is likely to:

- Impair its ability to:
  - Survive, reproduce or rear / nurture their young, and / or
  - Migrate.
- Significantly affect the local distribution or abundance of the species to which it belongs.

Note: in the UK, it is not an appropriate defence to claim that an impact upon a protected species was an 'incidental result of an otherwise lawful activity'. Therefore, in the UK, the potential for injury and / or disturbance must be assessed prior to commencement of relevant activities to determine the need for mitigation measures, or the need for a 'Disturbance Licence' where impacts may occur and cannot be mitigated. No such equivalent currently exists in the Falkland Islands.

10.4.2 Sources of underwater noise

Anthropogenic sources of underwater noise associated with the Phase 1 & 2 Development offshore include moderate intensity continuous (non-pulsed) sounds associated with:

- Drilling by a Mobile Offshore Drilling Unit (MODU),
- Noise from the Floating Production, Storage and Offloading (FPSO) vessel, and
- Vessel engine / thruster noise from the offshore support vessels, installation vessels and the CTTs.

Note: On examination, underwater noise from helicopters flying in accordance with (and in excess of) the FILFH (2024) minimum altitude was scoped out of the underwater noise assessment.

10.4.2.1 Drilling

Sound associated with drilling from the MODU will be created by rotating equipment such as generators, pumps and the drill string.

Drilling will occur during Stages 1 and 2 of the Phase 1 & 2 Development and noise will be continuously generated for sustained periods throughout the drilling operations.

In general, sound from drilling has been found to be predominantly low frequency (<1,000 Hz) with relatively low source levels (Greene, 1987; Huang, *et al.,* 2022; McCauley, 1998; Nedwell and Edwards, 2004). Furthermore, a study by Greene (1987) found that the sound generated by drilling activities from a semi-submersible did not exceed local ambient levels beyond one kilometre.

10.4.2.2 Installation

Transponders will not be required to site the FPSO or MODU. During construction, transponders may be used to site subsea equipment; these will be used for short periods of time and removed once the subsea construction phase is complete.

10.4.2.3 Vessel noise

Noise from vessels is generated by propeller cavitation, thrusters such as those used in Dynamic Positioning (DP) systems, and noise transferred to the ship's hull from the engine and other systems. Numerous vessels will be used during the Phase 1 & 2 Development.

Full detail on the type and purpose of all the vessels used throughout the Development is provided in Section 5.11.2.

Vessel noise will be present throughout all Stages of the Phase 1 & 2 Development (> 30 years). However, the frequency of vessel visits to the FPSO by the CTT will decrease over the life of the Field as oil production rates decline.

The relatively constant nature of the sound generated by the FPSO and direct offtake CTT vessels (when on site) means that animals are not subjected to sudden bursts (pulses) of noise. As the vessels, or animals, move through the water the sound intensity will increase, or decrease, gradually. The animals will be aware of sounds from large distances away and are unlikely to be startled.

The assessment within this section recognises that the source sound level will vary depending on activity. Although there is already a degree of vessel noise in the area (which is near a route taken by numerous fishing and trade vessels (Section 7.7.3.1)) during the course of the year, the static nature of the FPSO and several of the associated vessels represents a semi-permanent source of anthropogenic noise.

DP systems can be a specific source of marine noise given the relatively high-power thrusters employed. The approach of the CTT to the FPSO will be at low speed under its own propulsion and will be aided by a support vessel (tug) under low power that will hold the stern of the CTT under tension, sufficient to control heading (Section 5.10). During close approach, the CTT-tug combination will not operate on DP, although the tug would be DP-capable if required in an emergency. During offtake, the CTT-tug combination will again operate under relatively low power and low noise levels.

On departure, the CTT will move away at low speed, again under its own propulsion. When full, tankers will then either depart to market under main propulsion or remain in field maintaining position until the FPSO has a second cargo to offload, at which time the sequence will be repeated.

10.4.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts of underwater noise offshore warranted further investigation (Chapter 9). These include:

- Plankton (Section 7.4.1) and invertebrates in the North Falkland Basin (NFB) and around the Sea Lion Field (e.g., cephalopods and crustaceans) (Section 7.4.4.2),
- Fish in the NFB and around the Sea Lion Field (Section 7.4.4.2),
- Seabirds in the NFB and around the Sea Lion Field (Section 7.4.5.2), and
- Marine mammals in the NFB and around the Sea Lion Field (e.g., whales, dolphins and seals) (Section 7.4.6.2).

The above may be impacted upon as they either exist in, or spend time in, the zone influenced by anthropogenic sound. To varying degrees, all the above may use, or rely on, sound for various life functions and / or may be impacted upon directly by sound.

10.4.4 Characterising and quantifying the impact of underwater noise

When characterising and quantifying the impacts of underwater noise, it is necessary to consider:

- The behaviour of sound and how it is measured,
- Ambient noise levels,
- The concept of hearing thresholds in receptors (e.g., fish, seabirds and marine mammals),
- The nature of the impact on receptors, and
- Quantification of sound propagation - sound modelling.

10.4.4.1 The behaviour of sound and how it is measured and described

All sound travels in waves. Figure 10-10 illustrates a sound wave and the relationship between ‘peak pressure’ and ‘root mean squared pressure’. In understanding this chapter it is important to understand that:

- The 'Zero to Peak' Sound Pressure Level (PK) indicates the highest level of instantaneous sound received by a receptor at a given distance from the source (of note, ‘Zero to Peak’ is not used for continuous noise thresholds (i.e., for vessel noise)[55], and
- 'Root mean square' Sound Pressure Level (rms) is a means of displaying the average sound pressure over a period of time and is of greater use when assessing the potential for disturbance. This information is used to determine the distance at which injury and displacement / disturbance thresholds are exceeded.

Although continuous non-pulsed sounds (e.g., vessel noise) are often represented by an average, it should be noted that there will always be variability inherent in the sound source (i.e., peaks in sound output).

[55] SPLpk is not used in the updated modelling as the thresholds used are expressed in terms of rms SPL and SELcum. It is noted in the modelling report that the 0-pk level is estimated from rms levels accordingly: ‘For conversion of rms to zero-to-peak SPL, an increase of 3 dB has been assumed. This assumption is only valid for continuous sounds as it assumes an ideal sinusoidal wave and is therefore only an approximate conversion.

When reading this chapter, it is important to appreciate that the field of underwater acoustics utilises a great deal of technical terminology and to enable greater understanding of this chapter, the key terminology is defined in Table 10.18.

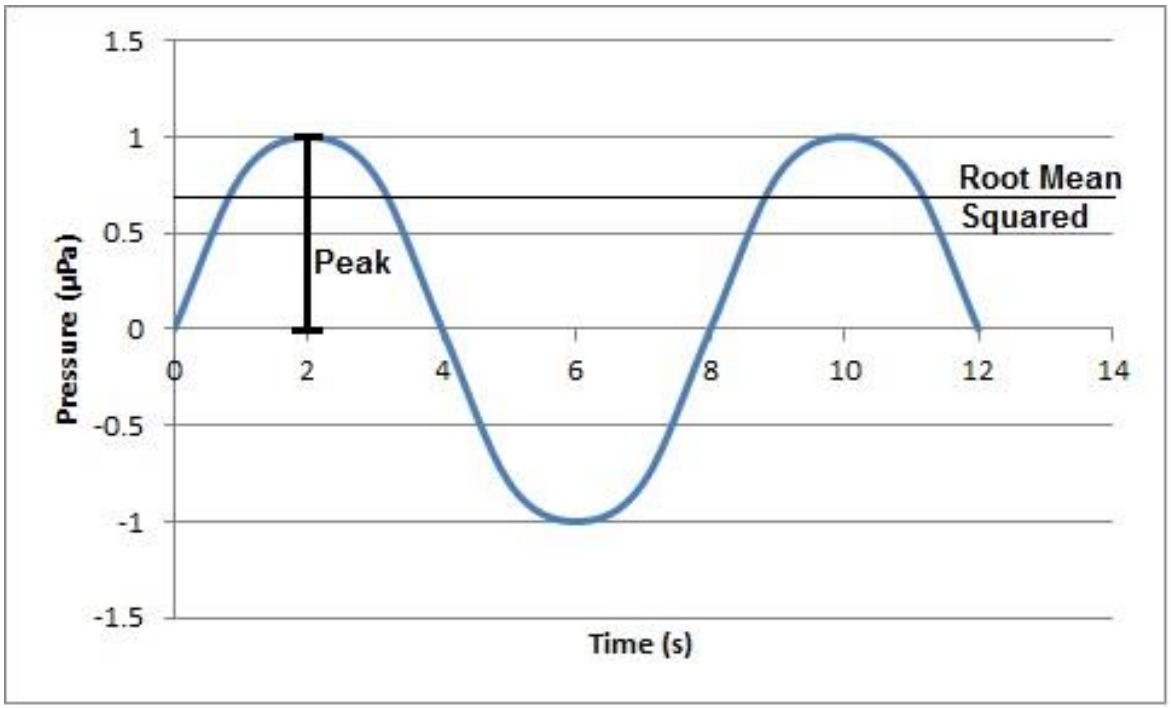

Figure 10-10: Sinusoidal wave showing changes in pressure over time, illustrating measurement parameters for Peak pressure (PK) and Root Mean Squared (rms) pressure

Table 10.18: Definitions of terms found in the text

Term	Definition
Hz	Hertz, a measurement of sound frequency (in cycles / waves per second). Differences in sound frequency are experienced by the listener as changes in pitch (a high frequency is high pitched whereas a low frequency is low pitched). Marine mammals have evolved to hear sounds over a specific range of frequencies, which are used to describe different hearing groups (e.g., low, moderate and high frequency cetaceans).
Recoverable injury	Recoverable injury, refers to injuries, including hair cell damage, minor internal or external bleeding. None of these injuries are likely to cause direct mortality.
TTS	Temporary Threshold Shift, a temporary, reversible increase in the threshold of audibility (i.e., a reduction in sensitivity) at a specified frequency or portion of an individual's hearing range (i.e., temporary deafness).
PTS	Permanent Threshold Shift; a permanent, irreversible increase in the threshold of audibility (i.e., a reduction in sensitivity) at a specified frequency or portion of an individual's hearing range (i.e., permanent, but not necessarily complete, deafness).
decibel dB (re. 1µPa)	The decibel (dB) unit is used to conveniently represent sound levels. re. 1µPa indicates a reference pressure for underwater sound The decibel (dB) is measured on a logarithmic scale. For example, the smallest audible sound (near total silence) is 0 dB. A sound 10 times more powerful is 10 dB., a sound 100 times more powerful than near total silence is 20 dB., and a sound 1,000 times more powerful than near total silence is 30 dB
Impulse sound	Sound sources that are typically short (less than 1 second) and of high intensity. Impulse sounds characteristically have high peak sound pressure with rapid rise and rapid decay. They can occur in repetition e.g., pile driving, or as a single event.

Term	Definition
Non-impulse sound	Generally, a continuous noise with little variation in level. Examples of non-impulse sound sources include drilling, marine vessels, aircraft, machinery operations / construction.
rms	Root mean square is the square root of the mean of the squares of the values under consideration, e.g., pressure levels measured. This can be used as a measure of the average sound pressure received. For conversion of rms to zero-to-peak SPL, an increase of 3 dB has been assumed. This assumption is only valid for continuous sounds as it assumes an ideal sinusoidal wave and is therefore only an approximate conversion.
Source level	Refers to the sound level at a nominal distance of one metre from the underwater sound source, expressed as dB re. 1 µPa @ 1m. In reality, it is not the actual sound level at one metre from the source, as the 'source level' is a construction based on long range measurement.
Sound Pressure Level (SPL)	A ratio of sound pressure and reference sound pressure, expressed in dB re. 1 µPa.
Zero to Peak Sound Pressure Level (PK)	Peak Sound Pressure is defined as the greatest absolute sound pressure within a specified time interval and frequency band. Although relevant to all sources of sound, zero to peak sound pressure is most relevant to impulsive sounds (e.g., short duration and high amplitude), which can create a greater risk of causing direct mechanical fatigue to the inner ear in comparison to sounds that are strictly non-impulsive. PK is expressed in dB re 1 µPa.
Cumulative Sound Exposure Level (SEL(cum))	A measure of the energy of a sound. This is therefore related to the Sound Pressure Level and time (exposure). SEL(cum)s are considered useful when making predictions about the physiological impact of noise: hearing damage can be modelled as a function of the acoustic energy of a stimulus, and the onset of temporary hearing damage depends on the SPL and exposure time (e.g., a subject can be safely exposed to a weaker stimulus for a longer time, but exposure to a loud stimulus would only be acceptable for a short time). SEL(cum) is expressed as dB re 1µPa^{2}s.
Hearing threshold	The average sound level, that is just audible to a subject (e.g., a human or a marine mammal) under quiet conditions.
Injury threshold	The sound threshold (intensity) at which a receptor may experience hearing injury, which would lead to a permanent shift in the receptors hearing ability.
Disturbance threshold	The sound threshold (intensity) at which a receptor may experience disturbance due to an inability to hear biologically significant sounds (such as communication calls) or may change its behaviour.
Avoidance / displacement threshold	The sound threshold below the injury threshold but sufficient for an animal to depart from an area to avoid disturbance. This can result in a cessation of feeding or mating behaviour.
Received noise level	The noise level at the receptor position of interest (in terms of modelling this can be thought of as the predicted level at the position of interest). This might be weighted to account for the hearing of the subject, if required.

10.4.4.2 Ambient noise

Hipsey *et al.* (2013) recorded ambient noise in the Sea Lion area and compared it to data gathered from other projects. The Sea Lion area was considered relatively quiet in terms of the rms SPL metric compared to other locations. Low frequency noise levels (10–100 Hz) however, were quite high compared to other regions, especially given the relative paucity of the anthropogenic sources that often dominate this part of the spectrum. Medium frequency noise levels (100–1,000 Hz) were lower than all but one of the other regions and those at higher frequencies (1,000-10,000 Hz) were comparable to most.

Recorded ambient noise levels were generally consistent with a remote, deep, continental shelf location in a temperate climate with occasional fishing activity but little or no regular mercantile shipping traffic. Ambient noise at the Sea Lion Field was considered to be mainly influenced by:

- Wind, waves and precipitation at the sea surface,
- Biological organisms,
- Shipping, and
- Distant seismic survey activity.

10.4.4.3 Hearing thresholds in receptors - the concept

It is important to acknowledge that the sound perceived by different species, and individuals within species, is not necessarily the same as the sound actually made. In other words, not all receptors (e.g., humans, marine mammals, seabirds) will perceive the same sound in the same way; to one it may be very loud while another cannot hear it at all. Similarly, hearing thresholds can differ between individuals and / or can change within an individual's lifetime.

For example, hearing sensitivity usually declines with age, particularly in the high frequency range. Such changes can occur naturally as a result of aging and associated wear and tear, or as a result of hearing injury caused by exposure to high intensity noise.

Irreparable damage to an individual receptor's hearing apparatus, and the associated shift in hearing sensitivity, is referred to as a 'Permanent Threshold Shift' (PTS). Shorter-term reversible changes to an individual's hearing ability (e.g., temporary tinnitus following exposure to loud music) is referred to as a 'Temporary Threshold Shift' (TTS) which can be experienced when individuals are exposed to sound levels below the PTS threshold.

Therefore, although perceived loudness is proportional to the 'Sound Pressure Level' (SPL), a SPL value in isolation would be meaningless if one wanted to predict how loudly another animal has perceived a sound, or whether a sound is likely to elicit a response or inflict injury. In part, this is because the hearing systems of animals are not equally sensitive to all frequencies. Therefore, in light of the above, an important concept is that of the 'hearing threshold'.

The hearing threshold is the level that is just audible to a subject under quiet conditions (Table 10.18). When the hearing threshold is plotted as a function of frequency, the plot is called an 'audiogram'. Figure 10-11 shows the audiograms for a range of receptor species. The audiogram plot indicates the average hearing threshold for a range of frequencies for each species. Note however, that the audiograms for most marine species remain unknown and those that have been published are often derived from a few individuals under artificial conditions. This is important in the context of baleen whales in the North Falkland basin.

Importantly, SPLs below the hearing threshold will not be detected at all.

To work through an example, in order to understand the audiograms (Figure 10-11), at a frequency of 1,000 Hz, the humpback whale has a hearing threshold of 42 dB re 1 µPa. This means that if a sound at 1,000 Hz was made, a humpback whale would not hear the received sound unless it was at or above a level of 42 dB re 1 µPa. The variables which affect whether or not a sound may be this loud include the nature of the source and the distance of the receptor from the sound.

When an animal experiences hearing loss due to excessive sound, the line displayed on the audiogram shifts upward (i.e., the animal would become less sensitive to sound at a given frequency).

This has resulted in the accepted use of weighting functions for some animal groups such as marine mammals that are applied to received noise levels to adjust them in relation to their hearing sensitivities, which is discussed further below.

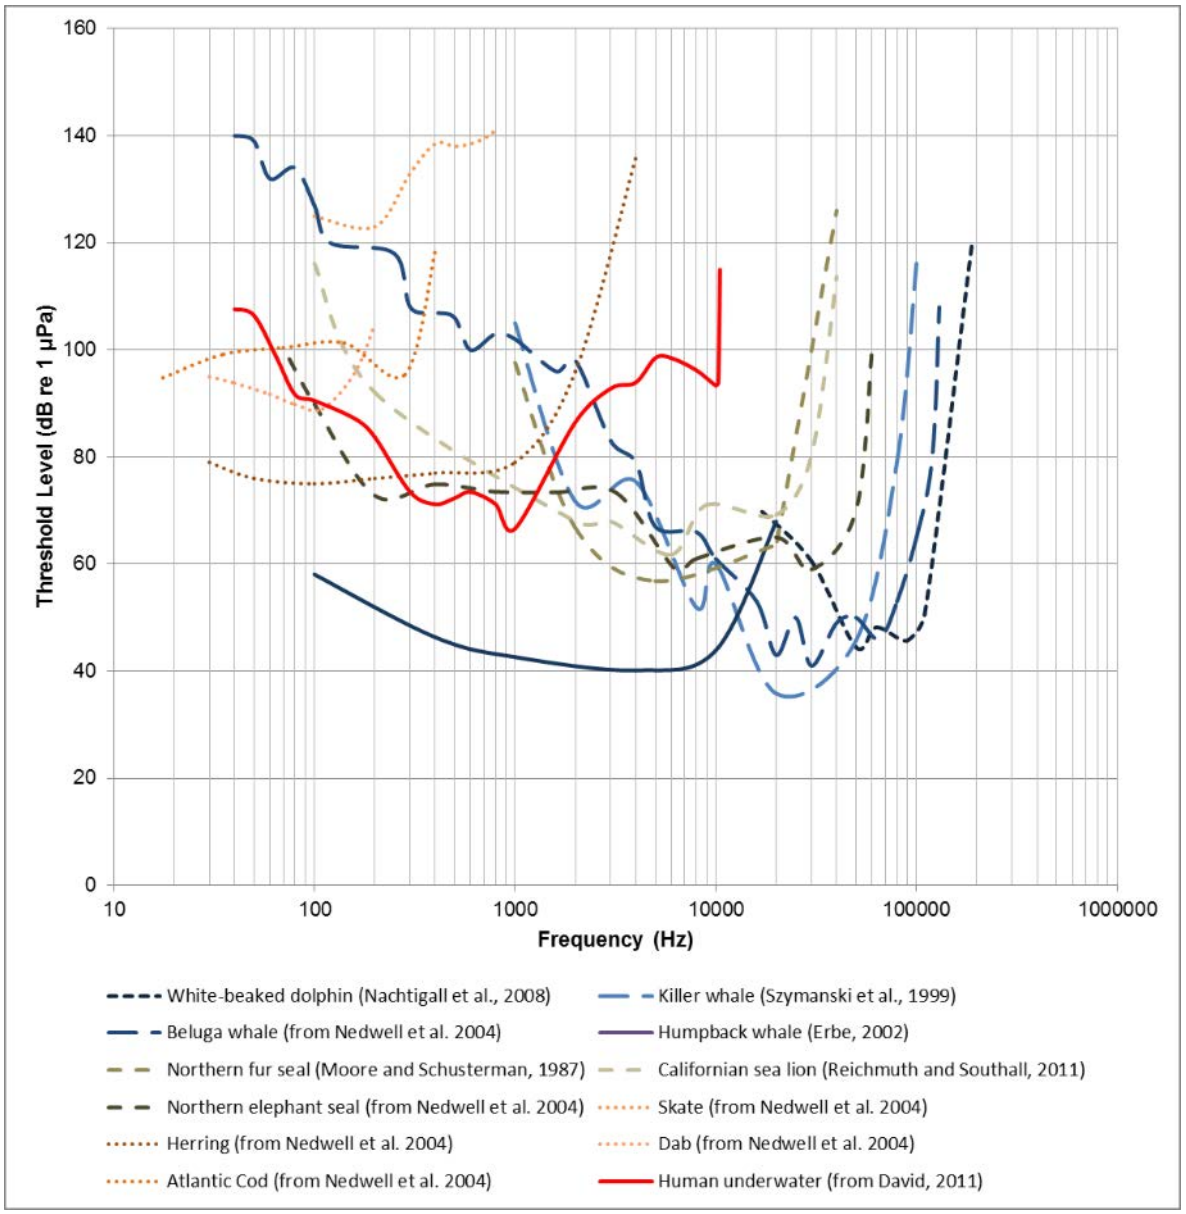

Figure 10-11: Audiograms covering a range of fish and marine mammal hearing groups and humans (underwater). Note that while some audiograms are measured others are estimated (e.g., humpback whale (Erbe, 2002)). This figure is included to give an understanding of audiograms only; these audiograms are not used in any later weighting functions but they have informed works like Southall *et al.* (2007; 2019)

10.4.4.4 Nature of the impact and the hearing thresholds of each receptor group

When assessing the impact of underwater noise on a given receptor there are two important considerations:

- Whether, and how, the sound will impact upon individual animals, and / or
- Whether, and how, the sound will impact upon the long-term viability of populations.

An action or activity becomes biologically significant to an individual animal when it interferes with normal behaviour and activity, or affects the animal's ability to grow, survive, and reproduce. Where a biologically significant proportion of a population is impacted, such effects may have consequences at the population-level and may affect the viability of the species (NRC, 2005). For receptor groups that are generally very numerous and reproduce often (such as invertebrates and fish) the impact at the population level is the key consideration. Where a species has a relatively small population size, and / or long generation time (e.g., marine mammals) the impact on individuals is more significant and may have direct implications for the local population.

10.4.4.4.1 Plankton

Research on the impacts of underwater noise to plankton is limited. Some research has shown that zooplankton can suffer various anatomical impacts because of noise exposure. Impacts can include internal cellular damage, disorientation, hearing loss and in some cases death (McCauley, *et al.,* 2017; Weilgart, 2018). Noise exposure can also cause elevated levels of stress hormones, which can have subsequent impacts on a variety of homeostatic processes (Nedelec, *et al.,* 2015). However these are mostly in response to impulse sounds such as seismic guns, which will not be used as part of the Phase 1 & 2 Development.

As no impulse sounds will be generated by the Sea Lion Development activities, plankton are not considered further within this chapter, or chapter 10.5 below.

10.4.4.4.2 Invertebrates

It is widely accepted that anthropogenic noise can impact invertebrates through:

- Physical effects (e.g., death, injury, damage to auditory system) (Harding and Cousins, 2022),
- Physiological effects (e.g., changes in stress levels, metabolism, immune responses), and
- Behavioural effects (e.g., avoidance responses, decreased foraging efficiency) (Celi, *et al.,* 2015; Edmonds, *et al.,* 2016; Hawkins and Popper, 2017; Vazzana, *et al.,* 2020).

However, while there is increasing research effort into understanding acute and chronic impacts of anthropogenic noise on invertebrates, it remains challenging to assess. This is in-part related to the difficulty associated with determining the sensitivity of marine invertebrates to sound (Hawkins and Popper, 2017).

The available evidence suggests that some species of cephalopod (e.g., squid and octopus) and crustaceans (e.g., crabs, lobsters and shrimps) are capable of detecting sound within the low frequency range, less than 3 kHz (OSPAR, 2009b). For example, Hu *et al.* (2009) discovered experimentally that the common octopus (*Octopus vulgaris*) can detect sounds between 400 Hz and 1,000 Hz. The bigfin reef squid (*Sepiotheutis lessoniana*) can detect a wider range of frequencies from 400 Hz to 1,500 Hz. The thresholds of *S. lessoniana* were generally lower than those of *O. vulgaris*, indicating greater sensitivity over a wider range of frequencies, and highlighting that species differ in their sensitivity to noise. The lowest thresholds for both species were at 600 Hz.

Other research has shown that some species of squid are similar to fish in their ability to detect sound (Mooney, *et al.,* 2010; OSPAR, 2009b) and are able to detect sounds of the types and frequency produced during O&G related activities. Further, studies have shown a potential behavioural response in squid, albeit to very high intensity underwater noise (e.g., seismic airguns of the kind that will not result from the Phase 1 & 2 Development) (McCauley, 2001). Nonetheless, in the absence of known injury or disturbance thresholds such as exist for fish, the potential impacts to squid have been assessed qualitatively. While commercially exploitable aggregations of squid are not known to occur

within the area of the Sea Lion Field (e.g., Section 7.7.3.1.1), it is necessary, from an ecosystem perspective, to assess the potential impact upon these animals.

Regarding other invertebrate groups, Wale *et al.* (2016) observed the effects of the playback of six hours of vessel noise to blue mussel *Mytilus edulis* in laboratory conditions. Algal clearance rates of noise-exposed mussels were significantly lower, and oxygen consumption rates higher than those of control animals, indicating stress. DNA damage in the gills and haemolymph was also observed.

10.4.4.4.2.1 Invertebrate injury / disturbance thresholds

There are no widely accepted criteria for the levels of sound likely to cause injury or disturbance to invertebrates. However, it has been suggested that further work on behavioral responses, effects of particle motion, development of dose-response data, hearing and population studies, would help to fill the research gaps required to develop robust thresholds and criteria (Hawkins and Popper, 2017).

Exposure to underwater sound from offshore shipping and construction activity can alter the contributions to fluid and particle transport from sediment dwelling invertebrates, which in turn could impact benthic nutrient cycling (Solan, *et al.,* 2016). The effects of sound may not be lethal, but could have significant functional, fitness and ecological consequences. For example, in the case of *Nephrops norvegicus*, Solan *et al.* (2016) showed that the addition of an anthropogenic sound source repressed burying and bio irrigation behaviour and reduced locomotion activity.

Jones *et al.* (2021) assessed the impact of pile driving underwater noise on feeding and alarm (defense) behaviour of longfin squid (*Doryteuthis pealeii*). They found that this type of impulsive noise can disrupt feeding behaviors. While there is no such impulsive noise planned during the Phase 1 & 2 Development, this demonstrates that squid are sensitive to certain types of underwater noise.

However, there is no reference in the literature to specific impact thresholds and as such, the potential for impacts to squid is assessed qualitatively in this chapter. In the absence of impulsive sounds from the Development activities, impacts to other invertebrates (e.g., crustacea) are not considered further within this chapter.

10.4.4.4.3 Fish

There have been some experimental investigations into the impacts of sound on fish but most of these investigations only concern a few fish species (and sometimes only a few individuals of these species). In many cases, the experimental design is flawed and the results vary widely (reviewed in Popper and Hastings, 2009). Nonetheless, it is understood that fish are able to both generate and detect sound which is used to communicate, sense their environment, and detect predators and prey (Popper, *et al.,* 2014). A recent study has shown that exposure to noise during breeding can have detrimental effects on the early-life development of common gobies (decreased yolk sac reserve and brood size, area and density decreased as noise increases) (Blom, *et al.,* 2024).

10.4.4.4.3.1 Fish hearing thresholds

Relatively little is known about sound perception in fish, particularly hearing sensitivity to particle motion (Popper and Hawkins, 2019). However, it is likely that particle motion is equally important as sound pressure in how fish and invertebrates perceive sound. It is known that otoliths (ear bones) and gas-filled bladders are both used to detect sound and fish can be broadly categorised according to the structures used for hearing (Table 10.19) (Hawkins and Popper, 2017).

The presence of a gas bladder is likely to increase the ability of many species of fish to detect sounds over a broader frequency range and at greater distances from the source than fish without such structures (Popper, *et al.,* 2014). Further, gas bladders, and their anatomical location within the body, make fish more susceptible to pressure-mediated injury to the ears and general body tissues than species lacking gas bladders.

In addition to the 'hearing' structures used, a number of other factors are likely to influence the impact of sound on any given fish species. These include:

- The hearing capabilities, whether generalist or specialist, and the lateral line structures of the fish,
- Life-styles (e.g., bottom dwelling *vs*. mid-water fish),
- The size of the individuals, and
- Behavioural responses to potential 'fright' stimuli (e.g., fish that stay in one location *vs.* species that swim away).

Most fish can hear, or detect, sound within the low range of <50Hz to 300 - 500 Hz (Popper and Hawkins, 2019) with some able to detect even lower frequencies. This range of frequencies overlaps with most anthropogenic sound sources in the marine environment and fish are known to react to approaching vessels at distances of 0.1 - 1.0 km (Mitson, 1995). Many species of fish also produce sounds for communication that are typically emitted at low frequencies below 1 kHz (Montgomery, *et al.,* 2006).

While many higher predators such as marine mammals and seabirds are considered of conservation importance, no specific marine fish species are listed in the 1999 or 2011 Falkland Islands Biodiversity Snapshots (Procter and Fleming, 1999; FIG, 2011) nor in the Falkland Islands Biodiversity Framework 2016-2030 and Falkland Islands Environment Strategy 2021-2040 (FIG, 2021a). Nonetheless, several species are important for commercial fishing.

Data are limited concerning the effects of sound on developing eggs and larvae. A study by Banner and Hyatt (1973) quoted in Buehler *et al.* (2015) found increased mortality was found in eggs and embryos of sheepshead minnow (*Cyprinodon variegates*) exposed to broadband noise (100–1,000 Hz) that was about 15 dB above ambient sound level. However, the same study found that hatched fry of sheepshead minnow and fry of longnose killifish (*Fundulus similes*) were not affected by the same exposure.

Table 10.19: Categorisation of fish hearing groups

Hearing Group	Characteristics
Fish with no swim bladder or other gas chamber (e.g., flatfish, skate)	These species are less susceptible to barotrauma and only detect particle motion, not sound pressure. However, some barotrauma may result from exposure to sound pressure.
Fish with swim bladders in which hearing does not involve the swim bladder or other gas volume (e.g., Atlantic salmon)	These species are susceptible to barotrauma although hearing only involves particle motion, not sound pressure.
Fish in which hearing involves a swim bladder or other gas volume (e.g., Atlantic cod, herring and relatives)	These species are susceptible to barotrauma and detect sound pressure as well as particle motion.
Fish eggs and larvae	For eggs and developing larvae, which may contain gas filled spaces, the inability to rapidly move away from sound sources make them susceptible to barotrauma

(Source: Popper, et al., 2014)

10.4.4.4.3.2 Responses of fish to anthropogenic sounds

The effect of exposure to excessive sound in fish can result in:

- Behavioural responses e.g., avoidance or an absence of response owing to masking of ambient sounds,
- Stress and other physiological responses,
- Hearing loss and damage to auditory tissue,
- Damage to non-auditory tissue e.g., damage to non-auditory swim-bladder and muscle tissue, and enhanced gas bubble growth and traumatic brain injury (see Richardson *et al.,* 1995; Hastings and Popper, 2005 for reviews),
- Mortality,
- Effects on the developing larvae and young fish in the presence of sound and / or after termination of sound, and / or
- Effects on larval behaviour and longer-term survival (Popper and Hastings, 2009).

There is evidence that fish react to vessel noise, which can be an issue for survey vessels conducting stock assessment research (Mitson, 1995). However, there is no suggestion that disturbance due to vessel noise causes long-term impacts on fish populations. Fish in the early stages of life are considered to be most vulnerable to sound (OSPAR, 2009b; Popper, *et al.,* 2014). Planktonic eggs and larvae may be more vulnerable than adult fish simply because they are unable to actively move away from a sound source. Further, eggs and larvae appear to be susceptible to barotrauma (pressure trauma) caused by rapid pressure changes resulting from impulse sounds (such as pile driving (which is not within the Phase 1 & 2 basis of design)); however, the available data suggests that mortality of eggs and larvae would only occur within a few metres of such sound sources (Popper and Hastings, 2009).

10.4.4.4.3.3 Fish injury and disturbance thresholds

Although data regarding the impact on fish is extremely patchy, a working group has published guideline thresholds for noise induced injury and disturbance in fish (Hawkins and Popper, 2014). Data gaps and critical questions concerning the effects of human-made sound on aquatic life are reviewed by Hawkins *et al.* (2015). The disturbance and injury thresholds for non-impulsive (e.g., vessel) noise are shown in Table 10.20 for fish grouped by their different hearing structures (Table 10.19 above). In some cases numerical guidelines are provided, expressed in appropriate noise metrics. In the context of fish injury thresholds, 'recoverable injury' refers to injuries, including hair cell damage, minor internal or external bleeding, none of which are likely to cause direct mortality. Although TTS injury is also, by definition, recoverable, TTS refers to changes in hearing sensitivity.

When there were insufficient data to support numerical values, the relative likelihood of effects occurring was evaluated at a range of distances from the source, although the actual likelihood of effects depends on the received level.

Table 10.20: Criteria for noise induced disturbance and injury in fish (shipping and continuous sounds)[1]

Fish type [2]	Thresholds for mortality and potential mortal injury	Impairment thresholds			Behaviour [4]
		Recoverable injury	Temporary Threshold Shift	Masking effect [3]	
Shipping and continuous sounds					
No swim bladder	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low

Fish type [2]	Thresholds for mortality and potential mortal injury	Impairment thresholds			Behaviour [4]
		Recoverable injury	Temporary Threshold Shift	Masking effect [3]	
Swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Swim bladder involved in hearing	(N) Low (I) Low (F) Low	170 dB rms for 48 hrs	158 dB rms for 12 hrs	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Eggs and larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

[1]*Source: Hawkins and Popper, 2014.*
[2] See Table 10.19 above.
[3] The phenomenon where ambient sounds an animal may ordinarily respond to are masked, and thus not heard, due to anthropogenic sound.
[4] Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I) and far (F).

10.4.4.4.4 Seabirds

The majority of seabirds do not spend prolonged periods underwater and are therefore not subjected to, or impacted by, anthropogenic underwater noise. However, some species; particularly penguins but also diving-petrels and shearwaters (many of which are recorded as present within the Sea Lion area (Section 7.4.5.2.1)), do spend considerable periods underwater.

Penguins are known to use contact calls to communicate when on the surface and there is some evidence to suggest that they vocalise underwater (Thiebault, 2019). Therefore, it is likely that penguins are able to sense sound underwater and may use sound to detect predators or prey (Thiebault, *et al.,* 2019). Recent research shows that gentoo penguins (*Pygoscelis papua*) show a graded reaction to underwater noise bursts, with little to no response up to 100 dB re 1 µPa to a strong reaction in nearly 60 % of playbacks at 120 dB (Sørensen, *et al.,* 2020). Although there has been limited dedicated research on these species, the presence of gas-filled spaces in these animals (i.e., lungs, inner ears) leads to the assumption that the impact of high intensity sound could result in barotrauma similar to that experienced by marine mammals and fish. Indeed, Cooper (1982) reports mortality of over 1,000 penguins and cormorants over a period of six months during which underwater blasting was carried out. In addition, a recent study showed that African Penguins (*Spheniscus demersus*) were temporarily displaced from their favoured fishing areas during seismic survey operations in South Africa, fishing significantly further from the seismic survey vessel during the operations and returning to the area once the operations ceased (Pichegru, *et al.,* 2017). Although the circumstances and intensity of the sound source during these observations were significantly higher than those predicted for the activities associated with the Sea Lion Development, these observations highlight the potential for underwater noise to impact seabirds.

Thiebault, *et al.* (2019) recorded a total of 203 underwater vocalisation from all three species of penguin during 4 h 43 min of underwater footage. Vocalisations were very short in duration (0.06 seconds on average), with a frequency of maximum amplitude averaging 998 Hz, 1,097 Hz and 680 Hz for king, gentoo and macaroni penguins, respectively. The vocalisations were emitted during feeding dives with more than 50 % directly associated with hunting. The function of these

vocalisations remain speculative. They seem to be related to hunting behavior and the authors conclude that this area warrants further research.

In addition, diving seabirds, such as penguins, are frequently observed reacting at close range (<100 m) to an approaching vessel (A. Black, *pers. obs*.). These birds abruptly change direction, swimming speed and dive duration, and are observed to flee (as if reacting to a predator) in a direction perpendicular to the vessel's course. However, it seems that these birds primarily react to the presence of the vessel rather than the sound, as the sound would be audible at a greater range. Further, penguins have been observed being positively attracted to stationary vessels (up to 100 in length) operating on DP control (A. Black, *pers obs*.).

10.4.4.4.4.1 Seabird injury / disturbance thresholds

Very little is known about the effects of underwater noise on seabirds. Current scientific understanding of the ability of seabirds to hear underwater is poor and it is not possible to undertake a quantitative assessment. For seabirds, there are no guidelines to determine what constitutes a behavioural disturbance or threshold sound level, although the work by Sørensen *et al.* (2020), would indicate that if penguins are <50 m from the sound source they may react to sounds at 120 dB re 1 µPa and above. However, it is recognised that seabirds foraging below the sea surface could be disturbed. Should this occur, it is predicted that seabirds will remain on the sea surface and will avoid being underwater until a specific vessel has moved away from the area, or the birds will temporarily relocate away. Temporary displacement from the area is not predicted to cause a significant effect as seabirds are recognised to have moderate to high level of habitat flexibility and are not constrained to the immediate area (Furness and Wade, 2012). It is therefore not expected that the proposed works will have a significant effect on bird species.

10.4.4.4.5 Marine mammals

The long-term continuous nature of vessel noise as a source of sound pollution could result in chronic impacts on a number of marine mammal species (Rolland, *et al.,* 2012; Hatch, *et al.,* 2008). It is understood that anthropogenic sources of sound in the ocean can disturb marine mammals (cetaceans and pinnipeds), evoking behavioural responses, similar to the response to predator risk, and can trigger physiological stress responses (Tyack, 2008; Rolland, *et al.,* 2012). Marine mammals are generally considered to be of the greatest conservation concern in relation to underwater noise pollution as they are protected species that are known to use sound to communicate over large distances, to navigate, and to detect potential prey or predators. Equally, the diving capacity of some marine mammals means that even sound energy emitted close to the seabed (e.g., from drilling) may be accessible to these receptors.

The Falkland Islands are a key area for beaked whales (MacLeod and Mitchell, 2023). Although beaked whale habitat normally occurs in deep waters (≥1000 m), Otley (2012) suggested that in the Falklands, beaked whales use shallower waters, which is known to occur elsewhere (Filatova, *et al.,* 2024).

Beaked whales are highly vulnerable to anthropogenic sound, which can displace the animals from foraging areas, cause permanent damage, or cause incidental mortality (Taylor, *et al.,* 2000; Barlow and Gisiner, 2006; Weilgart, 2013; Cholewiak, *et al.,* 2017; Joyce, *et al.,* 2018; Feyrer, *et al.,* 2024). However, quantifying impacts in open sea is extremely difficult, as the arrival of carcasses to the shore depend on environmental features and human population density (Faerber and Baird, 2010; Williams, *et al.,* 2011; Prado, *et al.,* 2013).

JNCC guidelines recommend that the proportion of the marine mammal population which could potentially be disturbed is assessed. Although there are sightings from various surveys and recordings from an acoustic monitoring study, there are currently no population estimates for any cetacean species in Falkland Islands waters. However, the available data do not indicate that the area

surrounding the Sea Lion Field is home to resident populations of marine mammals or is a feeding area of overriding importance for any species.

10.4.4.4.5.1 Marine mammal hearing thresholds

Cetaceans are known to emit sound over a large range of frequencies; from low frequencies (10 Hz) in the blue whale to higher frequencies (200 kHz) in some dolphins (OSPAR, 2009b). The hearing range of species however, is likely to extend beyond the known emitted sound range.

The auditory range of species can be determined through field observations, but this is extremely difficult for free-ranging animals in the marine environment. Auditory ranges may also be determined through experiments with animals in captivity. Of note, there is a lack of measured hearing range data for baleen whales. Furthermore, the full range of vocalisations used by many species encountered in the south-west Atlantic are poorly understood (Hipsey, *et al.,* 2013). Nonetheless, it is understood that different species of marine mammal are sensitive to different frequency ranges and animals can be categorised into one of five groups (Table 10.21). Inclusively, the range of frequencies utilised by an assemblage of marine mammal species can therefore be very extensive.

Table 10.21: Marine mammal hearing groups[1]

Functional hearing group	Estimated auditory bandwidth[2]	Species occurring in the Development area (Hipsey, *et al.,* 2013)
Low-frequency (LF) cetacean	7 Hz – 35 kHz	Southern right whale, humpback whale, fin whale, sei whale and minke whale (baleen whales)
High-frequency (HF) cetacean	150 Hz – 160 kHz	Sperm whale, southern bottlenose whale, long-finned pilot whale, killer whale and southern right whale dolphin (toothed whales and dolphins / porpoises)
Very high-frequency (VHF) cetacean	275 Hz – 160 kHz	Hourglass dolphin, Peale's dolphin and Commerson's dolphin
Phocid pinnipeds, (true seals, underwater)	50 Hz – 86 kHz	Southern elephant seal and leopard seal
Otariid pinnipeds, (eared seals, underwater)	60 Hz – 39 kHz	Fur seal species and South American sea lion

[1] **Note:** Both Southall *et al.* (2019) and the National Marine Fisheries Service (NMFS) (2018) provide estimated auditory bandwidths for hearing group categories. The 'Functional hearing Group' categories used in this chapter are those provided by Southall *et al.* (2019). While the NMFS (2018) use different names for the groups, both papers indicate the same frequency banding for the respective groups.
[2] Represents frequency band of hearing for entire group as a composite, individual hearing ranges are typically not as broad.

10.4.4.4.5.2 Diving capabilities of marine mammals

The diving capability of marine mammals is relevant because it indicates the potential for animals to be close to the source of the sounds made below the surface of the sea during the Phase 1 & 2 Development.

The water depth in the project area is in the region of 450 m. In terms of the position of receptors in the water column, while 450 m is deeper than the maximum diving range of fur seals and is on the limits of sea lion diving abilities (Riedman, 1990), this depth is well within the capabilities of southern elephant seals, which repeatedly dive to depths between 400 and 2,000 m (McIntyre, *et al.,* 2010; Piot, *et al.,* 2023). Massie, *et al.* (2015) recorded an average dive duration of 33 minutes for adult female elephant seals (maximum duration 95 minutes), which makes it difficult to visually track these animals.

Of the species of cetacean present in the NFB (Section 7.4.6.2), many are capable of diving to depths in excess of 450 m, the sperm whale, the pilot whale, beaked whales and orca are extreme divers,

with deeper and longer foraging dives than any other mammal species (Tyack, *et al.,* 2006; Schorr, *et al.,* 2014; Towers, *et al.,* 2019). Following habitat utilisation of beaked whales elsewhere, it is presumed that sighted individuals from fishing vessels operating in the Falklands might be residents (e.g., Gowans, *et al.,* 2000; MacLeod and Zuur, 2005; McSweeney, *et al.,* 2007; Falcone, *et al.,* 2009).

10.4.4.4.5.3 Responses of marine mammals to anthropogenic sounds

Underwater noise may result in a number of different impacts on marine mammals, as described in Table 10.22.

The strength of the effect on a marine mammal is affected by the sound received by the animal, which is related to the:

- The sound source level,
- Distance of the receptor from the sound source,
- Frequency of the sound, and
- Length of exposure to the sound.

However, although marine mammals will react to noise, the response between species and individuals also varies with context and is not only related to the sound level. For example, animals engaged in feeding may be reluctant to leave an area or animals that are accustomed to vessel noise may react to a lesser extent.

Further, it should be noted that behavioural changes in response to anthropogenic noise, such as moving away from an area for a short period of time, changes in dive-time, masking of communication signals or echolocation clicks for short periods, do not necessarily result in detrimental effects on the animals involved. A reaction lasting less than 24 hours, and not recurring on subsequent days, was not regarded as particularly severe by Southall *et al.* (2007). Though it should be noted that most project vessels will be attending the field for longer than 24 hours.

Table 10.22: The nature of potential impacts of sound upon marine mammals

Potential impact upon marine mammal	Nature of the impact
Masking	Masking occurs when anthropogenic sounds impair the ability of marine mammals to detect biologically significant sounds, such as communication calls, echolocation clicks or passive environmental sounds used in navigation or prey detection.
Behavioural disturbance – Avoidance / displacement	Behavioural disturbance is usually detected by changes in activity due to sound. This can range from strong avoidance behaviour (displacement) to subtle changes in vocalisations. The degree of behavioural change is very difficult to measure in the field and is likely to differ between, and within, individuals depending on their motivational state. For example, animals that are engaged in feeding may be more reluctant to change their behaviour and move away from a food source despite being subjected to noise.
Discomfort / stress	While Rolland *et al.* (2012) published results that correlate changes in stress related hormones with changes in the density of shipping traffic, there is limited information regarding stress in marine mammals as it is very difficult to measure. Consequently, the long-term impacts of noise induced stress are unknown.
Hearing loss	In more extreme cases, underwater noise may result in hearing loss, which could have severe consequences for animals through impaired communication and navigation skills and impaired prey / predator detection. Hearing loss can be classified as either: TTS (Temporary Threshold Shift), or

Potential impact upon marine mammal	Nature of the impact
	PTS (Permanent Threshold Shift). Recovery from TTS can occur over a relatively short period i.e., hours or days, whereas, PTS results from tissue or structural damage and is permanent. It is likely that behavioural changes will occur at thresholds below the TTS.
Tissue damage	Research on the non-auditory effects of sound on marine mammals (i.e., tissue damage) is in its infancy (OSPAR, 2012). However, there is evidence of enhanced gas bubble growth and traumatic brain injury (see Richardson *et al.,* 1995; Hastings and Popper, 2005 for reviews). It has been proposed that avoidance / displacement behaviour, induced by anthropogenic sound, may cause some deep-diving species (such as beaked whales) to surface rapidly or remain on the surface for extended periods. This can induce a condition similar to decompression sickness and has been proposed as a potential cause of stranding in these animals (Crum & Mao, 1996 in OSPAR, 2009b).

10.4.4.4.5.4 Marine mammal injury thresholds

The injury thresholds for marine mammal hearing groups, as provided by NMFS (2018) and Southall *et al.* (2019) are summarised in Table 10.23.

The PTS thresholds have been estimated from TTS levels, which have been derived for a limited number of species and TTS growth rates (change in TTS with increase in acoustic exposure) from studies of land mammal species. These PTS and TTS thresholds are taken for a single source (NMFS, 2018; Southall, *et al.,* 2019) and are used here to provide an indication for the potential injury from multiple sources.

Cumulative Sound Exposure Level (SELcum) is a measure of energy, summed over multiple exposures or a stated period of time (Table 10.18 above). It can be an extremely useful metric for assessing cumulative exposure because it enables sounds of differing duration, sometimes involving multiple exposures, to be compared in terms of total energy. The SEL values are weighted to account for the variable sensitivity to specific frequencies across these groups (Table 10.21 above).

Table 10.23: Marine mammal TTS and PTS injury criteria for non-impulsive sounds, as adopted in this assessment[1,2]

Hearing Groups [2]	Cumulative SEL (SELcum) Thresholds (dB re 1 µPa²s)	
	Permanent Threshold Shift (PTS)	Temporary Threshold Shift (TTS)
Low-Frequency Cetaceans (LF)	199	179
High-Frequency Cetaceans (HF)	198	178
Very High-Frequency Cetaceans (VHF)	173	153
Phocid pinnipeds in Water (PW)	201	181
Otariid pinnipeds in Water (OW)	219	199

[1] Note that these thresholds do not consider the cumulative or aggregate effect of multiple sources, and do not represent the entirety of an effects analysis but, rather, serve as one tool to help evaluate the effects of noise produced during a proposed action on a marine mammal.

[2] Sources: NMFS (2018) and Southall *et al.* (2019) - despite the difference in naming, the hearing groups proposed by NMFS (2018) and Southall *et al.* (2019) are equivalent and include the same marine mammal species. This report uses the Southall *et al.* (2019) terminology of marine mammal hearing groups.

[3] See Table 10.21 above.
[4] While the proposed activities do not include sources of impulsive noise, PK values are included for completeness as they can provide an upper limit threshold for both impulsive and non-impulsive sounds.

10.4.4.4.5.5 Marine mammal displacement and disturbance thresholds

The SPL thresholds for disturbance of marine mammals are as follows:

- Avoidance / displacement behaviour may occur at, or above, 160 dB re 1 µPa (rms), and
- Behavioural disturbance may occur at, or above, 120 dB re 1 µPa(rms).

These thresholds are given in Southall *et al.* (2007) and are unchanged by NMFS (2018) and Southall *et al.* (2019).

10.4.4.5 Quantification of the impacts - sound modelling

In order to quantify the potential impacts of underwater noise on fish and marine mammals, the sound generated by the different activities associated with the Phase 1 & 2 Development was modelled and compared with published thresholds for injury and disturbance (Section 10.4.4.4). Note however that there are currently no injury thresholds or disturbance guidelines for invertebrates or seabirds and therefore the impacts of underwater noise on these species are not specifically modelled. The modelling was carried out by Genesis Oil and Gas Consultants Ltd. using their in-house modelling software FARAM (Faunal Acoustic Risk Assessment Model). FARAM employs the parabolic equation and ray tracing algorithms developed by Collins (1993) and Porter and Liu (1994), respectively, for estimating received sound levels from various noise sources (Genesis, 2024a).

The modelling process was carried out in three main steps:

1) Identification of the levels of sound likely to be made by the Phase 1 & 2 sources of underwater noise. Source levels for use in the modelling have been derived from representative third octave band rms sound pressure level (SPL) frequency spectrums that have been obtained from published underwater sound measurements and mathematical models (Genesis, 2024a),
2) Use of a sound propagation model which assesses the way these sounds are likely to travel out from the sources and calculates the received levels at a given range. This utilises a fully range-dependent propagation model that includes bathymetry and properties of the water column and seabed, and
3) Assessment of the received sound levels against the defined injury and disturbance thresholds. As described in (Section 10.4.4.4), published data are available for:
   - Injury thresholds:
     - Fish (Popper, *et al.,* 2014), and
     - Marine mammals (NMFS, 2018; Southall, *et al.,* 2019).
   - Disturbance and behavioural response thresholds:
     - Fish (Popper, *et al.,* 2014), and
     - Marine mammals (Southall, *et al.,* 2007).

Scenarios were identified and modelled to assess the impacts of underwater noise associated with the different stages of the Phase 1 & 2 Development (Table 10.24).

To enable brevity in this section, the following provides only the information required to ensure appreciation and understanding of the modelling results and the impact assessments. Additional detail on the modelling methodology, the positioning of the sound sources, and results are provided in Genesis (2024a).

Table 10.24: Modelled offshore scenarios

Scenario ID	Project Description Phase	Sound Sources
Scenario 1	Drilling and Construction	1 x MODU (Mobile Offshore Drilling Unit) 2 x AHTs (Anchor Handling Tug) 1 x shared ERRV (Emergency Response Rescue Vessel) 2 x OCVs (Offshore Construction Vessel) 1 x PSV (Platform Supply Vessel)
Scenario 2	Steady State Production	1 x FPSO (Floating Production, Storage and Offloading unit) 1 x CTT (Conventional Trading Tanker) 2 x MRSV (Multi-Role Supply Vessel) 1 x shared ERRV
Scenario 3	SIMOPs (when Drilling, Construction and Production take place at the same time (Section 5.7))	Combination of all the sources in Scenarios 1 and 2, Only one ERRV is included in this scenario.

10.4.4.5.1 Step 1: Identification of Phase 1 & 2 Development source sound levels

Source levels for use in the modelling have been derived from representative third octave band rms SPL frequency spectrums that have been obtained from published underwater sound measurements and mathematical models (Genesis, 2024a). The representative levels are shown in Figure 10-12 and described in Table 10.25. It is anticipated that the Development activities will produce predominantly low frequency (<1,000 Hz) continuous sounds.

Vessel noise is primarily from propellers, propulsion and other machinery (Ross, 1976; Wales and Heitmeyer, 2002). Vessels are considered to be a continuous noise source. Where appropriate (based on vessel class), the JOMOPANS-ECHO model (MacGillivray and de Jong, 2021) has been used to estimate the source levels from the vessels in the described scenarios. The model uses the vessel length, speed and vessel class to determine the source level of the vessel. This model has been shown to provide a better match to measured vessel source level data compared to previous mathematical models such as the RANDI model (Breeding, *et al.,* 1996).

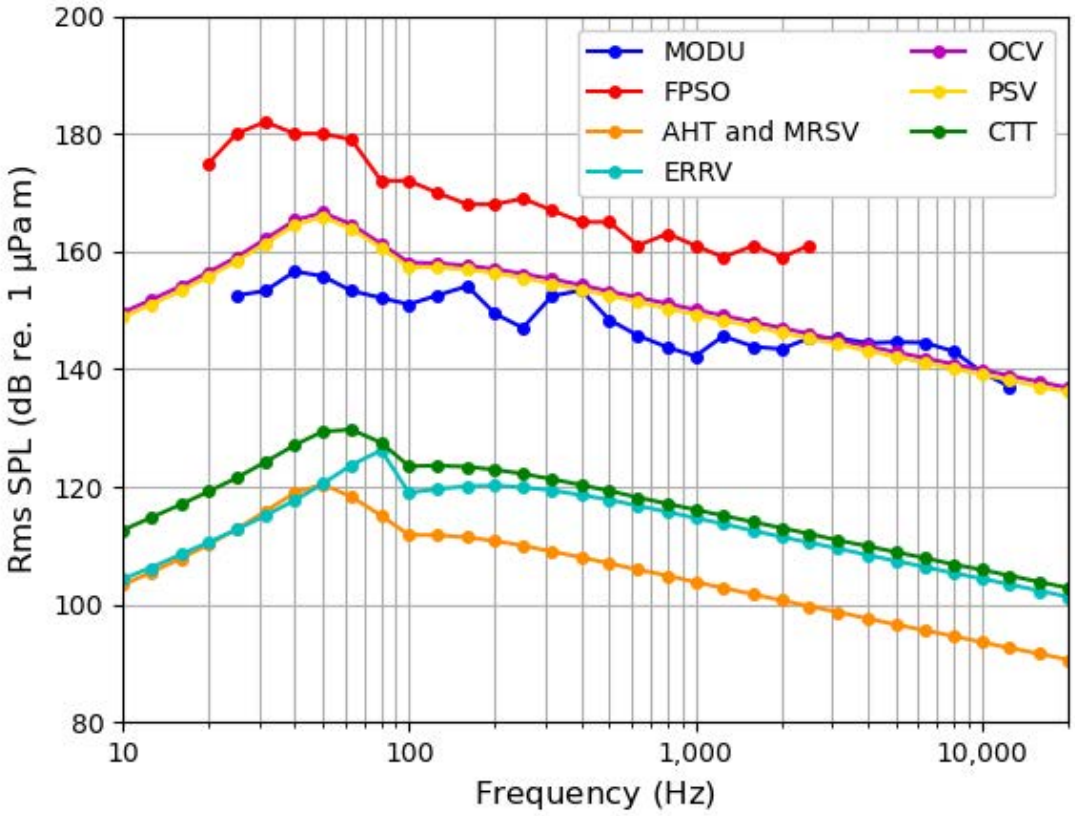

Figure 10-12: Generic vessel frequency spectrums used in noise modelling for Scenarios 1, 2 and 3

Table 10.25: Summary of specific source levels used in modelling[1]

Sound Source	Representative Source Spectrum Used in Modelling	Reference	Broadband rms SPL (dB re 1 µPa at 1 m)
MODU	Jack-up rig	Todd, *et al.,* 2020	165
AHT and MRSV	Bulker (speed = 2 knots, length = 282 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	127
OCV	Bulker (speed = 11 knots, length = 348 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	173
PSV	Bulker (speed = 11 knots, length = 319 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	172
ERRV	Emergency Vessel (speed = 2 knots, length = 185 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	133
FPSO	FPSO	Erbe, *et al.,* 2013	188
CTT	Tanker (speed = 2 knots, length = 820 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	137

[1] Please note the Broadband rms SPL values in Table 10.25 do not exactly correlate with the peak values shown in Figure 10-12 as those in Figure 10-12 are *generic* values for a range of vessels, whereas those in Table 10.25 are the specific vessel SPLs used in the model. The latter are, in fact, higher than the generic SPLs in Figure 10-12, to ensure a precautionary approach was taken in the modelling.

10.4.4.5.2 Step 2: Sound propagation modelling

The sound propagation models used in this assessment determine:

- The rms SPL, which indicates the received level of sound at a given distance from the source. This information is used to determine the distance at which injury and disturbance thresholds are exceeded, and
- The cumulative Sound Exposure Level (SELcum), which is a standardised measure of the overall sound energy that an animal will be exposed to (i.e., related to SPL and exposure time) over a specified length of time (a 24 hour period in this assessment).

As described in Southall *et al.* (2019), the SELcum was weighted according to the marine mammal hearing types (i.e., LF, HF, VHF and PW and OW hearing groups in Table 10.21 above). This accounts for the differences in the sensitivity of these groups to different frequencies.

10.4.4.5.3 Step 3a: Comparison of model results with injury thresholds

The purpose of the model is to determine whether or not the Phase 1 & 2 Development will emit sounds which can exceed the injury or disturbance thresholds, and the generalised area over which the injury or disturbance is likely to take place. Where available, the internationally recognised thresholds for injury and disturbance to fish and marine mammals have been used. There are no thresholds for assessing the impact of continuous sound on seabirds or squid. A qualitative assessment has therefore been undertaken for these receptor groups.

The descriptions below indicate where the relevant injury and disturbance thresholds for each receptor have been breached.

10.4.4.5.3.1 Fish injury

To quantitatively assess any potential injury to fish, fish eggs and larvae from the offshore activities, received noise levels in terms of unweighted rms SPL have been predicted and compared to the Popper *et al.* (2014) thresholds for injury for shipping and continuous sounds (Section 10.4.4.4.3.3).

Table 10.26 summarises (for all three scenarios described in Table 10.24 above) whether the thresholds for mortality and potential mortal injury for fish (Table 10.20 above) were breached for fish and, where appropriate, the distance from the source at which fish would be exposed to injurious sound. As shown, this threshold was not exceeded at any distance from the source in either of the scenarios (Table 10.26).

The modelling predicts that injury thresholds for fish with swim bladders involved in hearing will not be exceeded. For all other fish groups, the probability of mortality and potential mortal injury, recoverable injury and TTS is expected to be low at near, intermediate and far distances from the sound sources.

Figure 10-13 shows the maximum predicted rms SPL from the Scenario 3 activities in comparison to the Popper *et al.* (2014) rms SPL thresholds for potential injury to fish species. The offshore Scenario 3 result is the combination case (when Drilling, Construction and Production take place at the same time) and may be treated as the worst-case offshore setup. Figure 10-13 reflects the conclusions of Table 10.26, showing the recoverable injury threshold of 170 dB rms and the TTS threshold of 158 dB rms are not exceeded for fish. The other scenarios are presented in Genesis report: J-UK-00200-218436-Y-TN001-Sea Lion Project-Underwater Noise-Offshore-Report 0 (Genesis, 2024a).

The modelling predicts that the injury thresholds for fish with swim bladder involved in hearing will not be exceeded. For fish with no swim bladder and fish with swim bladder involved in hearing, the probability of TTS near to the sound source is moderate. For all other impairments and thresholds assessed, the probability of mortality and potential mortal injury, recoverable injury and TTS is expected to be low at near, intermediate and far distances from the sound sources.

Table 10.26: Predicted maximum distances from the offshore activities (all scenarios) where the rms SPL thresholds for injury to fish are exceeded

Fish Group	Impairment[1]	Threshold[1,2,3]	Maximum Distance to Threshold Exceedance (m)
Fish with no swim bladder	Mortality and potential mortal injury	Low	N/A[4]
	Recoverable injury	Low	N/A
	TTS	(N) Moderate (I) Low (F) Low	N/A
Fish with swim bladder not involved in hearing	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	Low	N/A
	TTS	(N) Moderate (I) Low (F) Low	N/A
Fish with swim bladder involved in hearing	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	170 dB rms SPL for 48 h	Threshold not exceeded
	TTS	158 dB rms SPL for 12 h	Threshold not exceeded

Fish Group	Impairment[1]	Threshold[1,2,3]	Maximum Distance to Threshold Exceedance (m)
Sea turtles	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	Low	N/A
	TTS	(N) Moderate (I) Low (F) Low	N/A
Eggs and larvae	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	Low	N/A
	TTS	Low	N/A

[1] See Table 10.20 above.
[2] Quantitative thresholds are expressed in terms of rms SPL.
[3] Quantitative thresholds were not established for all fish types or impairment types. Where this is the case, the risk of injury or impairment has been qualitatively assessed (Popper, *et al.,* 2014).
[4] Where there are no quantitative limits, the 'Maximum Distance to Threshold Exceedance' cannot be assessed. Therefore, for those rows this applies to, the notion that there is a maximum distance is not applicable.

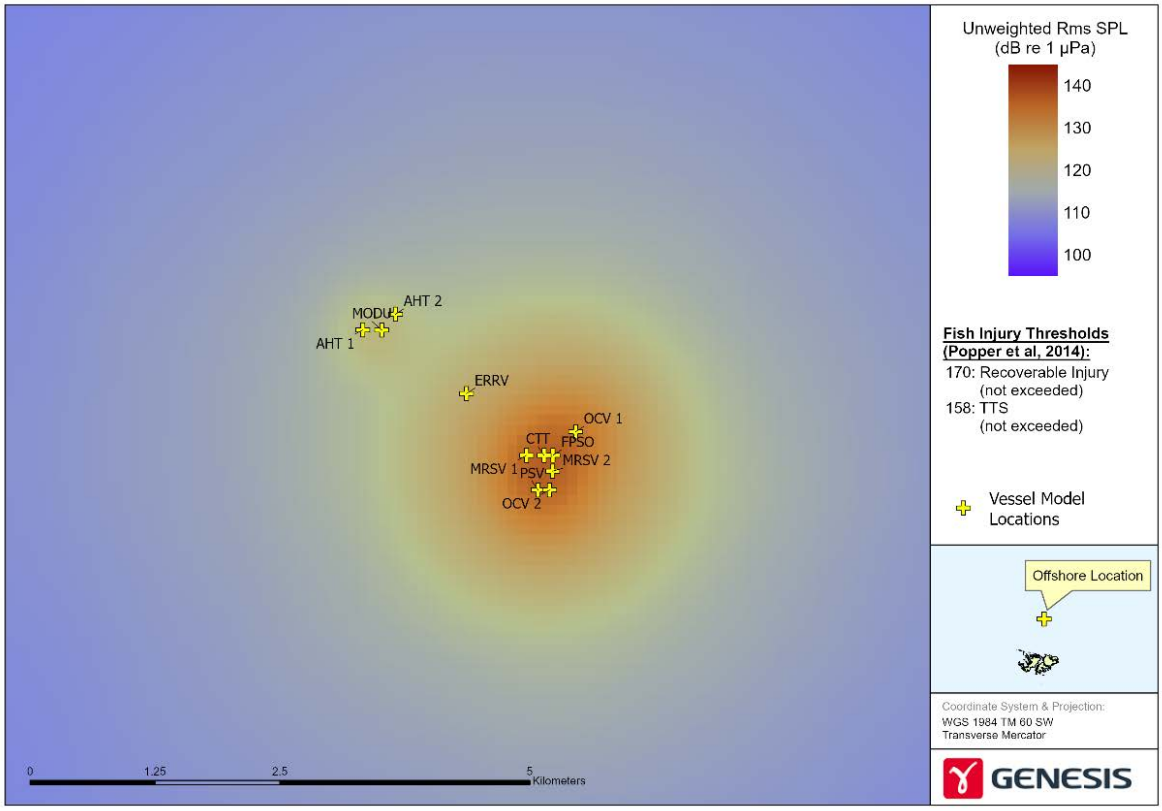

Figure 10-13: Maximum rms SPL received by fish in Scenario 3

10.4.4.5.3.2 Marine mammal injury

Received noise levels from the vessels in each modelling scenario have been predicted in terms of weighted cumulative SEL to identify the spatial area in which the onset of PTS or TTS may occur to marine mammals.

The marine mammal weightings are those given by Southall *et al.* (2019). In essence, these account for the hearing thresholds described in Section 10.4.4.3 and seen by the audiograms in Figure 10-11. The weighting curves are generalised forms for the different receptor groups described in Table 10.21.

Two situations are considered:

1) Where the mammals remain stationary, and
2) Where the mammals are assumed to flee from the noise source

Mammals assumed to be stationary

In the first situation, only the VHF cetaceans show a threshold exceedance (TTS threshold), and this is only for Scenarios 1 and 3 (Table 10.27). As well as assuming the marine mammals remain stationary in this case, the cumulative SEL results assume the period of interest is 24 hours. This means that in Scenarios 1 and 3, a VHF cetacean, e.g., a Peales's dolphin, would have to remain stationary within the respective 0.1 km^2 or 0.2 km^2 threshold exceedance areas for 24 hours for the TTS threshold to be breached, i.e., for a temporary hearing impairment to occur. The predicted areas where noise levels are above the cumulative SEL threshold for stationary mammals are summarised in Table 10.27.

Except for the VHF cetaceans, for all other marine mammal hearing groups (LF and HF cetaceans, and PW and OW pinnipeds), the cumulative SEL thresholds for PTS and TTS were not predicted to be exceeded over 24 hours for any of Scenarios 1 through 3. The exceedance VHF cetacean cases (for modelling Scenarios 1 and 3) are shown in Figures 10-14 and 10-15. These figures show the predicted cumulative SEL around the vessel location over 24 hours assuming that marine mammals remain stationary.

Table 10.27: Predicted areas where the cumulative 24-hour SEL may cause TTS[1] onset to marine mammals that remain stationary.

Scenario	Marine Mammal Hearing Group	Cumulative SEL TTS Threshold (dB re 1 μPa^2s)	Area of Threshold Exceedance [2,3] (km^2)
Scenario 1	VHF cetaceans	153	0.1[4]
Scenario 2	VHF cetaceans	153	Threshold not exceeded
Scenario 3	VHF cetaceans	153	0.2

[1] PTS thresholds are not included here as there are no scenarios where these are exceeded.
[2] Predicted areas have been rounded to the nearest 0.1 km^2
[3] Namely, the area surrounding the source within which the mammals may experience sounds which exceed the injury threshold.
[4] Navitas recognise that a TTS could be considered an injury and thus an offence under the Marine Mammals Protection Ordinance 1992 (section 1.1.1.1), however it is considered extremely unlikely that an animal would remain stationary within the areas identified for 24 hours in order to sustain the TTS impairment. This assessment demonstrates that impacts can only occur in an unrealistic situation.

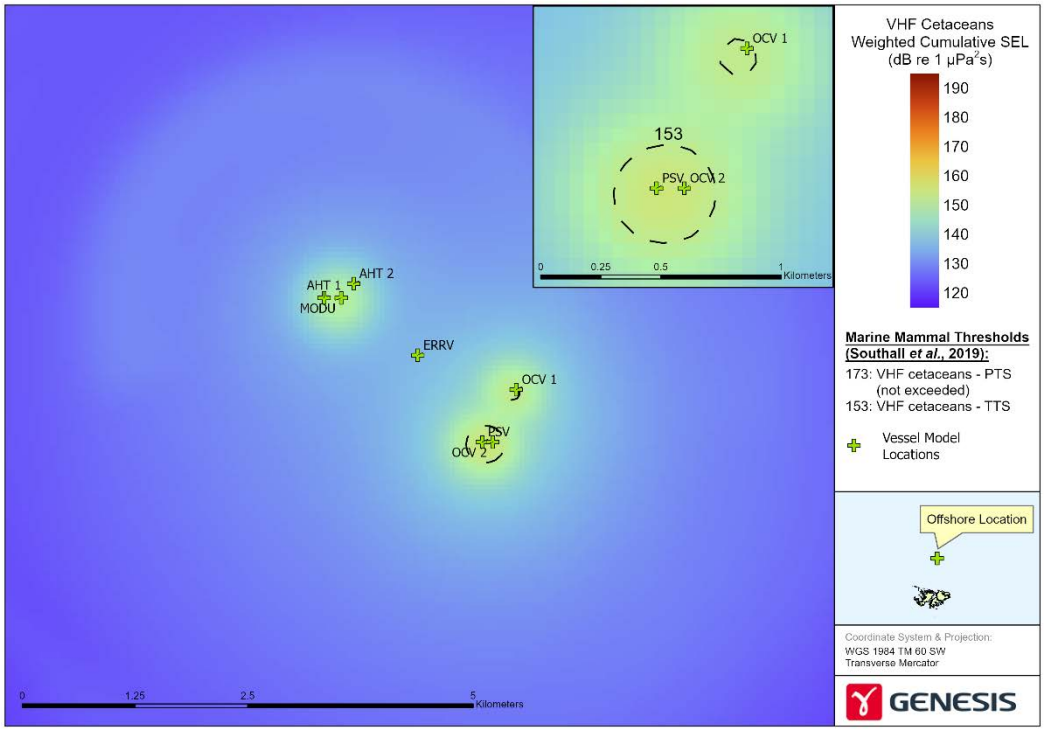

Figure 10-14: Predicted cumulative SEL received by VHF cetaceans during Scenario 1 over 24 hours; marine mammals are assumed to remain stationary

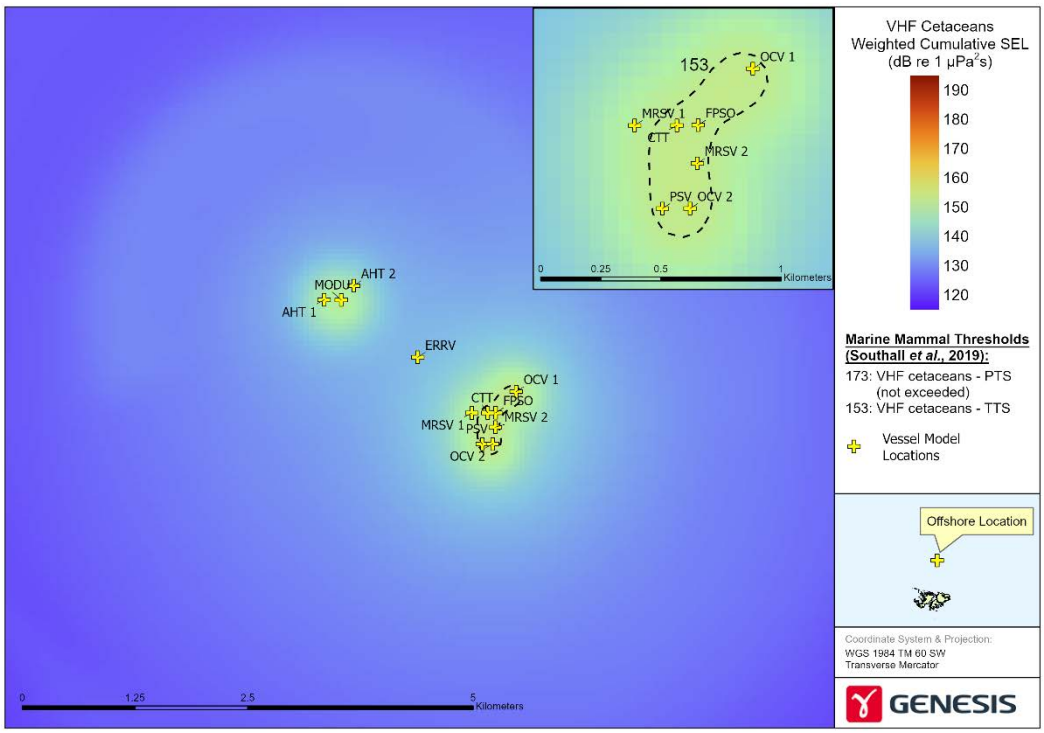

Figure 10-15: Predicted cumulative SEL received by VHF cetaceans during Scenario 3 over 24 hours; marine mammals are assumed to remain stationary

Mammals assumed to flee

In the second situation, marine mammals have been simulated swimming away from the vessel location at different swim speeds and from different initial starting distances from the vessel location. As the marine mammals swim away, their swim depth is allowed to change such that upon receiving sound, they are at the depth where sound levels are highest (note that the predicted received sound levels vary with depth). This is a conservative measure and will result in the highest predicted cumulative SEL received by the marine mammals as they swim away.

The vessel with the highest source level in each scenario has been used for the calculation. Here, this assumes a worst-case situation where the source levels of some vessels that may normally be stationary are instead taken to be moving at transit speed, i.e., are emitting more sound than usual. The relationships for many vessels noise source levels are related to ship speed; e.g., the JOMOPANS-ECHO model (MacGillivray and de Jong, 2021). For the Scenario 2 calculation, the CTT source levels used are the levels for the CTT at transit speed. Table 10.28 shows the vessel source levels of interest in the fleeing marine mammal calculations. Again, the cumulative SEL results assume the period of interest is 24 hours.

The predicted initial start distances from the source that marine mammals must be at, to not be exposed to sound levels exceeding the PTS and TTS thresholds, are summarised in Table 10.29. As shown, the modelling predicts that the marine mammal PTS and TTS thresholds will not be exceeded for any marine mammal hearing group in any offshore scenario provided that they swim away at a speed of at least 1.5 m/s from the vessel location. Therefore, it is expected that the risk of PTS or TTS occurring to any marine mammals will be low.

Table 10.28: Summary of source levels used in the fleeing marine mammal calculations

Sound Source	Representative Source Spectrum Used in Modelling	Reference	Broadband rms SPL (dB re 1 µPa at 1 m)
OCV	Bulker (speed = 11 knots, length = 348 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	173
CTT	Tanker (speed = 16 knots[1], length = 820 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	191

[1] Note the CTT will never be moving at 16 knots in the vicinity of the Sea Lion Field, this speed is used only to give the worst-case sound profile for the vessel within the model.

Table 10.29: Predicted initial starting distances from the vessel location where the adopted weighted cumulative SEL thresholds for non-impulsive noise[1] are exceeded for marine mammals swimming away from the vessel location at 1.5 m/s

Scenario	Representative Vessel	Marine Mammal Group	Distance to Threshold Exceedance[2] (m)	
			PTS	TTS
Scenario 1	OCV	All marine mammals	Not exceeded	Not exceeded
Scenario 2	CTT	All marine mammals	Not exceeded	Not exceeded
Scenario 3	CTT	All marine mammals	Not exceeded	Not exceeded

[1] See Table 10.23 above

[2] Namely, the area surrounding the source within which the mammals may experience sounds which exceed the injury threshold.

10.4.4.5.4 Step 3b: Comparison of model results with disturbance and behavioural response thresholds

Where noise levels fall below injury thresholds, animals exposed to long-term and continuous vessel noise can exhibit acute and / or chronic behavioural responses, rather than injury. The following sections discuss whether the modelled operations would result in potential disturbance and behaviour change in fish and marine mammals.

10.4.4.5.4.1 Fish disturbance by vessels

Documented behavioural effects of underwater noise on fish behaviour are variable, ranging from no discernible effect (Wardle, *et al.,* 2001) to startle reactions followed by immediate resumption of normal behaviour (Wardle, *et al.,* 2001; Hassel, *et al.,* 2004). Despite some documented behavioural effects, there are no well-established criteria or thresholds for assessing behavioural disturbance to fish. In fact, it was concluded in Popper *et al.* (2014) that there lacked sufficient evidence to recommend specific thresholds that correspond to behavioural disturbance to fish.

Popper *et al.* (2014) suggest that all fish are at high risk of masking[56] when they are close to continuous low frequency sources of noise, and those that use the swim bladder to detect sound are also at high risk at long range (Table 10.20). Fish that use the swim bladder are also at high risk of behavioural change when near to the source of noise (Table 10.20). However, if fish are disturbed during the proposed operations, it is assumed this would occur within the immediate vicinity of vessel activity. This area is very small in relation to the available area and the likely distribution of fish species

10.4.4.5.4.2 Marine mammal disturbance by vessels

While injury is very unlikely (Section 10.4.4.5.3.2), there is greater potential for long-term continuous vessel noise to cause behavioural disturbance. As described in Section 10.4.4.4.5.3, marine mammal responses to vessels vary but are generally not regarded as particularly severe (Southall, *et al.,* 2007)

Therefore, it is considered unlikely that a transiting vessel, such as those steaming to and from Stanley, would cause more than trivial disturbance that would be rapidly recoverable once the vessel passes (JNCC, 2010).

To predict distances at which potential behavioural disturbance to marine mammals may occur during the Development, received noise levels in terms of unweighted rms SPL have been estimated and compared to the adopted behavioural disturbance thresholds of 120 dB re µPa and 160 dB re µPa (Section 10.4.4.4.5.5).

The maximum unweighted rms SPL received from the vessels for all three modelling scenarios are shown in Figure 10-16 to Figure 10-18. The contours highlighted in the figures represent the threshold for signifying behavioural disturbance to all marine mammals.

The avoidance / displacement behaviour threshold 160 dB re 1 µPa is shown not to be exceeded in any of the modelling scenarios. However, there are a range of areas related to the activities of Scenarios 1, 2 and 3 where the behavioural disturbance 120 dB re 1 µPa threshold is exceeded. Scenario 3 (the combination case when Drilling, Construction and Production take place at the same time), results in the greatest area over which this behavioural threshold exceedance is seen (9 km^2, see Table 10.30 below. The table gives the predicted areas where noise levels are above the behavioural disturbance threshold.

The disturbance areas indicated should be treated as areas within which some (not all) marine mammals may exhibit behavioural responses. It is not suggested that all marine mammals will vacate

[56] Masking occurs when anthropogenic sounds impair the ability of an animal to detect biologically significant sounds.

these areas. Marine mammals will likely exhibit increased behavioural responses at distances closer to the vessel locations and there will be a reduced likelihood of response with increasing distance from the vessel locations (Southall, *et al.,* 2021).

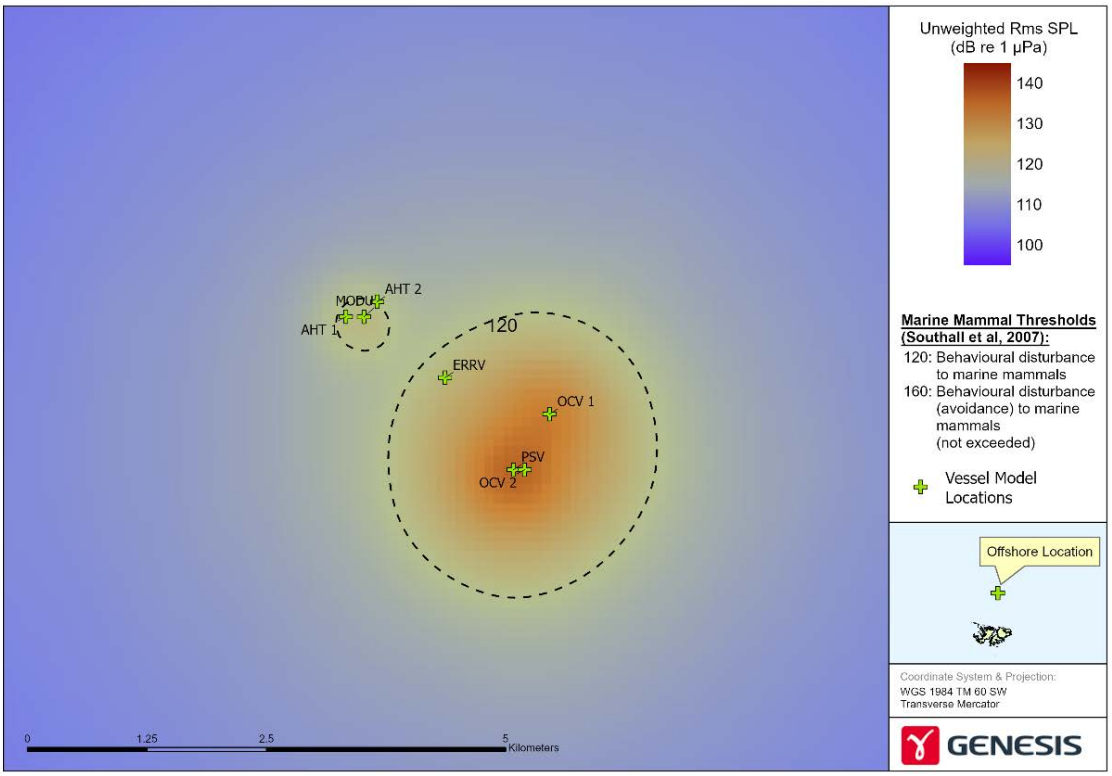

Figure 10-16: Predicted unweighted rms SPL received by marine mammals during Scenario 1

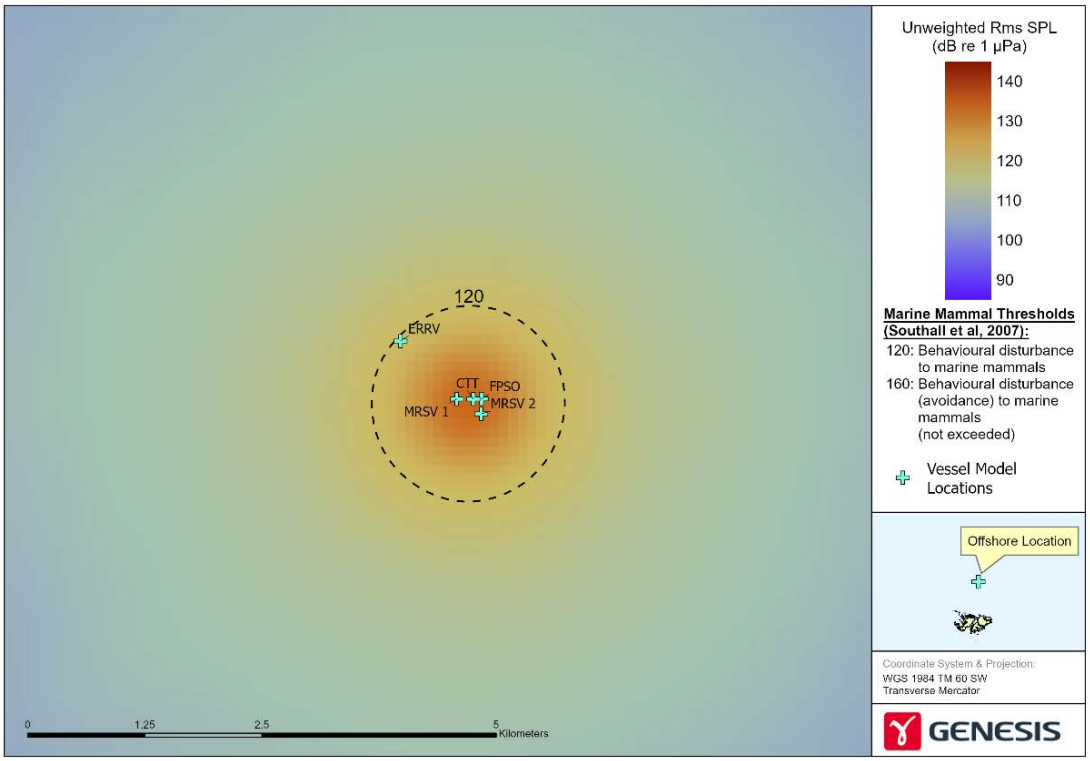

Figure 10-17: Predicted unweighted rms SPL received by marine mammals during Scenario 2

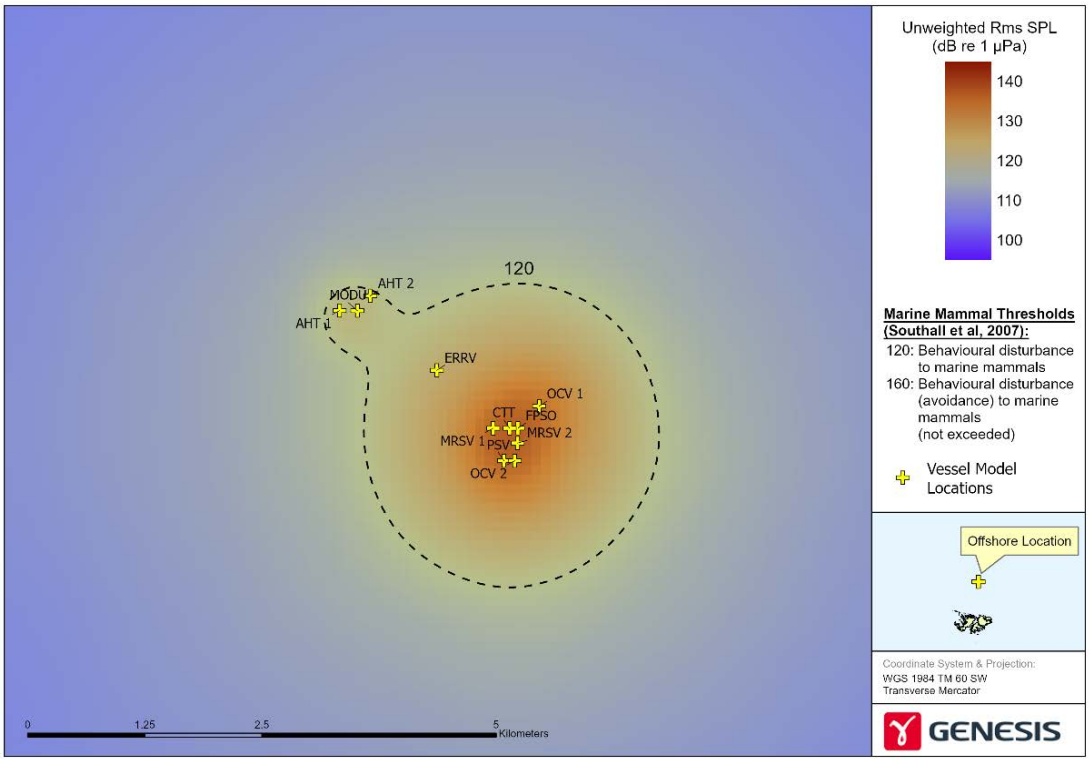

Figure 10-18: Predicted unweighted rms SPL received by marine mammals during Scenario 3

Table 10.30: Predicted area where the adopted unweighted rms SPL thresholds for disturbance to marine mammals is exceeded

Criteria	Behavioural Disturbance Threshold	Reference	Scenario	Area of Threshold Exceedance [1,2] (km^2)
Behavioural disturbance to all marine mammals	Rms SPL: 120 dB re 1 µPa	Southall, *et al.*, 2007	1	7
			2	4
			3	9
Behavioural disturbance (avoidance) to all marine mammals	Rms SPL: 160 dB re 1 µPa	Southall, *et al.*, 2007	1	Threshold not exceeded
			2	
			3	

[1] Predicted area has been rounded up to the nearest 1 km^2
[2] Namely, the area surrounding the source within which the mammals may experience sounds which exceed the injury threshold.

10.4.5 Industry standard mitigations

10.4.5.1 Vessel noise

There are no industry-standard mitigation measures specifically designed to reduce the impact of vessel noise on fauna. This is an area of developing good practice and improvements in ship design should be expected over time. For example, in 2014, the IMO published MEPC.1/Circ.833 Guidelines for the Reduction of Underwater Noise from Commercial Shipping to Address Adverse Impacts on Marine Life, and these were revised and approved in August 2023 (IMO, 2023). Also in 2023, the CMS produced a Technical Note on the Best Available Technology (BAT) and Best Environmental Practice (BEP) for mitigating noise from shipping (Section 10.4.1.1). These include considerations such as design measures to minimise noise due to propeller cavitation, improve hull flow and wake noise, the application of a 'radiated noise level' to ships, as well as reducing ship speed. These considerations are not as yet, an established part of marine vessel hire, but may form part of future environmental considerations. However, as part of the vessel hire process, Navitas will ensure vessels will be dry docked in accordance with their classification requirements and hulls and propellers will be cleaned accordingly. During operations, engines shall be maintained similarly and DP will be used only when necessary. All these actions will minimise underwater noise from all vessels.

Standard operating procedures, such as maintenance schedules, will help to minimise the noise generated by propeller cavitation. For fixed pitch propellers, sound generated is relative to vessel speed, whereas for variable pitch propellers the relationship between vessel speed and propeller speed (and the inception of cavitation) is more complex. All of the Sea Lion offshore vessels will have variable pitch propellers. Although speed restrictions are not proposed offshore, vessels operating in the vicinity of the Sea Lion Field are likely to be operating at low speed.

10.4.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of vessel noise on the varying receptors.

A summary of the impact assessment outcomes for this Development is tabulated in Section 10.4.12, which shows the worst-case impact for each activity and receptor and details are provided below.

10.4.6.1 Fish injury and disturbance

The sound modelling indicates that the thresholds for potential mortality to fish set by Hawkins and Popper (2014) are not exceeded for all three scenarios described in Table 10.24.

Although the influence of vessel noise may be detectable within the immediate vicinity of the Development (Section 10.4.4.5.4.1), this area is unlikely to contain significant populations of any species of fish (i.e., is unlikely to contain >1 % of the Falklands population). Therefore, the sensitivity of the receptor is considered to be '**Low**'.

Most species of fish in Falkland Islands waters are subject to commercial fisheries and any impact due to vessel noise from the Sea Lion Development will be insignificant in comparison. Therefore, the severity of the impact of vessel noise on fish is assessed as '**Slight**'.

Overall the significance of the impact of disturbance caused by vessel noise to fish is therefore considered to be '**Very Low (2)**'.

10.4.6.2 Invertebrates

Although there are no thresholds for the levels of sound likely to cause injury or disturbance to invertebrates such as squid, the literature suggests that impacts to feeding behaviour of invertebrates may be observed (albeit from impulsive noise) (Section 10.4.4.4.2).

While the influence of vessel noise may be detectable within the immediate vicinity of the Development, this area is unlikely to contain a significant abundances of any commercial squid species, and these would be transitory. Therefore the sensitivity of the receptor is considered to be '**Low**'.

Squid are subject to commercial fishing in the Falklands and any impact due to noise from the Sea Lion Development will be insignificant in comparison. Therefore the severity of the impact of vessel noise on squid is assessed as '**Slight**'.

Overall, the significance of the impact of disturbance caused by vessel noise to invertebrates is therefore assessed as '**Very Low (2)**'.

10.4.6.3 Seabirds

The presence of two of the four principle breeding species of penguin (rockhopper and Magellanic penguins) is highly seasonal within Falkland Islands waters, being far less numerous between May and September. However, the other two species (gentoo and king penguins) are present year-round and are more numerous in the NFB in the winter months. Therefore, it is possible to encounter penguins in the NFB throughout the year (Section 7.4.5.2.1). All of the species of penguin breeding in the Falklands (except the king penguin) are listed as priority conservation species and rockhopper penguins are classified as IUCN 'Vulnerable'. The Falklands population has shown a long-term decline in numbers and is the subject of a dedicated management plan (Kuepfer and Stanworth, 2023). Therefore, the worst-case sensitivity of receptor (penguins) is considered to be '**High**'.

There is nothing to suggest that vessel sound has any more than a very short-term and completely reversible impact on penguins. Indeed, it has been observed that some species of penguin, clearly evident in chinstrap penguins, are positively attracted to stationary research vessels (up to 100 m in length) operating on DP control (A. Black, *pers. obs*.). Although anecdotal, these observations indicate that penguins do not strongly avoid areas where vessel noise is prevalent, although have also been observed to flee in response to moving vessels (A. Black, *pers. obs*.). Additionally, research shows that penguins vocalise underwater and may use sound to detect predators or prey, with some penguins reacting to noise levels of 120 dB re 1 µPa, albeit only within 50m of the sound source (Section 10.4.4.4.4). Given the extent of available 'habitat' for penguins offshore, it is expected that

any impact would be transitory and therefore the severity of the effect on seabirds of disturbance due to vessel noise is assessed as '**Slight**'.

The overall significance of the impact of disturbance due to underwater noise is considered to be '**Low (4)**'.

10.4.6.4 Marine mammals

10.4.6.4.1 Marine mammal injury and vessel noise

Injury to marine mammals is not considered to be a credible possibility. Two situations were considered: marine mammals remaining stationary in the presence of the introduced noise, and the case where they flee in response to the noise.

For the stationary marine mammal situation (Section 10.4.4.5.3.2), only the VHF cetaceans (for Scenarios 1 and 3) are predicted to exceed the cumulative SEL TTS threshold. However, this would only occur if the animal remained stationary for 24 hours within (worst-case) a 0.2 km^2 area of the sound source. For all other marine mammal hearing groups (LF and HF cetaceans, and PW and OW pinnipeds), the cumulative SEL thresholds for PTS and TTS were not predicted to be exceeded over 24 hours for any of Scenarios 1, 2 or 3.

If the marine mammals are assumed to flee from the noise source, Section 10.4.4.4.3.2 shows that the marine mammal PTS and TTS thresholds will not be exceeded for any marine mammal hearing group, in any offshore scenario, provided that they swim away at a speed of at least 1.5 m/s from the vessel location.

Therefore it is expected that the risk of PTS or TTS occurring to any marine mammals will be negligible and the impact assessment is considered to be 'not applicable'.

It is assumed that animals would move away from the source of noise before being subject to a sound exposure level that would cause injury and therefore the impact of vessel noise is assessed as disturbance (below) rather than the potential for injury.

10.4.6.4.2 Marine mammal disturbance

The long-term continuous nature of vessel noise as a source of sound pollution could result in chronic impacts on a number of marine mammal species (Section 10.4.4.4.5).

Available evidence suggests that marine mammals are present within the zone of influence of vessel noise (within 30 km of the Development site) albeit with seasonal variation (Section 7.4.6.2.3). Although it is unlikely that the area under the influence of vessel noise around the Development site supports resident populations of cetaceans, it is likely that the area is traversed by numerous animals on migration (Section 7.4.6.2.3).

In terms of species sensitivity, the low-frequency cetaceans, such as fin, southern right and sei whales (all in the LF (7 – 3,500 Hz) hearing group), are considered the most sensitive receptors, due to their IUCN 'Vulnerable' and 'Endangered' statuses respectively and the overlap in their hearing range with vessel noise. To take a precautionary approach, it is assumed that the fin whale, known to be in the area year-round, and the sei whale, known to be seasonally abundant (Section 7.4.6.2.3), are the main receptor species. Additionally, within Falkland Islands waters all marine mammals are protected under the Marine Mammals Ordinance 1992 and all pelagic cetaceans, fur seals and sea lions are highlighted as Falkland Islands conservation priority species. Therefore, the sensitivity of the receptor is considered to be '**High**'.

Operations during the Phase 1 & 2 Sea Lion Development will add to the ambient noise levels in an area that normally experiences little anthropogenic sound (Section 10.4.4.2). Development activities

will produce predominantly low frequency (<1,000 Hz) continuous sounds (Section 10.4.4.5.1). Modelling of three typical scenarios (Table 10.24) was carried out and each scenario was shown to have spatially limited behavioral impact (Section 10.4.4.5.4.2):

- Avoidance behaviour / displacement of marine mammals: there was no exceedance of the 160 dB re 1 µPa threshold, and
- Behavioural disturbance of marine mammals: the areas shown in exceedance of the 120 dB re 1 µPa threshold are relatively localised (confined to the spatial extent of the development) and small, ranging from 4 - 9 km^2 across the three modelled scenarios.

Underwater vessel noise will occur throughout the Development's Field Life (*c.* 30 years), although it has been suggested that cetaceans can adapt to ambient noise and the area concerned is relatively small compared with the amount of available habitat. While a small increase in vessel noise around animals already subjected to, and possibly accustomed to, vessel noise may disrupt feeding and cause short-term stress, these impacts are very hard to measure. The constant nature of vessel noise means that marine mammals are gradually exposed to higher sound levels as they move closer to the source, hence they are able to change direction (i.e., move away from the sound source) before the impact causes any long-term effects. It is expected that any negative impact would be readily reversible once the animals move away from the source (as found by Rolland *et al.,* 2012). However, if the source was located in an area that was regarded as an important feeding or breeding ground the impact would be more significant. Globally, disturbance to marine mammals due to vessel noise is becoming a bigger issue (NOAA, 2004; Hatch, *et al.,* 2008), as the volume of vessel traffic increases year-on-year and the populations of these species (notably large baleen whales) increase following partial recovery from human exploitation. There is little information regarding the long-term implications of vessel noise on marine mammal populations and therefore a precautionary approach has been taken and the severity of effect has been assessed as '**Minor**'.

The overall significance of the impact caused by vessel noise emanating from the Development site has therefore been assessed as '**Moderate (8)**'.

10.4.7 Project-specific mitigation

Although the impact of moderate intensity sound (e.g., from vessel noise) is considered to be of 'Moderate' significance (mainly owing to the protected nature of the receptors and the precautionary assessment of the severity of effect) there are currently no guidelines governing anthropogenic noise that does not exceed the PTS threshold.

In some circumstances, a reduction in ship speed may reduce the level of underwater noise. However, this applies only to vessels with fixed pitch propellers when the speed becomes lower than the cavitation inception speed (i.e., it does not result in a lower sound with all vessels). Therefore, for ships equipped with controllable pitch propellers, there may be no reduction in noise with reduced speed (IMO, 2023).

The project incorporates a moored MODU. This has significantly lower noise impacts than a MODU that uses solely DP for station-keeping that would also be viable in this location. Additionally, the use of a tug to hold back and position the CTT during offloading also has a significantly lower noise impact compared with the use of a DP tanker. Lastly, the change in well design means that piling will not be required, which significantly reduces the underwater noise produced. However, it is noted that these options are chosen for reasons other than their environmental impact and are not implemented as mitigation to address any significant impacts or risks.

10.4.8 Residual impacts and risks

Disturbance due to vessel noise will continue throughout the *c.* 30 year Field Life of the Development and is the most significant impact associated with underwater noise. While there are means of reducing the amount of noise emitted by vessels, as described above, the most effective of these need to be built-into the design of the vessels concerned.

The degree of residual impact will therefore depend on the vessels contracted to work on the Sea Lion Development and, at the time of writing, these details are unknown. Therefore, as a precautionary approach at this pre-FEED stage in the process, the residual impacts from vessel noise, to all receptors, remain the same. Therefore, the worst-case impact remains as '**Moderate (8)**' with regard to behavioural disturbance to marine mammals.

10.4.9 Cumulative impacts

Commercial shipping is a major contributor of low frequency (5 - 500 Hz) background noise in the world's oceans and therefore there is the potential for cumulative impacts from increased 'concentration', increased 'extent and proportion' and increased 'duration' of underwater noise (Section 8.9.1).

Globally, the number of ships in operation has tripled in the last 50 years and shipping noise levels have increased at the rate of approximately 3 dB per decade (OSPAR, 2009b). Indeed, disturbance from vessel noise is becoming an issue in areas where high shipping density and cetaceans coexist (Hatch *et al.,* 2008).

Acoustic recordings indicate that the Sea Lion Field is subject to low ambient anthropogenic noise (Section 7.4.6.2.1.2) and therefore there will be little cumulative impact near the Field. Shipping routes around the Falkland Islands converge on Stanley and Berkeley Sound. Therefore, vessels associated with the Development travelling to and from Stanley have greater potential to add cumulatively to the existing vessel noise in inshore waters off the east coast of the Falklands (see Section 11.1).

The cumulative impact of underwater noise from other users of the NFB would fall under Category 2 (see Section 8.9.1) whereby the extent and proportion of the impact may be increased. The edge of the continental shelf to the south of the Development (along the 200 m isobath) is heavily fished by demersal trawlers. Although these vessels are not static and individually may not have a significant impact, where several vessels are fishing in the same general area, or a single vessel is fishing the same area for consecutive days, they could contribute to the disturbance impact.

In comparison to the impact of commercial fisheries on fish and cephalopod species in Falkland Islands waters, the impact of vessel sound during the Phase 1 & 2 Development is considered to be negligible.

10.4.10 Confidence

The noise sources modelled for disturbance impacts are representative of different stages of the project. The scenarios modelled form a realistic build-up of the likely underwater noise climate and established and peer reviewed thresholds for injury and disturbance have been explored to show the likely extent of impact. Importantly, a fully range dependent noise model has been utilised that incorporates:

- Site-specific bathymetric grids to account for the influence of varying bathymetry on noise propagation,
- Site-specific range and depth dependent water column temperature, salinity, and sound speed profiles based on modelled hydrological conditions,

- Acoustic properties of the predominant seabed sediments in the modelling area,
- Frequency dependent propagation effects (e.g., volume attenuation, reflection, scattering at different frequencies), and
- Specific properties of the noise source under consideration.

These factors combined are considered a best approach to making sound judgements on the impact to marine life from the Development's proposed noise related activities.

However, there is uncertainty over the long-term impact of less intense continuous underwater noise such as that from vessels and also over the marine mammal distribution on the NFB.

The uncertainty over the potential impact of noise disturbance on individual marine mammals and populations is acknowledged as a data gap. Furthermore, while there are some data available regarding the intensity of sound produced by vessels and activities associated with the O&G industry under operational conditions, the exact vessels to be used for the Sea Lion project have not yet been determined. Accurate input parameters are vital for modelling purposes.

With regard to the uncertainty over marine mammal distribution, previous observational and acoustic surveys give a reasonable indication of the species present but further surveys would help to determine the inter-annual variation in marine mammal abundance in the area and help to resolve the status of rare species. Furthermore, acoustic surveys would help to evaluate the vocal range of the species encountered within Falkland Islands waters. The inter-annual distribution and abundance of marine mammals in the NFB is acknowledged as a data gap.

With regard to other receptors considered, e.g., squid and diving seabirds, the impact assessments are qualitative, and the absence of disturbance or injury thresholds is acknowledged.

Therefore, on balance, the confidence in the assessment of noise disturbance is assessed as '**Uncertain**'.

10.4.10.1 Monitoring required

It is clear that disturbance due to vessel noise is becoming an increasingly significant issue and yet there is very little hard evidence to support the precautionary conclusions of this assessment and therefore monitoring will be required.

UK good practice will be followed and there will be Seabird and Marine Mammal Observers (SMMOs) on board vessels to provide ongoing monitoring. Monitoring of day-to-day operational noise *via* hydrophones (i.e. Passive Acoustic Monitoring (PAM)), including during activation of thrusters as well as various vessel scenarios will also be undertaken to understand baseline noise levels during operations.

A review of all SMMO reports will be carried out every six months and after the first three years of SMMO deployment to validate the EIA and to inform decisions on whether ongoing monitoring is necessary.

Navitas will investigate the use of noise minimisation in the design of vessels, where possible.

Detailed monitoring requirements have been established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline EMMP is provided in Chapter 15.

10.4.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

10.4.12 Findings summary

Table 10.31: Summary of the impact assessment for underwater noise offshore[1]

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity[1]	Severity[1]	Likelihood[1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Underwater Vessel noise	Continuous moderate intensity noise	Injury and disturbance to fish	Planned	1,2a, 2b & 3	Low	Slight	n/a	**Very Low (2)**	**n/a**	**Uncertain**	**Industry-standard:** None. **Project-specific:** None proposed.
		Injury and disturbance to invertebrates (including squid[2])		1,2a, 2b & 3	Low	Slight	n/a	**Very Low (2)**	**n/a**		
		Injury to seabirds		1,2a, 2b & 3	High	Slight	n/a	**Low (4)**	**n/a**		
		Injury to marine mammals		1,2a, 2b & 3	n/a	n/a	n/a	**n/a**	**n/a**		
		Behavioural disturbance to marine mammals		1,2a, 2b & 3	High	Minor	n/a	**Moderate (8)**	**Moderate (8)**		

[1] See Chapter 8 for definitions of sensitivity, severity, likelihood and significance.
[2] Squid and seabirds are qualitatively assessed as there are no thresholds against which to compare modelling outputs.

10.5.1 Introduction

Underwater noise will be generated by vessels operating in Berkeley Sound during two relatively short periods in the early years of Field Development.

Large Transport Vessels (LTVs), used for floating storage of the subsea infrastructure will be anchored for up to thirteen months to support the offshore construction stages of the Development. These will be periodically attended by Offshore Construction Vessels (OCVs) to which the infrastructure will be offloaded for transportation to the Sea Lion Field for installation. Thereafter there will be no project related vessels anchored in Berkeley Sound.

Note: the other impacts associated with vessel use are described elsewhere in this document, as summarised in Table 2.2, and the impacts of noise from vessels used offshore are assessed in Section 10.4.

Note: owing to the complexity of language used when assessing the impact of sound, it is advised that Section 10.4 be read first as many sections in the following chapter refer back to sections that provide common information to avoid repetition.

10.5.1.1 Relevant legislation

A summary of the key pieces of legislation relating to environmental impact from underwater noise is given in Section 10.4.1.1.

10.5.2 Sources and types of underwater noise associated with LTVs

Anthropogenic sources of underwater noise associated with the inshore activities of the Phase 1 & 2 Development include:

- Moderate intensity continuous (non-pulsed) sounds from vessels:
  - Use of LTVs during the offshore construction phase, and
  - Vessel engine / thruster noise generated by visiting OCVs.

Following the offshore installation campaigns, vessel presence within Berkeley Sound would be an exception (e.g., to shelter during bad weather), with the base case being zero project vessels within Berkeley Sound.

Note: On examination, underwater noise from helicopters flying in accordance with (and in excess of) the FILFH (2024) minimum altitude was scoped out of the underwater noise assessment.

10.5.2.1 Use of Large Transport Vessels (LTVs)

LTVs will be used to transport the following to the Falkland Islands where they will be stored onboard until they are required offshore:

- Drilling infrastructure e.g., Blow-Out Preventors (BOP's) (Section 5.4.10),
- Subsea Production System (SPS) infrastructure (Section 5.5.3),
- Subsea Umbilicals, Risers and Flowlines (SURF) (Section 5.5.3),
- The Floating Production, Storage and Offload (FPSO) vessel mooring infrastructure (Section 5.6),
- General equipment, and
- Bulks.

On arrival in the Islands, the LTVs will anchor in Berkeley Sound and function as floating storage / logistics barges. Materials and equipment will be collected from the LTVs by the OCVs and transported offshore to Sea Lion for installation.

A maximum of two LTVs at any one time will be present for around five months during Stage 1, two months during Stage 2a, and six months relating to Stage 2b (beginning one month before Stage 2b begins) (Section 5.5.1). Each vessel will have its own individual 500 m exclusion zone.

When at anchor and not offloading their cargo, the LTVs will maintain one generator to keep the ship's facilities running but otherwise they will be on the anchor, weather vaning, minimising the noise they produce. When offloading they will be fully powered to enable safe operations.

The proposed anchorage locations are shown in Section 5.5.1. However, Navitas will work with FIG FIMA / Fisheries to identify optimum locations within Berkeley Sound that will cause the least disruption to other users during periods of high marine traffic in the Sound.

10.5.2.2 Use of Offshore Construction Vessels (OCVs)

During the offshore installation campaigns the OCVs will visit the LTVs in Berkeley Sound to collect equipment required for the offshore installation. It is anticipated that during:

- Phase 1 drilling, the OCVs will visit Berkeley Sound 11 times, and
- Phase 2 drilling, the OCVs will visit Berkeley Sound four times.

10.5.2.3 Bunkering of LTVs

As required, a Stanley Services' tanker will supply Marine Gas Oil (MGO) to the LTVs.

10.5.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts of underwater noise warranted further investigation (Chapter 9). These include:

- Invertebrates (e.g., cephalopods and crustaceans) in Berkeley Sound (Section 7.4.4),
- Fish in Berkeley Sound (Section 7.4.4.3),
- Seabirds in Berkeley Sound (Section 7.4.5.3), and
- Marine mammals in Berkeley Sound (e.g., whales, dolphins and seals) (Section 7.4.6.3).

The above may be impacted upon as they either exist in, or spend time in, the zone influenced by anthropogenic sound. To varying degrees, all the above may use, or rely on, sound for various life functions and / or may be impacted upon directly by sound.

10.5.4 Characterising and quantifying the impact of underwater noise

When characterising and quantifying the impacts of underwater noise inshore, it is necessary to consider:

- The behaviour of sound and how it is measured and described,
- The concept of hearing thresholds in receptors (e.g., fish and marine mammals),
- The nature of the impact on receptors, and
- Quantification of sound propagation - sound modelling.

10.5.4.1 The behaviour of sound and how it is measured and described

The behaviour of sound and how it is measured is described in Section 10.4.4.1 of the offshore underwater noise chapter, along with a description of the key terminology used. In shallow water regions, there is significant interaction of the sound with the seabed through reflections and scattering effects, and strong attenuation may occur as sound penetrates the seabed.

10.5.4.2 The concept of hearing thresholds in receptors

The concept of hearing thresholds is described in Section 10.4.4.3 of the offshore underwater noise chapter.

10.5.4.3 The nature of the impact and the hearing thresholds of each receptor group

The nature of the impact of underwater noise on different receptor groups, along with details on their hearing thresholds and injury, displacement and disturbance thresholds, is described in Section 10.4.4.4 of the offshore underwater noise chapter. The following add details that are relevant and specific to Berkeley Sound and the inshore noise impact assessment provided in Section 10.5.6 below.

As described in underwater noise offshore, research on the impact of noise on plankton is limited (Section 10.4.4.4.1). However, given the abundance of plankton, it is not expected that the vessel activities within Berkeley Sound will have a significant overall impact. As such, plankton are not considered further within this chapter.

As described in Section 10.4.4.4.2, there are very few data on the impact of noise on invertebrates although there is some evidence that cephalopods may be similar to fish in their ability to detect sound (Hu, *et al.,* 2009). As there are no thresholds for impacts to squid, a qualitative assessment is presented in this chapter. Berkeley Sound does support spawning loligo squid but the size of the local population and distribution of spawning sites are poorly known (Section 7.4.4.3.2.1). Impacts to other invertebrates (e.g., crustacea) are not considered further within this chapter.

With regard to seabirds, Berkeley Sound contains significant populations of breeding seabirds, including 4.9 % of the Falkland Islands Gentoo penguin breeding population, 1.8 % of the Islands' rockhopper penguin population and close to 100 % of the king penguin population (at Volunteer Point) (see Section 7.4.5.3.3).

With regard to whales, Berkeley Sound is known to be a feeding site for sei whales and other marine mammals (Section 7.4.6.3). Specific to Berkeley Sound, Weir (2022) reports a decrease in southern right whale calls in relation to an increase in vessel noise. Southern right whales use Berkeley Sound to breed requiring that their contact calls (upsweeps) and song (gunshots) can be heard.

10.5.4.4 Quantification of sound impacts - noise modelling

Noise modelling has been undertaken to simulate the vessel activity in Berkeley Sound associated with the Sea Lion Development. The modelling was carried out by Genesis Oil and Gas Consultants Ltd. using the Genesis in-house modelling software FARAM (Faunal Acoustics Risk Assessment Model).

To enable brevity, the following Sections provide only the information required to ensure appreciation and understanding of the modelling results and the impact assessments. Additional details on the modelling methodology, the positioning of the sound sources, and results are provided in the following report (Genesis, 2024b): Genesis, 2024. Sea Lion Project-Underwater Noise-Inshore-Report. Document Number: J-UK-00200-218436-Y-TN002/0. As with the offshore noise modelling in Section 10.4.4.5, the modelling process was carried out in three main steps:

1) Identification of the levels of sound likely to be made by the underwater noise sources inshore. Source levels for use in the modelling have been derived from representative third octave band rms Sound Pressure Level (SPL) frequency spectrums that have been obtained from published underwater sound measurements and mathematical models (Genesis, 2024b),
2) Use of a sound propagation model which assesses the way these sounds are likely to travel out from the sources and calculates the received sound levels at a given range. This utilises a

fully range-dependent propagation model that includes bathymetry and properties of the water column and seabed, and

3) Assessment of the received sound levels against the defined injury and disturbance thresholds (Section 10.4.4.4).

Based on the inshore activities associated with the Sea Lion Development, two scenarios have been identified and modelled to assess the typical sound levels likely to be generated during inshore activities. These are shown in Table 10.32. A third scenario to indicate the baseline background level of noise from other vessels in Berkeley Sound was also modelled to inform the assessment of cumulative impacts. This is described in Section 10.5.9 below.

Table 10.32: Modelled inshore scenarios

Scenarios	Description	Associated sound sources
Scenario 1: Arrival of OCVs	2 x LTVs at anchor and OCV entering the Sound	LTVs anchored and OCV travelling at eight[1] knots.
Scenario 2: LTVs at anchor, OCV loading	2 x LTVs at anchor and OCV attending LTV	LTVs anchored, OCV anchored on low power

[1] As a project-specific mitigation to reduce the likelihood of collisions with marine mammals inshore, vessels within Berkeley Sound will be travelling at reduced speeds of no more than eight knots (Section 10.11.7).

10.5.4.4.1 Step 1: Identification of source sound levels

The noise levels generated by vessels depend on many factors. The primary sources of sound from vessels are from propellers, propulsion and other machinery (Ross, 1976; Wales and Heitmeyer, 2002). Vessels are considered to be a continuous noise source. Larger vessels tend to produce lower frequency noise than smaller vessels (OSPAR, 2009b). However, the level of noise will vary depending on the vessel's speed and activity, with vessels using thrusters generally producing higher sound levels (OSPAR, 2009b).

Some vessel sound measurements were taken by Cerchio *et al.* (2022) reported in Weir (2022) inside Berkeley Sound recording a peak of 130 dB rms re: 1µPa in relation to either a reefer or a tanker although it is unknown at what distance the vessel was from the hydrophone at the time. As such, a model has been used to determine vessel source noise.

The JOMOPANS-ECHO model (MacGillivray and de Jong, 2021) has been used to estimate the source levels from the Development vessels used in Berkeley Sound. The model uses the vessel length, speed and vessel class to determine the source level of the vessel. This model has been shown to provide a better match to measured vessel source level data compared to previous mathematical models such as the RANDI model (Breeding, *et al.,* 1996). The broadband rms SPL and vessel frequency spectrums used to estimate source sound levels from vessel activity for each modelled scenario are presented in Figure 10-19 and Table 10.33.

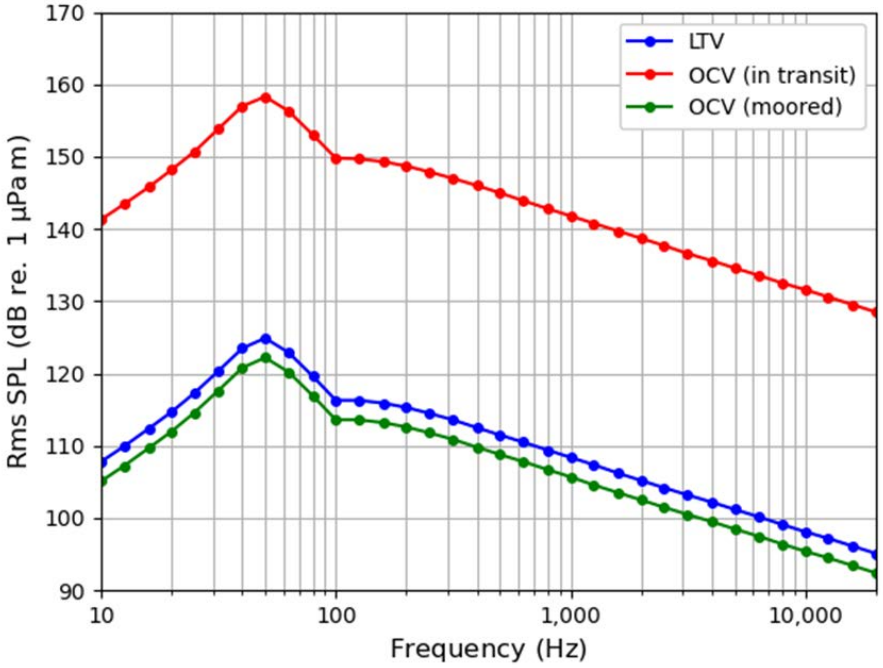

Figure 10-19: Generic vessel frequency spectrums used in noise modelling for Scenarios 1 and 2

Table 10.33: Summary of specific source levels used in the modelling[1]

Vessel Type	Representative Source Spectrum Used in Modelling	Reference	Broadband rms SPL (dB re 1 µPa at 1 m)
LTV	Bulker (speed = 2 knots, length = 475 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	131
OCV (in transit)	Bulker (speed = 8 knots, length = 348 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	165
OCV (moored)	Bulker (speed = 2 knots, length = 348 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	129

[1] Please note the Broadband rms SPL values in Table 10.25 do not exactly correlate with the peak values shown in Figure 10-12 as those in Figure 10-12 are *generic* values for a range of vessels, whereas those in Table 10.25 are the specific vessel SPLs used in the model. The latter are, in fact, higher than the generic SPLs in Figure 10-12, to ensure a precautionary approach was taken in the modelling.

10.5.4.4.2 Step 2: Sound propagation modelling

The results of the sound propagation models used in this assessment determine:

- The rms Sound Pressure Level (SPL), which indicates the received level of sound at a given distance from the source. This information is used to determine the distance at which injury and displacement / disturbance thresholds are exceeded, and
- The cumulative Sound Exposure Level (SELcum), which is a standardised measure of the overall sound energy that an animal will be exposed to (i.e., related to the SPL and exposure time) over a specified length of time (a 24 hour period in this assessment).

As described in Southall *et al.* (2019), the SELcum was weighted according to the marine mammal hearing types (i.e., LF, HF, VHF and PW and OW hearing groups as described in Table 10.21 in Section

10.4.4.4.5.1). This accounts for the differences in the sensitivity of these groups to different frequencies.

10.5.4.4.3 Comparison of model results with injury thresholds

Where available, the internationally recognised thresholds for injury and disturbance to fish (Section 10.4.4.4.3) and marine mammals (Section 10.4.4.4.5) have been used. There are no thresholds for assessing the impact of continuous sound on seabirds or squid so qualitative assessments have been undertaken for these receptor groups.

10.5.4.4.3.1 Fish injury

To quantitatively assess any potential injury to fish, fish eggs and larvae from the inshore activities, received noise levels in terms of unweighted rms SPL have been predicted and compared to the Popper *et al.* (2014) thresholds for injury for shipping and continuous sounds. The maximum predicted distances where the thresholds are exceeded are summarised in Table 10.34. The table represents the inshore Development Scenarios 1 and 2.

The modelling predicts that the injury thresholds for fish with swim bladder involved in hearing will not be exceeded. For all other fish groups, the probability of mortality and potential mortal injury, recoverable injury and TTS is expected to be low at near, intermediate and far distances from the sound sources.

Table 10.34: Predicted maximum distances where rms SPL thresholds for injury to fish are exceeded for Scenario 1 and Scenario 2

Fish Group	Impairment	Threshold [1,2]	Maximum Distance to Threshold Exceedance[3] (m)
Fish with no swim bladder	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	Low	N/A
	TTS	(N) Moderate (I) Low (F) Low	N/A
Fish with swim bladder not involved in hearing	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	Low	N/A
	TTS	(N) Moderate (I) Low (F) Low	N/A
Fish with swim bladder involved in hearing	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	170 dB rms SPL for 48 h	Threshold not exceeded
	TTS	158 dB rms SPL for 12 h	Threshold not exceeded
Eggs and larvae	Mortality and potential mortal injury	Low	N/A
	Recoverable injury	Low	N/A
	TTS	Low	N/A

[1] Quantitative thresholds are expressed in terms of rms SPL.

[2] Quantitative thresholds were not established for all fish types or impairment types. Where this is the case, the risk of injury or impairment has been qualitatively assessed (Popper *et al.,* 2014).

[3] Namely, the area surrounding the source within which the mammals may experience sounds which exceed the injury threshold.

10.5.4.4.3.2 Marine mammal injury

Received noise levels from the vessels in each modelling scenario have been predicted in terms of weighted cumulative SEL to identify the spatial area in which the onset of PTS or TTS may occur to marine mammals as a result of the inshore Development activities (Table 10.32 above).

The marine mammal weightings are those given by Southall *et al.* (2019). In essence, these account for the hearing thresholds described in Section 10.4.4.3 of the offshore underwater noise chapter and the audiograms in Figure 10-11. The weighting curves are generalised forms for the different receptor groups described in Table 10.21 of the offshore underwater noise chapter.

Two situations are considered:

1) Where the mammals remain stationary, and
2) Where the mammals are assumed to flee from the noise source.

Mammals assumed to be stationary

In both modelled scenarios, the cumulative SEL thresholds for PTS and TTS were not predicted to be exceeded over 24 hours for any marine mammal hearing group. This means that if a marine mammal was to remain stationary for 24 hours within the vicinity of the inshore activities, the PTS and TTS thresholds would not be exceeded, i.e., the risk of permanent or temporary impairment is very unlikely.

An example of the predicted cumulative SEL (due to Development vessel noise) is shown in Figure 10-20, which depicts the cumulative SEL received by LF cetaceans during Scenario 1 over 24 hours. The representation assumes that the LF cetaceans remain stationary.

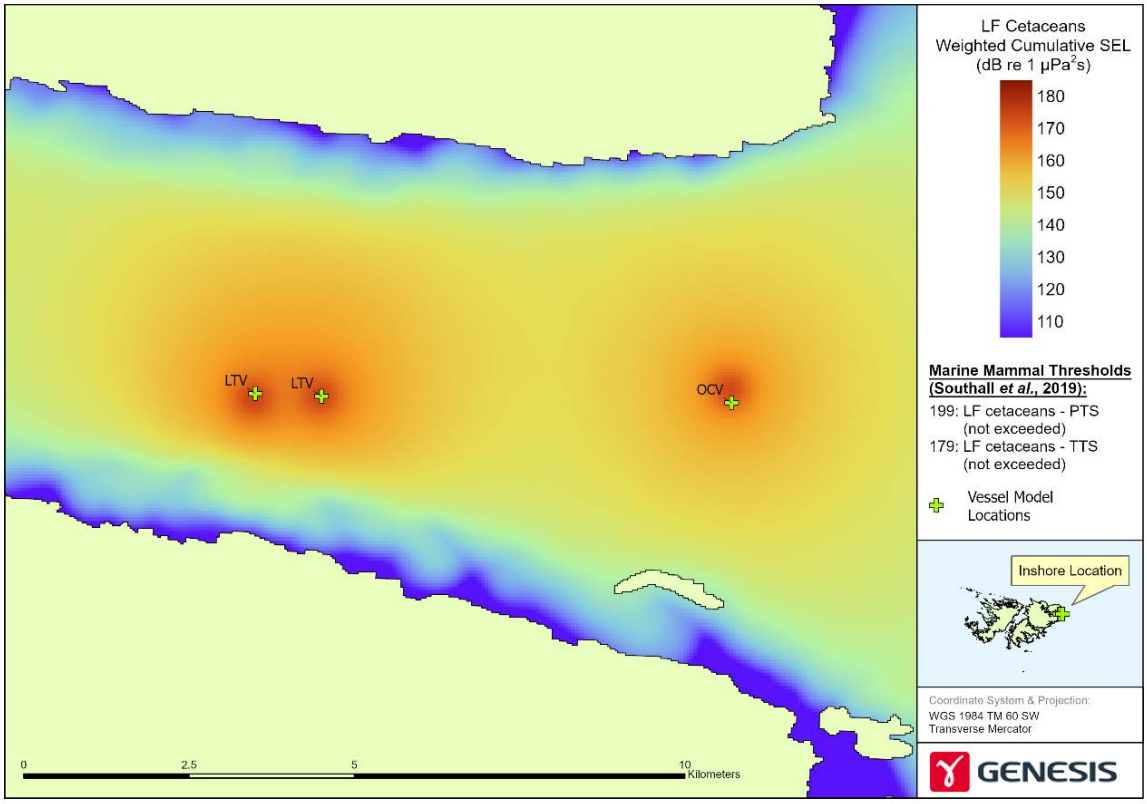

Figure 10-20: Predicted cumulative SEL received by stationary LF cetaceans during Scenario 1 over 24 hours

Marine mammals assumed to flee

The cumulative SELs received by marine mammals belonging to the different hearing groups when they swim away from the vessel location was also calculated. The vessel with the highest source level in each scenario was used for the calculation. Marine mammals have been simulated swimming away from the vessel location at different swim speeds and from different initial starting distances from the vessel location. As the marine mammals swim away, their swim depth is allowed to change such that upon receiving sound they are at the depth where sound levels are highest (note that the predicted received sound levels vary with depth). This is a conservative measure and will result in the highest predicted cumulative SEL received by the marine mammals as they swim away.

The predicted initial start distances from the sound source that marine mammals must be at to not be exposed to weighted cumulative SELs sound levels exceeding the PTS and TTS thresholds, are summarised in Table 10.35. The modelling predicts that the marine mammal PTS and TTS thresholds will not be exceeded for any marine mammal hearing group in Scenario 1 or 2, provided that they swim away at a speed of at least 1.5 m/s from the vessel location. As such, it is expected that the risk of PTS or TTS occurring to any marine mammals will be low.

Given that the sound sources associated with inshore operations do not exceed internationally recognised thresholds for injury, the remainder of the assessment focusses on the potential for vessel noise to induce avoidance behaviour or disturbance.

Table 10.35: Predicted initial starting distances from the vessel location where the adopted weighted cumulative SEL thresholds for non-impulsive noise are exceeded for marine mammals swimming away from the vessel location at 1.5 m/s

Scenario	Representative Vessel	Marine Mammal Group	Distance to Threshold Exceedance (m)	
			PTS	TTS
1	OCV (in transit)	All marine mammals	Threshold not exceeded	Threshold not exceeded
2	LTV	All marine mammals	Threshold not exceeded	Threshold not exceeded

10.5.4.4.4 Comparison of model results with disturbance and behavioural response thresholds

10.5.4.4.4.1 Fish disturbance from vessels

Documented behavioural effects of underwater noise on fish behaviour are variable, ranging from no discernible effect (Wardle, *et al.,* 2001) to startle reactions followed by immediate resumption of normal behaviour (Wardle, *et al.,* 2001; Hassel, *et al.,* 2004). Despite some documented behavioural effects there are no well-established criteria or thresholds for assessing behavioural disturbance to fish. In fact, it was concluded in Popper *et al.* (2014) that there lacked sufficient evidence to recommend specific thresholds that correspond to behavioural disturbance to fish.

Popper *et al.* (2014) suggest that all fish are at high risk of masking[57] when they are close to continuous low frequency sources of noise, and those that use the swim bladder to detect sound are also at high risk at long range (Table 10.36). Fish that use the swim bladder are also at high risk of behavioural change when near to the source of noise (Table 10.36).

Table 10.36: Assessment of disturbance to fish (Popper *et al.,* 2014)

Fish Group	Impairment	Assessment
Fish with no swim bladder	Masking	(N) High

[57] Masking occurs when anthropogenic sounds impair the ability of an animal to detect biologically significant sounds.

Fish Group	Impairment	Assessment
		(I) High (F) Moderate
	Behaviour	(N) Moderate (I) Moderate (F) Low
Fish with swim bladder not involved in hearing	Masking	(N) High (I) High (F) Moderate
	Behaviour	(N) High (I) High (F) Moderate
Fish with swim bladder involved in hearing	Masking	N) High (I) High (F) High
	Behaviour	(N) High (I) Moderate (F) Low
Eggs and larvae	Masking	(N) High (I) Moderate (F) Low
	Behaviour	N) Moderate (I) Moderate (F) Low

10.5.4.4.4.2 Seabirds disturbance from vessels

For seabirds, there are no guidelines to determine what constitutes a behavioural disturbance or threshold sound level. Section 10.4.4.4.4.1 of the offshore chapter notes that the current scientific understanding of seabird hearing underwater is limited and poor. However there is some evidence to suggest that penguins may vocalise underwater (Thiebault, *et al.,* 2019), and may show behavioural changes when exposed to noise levels of 120 dB re 1 µPa within 50m of the sound source.

As such, it is recognised that seabirds foraging below the sea surface could be disturbed. Should this occur, it is predicted that seabirds will remain on the sea surface and will avoid being underwater until a specific source has ceased, or the birds will temporarily relocate away. Section 10.4.4.4.4.1 also notes that a temporary displacement from the area is not predicted to cause a significant effect as seabirds are recognised to have moderate to high level of habitat flexibility and are not constrained to the immediate area.

10.5.4.4.4.3 Marine mammal disturbance from vessels

While the modelling has indicated that injury is very unlikely in marine mammals, there is the potential for long-term continuous vessel noise to cause behavioural disturbance. However, as described in Section 10.4.4.4.5.3, reactions to infrequent noise lasting <24 hours is unlikely to have any lasting effect (Southall, *et al.,* 2007). While it is understood that project vessels are likely to be at the inshore location for >24 hours, it is considered unlikely that vessels engaged in inshore operations would cause more than trivial disturbance that would be rapidly recoverable once the operation is complete (JNCC, 2010).

To predict distances at which potential behavioural disturbance to marine mammals may occur during the Development, received noise levels in terms of unweighted rms SPL have been estimated and compared to the adopted behavioural disturbance thresholds of 120 dB re µPa and 160 dB re µPa (Section 10.4.4.4.5.5).

The maximum unweighted rms SPL received from the vessels related to the Development are shown in Figure 10-21 and Figure 10-22; these show the cases for Scenarios 1 and 2 respectively. The contours highlighted in the figures represent the threshold for signifying behavioural disturbance to all marine mammals.

The avoidance / displacement behaviour threshold (160 dB re 1 µPa) is shown not to be exceeded. However, there are some small areas around the vessels in Scenarios 1 and 2 where the behavioural disturbance threshold (120 dB re 1 µPa) is exceeded. For both scenarios, the modelling predicts that disturbance to marine mammals may occur over a total area of 2 km^2 in Berkeley Sound.

The results are summarised in Table 10.37, which gives the predicted areas where noise levels are above the adopted behavioural disturbance threshold.

The disturbance areas shown should be treated as areas within which some (not all) marine mammals may exhibit behavioural responses. It is not suggested that all marine mammals will vacate these areas. Marine mammals will likely exhibit increased behavioural responses at distances closer to the vessel locations and there will be a reduced likelihood of response with increasing distance from the vessel locations (Southall, *et al.,* 2021).

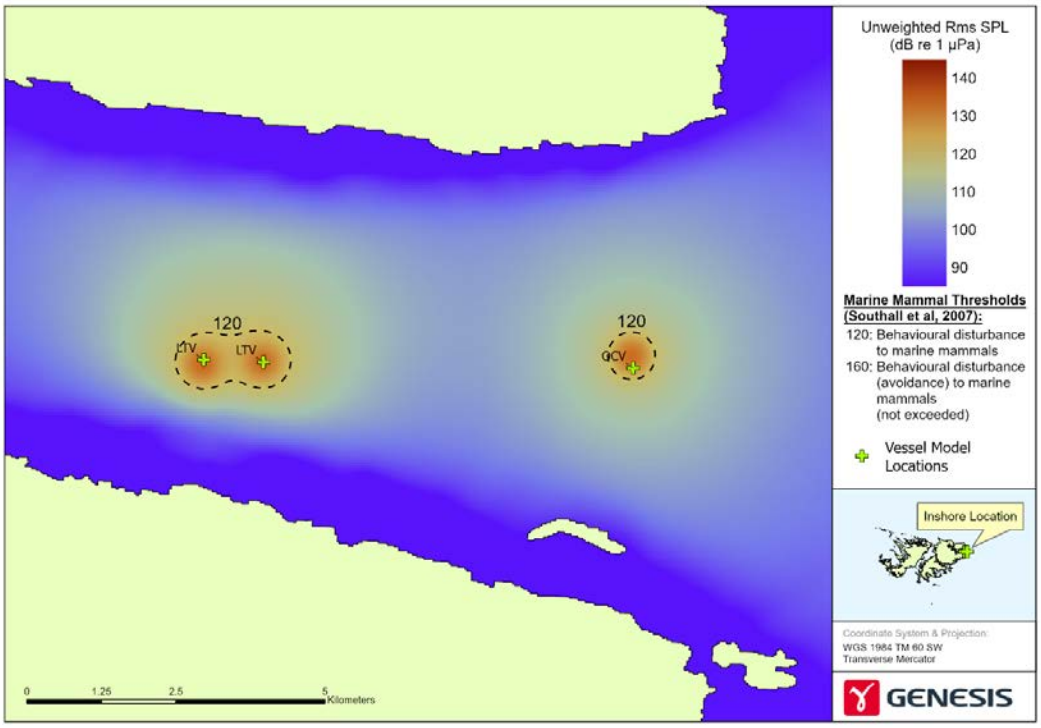

Figure 10-21: Predicted unweighted rms SPL received by marine mammals during Scenario 1

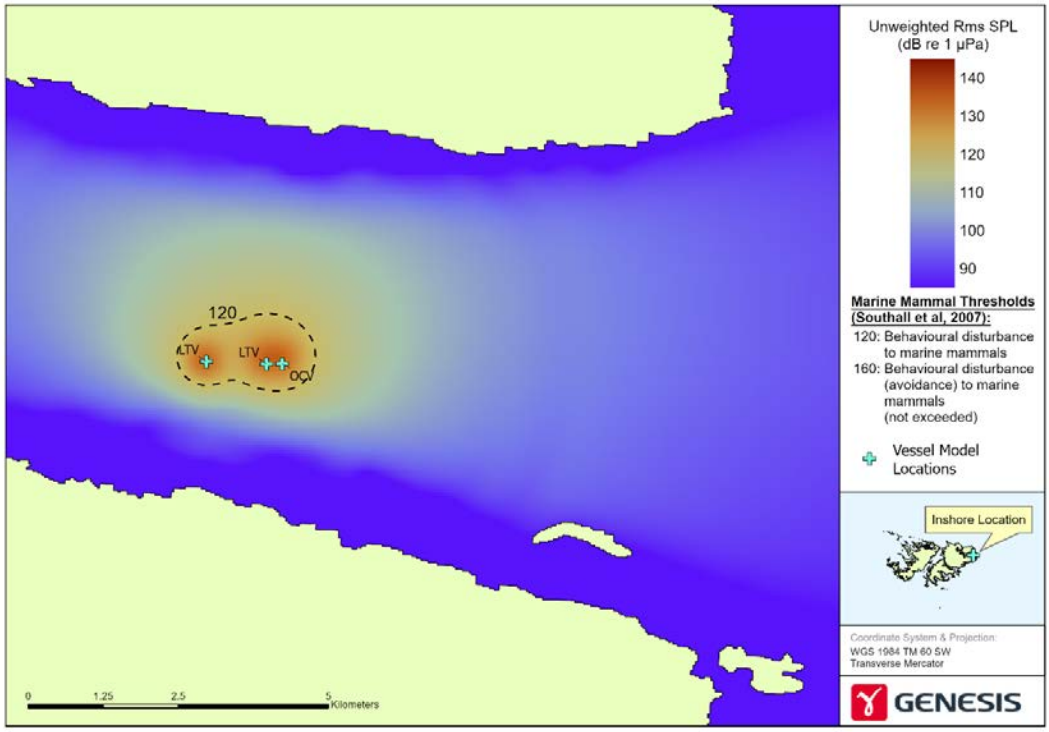

Figure 10-22: Predicted unweighted rms SPL received by marine mammals during Scenario 2

Table 10.37: Predicted area where the adopted unweighted rms SPL thresholds for disturbance to marine mammals are exceeded

Criteria	Behavioural Disturbance Threshold	Reference	Scenario	Area of Threshold Exceedance [1] (km^2)	% of available area in Berkeley Sound
Behavioural disturbance to all marine mammals	Rms SPL: 120 dB re 1 µPa	Southall *et al.*, 2007	1	2	1.1
			2	2	
Behavioural disturbance (avoidance) to all marine mammals	Rms SPL: 160 dB re 1 µPa	Southall *et al.*, 2007	1	Threshold not exceeded	0
			2		

[1] Namely, the area surrounding the source within which the mammals may experience sounds which exceed the injury threshold.

10.5.5 Industry-standard mitigation measures

As stated in Section 10.4.5, there are no industry-standard mitigation measures specifically designed to reduce the impact of vessel noise on fauna. However, standard operating procedures, such as maintenance schedules, will help to minimise the noise generated by propeller cavitation.

10.5.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of vessel noise on the varying receptors.

A summary of the impact assessment outcomes for this Development is tabulated in Section 10.5.12, which shows the worst-case impact for each activity.

Note: as described in Section 10.5.4.4.3, injury thresholds were not breached for fish or marine mammals such that these can effectively be scoped out from further consideration.

10.5.6.1 Fish displacement and disturbance

Fish occur in low numbers of geographical importance in Berkeley Sound and therefore the sensitivity of the receptor is considered to be '**Low**'.

It is recognised that masking effects may be high when fish are close to continuous low frequency sources of noise, and fish that use the swim bladder to detect sound are also at high risk at long range (Table 10.36). Fish that use the swim bladder are also at high risk of behavioural change when near to the source of noise (Section 10.5.4.4.4.1), any impacts during the manoeuvring of the OCV will be intermittent and very short-term. Therefore, it is expected that any impact will be fully reversible such that the level of disturbance would be barely detectable above background variability and the severity of the effect is considered to be '**Slight**'.

The overall significance of the impact of vessel noise on fish is considered to be '**Very Low (2)**'.

10.5.6.2 Invertebrate displacement and disturbance

Although there are no thresholds for the levels of sound likely to cause injury or disturbance to invertebrates, the literature suggests that impacts to feeding behaviour of invertebrates may be observed (albeit from impulsive noise) (Section 10.4.4.4.2).

Berkeley Sound does support spawning loligo squid but the size of the local population and distribution of spawning sites are poorly known (Section 10.5.4.3). However, there are unlikely to be any significant aggregations within the zone of influence of underwater noise generated by inshore operations. While the influence of vessel noise may be detectable within the immediate vicinity of the LTVs, this area is unlikely to contain significant abundances of any commercial squid species, and these would be transitory. The sensitivity of the receptor is considered to be '**Low**'.

Squid are subject to commercial fishing in the Falklands and any impact due to noise from the Sea Lion Development will be insignificant in comparison. Therefore the severity of the impact of vessel noise on squid is assessed as '**Slight**'.

Overall, the significance of the impact of disturbance caused by vessel noise to squid is therefore assessed as '**Very Low (2)**'.

10.5.6.3 Seabird displacement and disturbance

As described in Section 10.4.4.4.4.1, there are no quantified thresholds for assessing the impacts of displacement or disturbance to seabirds.

Berkeley Sound contains significant populations of breeding seabirds (Section 10.5.4.3). Of these, the rockhopper penguin is described as 'Vulnerable' by the IUCN and is on the Falkland Islands list of priority species. Consequently, the sensitivity of the receptor is considered to be '**High**'.

Noise modelling indicates that levels of sound during inshore operations will be similar to the noise levels currently occurring within Berkeley Sound (see Section 10.5.9 on cumulative impacts) and therefore, there will be little or no additional impact from underwater noise on seabirds present in the area. However, the period of inshore activity may extend throughout the summer months (August to March), which extends the period of 'normal' shipping activity in the Sound. While there are no published disturbance thresholds for birds, if loud enough, the levels of noise could cause birds to

temporarily relocate, reduce feeding activity underwater or remain above water for the time operating vessels pass by.

Nonetheless, impacts from underwater noise during the maneuvering of the project vessels will be localised, infrequent, very short-term and fully reversible such that the level of disturbance would be barely detectable above background variability. Therefore, the severity of the effect is considered to be '**Slight**'.

The overall significance of the impact of vessel noise on seabirds is considered to be '**Low (4)**'.

10.5.6.4 Marine mammal displacement and disturbance

Although a number of marine mammal species may occasionally occur within Berkeley Sound, the most regularly recorded are sei, southern right and Antarctic minke whales, Commerson's and Peale's dolphins, South American sea lions and fur seals. Southern right whales in particular are known to use Berkeley Sound to breed (Section 10.5.4.3). All marine mammals are conservation priority species in the Falkland Islands and therefore the sensitivity of the receptor is considered to be '**High**'.

The SPL threshold for displacement behaviour by marine mammals is 160 dB re 1 µPa (rms) and that for disturbance is 120 dB re 1 µPa(rms) (Section 10.4.4.4.5.5).

Noise modelling undertaken indicates that the displacement thresholds are not exceeded in Scenarios 1 or 2. However, the lower *disturbance* threshold is exceeded such that marine mammals of all hearing groups may exhibit altered behaviour within an area of 2 km^2 around the vessels (Section 10.5.4.4.4.3). Noise generated by the transiting vessels could lead to disturbance *via* reduced communication and reduced feeding, swim speeds and dive intervals. Berkeley Sound is known to be a feeding site for sei whales and other marine mammals (Section 10.5.4.3). Importantly however, noise from transiting vessels will be intermittent, of very short duration (Section 10.5.2) and the affected area accounts for only 1.1 % of the available area in Berkeley Sound (Section 10.5.4.4.4.3). Once the vessels have stopped, noise levels will reduce to background levels. In consequence, any additional disturbance impacts will quickly return to existing background levels.

It is therefore expected that the level of disturbance would be barely detectable above background variability and, therefore, the severity of the effect is considered to be '**Slight**'.

The overall significance of the impact of vessel noise on marine mammals is considered to be '**Low (4)**'.

10.5.7 Project-specific mitigation

The significance of the impact of underwater noise associated with inshore operations within Berkeley Sound is assessed as '**Low**' or '**Very Low**' for all receptors and therefore project-specific mitigation is not required.

10.5.8 Residual impacts

Not applicable.

10.5.9 Cumulative impact

All vessel use during the Phase 1 & 2 Development will contribute to the existing vessel activity and background noise in Berkeley Sound and, therefore, may lead to cumulative impacts *via* increased 'concentration', increased 'extent and proportion' and increased 'duration' (Section 8.9.1).

Scenarios 1 and 2 for the Development inshore vessels were modelled assuming that no other sources of underwater noise were present in Berkeley Sound which is rarely the case. The baseline number of vessels using Berkeley Sound varies considerably from one year to the next, which is linked to the amount of squid caught in any particular year. A total of 232 vessels were recorded in the Sound in 2022 (Section 7.7.3.2). Fishing vessels and reefers were the most frequent vessel with 201 recorded

over the 12 month period. A further 23 tankers and eight other assorted vessels were also recorded over the same period (FIMA, 2024).

There are also considerable month-to-month differences in the number of vessel visits, with the highest number of visits between March and June (Section 7.7.4.1.4). Further, there are seasonal and potentially inter-annual variations in the number of receptors present (such as sei and southern right whales) such that the cumulative impact will be highly variable.

To quantify the baseline noise levels associated with other vessels in Berkeley Sound, a third Scenario was modelled using the same method as was used for Scenarios 1 and 2 (Section 10.5.4.4). Scenario 3 assumed the presence of six fishing vessels, a tanker and a reefer.

The JOMOPANS-ECHO model (MacGillivray and de Jong, 2021) was used to estimate the source levels from the types of other vessels used in Berkeley Sound. The model uses the vessel length, speed and vessel class to determine the source level of the vessel. The broadband rms SPL and vessel frequency spectrums used to estimate source sound levels from vessel activity in Scenario 3 are presented in Table 10.38 and Figure 10-23.

The unweighted rms SPL values for Scenario 3 are shown in Figure 10-24. The contours highlighted in the figures represent the threshold for signifying behavioural disturbance to all marine mammals. As seen in Figure 10-24, the lower disturbance threshold (120 dB re 1 µPa(rms)) is exceeded over a larger area than that affected by the Sea Lion Development vessels alone and other vessel activity in the Berkeley Sound is likely to have a greater impact on the overall underwater noise environment than the activities associated with the Sea Lion project. Nonetheless, when the Development vessels are added there will be an increased 'concentration' and potentially an increased duration given the seasonality of other vessels. However, the LTVs and the attendant OCVs will only be in the Sound for a total of 13 (non-consecutive) months and the overall level of noise is not predicted to rise significantly above the current levels, which may already cause a degree of disturbance.

It is concluded that the short-term and temporary nature of the additional vessels is unlikely to significantly alter the baseline noise levels already experienced by the receptors.

Table 10.38: Summary of source levels used in the Scenario 3 modelling

Vessel Type	Representative Source Spectrum Used in Modelling	Reference	Broadband rms SPL (dB re 1 µPa at 1 m)
Fishing vessel	Fishing vessel (speed = 10 knots, length = 150 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	176
Tanker	Bulker (speed = 16 knots, length = 500 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	186
Reefer	Bulker (speed = 16 knots, length = 1200 ft)	JOMOPANS-ECHO model (MacGillivray and de Jong, 2021)	195

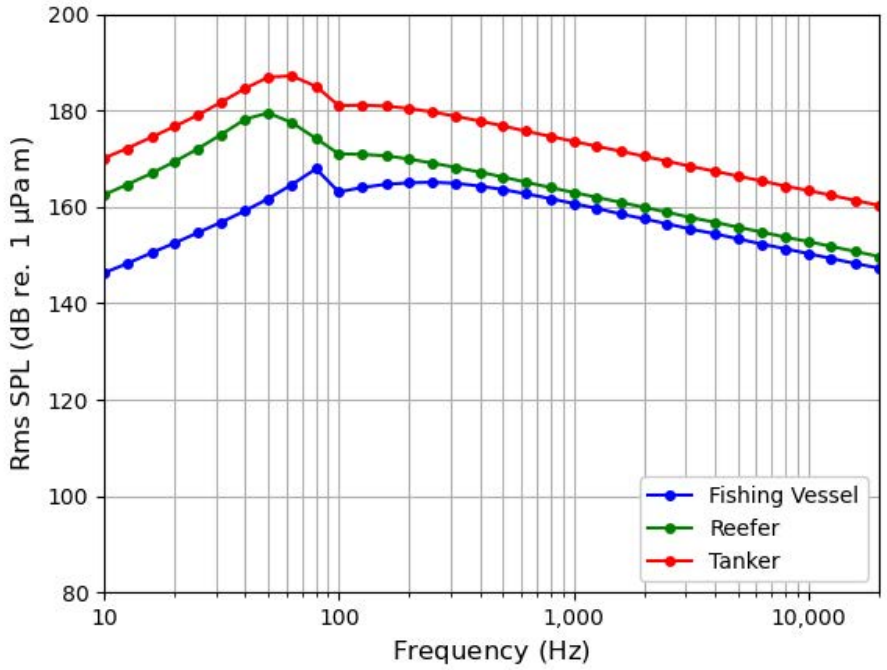

Figure 10-23: Vessel frequency spectrums used in noise modelling for Scenario 3

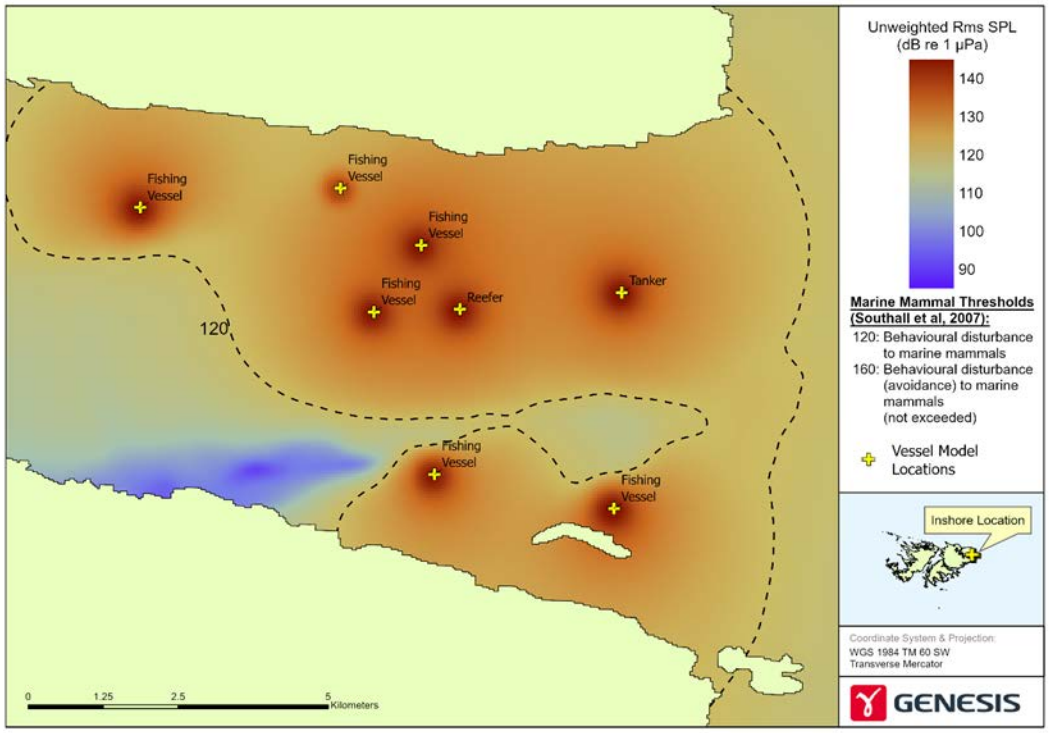

Figure 10-24: Predicted unweighted rms SPL received by marine mammals during Scenario 3

10.5.10 Confidence

Sound propagation in water is well understood and models used to determine this are utilised extensively but there has been, and to some extent remains, limited information on vessel noise. The vessels used in the modelling described above are considered representative of the proposed project vessels, and utilise the most recent published material, e.g., JOMOPANS-ECHO model (MacGillivray and de Jong, 2021). Section 10.4.10 of the offshore chapter describes in greater detail the nature of the fully range dependent noise model also used for the inshore modelling.

The location of the LTV mooring and OCV is variable since there are planned to be three locations (although only two LTVs at any one time), and these may be adjusted in discussion with FIG / Fisheries to agree locations that cause the least interference. Nevertheless, the predictions represent plausible noise scenarios and the results are interpreted in this context.

The status of the potential receptors in Berkeley Sound is relatively well understood, although the documented influx of southern right whales in the winter of 2017 (Section 7.4.6.3.1.1) highlights that unusual years do occur and long-term trends can change. The seasonal distributions of the regularly occurring marine mammals, birds and fish are broadly known, although, with the exception of the breeding seabirds, there is limited information on their population sizes. The inter-annual distribution and abundance of marine mammals are acknowledged as a data gap, as is the spatial / bathymetric distribution and habitat characterisation of loligo spawning sites.

Less is known on the sensitivity of the receptors to noise. Studies on physiological effects or behavioural responses to underwater noise are limited to a relatively few species of marine mammal and fish and very little is known on the ability of cephalopods or birds to detect sound underwater, or indeed to vocalise underwater (Thiebault, *et al.,* 2019) and, again, these issues are acknowledged data gaps.

Based on the predicted severity of effect from vessel noise, there is enough information to have a 'Probable' degree of confidence in the conclusions of this assessment. However, due to the gaps in understanding, in particular relating to the physiological and behavioural responses to noise by species likely to be present within the Sound, the confidence in the assessment is conservatively assessed as '**Uncertain**'.

10.5.10.1 Monitoring

Disturbance to marine mammals due to vessel noise is becoming an increasingly significant issue globally. It is known that Berkeley Sound supports a significant assemblage of marine mammals and therefore monitoring of the impacts of vessel activity on these animals will be undertaken as follows:

- Seabird and Marine Mammal Observers (SMMOs) will be placed on the OCVs and records of animal behaviour will be kept for subsequent analysis,
- A review of the inshore SMMO reports will be conducted after operations in Berkeley Sound have ceased in order to validate the EIA, and
- Investigation of the use of noise minimisation in the design of vessels, where possible.

Two projects studying the inshore cetaceans of the Falklands, with a focus on Berkeley Sound, have recently completed (Weir, 2020; 2021). The results from these studies have helped to better understand the Falkland Islands' cetacean populations and may focus future monitoring.

Detailed monitoring requirements have been established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline EMMP is provided in Chapter 15.

10.5.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

10.5.12 Findings summary

Table 10.39: Summary of the impacts from vessel noise during inshore operations

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Vessel operations within Berkeley Sound	Intermittent moderate intensity noise during inshore operations	Injury to Invertebrates, fish, seabirds and marine mammals[2]	Planned	1, 2a &2b	n/a	n/a	n/a	**n/a**	**n/a**	**n/a**	**Industry-standard:** None. **Project-specific:** None proposed
		Displacement and behavioural disturbance to fish		1, 2a & 2b	Low	Slight	n/a	**Very Low (2)**	**n/a**	**Uncertain**	
		Displacement and behavioural disturbance to invertebrates (including squid[3])		1, 2a & 2b	Low	Slight	n/a	**Very Low (2)**	**n/a**	**Uncertain**	
		Displacement and behavioural disturbance to seabirds		1, 2a & 2b	High	Slight	n/a	**Low (4)**	**n/a**	**Uncertain**	
		Displacement and behavioural disturbance to marine mammals		1, 2a & 2b	High	Slight	n/a	**Low (4)**	**n/a**	**Uncertain**	

[1] See Chapter 8 for definitions of sensitivity, severity, likelihood and significance.
[2] Noise modelling results indicate that noise levels within Berkeley Sound that could cause injury (as opposed to disturbance) will not occur during any stage of Phase 1 & 2 Sea Lion development to any of the receptors.
[3] Squid and seabirds are qualitatively assessed as there are no thresholds against which to compare modelling outputs.

10.6.1 Introduction

Drilling fluids will be used during all Phase 1 & 2 drilling operations and will consist of a liquid phase into which various chemicals and solids have been added to modify the operational properties of the drilling system (Section 5.4.6). The wells will be drilled in sections and will generate drill cuttings as a waste product. Both the used drilling fluid and the cuttings must be disposed of responsibly as with any other waste product. The use of chemicals during the Phase 1 & 2 Development was raised as a concern by stakeholders during scoping consultations (Chapter 6).

This chapter assesses the impacts associated with the discharge of solid and liquid drilling wastes. Modelling was carried out to enable greater understanding of the impacts.

Note: the impacts associated with other sources of disturbance to the seabed, liquid waste discharges and solid waste management are described elsewhere in this document, as described in Table 2.2.

10.6.1.1 Relevant legislation

Conventions and legislation relevant to drilling discharges to sea include:

- OSPAR Decisions:
  - OSPAR Decision 2000/2 on a Harmonised Mandatory Control System (HMCS) for the Use and Reduction of the Discharge of Offshore Chemicals.
  - OSPAR Decision 2000/3 on the Use of Organic-Phase Drilling Fluids (OPF) and the Discharge of OPF-Contaminated Cuttings (16 January 2001).
- UK legislation:
  - Offshore Chemical Regulations (OCR) 2002 (and all amendments).
  - Offshore Petroleum Activities (Oil Pollution Prevention and Control) (OPPC) Regulations 2005 (and all amendments).
  - Conservation (Natural Habitats, &c.) Regulations 1994 and Conservation of Habitats and Species Regulations 2017.
- Falkland Islands requirements:
  - Petroleum Operations Notice (PON) No.10 - Application to Use and Discharge Non-Aqueous Drilling Fluids (NADF) and Associated Cuttings.
  - Falkland Islands Maritime Ordinance 2017.

Under the above, there are numerous compliance requirements with regard to the receiving habitat, oil content on cuttings and chemical selection.

10.6.1.1.1 The PON 10 and oil on cuttings compliance

The discharge of cuttings contaminated with Non-Aqueous Drilling Fluid (NADF) must be managed in accordance with the FIG PON 10 to ensure best practice. The FIG PON 10 reflects the requirement of OSPAR Decision 2000/3 and prohibits the following:

- The discharge of whole Organic Phase Fluids (OPF) e.g., NADF,
- The discharge of whole OPF when drilling tophole sections, and
- The discharge of cuttings contaminated with OPF at a concentration >1 % by weight on dry cuttings.

Appendix I of OSPAR Decision 2000/3 also states that Best Available Techniques (BAT) and Best Environmental Practice (BEP) must be utilised to minimise oil concentration on discharged cuttings.

10.6.1.1.2 Chemical compliance

Navitas proposes to manage offshore chemicals in a similar way to the UK system where offshore chemicals have been controlled since 1979 *via* the Offshore Chemical Notification Scheme (OCNS). This has developed into an OSPAR-wide control scheme *via* the Harmonised Mandatory Control System (HMCS) which is an outcome of OSPAR Decision 2000/2, Recommendations 2010/3 and 2010/4, and which continues to be developed. This contains requirements for chemicals to be pre-screened by applying standardised laboratory tests in an application known as the Harmonised Offshore Chemical Notification Format (HOCNF). Those with acceptable properties are given rankings as to their potential risk in typical usage are added to the Centre for Environment, Fisheries and Aquaculture Science (Cefas) Definitive Ranked List of Registered Products (https://www.cefas.co.uk/data-and-publications/ocns/downloads-and-useful-links/). Only chemicals from this list may be used or discharged offshore for O&G purposes.

Chemicals with the best performance (lowest toxicity, lowest bioaccumulation and lowest persistence) are given a classification of 'Gold'. In the UK and Netherlands, the risks are assessed at a distance of 500 m from the discharge using a dispersion calculation known as the Chemical Hazard and Risk Model (CHARM). For those chemicals that cannot be assessed using CHARM, such as inorganic chemicals, a separate OCNS classification is given from 'A' to 'E', with 'E' being the best environmental performance. Chemical discharge must be subject to a risk assessment unless they are:

- Categorised as Posing Little Or No Risk (PLONOR) to the environment according to OSPAR Agreement 2013/6 (including, for example, inert minerals, nut fibres, methanol and mono-ethylene glycol),
- Are given a Hazard Quotient (HQ) of 'Gold' under the HCMS (unless the Cefas template dosage is exceeded which will require a site and use-specific risk assessment), or are
- Categorised as 'E' under the OCNS.

For any chemicals that have specific undesirable properties around biodegradation, toxicity and bioaccumulation, these are given a 'Substitution Warning' which means that their use must be justified, and replacements sought. The goal was a phase out of discharge of these chemicals by 1st January 2017, and this was largely achieved but there remain in use some chemicals whose function requires them to be biocidal or persistent for example, and their use and discharge must be justified in applications. Chemicals with traces of certain undesirable substances such as particular metals, including those on a list for priority action (OSPAR 2004-12, revised 2023) are given a 'Product Warning' code and their use must be specifically justified in applications.

All chemicals dosed into the drilling muds will be selected to minimise the potential environmental impacts as much as possible in line with the OSPAR Decision 2000/2.

During the Phase 1 & 2 Development, chemicals with the best environmental rating (e.g., PLONOR, Gold or OCNS 'E') will be selected where possible. Where technical feasibility issues dictate otherwise, full justification of the chemical use will be provided as instructed by FIG with the options to substitute for less harmful chemicals over the course of the drilling campaign kept under review.

10.6.2 Sources of drill cuttings and fluids discharges

For the Phase 1 & 2 Development a maximum of 26 wells will be drilled by the Mobile Offshore Drilling Unit (MODU) (only 23 of which will be completed for operation) and will be connected ('tied-back') to the Floating Production, Storage and Offloading (FPSO) unit. The 23 completed wells will comprise:

- 16 x oil production wells (hereafter referred to as OP or 'production' wells),
- 6 x Water Injection (WI) wells, and

- 1 x GI (Gas Injection) well.

As stated, there may be up to 26 actual drilling operations to result in the above. This is because:

- In the event the planned GI well location is unsuitable for gas injection, e.g., oil is encountered on the NW flank instead of gas, a second GI well will be drilled at a different location, and
- A contingency is allowed for re-drilling of two wells that may be required if a problem is encountered with any of the primary wells above.

Therefore, while only 23 wells will be completed, cuttings may be generated from up to 26 penetrations.

The Phase 1 & 2 Development wells will be drilled from six Drill Centres (DC) with a contingency for an alternative gas injection DC. The distribution of the wells over the DC's is as follows, noting that the two additional potential redrills allowed for could be at any location:

- Phase 1 (Stages 1 and 2a):
  - 7 x OP Wells,
  - 3 x WI Wells,
  - 1 x GI well, and
  - 1 x contingent GI well at the 'Casper' gas reservoir.
- Phase 2 (Stage 2b):
  - 9 x OP wells, and
  - 3 x WI wells.
- Either Phase 1 or Phase 2
  - Two contingent re-drills (the complete re-drilling of individual wells, or of sections of wells (collectively referred to as 're-drills'), may be required in response to technical problems (Section 5.4.4.5).

Details on the well profiles with regard to section diameters and lengths are provided in the Development Description (Section 5.4.5.2).

Note: to ensure that a conservative worst-case is assessed with regard to spatial extent, concentration and thickness of cuttings, the modelling described in Section 10.6.4.3.4 covers the maximum number of wells (26) being drilled.

Specifically, the discharges will include:

- Tophole sections: seabed discharges of seawater, bentonite mud and associated drill cuttings,
- Bottomhole sections: surface discharges of drill cuttings contaminated with NADF at a target average concentration of <0.5 % by weight on dry cuttings, and
- Resuspension of cuttings during clearing of equipment.

10.6.2.1 Tophole discharges

The two tophole sections of each well will be drilled with seawater and bentonite sweeps followed by a displacement mud. All tophole drilling fluid and cuttings will be discharged directly to the seabed as no marine riser will be in place to enable cuttings to be returned to surface.

10.6.2.2 Bottomhole discharges

The OP wells will each comprise two or three lower sections, whilst the WI wells and the GI wells will contain two. The lower sections of all the wells will all be drilled using NADF. The use of NADF for the lower hole sections of the OP and WI wells provides much improved control of hole stability and shale performance when drilling at highly deviated angles (Section 5.4.5.3.1). However, for the GI wells, the final decision with regard to the choice of drilling mud (i.e., Water-based Mud (WBM) or NADF) used for the lower well sections will depend upon the success of the batch drilling process and which type of drilling fluid the MODU is configured to at that time (Section 5.4.5.2 and 5.4.5.3).

The NADF cuttings will be returned to the rig and treated by shale-shakers to recover most of the drilling fluid for re-use. The remaining cuttings will then be treated by a Thermomechanical Cuttings Cleaner (TCC) to remove most of the base oil. The recovered base oil will be returned to the NADF system on the rig, leaving <0.5 % oil on cuttings by dry weight to ensure compliance with legislation (Section 10.6.1.1). The TCC unit also grinds the cuttings to a finer grain material in the process.

The treated NADF cuttings will then be discharged from a cuttings chute extending up to 20 m below the sea surface after re-mixing with the recovered water (from the TCC unit) which allows a slurry to be formed, which will flow and descend in the water column. The exact depth of discharge is dependent on the rig and equipment and may be shallower than 20 m, but cuttings modelling based on a 20 m depth is conservative as a shallower discharge will provide more opportunity for dispersion of the cuttings before reaching the seabed.

In the event that it is not possible to treat and discharge the NADF cuttings offshore, it would be necessary to transfer the cuttings to shore for storage and / or eventual treatment and disposal. However, facilities for the onshore treatment and disposal of NADF cuttings is not available in the Falkland Islands (Section 10.10). Therefore, it is necessary to ensure that a high availability of the offshore treatment process is maintained. Therefore, the following measures will be in place:

- The contractor management process will ensure that the selected TCC supplier can demonstrate a high level of uptime and reliability for the TCC e.g., established TCC unit operators claim, on average, a 99.5 % uptime based on historical performance. This demonstration will form part of the initial contractor management selection process and the subsequent audit process (Section 3.2.15 and Section 3.2.13),
- Planned preventative maintenance and condition monitoring programmes,
- Flexibility in scheduling for alternative work i.e., should there be any major issues with the TCC unit, Navitas will be able to suspend the well, recover the BOP and continue with alternative tophole work. This is consistent with Navitas' batching and BOP maintenance philosophy, aiming to have alternative tophole work available, and
- Spares will be carried to ensure maximum uptime of the equipment. As the supply chain to the Falkland Islands is challenging, Navitas will hold sufficient spares commensurate to the remote area of operations. For example, discussion with the TCC suppliers indicates that the 'sparing package' should include a complete spare mill and engine.

10.6.2.3 Resuspension of cuttings

The cuttings discharged directly at the seabed (the vast majority of which come from the tophole sections) may accumulate around the well and can reach up to two metres in height. Experience from operations on the UK Continental Shelf (UKCS) indicates that the settlement of cuttings can sometimes obscure subsea equipment and risk the integrity of the various components e.g., self-sealing control fluid lines. In order to ensure that these components are kept clear of cuttings, very localised planned mobilisation of cuttings is anticipated using ROV-mounted dredging equipment at any such locations.

Using the ROV water pump, the cuttings will be sucked or blown so that they are relocated a distance of a few metres from the O&G infrastructure. This operation is kept to the minimum necessary to allow good access to the subsea equipment. The impact of this activity on the initial water column and sediment is very similar to that which occurs when the cuttings first settle, and so is considered to be inherent in the impact assessment that follows.

10.6.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts of drilling discharges warranted further investigation (Chapter 9). These include the impacts to:

- Water quality,
- Seabed sediments offshore (Section 7.3.7.1),
- Phytoplankton and zooplankton in the North Falkland Basin (NFB) (Section 7.4.1),
- Benthic organisms offshore (Section 7.4.3.2), and
- Fish and squid in the NFB (Section 7.4.4.2).

The above may be affected by the settlement of solids and suspended particles at the seabed which may bury animals, affect the sediment chemistry and grain size, water chemistry and water turbidity. These physical impacts may in turn affect plankton, benthic organisms and / or fish and squid species during vulnerable life stages.

10.6.4 Characterising and quantifying the impact of drilling discharges

When characterising and quantifying the impacts of drilling discharges, it is necessary to consider the following:

- Influencing factors:
  - Ocean hydrodynamics,
  - Background sediment, and
  - Drilling fluid composition.
- The nature of the impact on each of the different receptors, and
- Quantification of the drilling discharges using discharge modelling.

10.6.4.1 Influencing factors

10.6.4.1.1 Ocean hydrodynamics

The surface currents in the Sea Lion Field predominantly move in northerly and north-westerly directions, with the current speed generally being <15 cm/s. At the seabed, the currents tend to move in westerly directions with the current speed typically being <10 cm/s (see Section 7.3.5.2).

10.6.4.1.2 Background sediments

The sediment survey for the NFB Licence Areas, PL032, PL033 and PL004 (Gardline, 2012; Section 7.2.2) concluded that the mean sediment grain size at the Sea Lion area is 27 µm. The sediments were found to comprise, on average, 70.5 % of fines, 27.9 % of sand and 1.6 % of gravel across the survey area (Section 7.3.7.1.1).

10.6.4.1.3 Drilling Fluid composition

10.6.4.1.3.1 Chemicals

Both the bentonite mud and the NADF will contain the chemical additives required to ensure:

- The correct weight of the drilling fluid so that wells are sufficiently 'overbalanced' (weighted) to prevent 'kicks' of oil / gas from the reservoir into the wellbore (Section 5.4.9), and
- Optimal performance to prevent problems when drilling e.g., the drillbit becoming stuck.

In line with the OCNS, every effort will be made to ensure that chemicals with low environmental impact are selected for use (Section 10.6.1.1.2).

The bentonite sweeps used when drilling the tophole sections will contain:

- Barite (OCNS E, PLONOR),
- Bentonite (OCNS E, PLONOR),
- Caustic soda (OCNS E, PLONOR),
- Soda ash (OCNS E, PLONOR), and
- Lime (OCNS E, PLONOR).

Caustic soda, soda ash and lime were not included as a mud component in the discharge model (Section 10.6.4.3) due to their PLONOR status but are accounted for as a contributor to the total drilling fluid mass. Although barite and bentonite are also included on the PLONOR list as inert minerals and require no risk assessment under OSPAR rules, scientific studies have identified pseudo-toxic properties for zooplankton and filter feeders, primarily due to the particle size and sharpness of the minerals compared with natural suspended solids (Smit, *et al.,* 2006). As such, these two components are included in the modelled risk assessment.

Note: the bentonite displacement mud used in the topholes comprises the same components as the bentonite sweeps with the exception of lime.

The additives that will be required within the NADF are not yet known, but a typical NADF comprises:

- Barite (OCNS E),
- Non-aqueous fluid,
- Emulsifiers,
- Brines, and
- Gelling agents.

10.6.4.1.3.2 Metals

A comparison was made between the background metal concentrations in sediment in the Sea Lion area (Gardline, 2012) and the levels contained within an analogous Water-based Mud (WBM) (Table 10.40). As shown, the concentrations of cadmium, copper, iron, mercury, lead and zinc would all be higher in the drilling fluid than in the background sediment.

Table 10.40: Metal concentrations of MI-High[1] drilling fluid and Sea Lion sediment

Metal	Mi-High ($\mu g.g^{-1}$)[1]	Sea Lion Sediment ($\mu g.g^{-1}$)
Cadmium (Cd)	0.77	0.3
Chromium (Cr)	6.5	46
Copper (Cu)	88	22
Iron (Fe)	9,270	-
Mercury (Hg)	5.9	0.03
Lead (Pb)	243	7.5
Zinc (Zn)	167	71
Nickel (Ni)	-	18

[1] Mi-high is a type of barite used in WBM and is used as a conservative estimate of metal content within UK-market sourced drilling mud barite (Neff, 2005).

10.6.4.2 Nature of the impact on receptors

10.6.4.2.1 Water quality

The primary impacts of drilling discharges on water quality, at the seabed or from the surface, arise from the suspension of particulate matter in the water and the presence of chemicals within the discharge. Importantly, the impact on water quality is closely tied to the impacts on marine organisms.

Nonetheless, the Sea Lion Field is located in an area within the Falkland Islands continental shelf that is directly influenced by both Patagonian Shelf waters and superficial sub-Antarctic waters which spread over wide areas of the continental shelf and serve to rapidly disperse and dilute any discharges (Section 7.3.3). Further, all chemical components within the discharges will be selected to ensure minimal impact (Section 10.6.1.1.2).

10.6.4.2.2 Seabed sediment

The main recognised impacts from the discharge of drill cuttings and associated muds are on the sediment and to the epifauna and infauna.

Sediment quality at the Phase 1 & 2 drill sites will primarily be affected by the discharge of drill cuttings direct to the seabed from the two tophole sections of each well (Section 10.6.2.1) and the impacts on the sediment are closely tied to the impacts upon benthic fauna.

The cuttings deposition will result in a localised increase in average grain size from the existing average of 27 µm, and therefore has the potential to change sediment structure in the immediate vicinity of the wells. While these sections will also be circulated with bentonite sweeps, which contain barite, bentonite, caustic soda, soda ash and lime (Section 10.6.4.1.3), toxicologically, these components are virtually inert (Neff, 2005). Therefore, while the tophole drill cuttings may impact the sediment with regard to particle size modification, they are not expected to alter the sediment chemistry unless the water concentration in the sediment pores exceeds the published 'Predicted No Effect Concentration' (PNEC).

As the NADF cuttings will be ground by the TCC prior to discharge from the surface (Section 10.6.2.2), the particles of thermally treated cuttings are expected to be smaller than those discharged as part of the WBM cuttings. Therefore, smothering from NADF treated cuttings is expected to be less than for WBM cuttings (Aquateam COWI, 2014).

10.6.4.2.3 Phytoplankton and Zooplankton

Surface drilling discharge suspensions may lead to increased turbidity which can reduce light penetration in the upper water column. The waters of the NFB are highly productive during the austral spring (Section 7.4.1.2.1) and any significant reduction in light penetration could potentially affect primary production *via* a shorter, or shifted, phytoplankton bloom period, or even changes in species composition if impacts were over a wide enough area and / or for a significant period of time.

However, experiments assessing the impact of WBM concentrations on survivorship of the marine diatom (*Thalassiosira pseudonana*) following exposure to 50 mg/l for a period of 10 days did not show any significant changes in algae biomass or physiological condition (Cranford, *et al.,* 1998a).

Runciman (2001) carried out water-phase exposures in accordance with OSPAR methods (using the phytoplankton *Skeletonema costatum*) for assessing aqueous toxicity using WBM samples collected from seabed cuttings piles. The study concluded that it was very unlikely that significant effects on phytoplankton productivity would occur during a short-term exposure if this type of material were re-suspended in the water column.

With regard to zooplankton, high concentrations of suspended particulates may cause impacts owing to physical interaction with the gills, gastrointestinal tract and feeding behaviour which are expected

to be of greater concern than impacts from chemical toxicity (Smit, *et al.,* 2006). Nonetheless, in a review of impacts, Wills (1999) concluded that water column organisms would rarely be exposed to drilling fluids long enough and at sufficiently high concentrations to elicit any acute or sub-lethal responses.

In terms of impacts from NADF heat treated cuttings, a Norwegian study concluded that the environmental risk associated with these discharges is comparable to that from WBM discharges (Aquateam COWI, 2014).

10.6.4.2.4 Benthic fauna

Surveys carried out on the NFB (Section 7.2.2) indicated that the benthic communities in the area were typical of the sediment type and were fairly homogeneous throughout the surveyed area (Section 7.4.3.2). Further, there are no known habitats in the area equivalent to those of conservation significance in the UK (Section 7.4.3.2.2). Although some indicator taxa of important habitats are predicted to be present (≥50 % probability) (Section 7.4.3.2.3), these are likely to occur in low densities and not in aggregations as would typically contribute to the definition of important habitats.

Nonetheless, impacts to benthic fauna from drilling discharges may include:

- Disturbance and smothering caused by burial,
- Changes to species assemblages owing to modified sediment structure (particle size),
- Changes to availability of oxygen within the sediment, and / or
- Physical impacts caused by suspended particles.

10.6.4.2.4.1 Disturbance and smothering

The impacts of disturbance, smothering and burial of benthic organisms by cuttings are direct and immediate and will affect only those organisms directly beneath the deposition. Studies have indicated that there is a risk of impact to benthic fauna when burial layers exceed a thickness of 6.5 mm (Trannum, 2004; Kjeilen-Eilertsen, *et al.,* 2004; Neff, 2005; Smit, *et al.,* 2006).

10.6.4.2.4.2 Changes to sediment structure

Of greater impact to the benthos in the longer term is the potential for change in the sediment structure which could affect the suitability of the seabed for re-colonisation by species normally characteristic of the area. It is thought that such effects can persist for many years (Genesis, 2015a). It is suggested by Smit *et al.* (2006) that, in the absence of any other stressors, a 95 % increase in the existing median grain size (i.e., to >52 µm) would be sufficient to carry the risk of impacting upon 5 % of the most sensitive benthic organisms present.

Studies have shown that re-colonisation of cuttings pile sediments may commence 1-2 years after the cessation of cuttings discharges (UKOOA[58], 1999; Neff, 2005) and such predictions are supported by results from environmental surveys conducted in the Sea Lion area during 2012 (Section 7.2.2). Studies were carried out comparing data from baseline surveys where no drilling had previously taken place, with those from post-drilling surveys around areas of historical drilling activity carried out in 2009 (Section 7.2.2). These surveys indicated that there was no evidence of sustained disturbance as a result of historical drilling activities and that species diversity, community assemblage and abundance were typical of those found in background / undisturbed areas (Section 7.4.3.2). Additionally, environmental surveys carried out during the FOSA drilling campaign in 1998 included pre- and post-drilling surveys around the 'Little Blue A' well and indicated no change in the composition of dominant species, and

[58] Now known as Offshore Energies UK (OEUK).

similar levels of abundance and species diversity in both surveys (Section 7.3.7.1.1). Therefore, exploration drilling activities did not appear to appreciably disturb the benthic community in the area.

10.6.4.2.4.3 Availability of oxygen

While impacts on benthos are most commonly assumed to occur as a result of direct burial, Trannum *et al.* (2010) conducted experiments comparing the impacts of burial by WBM cuttings versus burial by natural sediments. The study found a significant reduction in number of taxa, abundance, biomass and diversity of macrofauna with increasing thickness of drill cuttings, which was not observed for the natural sediment particles and it was thought that the WBM influenced oxygen consumption and oxygen penetration depth in the sediment (Trannum, *et al.,* 2010).

It was concluded that drill cuttings initiated a typical eutrophication response and that impacts to benthos were not, therefore, limited to the physical disturbances caused by direct burial but could also result from changes to the sediment environment (Trannum, *et al.,* 2010). It is suggested by Smit *et al.* (2006) that oxygen depletion of >20 % would be sufficient to carry the risk of impacting upon benthic organisms.

10.6.4.2.4.4 Physical impacts

Benthic filter feeding organisms, such as bivalve molluscs, are known to be affected by suspended particulate matter due to clogging in the gills (Cranford, *et al.,* 1998b). Indeed, laboratory studies have shown that elevated concentrations of bentonite and barite can affect the growth of filter feeding organisms (Cranford and Gordon, 1992; Cranford, *et al.,* 1999; Barlow and Kingston, 2001). Nonetheless, particles such as barite settle out rapidly resulting in declining concentrations of barite in the water column, and even in the benthic boundary layer where most bivalves feed, it is considered probable that barite has limited effect (Neff, 2010).

10.6.4.2.5 Fish and squid

Impacts to fish and squid from drilling discharges may include:

- Displacement of adults from feeding grounds, and
- Disturbance to eggs, larvae and juvenile stages.

The potential for metal contamination is also discussed below.

10.6.4.2.5.1 Displacement from feeding grounds

As stated above, surface and seabed drilling discharges can result in high levels of suspended particulate matter within the water column prior to its settlement on the seabed. Studies suggest that concentrations of suspended particulate matter of approximately 200 mg/l may damage the gills of fish while higher concentrations may inhibit feeding activity (Smit, *et al.,* 2006). While adult fish are able to move away from turbid areas, such avoidance behaviour may serve to displace them from important feeding areas.

The proposed well locations are situated within the Falkland Islands Northern Slope (NS) habitat zone which has been identified as an important feeding area for a number of fish species, whose abundance varies with season (Section 7.4.4.2.2.1). As the drilling operations are scheduled to occur over a duration spanning more than one year, they may be ongoing at any time of year and could therefore coincide with recorded high abundances of numerous fish species, many of which are of commercial importance (Section 7.4.4.2.4). Although, it should be noted that the important fishery areas are in the shallower zones of the NS (250-350 m depths).

10.6.4.2.5.2 Disturbance to eggs, larvae and juveniles

Experiments carried out by Cranford *et al.* (1998a) assessing the impact of turbidity on survivorship of fish embryos and larvae showed a significant decrease in survivorship in late-stage haddock embryos (8-12 days old) and yolk sac larvae (3-7 days post-hatch) at the highest WBM concentrations tested

(100 mg/l). In contrast, early stage embryos (1-4 days old) and feeding larvae (13-17 days post-hatch) showed no significant response to any of the WBM concentrations (Cranford, *et al.,* 1998a).

Whilst a number of fish and squid species spawn within the Falkland Islands waters, no commercial species are known to have spawning grounds within the area of the Sea Lion Field and many migrate outside of Falkland Islands waters to spawn (Section 7.4.4.2.3). However, some non-commercial species e.g., species of fathead sculpins such as *Psychrolutes marmoratus* and small morid cods are likely to spawn in the area (Section 7.4.4.2.3). Equally, it is understood that a number of skate species breed in the area due to their distributions and based on the known occurrence of egg cases, hatchlings and reproductively active females (Arkhipkin, *et al.,* 2008; Pompert, 2011; Arkhipkin, *et al.,* 2012a; P Brickle, *pers. obs*.).

10.6.4.2.5.3 Metal contamination and bioaccumulation in marine organisms

A concern over potential metals contamination of demersal finfish, including the Patagonian toothfish, was raised during scoping consultations carried out under the previous operator (Chapter 6).

Metals in general have been shown to biomagnify[59] through food chains, including 'heavy metals', which is a loose term for certain metals and non-metals that have more harmful effects (OSPAR, 2000). However, heavy metals in barite, which is contained within WBM and NADF (Section 10.6.4.1.3), occur as virtually insoluble salts and their bioavailability is therefore very limited (Carroll, *et al.,* 2000). Indeed, numerous studies have concluded that the heavy metals present in drilling fluids, at the given concentrations, are not likely to be biologically available at all.

For example, a study undertaken by Neff *et al.* (1988a) exposed four species of benthic marine animals to marine sediments containing barite from WBMs. The results indicated that when exposed over a long period at high concentrations, the benthic organisms had a slight tendency to accumulate heavy metals in the gut and the gills in the form of unassimilated barite particles. However, the concentrations of barite used in the experimental sediments were much higher than would be found in the environment surrounding the drill cutting piles. It was therefore concluded that the likelihood of heavy metal uptake from WBM barites in the field was minimal.

Neff *et al.* (1988b) undertook another experiment, again to assess the biomagnification of heavy metals (barium and chromium) from barite. Flounder and lobster were provided with sandworms (*Neanthes virens*) that had been exposed to sediments containing the settle-able fraction of drilling fluids. The results indicated that neither barium nor chromium had been accumulated by the lobster or the flounder. Again, the barium and chromium that was present in the sandworm was found in the ingested sediments in the gut, rather than in the animal's tissues.

The level of heavy metals in heat treated NADF cuttings is expected to be the same as that in WBM cuttings so similar impacts, or lack thereof, are expected (Aquateam COWI, 2014). Indeed, Stagg and McIntosh (1996) investigated the bioaccumulation of metals from NADFs using variations in sediment contamination and found no differences in the liver or muscle of the demersal fish used (the Dab (*Limanda limanda*)) between treatments. In addition to this, the fish exposed to the drill cuttings directly did not exhibit increased concentrations of metals, again indicating that the metals were non-bioavailable.

Bowmer *et al.* (1996) also showed that there was no evidence of bioaccumulation of metals in the cardiid bivalve mollusc (*Cerastoderma edule*), the tellinid bivalve mollusc (*Macoma balthica*) or the arenicolid polychaete annelid (*Arenicola marina*). The concentrations of metals in the test organisms were not significantly different to those exposed to control sediments.

[59] Biomagnification is the increase in concentration of chemicals in each organism up the food chain. This is as opposed to bioaccumulation which is the buildup of absorbed chemicals in an organism over time.

In contrast to the above studies, Farestveit *et.al.*, (reported in Fjogstad, *et al.,* 2000) who also investigated the bioavailability of weighting materials such as barite, did find some evidence for bioaccumulation of metals. Toxicological studies were conducted using fish-feed with a 10 % addition of high lead (5,000 ppm) barite and while no acute metal poisoning occurred during the 10 week test, the barite-exposed fish did show enriched values of lead in both liver and blood. Importantly however, the study used an extremely high dose that could not be experienced in practice (i.e., twenty times the levels reported for 'high' metals barite in Table 10.40 above), and ten times that used in exploration campaign barite, which was <500 ppm. Similarly, Schaaning *et al.* (2002) also found bioaccumulation of metals in polychaetes and gastropods fed on barite-spiked sediments for 28 days, however, with the exception of lead, similar bioaccumulation levels were also observed in organisms fed on uncontaminated sediments so it was unclear as to whether adequate depuration time had been observed before analysing the gastropods.

With regard to the background in the Sea Lion area, there has been little work carried out on the baseline levels of heavy metals in fish inhabiting the Falkland Islands, let alone on the North Slope or areas adjacent to the Sea Lion Field. Therefore, little baseline information is available. However, Hanchet *et al.* (2012) analysed muscle tissue samples collected from Antarctic toothfish and Patagonian toothfish, and some of their prey species, from the Ross Sea off Antarctica to determine their mercury content. The levels were highly variable within, and between, the species studied but were positively correlated with fish length in four of the five species studied (toothfish and their prey). In particular, the mercury levels in Patagonian toothfish were more than four times greater than in Antarctic toothfish. Hanchet *et al.* (2012) suggested that the differences between the two toothfish species could be explained through differences in their distribution and differences in their positions in the food web. However, the low levels of mercury in Antarctic toothfish relative to its prey species, could only be explained by a lower rate of mercury assimilation within this species and / or a higher rate of mercury elimination.

It is clear that a baseline is required for toothfish and other species in this environment. Given the low concentrations of heavy metals in MI-High drilling mud, the finite period of drilling and low levels in Sea Lion sediment in conjunction with the relatively low abundances of toothfish in this area it is very unlikely that drilling will have an impact on the rate of bioaccumulation of heavy metals in the ichthyofauna of the area.

10.6.4.3 Quantification of the discharges - discharge modelling

To enable greater understanding of the impacts associated with drilling discharges, Navitas conducted the following modelling:

- 'DREAM' (Dose-related Risk and Effect Assessment Model) / 'ParTrack' (Particle Tracking)) model published by the Foundation for Scientific and Industrial Research (SINTEF) (v6.5.1, v8.0 and v14.1).

The OP and WI wells will be drilled over six DCs plus a second remote GI well if required (Section 10.6.2). The modelling below therefore covers the maximum number of wells being proposed across all the DCs (Section 5.4.4).

The aim of the model is to estimate:

- Impacts to the sediment which requires assessment of the:
  - Thickness of the mud and cuttings layer on the seabed, and
  - Overall environmental risk to the sediment based on:
    - Grain size change,
    - Toxicity, and

        - Pore water oxygen depletion.
- Water column impacts:
    - Environmental risk in the water column resulting from:
        - Toxicity, and
        - Particle suspension.
- Recovery of the water column and sediments over time.

10.6.4.3.1 The DREAM / ParTrack modelling approach

The DREAM / ParTrack model calculates particle dispersion in the water column and deposition on the seabed and also calculates the time required for concentrations of contaminants to return to previous levels once the discharges have ceased. In doing so, the model factors in processes such as:

- Mixing,
- Re-suspension and dilution due to currents,
- Sediment re-colonisation leading to bioturbation and biodegradation of the sediments, and
- Changes in chemical toxicity over time.

The DREAM / ParTrack model predictions have been validated through field measurements at the Trolla Field in water depths of 265 m in the Norwegian Sea. Here, a correlation was observed between the simulated and the measured deposition of the cuttings on the sea floor (Rye, 2010; Jødestøl and Furuholt, 2010). Indeed, the observed deposition thickness was lower than that predicted by the ParTrack model, which suggests that the modelling results can be considered conservative.

To enable brevity in this section, the following describes only the information required to ensure appreciation and understanding of the modelling results. Detail with regard to the modelling parameters utilised e.g., metocean data (currents, wind, temperature and salinity and bathymetry) is provided in Section 7.3.2.

10.6.4.3.2 Discharge parameters and assumptions used in DREAM / ParTrack

DREAM/Partrack version 14.1 was used in the modelling, being the current version at the time of EIS preparation. Details on the well profiles are provided in the Development Description (Section 5.4.5). For the purposes of this assessment, the total weight of drilling fluids used and associated cuttings are summarised in Table 10.41 and here include drilling fluids carried over from one well section to the next as part of the batch drilling process.

Within the model, the wells were placed according to the design layout (Figure 10-25). Further, in addition to the maximum well count being modelled, it was assumed that the wells drilled at each DC location would be drilled consecutively. The exact spud locations (i.e., the place where the first tophole section is drilled) may vary slightly as design and operations progress, and if a tophole section is unsuccessful it may need to be re-drilled in an adjacent location (Section 10.6.2), but overall the wells are expected to be drilled within the same overall area. It is possible that if the progress of a well is not satisfactory, the whole well will be re-drilled. This is difficult to predict but two re-drills have been allowed for (within the NA-P-01 DC cluster). Note that these re-drills, and associated additional cuttings, are included in the model and are within the maximum well count of 26 (Table 10.41).

The oil content in the model is represented by an aliphatic component with a toxicity of 70 mg/l in pore water, as adopted in OSPAR Agreement 2015/05. In the model, the component has been modified to give it a low vapour pressure, as would be expected after going through a thermal treatment process.

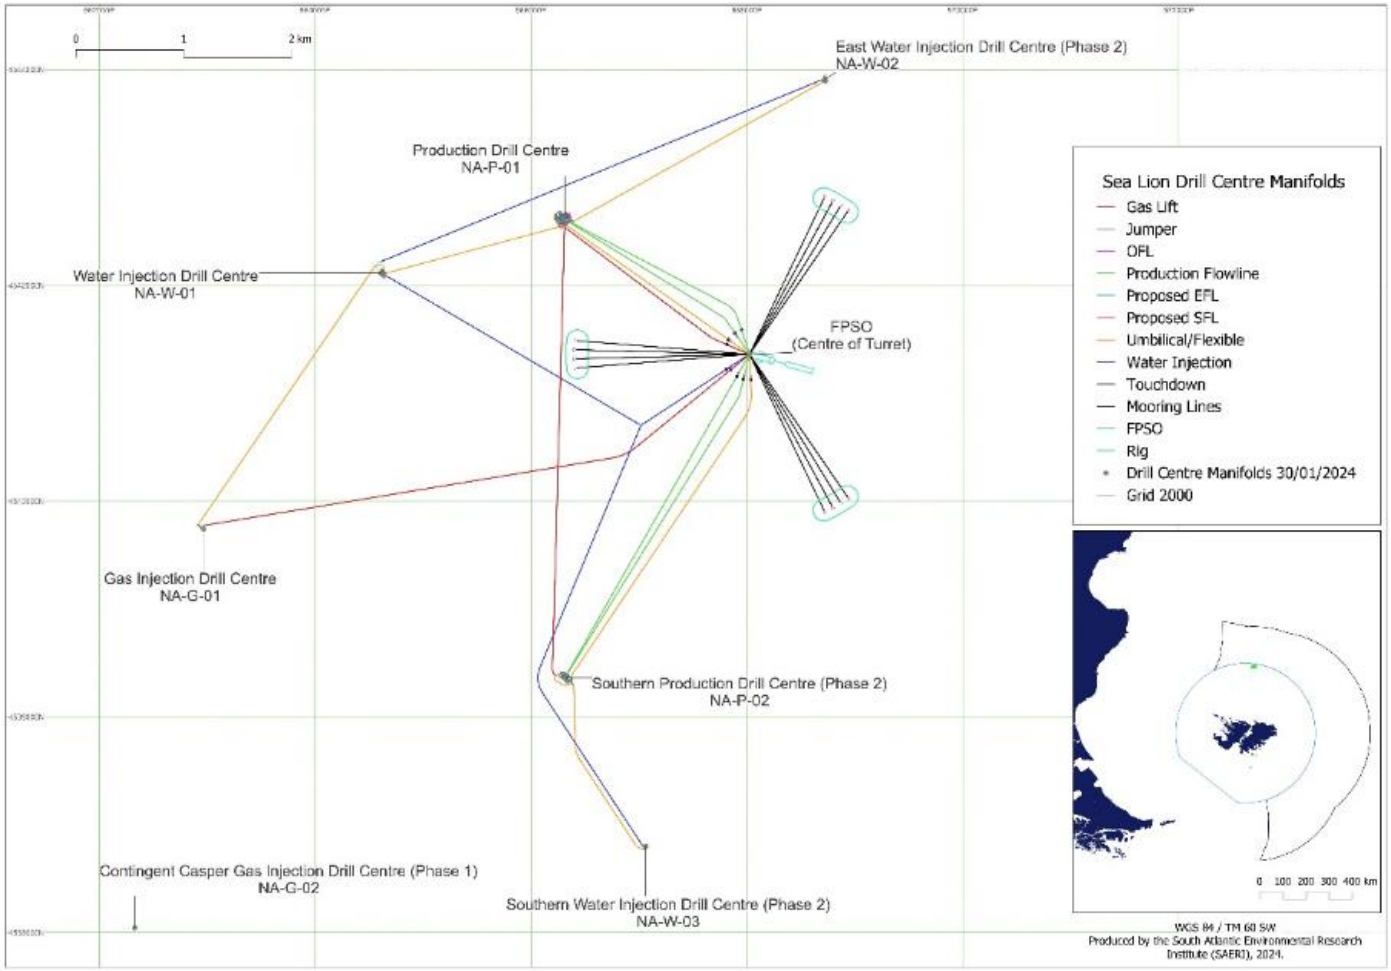

Figure 10-25: Modelled production, water injection and gas injection drill centres

Table 10.41: Summary of drilling fluid and cuttings totals[1]

Well type	Max. no. of wells	WBM on cuttings (t)	WBM discharged (t)	NADF cuttings (t)	Base oil on cuttings (t)
Production	16	12,276	14,884	13,809	78
Production redrills[2]	2	1,260	1,414	2,712	8
Water injection	6	3,744	4,788	3,924	18
Gas production / injection	2	1,476	1,860	460	2
Total	**26**	**18,756**	**22,946**	**20,905**	**106**

[1] These figures are as provided by Navitas and include drilling fluids carried over from one well section to the next.
[2] Two potential redrills have been included as production wells for the purposes of modelling, although any of the wells could be redrilled.

10.6.4.3.3 Understanding the model - PEC:PNEC ratio and Environmental Impact Factor (EIF)

10.6.4.3.3.1 PEC:PNEC

The DREAM model was originally designed to assess the impacts of produced water discharge. While the model can be adapted to assess drilling discharges, the factors considered for water column and sediment impacts differ slightly and are based on comparisons of the PEC:PNECs as follows:

- Sediment (PEC:PNEC$_1$):
  - PEC$_1$ (Predicted Environmental Change) i.e., the level of change to the sediment with regard to the following stressors:
    - Concentration of a chemical in pore water to which marine organisms could be exposed during and after the discharge,
    - Thickness of the deposition,
    - Degree of change to grain size, and
    - Oxygen content depletion.
  - PNEC$_1$ (Predicted No Effect Change) i.e., the highest level of changes caused by the above stressors at which no harmful effects are expected to occur to marine organisms, as determined from scientific literature.
- Water column (PEC:PNEC$_2$):
  - PEC$_2$ (Predicted Environmental Concentration) i.e., the concentration of a chemical, oil or suspended matter to which marine organisms in the water column would be exposed during and after the discharge as predicted by the model, and
  - PNEC$_2$ (Predicted No Effect Concentration) i.e., the highest theoretical concentration of the same components at which no harmful effects are expected to occur to marine organisms in the water column.

Despite the differing definitions however, the interpretation of the PEC:PNEC ratio is the same for both the sediments (PEC:PNEC$_1$) and water column (PEC:PNEC$_2$), and both are referred to as 'PEC:PNEC' hereafter. While the PEC is predicted by the model, the PNEC is defined as the change / concentration at which the Potentially Affected Fraction (PAF) of a species is 5 %.

A PAF of 5 % corresponds to a PEC:PNEC ratio of 1 and is a generally accepted risk level representing the concentration below which marine organisms are unlikely to be affected (EC, 2003). Where the PEC:PNEC ratio is >1, adverse effects from the discharges are anticipated and this is referred to as having a 'risk >5 %'.

10.6.4.3.3.2 Environmental Impact Factor

The model expresses the impacts to the water column and sediment in terms of the Environmental Impact Factor (EIF):

- For water column modelling, an EIF of 1 is defined as a cuboid volume of water equal to 100 m x 100 m x 10 m (0.0001 km^3), in which the calculated PEC exceeds the PNEC i.e., there is a risk to >5 % of the most sensitive species present in 0.0001 km^3,
- For sediment modelling, an EIF of 1 is defined as a square equal to 100 m x 100 m (0.01 km^2), in which the calculated PEC exceeds the PNEC i.e., there is a risk to >5 % of the most sensitive species present over 0.01 km^2,
- The results of the model are therefore expressed as:
  - The volume (km^3) in which there is a risk to >5 % of the most sensitive species present in the water column e.g., an EIF of 12 means that there is a risk to >5 % of the most sensitive species in 12 km^3 of water, and
  - The area (km^2) in which there is a risk to more than 5 % of the most sensitive species present on the seabed an EIF of 12 means that there is a risk to more than 5 % of the most sensitive species in 12 km^2 of seabed.

10.6.4.3.4 Modelling results

10.6.4.3.4.1 Seabed impacts

The model estimates the thickness of the deposited layer of matter, the grain sizes of the deposition, the toxicity of oil / chemical components in the deposited material and the depletion of oxygen by any biodegradation of organic matter (in this case both toxicity and oxygen depletion are caused by the oil content of the TCC cleaned cuttings). All four parameters are used to inform the assessment of the total risk to the sediment (i.e., the EIF). To best reflect this relationship, the modelling results are shown in Table 10.42 to show the contribution of deposition thickness and changes in grain size to the overall risk.

Table 10.42: Modelling results for the environmental risk to the sediments around the drill centres

Deposition thickness	Sediment grain size, toxicity and oxygen depletion
Figure 10-26 shows the predicted worst-case deposition thickness at the end of drilling all 26 wells. Burial thickness accounts for 56 % of the predicted risk. There is no significant overlap in deposition between the main drilling locations. In the absence of any other stressors, it was estimated by Smit *et al.* (2006) that a burial thickness exceeding 6.5 mm could result in 5 % of the most sensitive species being impacted (Section 10.6.4.2.4.1). Deposition thicknesses were predicted to exceed 6.5 mm up to around 120 m from the centre of the NA-P-01 DC, with smaller deposition areas at the NA-P-02 and the eastern drill centres, extending to only 50 m from the GI wells. As anticipated, the thickest areas of deposition are immediately around each drilling location (out to approximately 60 metres from each well) with a maximum deposition thickness of around 1,000 mm at the NA-P-01 DC (Figure 10-27) although there may be local fluctuations around these figures. This thickness is mainly due to the larger cuttings particles from the tophole sections which are discharged directly onto the seabed. The total depositional thickness at the end of drilling the wells was found to exceed 6.5 mm over an area of up to 0.42 km^2. Beyond this area, the thickness decreases rapidly with distance from the wells to <1 mm at approximately 400 m from the NA-P-01 DC, 290 m from the NA-P-02, NA-W-02 and NA-W-03 DC and 150 m from the GI well DCs (Figure 10-27). A wider area is covered by a thinner deposition layer resulting from the finer barite, bentonite and cuttings particles that are discharged at the sea surface following treatment of the NADF cuttings. Since these barite and bentonite particles are discharged 20 m below the sea surface rather than at the seabed, they can be carried long distances by ocean currents (several kilometres) before settling.	The predicted influence of drill cuttings on grain size, toxicity and oxygen depletion at the NA-P-01 DC (which has the highest number of wells drilled) are shown in Figure 10-28. The risk contribution of 20 % from grain size change is due to smaller particles depositing far from the well, and larger particles (> 52 µm, Section 10.6.4.2.4.2) depositing in the areas immediately around the wells. Outside the immediate vicinity of the wells, oxygen depletion and burial thickness are the main contributors to environmental risk in the seabed, representing 23 % and 56 % of risk respectively. Oil toxicity is relatively small and diminishes over time as the oil biodegrades, although this transfers to oxygen depletion in the process, which 'grows in'. This is caused by the breakdown of the oil component which consumes oxygen, and the oxygen levels are restored very slowly from oxygen dissolved in seawater. This, too, will diminish over time and will eventually disappear. Overall, the aggregate oxygen depletion starts to reverse and shows a net recovery beginning about 2 months after the end of drilling.
Total environmental risk to the sediment (based on the EIF)	
Figure 10-29a shows the environmental risk to the seabed around the NA-P-01 DC at the end of drilling. The total environmental risk incorporates the estimates of burial thickness, grain size change, toxicity and pore-water oxygen depletion. The area of seabed around the NA-P-01 DC wells in which there is >5 % risk to sensitive species present is 2.51 km^2 at the end of drilling, and is predicted to extend to around 1 km at the furthest point immediately after drilling has ceased. Figure 10-29b shows the recovery of the seabed five years after drilling has ceased, after which time substantive recovery of the pile is normally observed, and the maximum extent of the area of 5 % risk has reduced significantly. Twenty years after drilling, there is substantial recovery, with the 5 % risk area reducing to 0.53 km^2 and extending to around 80 m Figure 10-29d. At that point, the seabed is expected to have returned to a productive state, albeit modified compared to its original condition.	

Given that the DCs are sufficiently far from each other, there are not expected to be any cumulative impacts from the drilling at these locations.
Contributions to the environmental risk to sediment
The sediment risk caused by drilling is predicted to be primarily due to burial thickness (Figure 10-28) resulting from the deposition of cuttings and mud solids. Oxygen depletion, grain size and chemical toxicity change follow in order of the stress they cause to the seabed. Recovery is expected rapidly at first and a permanently modified area of around 80 m from the wells and within the 500 m zone of the DCs and GI wells is ultimately expected at the end of Field Life[1].

[1] Note the modelling uses very conservative assumptions. The deposition thickness modelling covers the maximum number of wells drilled (26, with only 23 completed). The sediment risk (grain size, toxicity and oxygen depletion) and total environmental risk scenarios were modelled for the NA-P-01 DC wells as this location has the highest number of wells and is therefore a worst-case proxy.

10.6.4.3.4.2 Water column impacts

The modelling predicted that the plume of suspended particles and fluids generated during the drilling of each well section would disperse before drilling of the next section is commenced. These results therefore focus on two worst-case example plumes:

- One generated during the largest tophole discharge of bentonite sweeps and drilling fluid (WBM) at the seabed during the drilling of a representative 32'' well section, and
- One generated during discharge of the largest batch of treated NADF cuttings from the MODU, 20 m below the sea surface, following drilling of a representative 12 ¼'' well section.

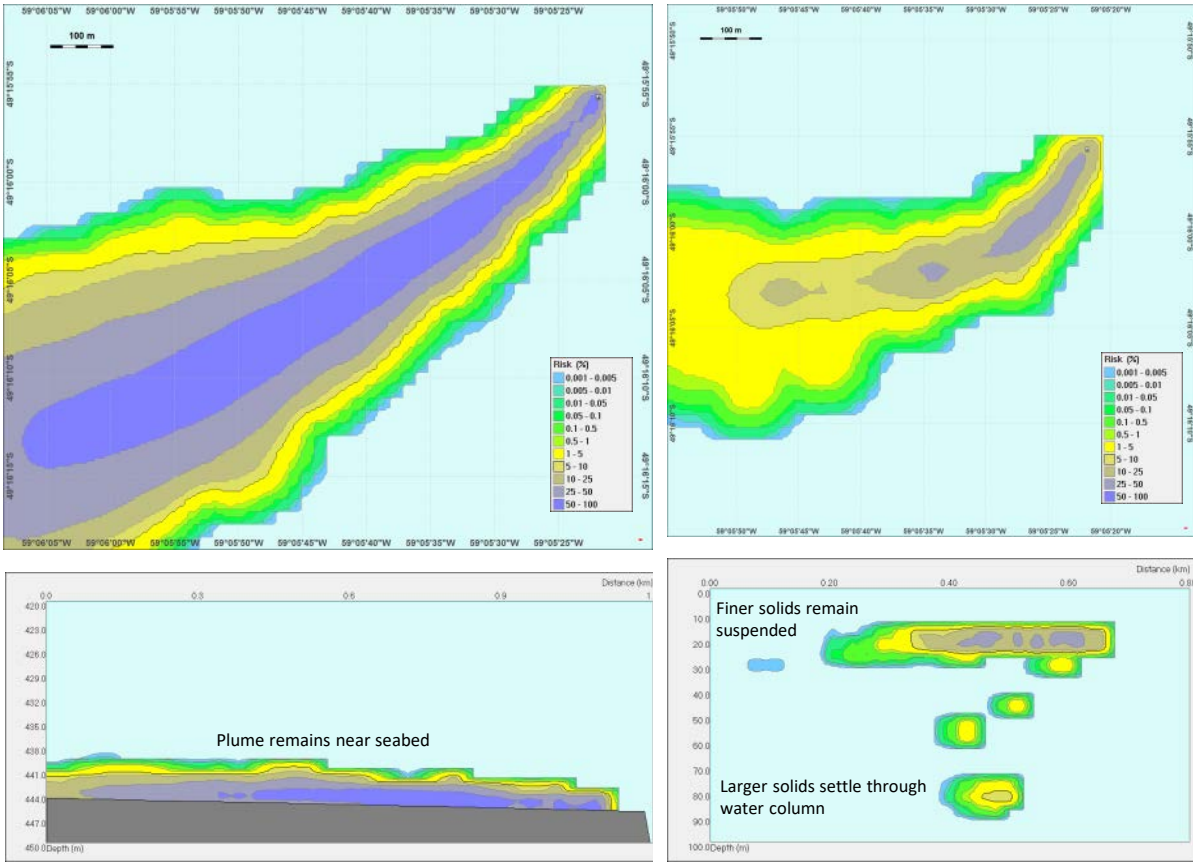
The predicted instantaneous risk to the water column from these two plumes is shown in Figure 10-30.

During drilling of the tophole section, the risk was >5 % up to 4 km from the discharge point (at the seabed) and fell to <5 % at 4 km, 2.5 days after drilling had ceased. The plume was confined to the bottom 50 m of the water column (Figure 10-30a). The total volume of water impacted at >5 % during the entire discharge was 0.011 km^3 and the main contributors to water column risk were the bentonite particles used in the tophole drilling fluid, followed by the cuttings particles (Figure 10-30a). The risk from these particles quickly falls as the materials are dispersed and settle out of the water column.

As shown in Figure 10-30b, the plume of treated NADF cuttings, discharged from the surface after drilling the 12 ¼'' production well section, was dispersed quickly away from the discharge point owing to the:

- Strong sub-surface currents,
- Dispersion horizontally and vertically *via* settlement of larger particles, and
- Lower rate of discharge than occurs with the tophole sections that have a larger borehole diameter and no recycling of the drilling fluid.

As a result, the risk associated with NADF cuttings surface discharges was very small and fell to <5 % after only five hours. During the discharge, and at most, 0.0061 km^3 of water column was at >5 % risk and this was mainly confined to the top 50 m of the water column (Figure 10-30b). The majority of the risk is caused by the concentration of oil in the discharge followed by the barite and cuttings particles.



a) Seabed discharges from the 32'' production well tophole section (above = plan, below = cross section)

b) Surface (-20 m) discharges from the 12¼'' production well section (above = plan, below = cross section)

Figure 10-30: Predicted instantaneous risk to the water column

10.6.5 Industry-standard mitigation measures

The following base-case and industry-standard mitigation measures were factored into the initial impact assessment:

- NADF drilling fluids will be re-circulated with cuttings being separated from the muds and the mud being re-used to minimise discharges of cuttings and waste mud as far as possible,
- NADF cuttings will be returned to the rig and thermally treated with the TCC to ensure the oil content complies with legislation as a minimum (Section 10.6.1.1), with the aim of exceeding the compliance requirement prior to discharge (i.e., <0.5 % oil on cuttings by dry weight**:** the main reason for targeting 0.5 % oil on cuttings is to limit the risks to both the sediments and the water column. Such a target is also routinely achieved in practice and therefore is considered BAT), and
- Selection of the most environmentally benign chemicals available on the Cefas list of registered products where possible (notwithstanding the need for optimal operational performance).

10.6.6 Impact Assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

A summary of the impact assessment outcomes is tabulated in Section 10.6.12, which shows the worst-case impact for each activity and receptor.

10.6.6.1 Water quality

All discharges are to the open ocean in depths of 450 m, and the affected water column is influenced by numerous currents (Section 10.6.4.1.1) and therefore, the sensitivity of the receptor is considered to be '**Very Low'**.

The discharge of drill cuttings is expected to result in a very localised reduction in water quality both in surface waters and in the lower part of the water column, due to an increase in turbidity and the presence of chemicals (Section 10.6.4.3.4). While the worst-case modelling results indicate that a seabed plume of tophole discharges (at seabed) could extend several km down-current from each well location, affecting a maximum volume of 0.011 km^3, turbidity in the water column is not expected to extend more than 50 m above the seabed whilst drilling the tophole sections, or significantly below 50 m of the sea surface whilst drilling the lower well sections (Section 10.6.4.3.4). On completion of drilling operations, the oceanic currents will rapidly dilute the suspended particles within the water column which is predicted to recover within 2.5 days of each tophole section and five hours of each lower well section being drilled (Section 10.6.4.3.4). Based on the relatively small volume of water being affected and the rapid and full recovery once the activity ceases such that any effect is unlikely to be detectable against background levels, the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of impact to water quality is considered to be '**Very Low (1)**'.

10.6.6.2 Phytoplankton and zooplankton

Both phytoplankton and zooplankton are widely distributed throughout the Falkland Islands Continental Shelf and do not represent any rare or vulnerable species. Therefore, the sensitivity of the receptor is considered to be '**Very Low'**.

The impact on phytoplankton and zooplankton will be very localised and temporary. The increase in water column turbidity, and reduced light penetration, resulting from suspended fine particulates is expected to be localised and the upper water column is predicted to rapidly recover (Section 10.6.4.3.4). Given the negligible nature of the impact based upon the literature (Section 10.6.4.2.2), and that the environmental risk from each discharge plume is predicted to be very localised with rapid and full recovery such that any affect is unlikely to be detectable against background levels, it is anticipated that any effects will be fully-reversible with no potential for cumulative effects. Therefore, the severity of effect to plankton is considered to be '**Slight**'.

Therefore, the overall significance of impact to phytoplankton and zooplankton is considered to be '**Very Low (1)**'.

10.6.6.3 Seabed sediments

Given that the habitat is undesignated and that there is no potential to transfer contaminants to any nearby sensitive areas (Section 10.6.4.2.2), the sensitivity of the receptor is assessed as '**Very Low**'.

The impact of grain size change will diminish rapidly with increasing distance from the wells and sediment risks >5 % due to grain size change are expected to be confined to within around 60 m of each well (Section 10.6.4.3.4). The impact is expected to be restricted to a very localised area such that there will be a barely detectable impact on habitats, however, there is expected to be a long-term impact to 0.53 km^2, 20 years after the drilling operation (Table 10.42 above). Therefore, on balance, the severity of the effect to sediment quality is considered to be '**Moderate**'

Therefore, the overall significance of impact to seabed sediments is considered to be '**Low (3**)'.

10.6.6.4 Benthic fauna

According to the surveys already carried out (Section 10.6.4.2.4), there are no known vulnerable species recorded within the benthos and the community structure is widespread and typical of the area. Although some indicator taxa of important habitats are predicted to be present, as described in Section 10.6.4.2.4 above, these are likely to occur in low densities and not in aggregations that would typically contribute to the definition of important habitats. Predicted habitats are found widely in areas adjacent to the license area, and as such any potential impacts within the license area are not likely to impact the health of the local population. However, a data gap exists because the Sea Lion environmental baseline survey did not sample the specific drilling locations. Whilst differences in benthic habitat are considered to be very unlikely, and the sensitivity of the receptor is likely to be 'Very Low', to take a precautionary approach it is assessed here as '**Low**'.

Deposition thicknesses were predicted to exceed 6.5 mm up to 120 m from the centre of the NA-P-01 DC (at the maximum reach) and up to 50 m from the GI well(s) (at the maximum reach) (Section 10.6.4.3.4.1, Table 10.42) and the impacts of disturbance and smothering will be restricted to sessile organisms within these distances (Section 10.6.4.2.4.1). Increases in grain size that could result in a change to sediment structure were predicted to extend to a maximum of 1 km from each well (Section 10.6.4.3.4.1, Table 10.42). The model indicates that a risk to >5 % of the species present around the main DC is expected to occur in an area of 2.51 km^2 at the end of drilling (Section 10.6.4.3.4). While this area is small, the model also predicts that the area will be reduced in five years and is expected to reduce to approximately 0.53 km^2 after 20 years (Section 10.6.4.3.4). However, as described in Section 10.6.4.2.4, field studies in the area have indicated that recovery periods for exploration drill cuttings piles are far quicker than estimated in the model and that the model tends to overestimate deposition thickness. Additionally, both literature and ground-truthing (albeit from WBM well sites) indicate that recolonisation of the pile will commence within 1-2 years (Section 10.6.4.2.4.2). Other studies support the modelled outputs in concluding that the fine layer of barite that may settle out from the discharge of treated NADF cuttings is unlikely to have any toxic effect (Section 10.6.4.2.5.3).

Further, as stated in Section 10.6.4.3, the modelling carried out is highly conservative as it assumes the maximum number of 26 wells being drilled from the new subsea layout (namely 23 completed wells, one contingency GI well and two side-track / redrill potentials), with worst-case assumptions used for well length. It also assumes the worst-case use of NADF in the lower well sections of the GI wells. The modelling also assumes that the wells are drilled consecutively at each DC i.e., with no drilling break.

However, the planned Sea Lion drilling programme includes several rig moves between the drill centres. The modelling assumptions include this level of well sequencing detail, although the operations are more closely spaced in time in the model than expected in reality to conserve computing power, and are therefore likely to overestimate the impacts slightly, because sediments are buried more quickly and have less time to recover between discharges.

In conclusion, and on balance, the severity of the effect to the benthic fauna is considered to be '**Moderate**'.

Therefore, the overall significance of impact to benthic fauna is considered to be '**Moderate (6)**'.

10.6.6.5 Fish and shellfish

The modelling indicates that a maximum instantaneous volume of water of 0.11 km^3 would be at >5 % environmental risk during the drilling operations (Section 10.6.4.3.4). The spatial extent (volume) of the habitat predicted to be affected by the total drilling discharges is therefore of little to no geographical importance (<0.001 % of available habitat) to the fish populations migrating to the area to feed. Further, while the grey-tailed and yellownose skate and the spurdog both have an IUCN status of 'Endangered' or 'Vulnerable', such elasmobranchs are highly mobile species and have the ability to

move to another area of habitat if disturbed by drill cuttings discharges. Further they are generally found in shallower waters, are not abundant within the zone of influence and are dispersed spawners (Section 10.6.4.2.5). Therefore, due to the very small proportion of key species that could be affected, the sensitivity of the receptor is considered to be '**Low**'.

Owing to the localised area and short-term and reversible nature of the effect, the severity of the effect to fish species is considered to be '**Minor**'.

Therefore, the overall significance of impact to fish and shellfish is considered to be '**Low (4)**'.

10.6.7 Project-specific mitigation measures

The impacts are anticipated to range from '**Very Low**' to '**Moderate**'. Since the majority of risk to the seabed is caused by the oil content of treated cuttings through oxygen depletion, the key project-specific mitigation measure is the efficient operation of the TCC unit to minimise oil content which is part of the base-case (Section 5.13) and is thus factored into the initial impact assessment. Although the process has not been trialled in this specific geology before, the strata are of types experienced elsewhere and experience worldwide is that 0.5 % oil (by dry weight) on cuttings is rarely exceeded. On a long campaign such as this there is time to optimise, and continually improve, the process to achieve lower levels of oil on cuttings discharged.

Pre-drilling environmental surveys will also be carried out to confirm that no habitats or species of conservation significance are present within the zone of influence, and analysis of PAH content of treated NADF cuttings will be undertaken. Seabed grabs for sediment characterisation, benthos, chemistry and heavy metal analysis will also take place post first drilling (Section 10.6.10.1).

10.6.8 Residual impacts

10.6.8.1 Impacts to benthic fauna

The initial assessment takes account of all the mitigation measures which are built-in to the project (i.e., use of the TCC unit), and while continuing efforts to improve the oil on cuttings concentration may reduce the impact slightly if improvements can be made over the duration of the drilling campaign, this is not guaranteed. As such, the residual impact and risk assessments remain the same such that the impact to benthic fauna remains '**Moderate (6)**'.

Note: it is anticipated that the outcomes of the pre-drilling survey will indicate that the benthos in the Sea Lion Field is the same as the surrounding areas (which have been surveyed extensively). Should this occur, the sensitivity of the receptor would be reduced to 'Very Low', thus reducing the overall impact significance to 'Low (3)', however the impact is left as 'Moderate (6)' for now to take a precautionary approach.

10.6.9 Cumulative impact

In terms of cumulative impacts resulting from increased 'concentration' and the 'extent and duration' (Section 8.9.1) of drill cuttings discharges, there are no other O&G activities currently scheduled to occur in the NFB during the Sea Lion Phase 1 & 2 drilling campaign. Nonetheless, exploration drilling has occurred on the NFB since 1998 and each of the exploration wells, carried out by numerous operators, discharged WBM and cuttings both at the seabed and the surface.

A number of wells have been drilled in the area to appraise the initial Sea Lion discovery, as is shown in Figure 10-31. The closest well to the NA-P-01 DC is 14/10-4, which is an abandoned well, approximately 555 m to the south-east and was spudded in March 2011.

In March 2012, Gardline Environmental conducted a post-drilling survey at five well locations within the Sea Lion Field (Gardline, 2013b). In summary, 32 stations were sampled surrounding wells that had

been drilled in 2009 with WBM (14/10-1, 14/10-2, 14/10-6, 14/10-9 and 14/15-4a). The results indicated that, there was little detectable change at these locations from the surrounding areas. The survey showed that:

- The sediment was dominated by medium and coarse silt,
- Hydrocarbon and metal concentrations recorded during the survey were generally within the expected range for the region,
- Depth and sediment type gave no evidence of any previous point source contamination, and
- The fauna recorded was considered homogeneous, with no evidence of any previous disturbance to the benthic community as a result of historical drilling activity at the existing wells (Gardline, 2013b).

The lack of detectable change from background levels at these abandoned well sites indicates that there is unlikely to be any significant cumulative impact between the current proposed operation and previous exploration drilling campaigns in the region.

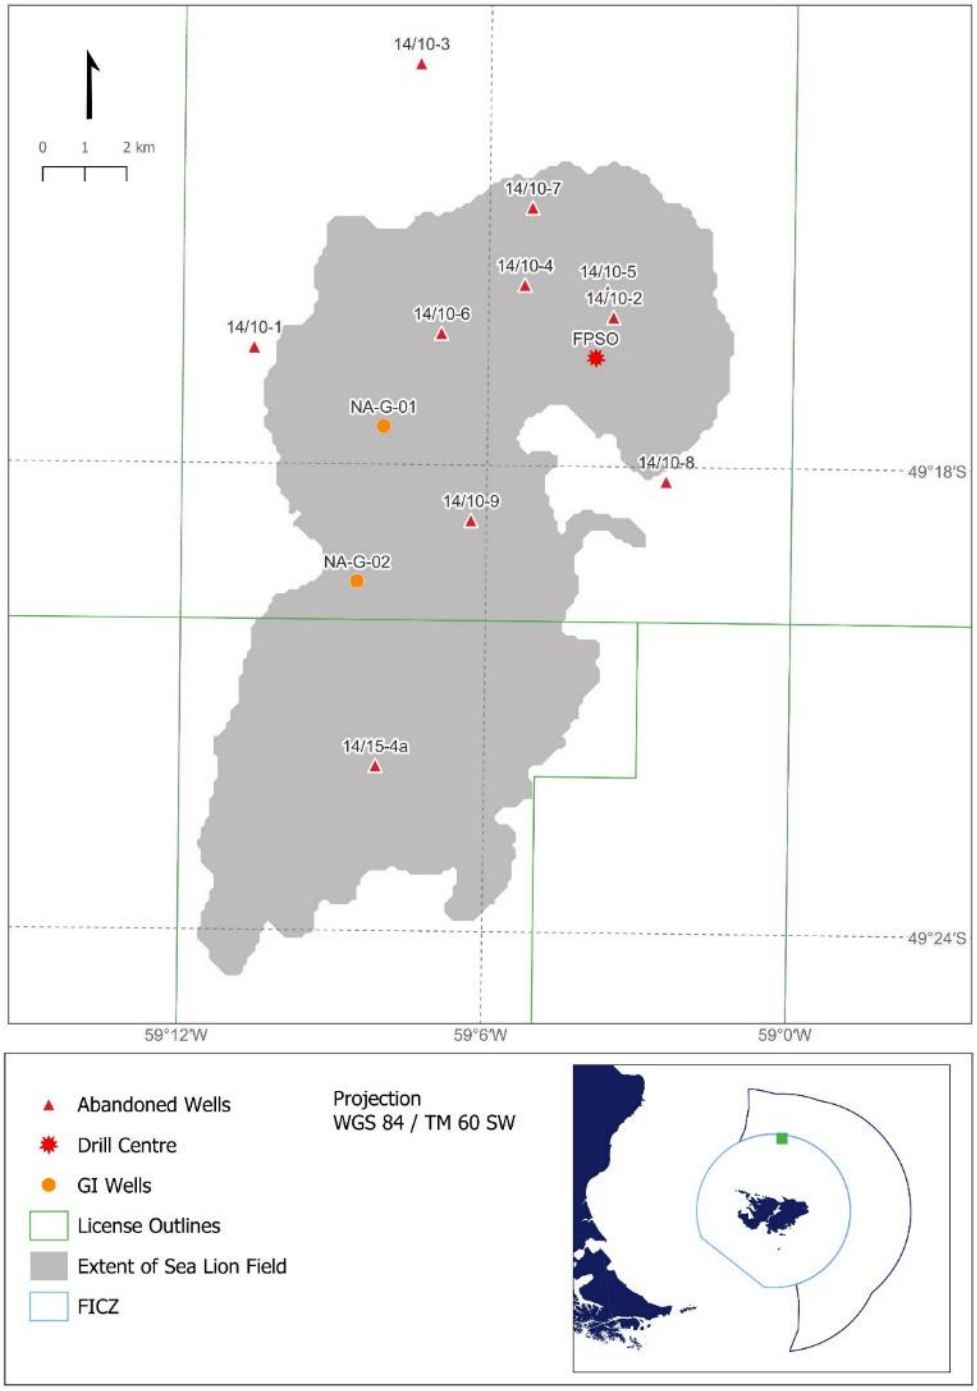


Figure 10-31: The locations of existing (abandoned) wells within 2.5 km of the drill centre

10.6.10 Confidence

The details of the drilling campaign are clearly defined and the quantities of drilling mud and cuttings have been estimated on a conservative basis. The nature of the impact of drilling discharges is relatively well known from several decades of research, model validation studies conducted by SINTEF and the ground-truthing study carried out following the 2012 Sea Lion survey described above (Section 10.6.4.2.4.2). Modelling uncertainties have been identified (Table 10.43) and while their potential to materially alter the outcome of the modelling has been considered within the assessments above, it is acknowledged that improvements in the modelling design could increase the accuracy of

quantification of the impact. Indeed, improvements in the modelling process may lead to predictions of lesser impacts, as was indicated by the ground-truthing study carried out in the Trolla Field (Section 10.6.4.3.1).

While the Gap Analyses Programme (GAP) identified benthic ecosystems as a priority area which would benefit from further research to inform environmental assessments (Section 7.2.4.1), benthic data collected in the drilling area so far has not indicated the presence of any species or habitats of conservation concern and the benthos is believed to be relatively homogeneous across the area (Section 7.4.3.2). Nonetheless, the absence of a site-specific benthic survey to date is acknowledged as a data gap, although it is considered unlikely that these data gaps have the potential to significantly change the outcome of the assessment. If anything, completion of the pre-drilling survey may enable a less precautionary approach with regard to the assessment of the sensitivity of benthic species and habitats as a receptor. Note that Rockhopper and POEPL commissioned an extensive benthic survey of the PL032 licence block comprising drop down cameras and benthic grabs in the vicinity (Section 7.2.2).

On balance, owing to the uncertainties within the model and the acknowledged data gap, the degree of confidence in the impact assessment is considered to be '**Probable**'.

Table 10.43: Modelling uncertainties

Uncertainty	Description
Discharge quantities	The discharge geometry is constrained by operational equipment and typical drilling rig design and is unlikely to significantly change. The downhole conditions are potentially quite variable in terms of volumes of mud required but this is allowed for in the inputs provided to the model, which are based on conservative assumptions.
Cuttings particle size distribution	The size distribution of the cuttings particles is based on an average of data from drilling in the Norwegian Sea and on Navitas-supplied analysis from representative drilling projects. Regional variation is possible relating to the rock types being drilled and it would be beneficial to report on cuttings particle size distribution from ongoing drilling campaigns in this region to inform future modelling.
Metocean conditions	The metocean dataset covers three years. This provides a wide range of weather conditions and the modelling results consistently show a tendency for dispersion tending towards the north-west of the site. However, the currents do move in all directions at different times and deposition is locally variable due to the short nature of each discharge such that the plumes may disperse more efficiently than is indicated in the model.
Environmental sensitivities	Grain size change is an important parameter and the threshold for this parameter within the risk assessment is based on the analysis of environmental monitoring data from the Norwegian Continental Shelf covering 246 species. Burial thickness is based on data from Europe and the United States. Importantly, there may be regional differences in prevailing fauna that would mean different thresholds are appropriate in the Sea Lion area. Nevertheless, the basis of the thresholds is considered to represent the best available data and covers a wide range of benthic fauna.

10.6.10.1 Monitoring required

The following monitoring will be carried out to improve the degree of confidence in the impact assessment:

- Pre-drilling survey: this will typically involve video only to determine the nature of the seabed at the precise drilling site,
- Post-drilling benthic survey: Post-drilling benthic surveys will be carried out every five years in line with the methodology recommended by the GAP project which includes seabed grabs, for sediment characterisation, benthos, chemistry and heavy metal analysis, video and water column sampling,

- Post-drilling cuttings pile analysis: the assumptions used in the modelling have a large impact on the predicted environmental risk to the seabed. Navitas will conduct sediment sampling of the seabed post-drilling in order to inform future assessments of drilling discharges in the region, and
- Analysis of PAH content of treated cuttings from the TCC unit.

Detailed monitoring requirements have been established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline EMMP is provided in Chapter 15.

10.6.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

10.6.12 Findings summary

Table 10.44: Summary of the impact assessment for discharge of drill cuttings during the Phase 1 & 2 Development

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Drilling operations	Discharge of: Seawater and bentonite sweeps, Tophole drill cuttings, and Thermally treated and ground NADF drill cuttings	Water quality: Suspension of particles leading to increased turbidity	Planned	1 & 2	Very Low	Slight	n/a	**Very Low (1)**	**n/a**	**Probable**	**Industry-standard:** Drilling discharges to be minimised as far as possible in line with BAT, Selection of benign chemicals where possible, NADF cuttings returned to the rig and thermally treated to minimise oil on cuttings (aiming to exceed compliance requirements), and Post-drilling monitoring of seabed recovery. **Project-specific:** Continual improvement so that oil on cuttings will be minimised, as far as is possible, during drilling campaign to below a 0.5 % average
		Plankton: Reduction in the ambient light, chemical content or plume and barite particles may affect zooplankton			Very Low	Slight		**Very Low (1)**	**n/a**		
		Seabed sediment: Deposition of drill cuttings modifying sediment particle size			Very Low	Moderate		**Low (3)**	**n/a**		
		Benthic fauna: Burial of benthic fauna, modification of habitat, toxicity and oxygen depletion			Low	Moderate		**Moderate (6)**	**Moderate (6)**		
		Fish and shellfish: Suspended barite particle may affect gill structures			Low	Minor		**Low (4)**	**n/a**

10.7.1 Introduction

Numerous discharges to sea will occur throughout the Phase 1 & 2 Development. These will include domestic wastewaters, drain, bilge and ballast waters from vessels throughout the Field Life, drill cuttings and fluids during Stages 1, 2a & 2b of the Development, and operational and marine discharges which will occur mostly during steady state production (Stage 3). The use of chemicals during the Phase 1 & 2 Development was raised as a concern by stakeholders during scoping consultations (Chapter 6).

This chapter assesses the impacts and risks associated with operational and domestic discharges, including:

- Hydrotesting water – which is used to test for leaks when commissioning flowlines etc., and may contain dyes so that leaks can be identified and other preservatives.
- Wellbore clean-up and completion fluids – water that has been flushed through the wellbore to clean out any debris and residual drilling fluids,
- Cooling water (CW) – filtered seawater used within the cooling system, which may contain chemicals intended to preserve the system pipework e.g., by preventing algal growth,
- Subsea hydraulic fluids – which provide energy transmission and lubrication within valves. These are glycol based fluids that are usually discharged when valves actuate,
- Produced water (PW) - a by-product of oil production as the reservoir depletes. Water already present in the reservoir and water injected into the reservoir are produced alongside the oil, and this produced water will contain oil, production chemicals and other contaminants,
- Grey and black water – domestic wastewater and sewage,
- Food waste,
- Drainage and bilge water, and
- Hypersaline water – which is a by-product of the water-makers held on the vessels and installations.

Note: the impacts associated with other discharges to sea e.g., drill cuttings discharges and ballast water and warm water from cooling systems are described elsewhere in this document as indicated in Table 2.2.

10.7.1.1 Relevant legislation

Conventions and legislation relevant to operational discharges to sea include:

- International Conventions:
  - International Convention for the Prevention of Pollution from Ships (MARPOL) 1973/78:
    - Annex I – Regulations for the Prevention of Pollution by Oil,
    - Annex IV – Prevention of Pollution by Sewage from Ships, and
    - Annex V – Prevention of Pollution by Garbage from Ships.
  - Convention on the Protection of the Marine Environment of the North East Atlantic 1992 (OSPAR Convention):
    - OSPAR Recommendation 2001/1 for the Management of Produced Water from Offshore Installations as amended by OSPAR Recommendation 2006/4.
    - OSPAR Decision 2000/2 on a Harmonised Mandatory Control System (HMCS) for the Use and Reduction of the Discharge of Offshore Chemicals.

  - OSPAR Recommendation 2012/5 for a Risk-based Approach to the Management of Produced Water Discharges from Offshore Installations, associated guidelines in OSPAR Agreement 2012/7 and PNEC data in OSPAR Agreement 2014/05.
  - OSPAR Agreement 2005/8 on a Monitoring Programme for Concentrations of Radioactive Substances in the Marine Environment (updated 2011).
- Key UK Legislation:
  - Offshore Petroleum Activities (Oil Pollution Prevention and Control) (OPPC) Regulations 2005 (and all amendments).
  - The Merchant Shipping (Prevention of Pollution by Sewage and Garbage from Ships) Regulations 2008 which implement Annex IV and Annex V of MARPOL 73/78 and provide a general prohibition against the overboard disposal of all types of garbage waste from vessels and offshore installations.
  - Offshore Chemical Regulations (OCR) 2002 (and all amendments).
  - The Environmental Authorisations (Scotland) Regulations 2018 which replaced The Radioactive Substances Act 1993 Amendment (Scotland) Regulations.
- Relevant Falklands legislation:
  - Marine Environment (Protection) Ordinance of 1995.
  - Environment Protection (Overseas Territories) Order of 1988.
  - Environment Protection (Overseas Territories) (Amendment) Order of 1997.
  - Offshore Petroleum (Licensing) Regulations 1995 and 2000.
  - Oil in Territorial Waters Ordinance (1960).
  - Maritime Ordinance 2017 (Dumping and Deposits at Sea), Part 14.
- Relevant Falklands operational notices:
  - Petroleum Operations Notice (PON) No. 8.

Under the above, there are numerous compliance requirements with regard to oil content, chemical selection and the discharge of PW as a whole.

10.7.1.1.1 Produced water compliance

10.7.1.1.1.1 Oil in water

The OSPAR Convention, and its associated Recommendations, contains an underpinning requirement to use Best Available Techniques (BAT) and Best Environmental Practice (BEP) to minimise pollution and this extends to the management of PW. OSPAR 2006/5 introduced a presumption that Produced Water Reinjection (PWRI) would be taken as a starting position in determining what is BAT for a particular asset or discharge.

OSPAR Recommendation 2001/1 specifies that all discharges of PW must comply with a monthly average dispersed oil in water (OiW) content of 30 mg/l or less, and that no single discharge should exceed 100 mg/l. PW must be treated to minimise the OiW content using BAT/BEP. In the UK, consent conditions normally require sampling and analysis of PW two times per day when discharging, or once per month when reinjecting. Other requirements are included in guidance and consent conditions including those for metering, management of critical elements and the reporting of unusual oily sheens visible beyond 500 m from the installation.

FIG PON8 guidance specifies a target of 40 mg/l for PW although Navitas understand that FIG expects to adopt a 30 mg/l monthly average standard in line with the UK, averaged over those days when a discharge occurs and ignoring days when there is no discharge (e.g., because PWRI is online).

10.7.1.1.1.2 Produced water as a substance

In addition to reservoir hydrocarbons, chemicals and NORM, PW also contains other naturally occurring substances that are present in the hydrocarbon reservoir. In line with OSPAR requirements these are analysed and reported twice a year.

The OSPAR commission aimed to achieve a reduction in the discharge of hazardous substances to sea and targeted the cessation of hazardous discharges by 2020. The ultimate aim is to achieve concentrations in the marine environment which are near background levels for naturally occurring substances, and close to zero for man-made substances. To this end, OSPAR embarked on a process of risk-based assessment of PW discharges and formalised this approach in OSPAR Recommendation 2012/5, and Agreement 2012/7. These were adopted with a view to understanding the toxicity of PW as a whole substance in efforts to achieve the 2020 goal. OSPAR has set new strategic objectives in its North-East Atlantic Environment Strategy 2030, including to ensure by 2027 that measures to eliminate discharges, emissions, and losses of hazardous substances are in place to achieve or maintain good environmental status, which parallels EU marine strategy. The emphasis therefore moves to controlling the effects of hazardous substances rather than their elimination *per se*.

All parties contracting to OSPAR are required to use a Risk-Based Approach (RBA) when assessing the environmental risk posed by their PW discharges. The RBA is a method of:

- Assessing the toxicity of 'whole PW' as a substance in its own right, and
- Prioritising mitigation actions for discharges or substances that pose the greatest risk.

In the UK, this resulted in a voluntary implementation programme that engages all discharging assets in undertaking an RBA. For assets that can clearly show the risks are adequately managed according to certain tests, they can 'drop out' of the tiered assessment process with no further action. For many assets however, the process shows scope for risk minimisation and a plan is required to identify future steps to minimise risks.

The process informs justifications presented in ongoing submissions under the OPPC Regulations and under the Offshore Chemicals Regulations.

10.7.1.1.2 Chemical compliance

The UK has controlled the use and discharge of offshore chemicals since 1979 *via* the Offshore Chemical Notification Scheme (OCNS). This has developed into an OSPAR-wide control scheme *via* the Harmonised Mandatory Control System (HMCS) which is an outcome of OSPAR Decision 2000/2 and Recommendations 2010/3 and 2010/4. This contains requirements for chemicals to be pre-screened by applying standardised laboratory tests in the Harmonised Offshore Chemical Notification Format (HOCNF). Those with acceptable properties are given rankings as to their potential risk in typical usage and are added to the Cefas (Centre for Environment, Fisheries and Aquaculture Science) Definitive Ranked List of Registered Products. Only chemicals on this Cefas list may be used or discharged offshore for Oil and Gas (O&G) purposes. Chemicals with the best performance (lowest toxicity, lowest bioaccumulation and highest biodegradation) are given a classification of 'Gold'.

In the UK and Netherlands, the site-specific risks of chemical discharge are assessed at 500 m from the discharge using a dispersion calculation known as the Chemical Hazard and Risk Model (CHARM). For those chemicals that cannot be assessed using CHARM, such as inorganic chemicals, a separate OCNS classification is given from 'A' to 'E', with 'E' being the best environmental performance. Chemical discharge must be subject to a site-specific risk assessment unless they are:

- Categorised as Posing Little Or No Risk (PLONOR) to the environment according to OSPAR Agreement 2013/6 (including, for example, inert minerals, nut fibres, methanol and monoethylene glycol),

- Are given a Hazard Quotient (HQ) of 'Gold' under the HCMS (provided the Cefas Template dosage is not exceeded, in which case a site and use-specific risk assessment may be required), or are
- Categorised as 'E' under the OCNS.

Chemicals that have specific undesirable properties regarding their biodegradation, toxicity and / or bioaccumulation characteristics, are given a 'Substitution Warning' (SUB) which means that their use must be justified and replacements sought within a specified timescale. The goal was a phase-out of the discharge of SUB chemicals by the 1st January 2017. This was largely achieved but there remain in use some chemicals whose function requires them to be biocidal or persistent for example, and their use and discharge continues, but must be justified in applications. Chemicals with traces of certain undesirable substances such as particular metals, including those on a list for priority action (OSPAR 2004-12, revised 2023) are given a 'Product Warning' code and their use must also be specifically justified in UK chemical permit applications.

All chemicals dosed into the Cooling Water (CW) and Produced Water (PW) will be selected to minimise the potential environmental impact in line with OSPAR Decision 2000/2. They will be subject to ongoing review and improvement where practicable.

10.7.1.1.3 Non-Aqueous Drilling Fluids in well clean-up and completion fluids

The Offshore Chemical Regulations (OCR) include the discharge of hydrocarbon chemicals or substitute hydrocarbon chemicals (i.e., Non-Aqueous Drill Fluids (NADF) such as Oil Based Muds (OBM)). If any NADF is to be discharged within well fluids, such as clean-up or completion fluids, the discharge will be conditioned to meet certain maximum discharge volumes and concentrations. The O&G UK (now OEUK) Well Clean-up Good Practice Guidelines provide information on the industry standards (Section 10.7.5). It is noted that, in the UK, any reservoir oil in clean-up or completion fluids would be managed separately under the OPPC Regulations.

Representative samples of the discharged material shall be collected at regular intervals during the course of the discharge to determine the hydrocarbon chemical or substitute hydrocarbon chemical content of the discharge. In the event of any discharge giving rise to a visible 'oil sheen' on the sea surface, FIG will be notified of the discharge operation in line with the PON8 (Section 10.7.1.1.5) and all discharges will be reported to FIG following completion of the operation.

10.7.1.1.4 Naturally Occurring Radioactive Materials (NORM)

In the Northern European marine environment, the OSPAR Radioactive Substances Strategy relates to discharges of all radioactive substances and includes the aim of attaining 'concentrations in the environment near background values for naturally occurring radioactive substances' (Gwynn, *et al.,* 2022).

Under OSPAR Agreement 2013/11, it is necessary in the UK to sample discharged PW on a quarterly basis to test for quantities of radionuclides which can occur naturally in the PW.

10.7.1.1.5 The PON 8 and oil sheen reporting

The FIG PON8 is primarily intended for use when reporting oil spills. However, as per the guidance below, the *pro forma* must also be used to report on oil sheens which may result from PW discharges. This guidance is intended to reflect the fact that all oil spills are reportable under law but that normally operating PW discharge streams (if applicable) are already reported *via* the installation's PW monitoring records and returns.

The PON 8 directly specifies the following:

- If the sheen does not result directly from the PW stream it must be reported using the PON 8 regardless of its size. There is no lower limit to the size of spill / sheen reported.
- If the sheen results from the PW stream and the discharge contains in excess of 100 mg/l oil in water then it must be reported using the PON 8 regardless of its size. There is no lower limit to the size of spill / sheen reported.

Therefore, if the sheen results from the PW stream and the discharge contains less than 100 mg/l of oil in water, then a spill need not be reported. However, if the appearance of the sheen is unusual, or if another source or discharge is causing an unusual coloration of the water around the installation then the Department of Mineral Resources (DMR) and the Falkland Islands Maritime Authority (FIMA) should be informed of the incident by telephone as soon as possible. This should not be treated or recorded as an oil spill. The purpose of the report will be to enable the Departments to respond to enquiries from third parties (spotter planes, civilian aircraft, ship's masters etc.). The decision as to whether the sheen is 'unusual' in appearance is left to the common sense and judgement of the Offshore Installation Manager (OIM) at the time.

10.7.1.1.6 Sewage and food waste

In compliance with MARPOL Annex IV, which applies to vessels > 400 GT or certified to carry > 15 persons on board, untreated black water (sewage) may only be discharged beyond 12 nm from shore whilst the vessel is moving. Between 3-12 nm, sewage must be treated prior to disposal at sea and only if vessels are moving at a speed of greater than or equal to four knots. Depending on the vessel's sewage treatment equipment, some sewage may be discharged within three nm, and again only if it is travelling at a minimum of four knots. For stationary offshore 'vessels' such as the Floating Production, Offloading and Storage (FPSO) unit and the Mobile Offshore Drilling Unit (MODU), although they are >12 nm from shore, sewage must be treated before discharge to sea.

Food waste must be macerated to ensure a maximum solid particle size of 25 mm prior to discharge as required under MARPOL Annex V, to aid its dispersal and decomposition in the water column.

All vessels must maintain a Waste Disposal Log.

10.7.1.1.7 Oil content in drainage and bilge water

Under MARPOL Annex I, the discharge to sea of drainage or bilge water by vessels at sea is prohibited unless the oil content of the discharge, without dilution, is less than or equal to 15 parts per million (ppm). Discharges must cease in the event that a sheen becomes visible.

Under the OPPC regulations, the discharge of drainage water from offshore installations is prohibited unless the oil content of the discharge, without dilution, is less than or equal to 40 mg/l (mg/l is another way of measuring concentration that is very close to ppm).

When in transit, both the MODU and the FPSO will qualify as vessels under MARPOL and will thus adhere to the 15 ppm limit. When stationary and operational however, the MODU and FPSO will qualify as offshore installations under OPPC and would be required to adhere to the 40 mg/l limit. However, Navitas has committed to adhering to the lower 15 ppm limit once on station as well as when in transit for both the MODU and FPSO.

All vessels must use an Oil Record Book to record all oil discharges from drainage and bilge water.

10.7.2 Sources of operational discharges to sea

Operational discharges to sea during the Phase 1 & 2 Development include:

- Hydrotesting water and ballasting liquids at the pre-commissioning stage,
- Wellbore clean-up fluid,

- Cooling water (CW) throughout steady state production,
- Hydraulic fluids during operation of subsea valves,
- PW when it first starts to appear and the Produced Water Re-Injection (PWRI) system is being commissioned which may take three to six months,
- PW during unplanned PWRI downtime at any time throughout the Field Life,
- Grey water e.g., wastewater from showers, cooking, cleaning, food preparation,
- Black water e.g., sewage,
- Food waste,
- Drainage and bilge water from the MODU / FPSO, and
- Hypersaline water from the creation of potable water.

10.7.2.1 Hydrotesting and ballasting discharges to sea

During installation in Stage 1 of the Development, structures, and Subsea Umbilicals, Risers and Flowlines (SURF) will be lowered to the seabed. To control buoyancy and vertical position, these are often filled with a carrier liquid which can be topped up using liquids in attached bladders, often inhibited seawater or an inhibited mix of water and monoethylene glycol. During descent to the seabed, some of these liquids are discharged and during connection of the equipment and disconnection of the installation vessel, all of the liquids may be discharged.

During pre-commissioning in Stage 1 of the Development, it will be necessary to hydrotest the SURF. Hydrotesting of the flowlines and risers is an important step in confirming their structural integrity and to demonstrate the absence of leaks.

During the test, the SURF will be flooded with inhibited seawater or an inhibited mixture of water and monoethylene glycol and the lines will be pressurised and monitored for a period (typically less than 24 hours) to check for leaks before the water is released in a controlled discharge to sea. Pipeline hydrotesting normally involves pumping a biodegradable gel ahead of the flushing water to ensure the whole pipeline contents are displaced, leaving the pipeline with the correct preservation fluids prior to startup.

10.7.2.2 Wellbore clean-up and completion fluids

When each well is displaced from Non-Aqueous Drill Fluid (NADF) to brine during completion, NADF contaminated water is returned to the mud pits on the MODU, becoming progressively cleaner as water circulates around the well. The NADF is skimmed off and the water sheen tested before discharge to the sea. This typically results in about 3,000 bbls (approximately 477 m^3) per well (78,000 bbls / 12,394 m^3 for the total drilling campaign) of visibly oil-free water being discharged offshore. Navitas will operate an oily water separator on the MODU to further remove oil from such discharges. Any residuals that cannot be discharged will be returned to the supply base for incineration.

The visibly oil-free water will be discharged in line with legislation (Section 10.7.1.1.1.1) and the O&G UK (now OEUK) Well Clean-up Good Practice Guidelines (Section 10.7.5).

10.7.2.3 Cooling water discharges to sea

As described in Section 5.8.4.2, the cooling water system will use cold seawater to absorb heat from a cooling medium system *via* a series of heat exchangers, with the warm seawater being discharged back to sea on a continuous loop. These cooling water (CW) discharges will be at an elevated temperature of approximately 28°C. This discharge is assessed in Section 10.8.

10.7.2.4 Hydraulic fluids during operation of subsea valves

Valves that control flow and operation of the subsea system are operated by means of hydraulic fluids pumped from the FPSO. The control system includes dual high pressure and low pressure hydraulic control lines for full redundancy. The distribution networks shall be designed to avoid common modes of failure and promote reliable operations. Self-sealing connectors are provided between the control lines within the umbilicals and the subsea manifolds so that there is negligible discharge of fluids during connection and maintenance. Each time a valve is operated, an amount of fluid is released. A small amount of fluid also passes across the valve seals during normal operations as the liquid is held in a pressurised state. Industry guidance on the management of such fluids will be followed (Energy Institute, 2016a).

A biodegradable water / glycol-based fluid will be used. These are typically composed of water and monoethylene glycol which is a PLONOR chemical along with a dye to help pinpoint any leaks should they occur. This selection may be subject to change (e.g., a different manufacturer) as the design progresses but a glycol-based fluid with a similar performance would be chosen, and no substitution chemicals will be used.

10.7.2.5 Produced water discharges to sea

Produced water comprises formation water which has been trapped within the reservoir for millions of years and / or a mixture of seawater and formation water, when seawater has been injected in order to maintain pressure in the reservoir during oil and gas production (Hosseini, *et al.,* 2012).

Once into steady state production, PW will be treated and a concentration of 10 mg/l dispersed OiW will be targeted for PW treatment performance. Treated PW will be mixed with treated seawater before reinjection into the reservoir at a maximum concentration of 10 mg/l dispersed OiW *via* one of two PWRI units. This is intended to enhance oil recovery from the reservoir (Section 5.8.5.6) and alleviate the need to discharge PW to sea during normal production operations. This effectively ensures the long-term re-use of a major discharge stream with zero planned PW discharges to sea during normal operations.

However, when PW from the oil production wells first starts to arrive on the installation, there is the potential that some PW will be discharged while the PWRI units are commissioned. The volumes of PW that may be discharged during commissioning are, as yet, unknown but are expected to be small and short-lived as the PWRI units will be brought online as soon as possible. Additionally, throughout Field Life, it may be necessary to discharge PW in the event that the PWRI units malfunction or that the water cannot be cleaned to the necessary 10 mg/l dispersed OiW required for reinjection.

In the event of PW discharge during commissioning or unavailability of the PWRI option, the water will be cleaned prior to discharge to ensure that, as a minimum, it is compliant with PW legislation (Section 10.7.1.1.1), namely a dispersed oil concentration of no more than 30 mg/l monthly average and 100 mg/l in any one sample. It is anticipated that such discharges will carry an OiW concentration in the region of 10 - 15 mg/l. In the event that the OiW concentration is higher, the water can be diverted to the off-spec tank temporarily.

Legally compliant PW discharges, in the event of PWRI unavailability during early and late Field Life, were modelled using DREAM (Section 10.7.4.5) to assess the impact of PW discharges and to align with the RBA requirements of OSPAR Recommendation 2012/5 (Section 10.7.1.1.1.2). Although it is not a requirement in the UK to apply RBA until first water production, it has been applied here as a good practice to help identify any issues that would be addressed more efficiently at this stage and as a means of predicting the scale of potential impacts.

10.7.2.6 Grey and black water

Grey water (e.g., domestic wastewater from showers, dishwashing etc.) and black water (sewage) will undergo treatment prior to discharge as described in Section 10.7.1.1.6.

The sewage discharge points will be at minimum draught (*c.* 7 - 9m) below the surface of the water.

10.7.2.7 Food waste

Food waste from the galley will be macerated prior to discharge as described in Section 10.7.1.1.6. The discharge points will be at minimum draught (*c.* 7 - 9 m) below the surface of the water.

10.7.2.8 MODU / FPSO bilge and drainage water

The MODU is a registered ship and will adhere to the 15 ppm limit while acting as a ship and also when moored and operating as a mobile O&G drilling installation (Section 10.7.1.1.7).

The FPSO will be registered as a ship for transit (and potentially thereafter). However, when moored in the exclusion zone, the FPSO would qualify as an offshore installation to which OPPC would apply in the UK and therefore, in principle, it would be normal for an upper limit of 40 mg/l to apply to all drainage.

However, the requirement to demonstrate BAT would also apply and it is expected that the FPSO's bilge and slops oily water systems will discharge at an upper limit of 15 ppm. The FPSO bilge water system will accept drainage from 'machinery spaces' (mainly the engine room) and will have a MARPOL-compliant bilge water treatment system that cannot discharge water in excess of 15 ppm.

The oil separated from the drainage and bilge water will typically be returned to the processing facilities on the MODU and FPSO. However, occasionally the recovered oil may be sufficiently 'off spec' that it will not be suitable for processing offshore and in these instances it will be collected and stored in drums / transit tanks and will be shipped back to the onshore supply base. From there it will be transferred into a sludge truck for disposal at the FIG Stanley incinerator. It is understood that the FIG Stanley Incinerator will be operational by end of 2026. However, should the FIG Stanley incinerator not be available, Navitas would store the waste in suitable containers onshore until:

- The FIG incinerator is available,
- Offshore treatment on board either the MODU or FPSO is available / possible, or
- A suitable volume is ready for export to the UK.

Waste oils from this process shall always be considered candidates for re-use and incineration is a secondary solution. For example, with the agreement of FIG and Stanley Services Ltd, waste oils may be provided to local businesses for use in oil burning heaters.

10.7.2.9 Hypersaline discharges

Hypersaline water will be generated by desalination plants used to generate freshwater from seawater. The freshwater will be used for numerous operations as well as for consumption, as described in Section 5.11.4.2. The hypersaline water will be discharged to sea.

10.7.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts and / or risks associated with operational discharges to sea warranted further investigation (Section 9.2).

Marine environmental receptors, which may be impacted by operational discharges, are:

- Water quality,

- Plankton (Section 7.4.1),
- Benthos (including sediment) (Section 7.4.3),
- Fish and squid (Section 7.4.4.2),
- Seabirds (Section 7.4.5.2), and
- Marine mammals (Section 7.4.6.2).

The above are considered to be receptors owing to the potential for acute and chronic impacts associated with the oil, chemical and natural components of operational discharge plumes. Of note, to avoid repetition, the impacts to these receptors are not assessed individually below and instead they are grouped and assessed as 'marine organisms'.

10.7.4 Characterising and quantifying the impact and risk of operational discharges to sea

When characterising and quantifying the potential impacts and risks of operational discharges, it is necessary to consider the following:

- The composition, behaviour and fate of discharges,
- Nature of the potential impact e.g., acute and chronic effects,
- The potential for oil sheen formation,
- Volume of planned operational discharges, and
- Estimation of volumes associated with unplanned PW discharges, and the associated risks.

10.7.4.1 Composition, behaviour and fate of discharges

10.7.4.1.1 General operational fluids

For the purposes of this section, general operational fluids refers to hydrotest, wellbore clean-up / completion fluid and cooling waters. The composition, behaviour and fate of the hydrotest, wellbore clean-up / completion fluid and cooling waters, and that of the hydraulic fluids is provided in Table 10.45. All chemicals will be selected in line with the OCNS (Section 10.7.1.1.2).

Table 10.45: Discharge composition, behaviour and fate

Discharge fluid	Composition, behaviour and fate
Hydrotest water	The SURF will be flooded with inhibited seawater which will be dosed with chemicals such as oxygen scavengers, corrosion inhibitors and biocides[1]. The exact volumes of water and chemicals to be discharged to sea are yet to be determined and will be defined during the Front End Engineering and Design (FEED) process. However, it is anticipated that water discharged at the seabed will be rapidly dispersed and diluted. All chemicals dosed into the hydrotesting and ballasting water and will be selected to minimise the potential environmental impact in line with OSPAR Decision 2000/2. They will be subject to ongoing review and improvement where practicable.
Wellbore clean-up and completion fluids	Wellbore clean-up and completion fluid discharged to sea may contain traces of NADF and potentially reservoir hydrocarbons. All NADF chemicals will be selected in line with the OCNS (Section 10.7.1.1.2). Discharges will be in discrete volumes at the end of each well allowing time in between discharges for the water to disperse. The water will be discharged at depth (most likely through the cuttings discharge line), which will aid mixing and dispersion.
Cooling water	CW will be dosed with a biocide to prevent marine growth in the heat exchange system and therefore, discharges will contain biocides. Given the temperature and salinity of the CW discharges, it is expected that the CW plume will be buoyant and will remain in the top 200 m of the water column. All chemicals dosed into the CW and will be selected to

Discharge fluid	Composition, behaviour and fate
	minimise the potential environmental impact in line with OSPAR Decision 2000/2. They will be subject to ongoing review and improvement where practicable.
Hydraulic fluids	Hydraulic fluids are a single substance used to enable subsea valve actuation. A biodegradable water / glycol-based fluid will be used; these typically have no Substitution Warning (Section 10.7.1.1.2) and high biodegradability, with their main components being water and monoethylene glycol which is a PLONOR chemical along with a dye to help pinpoint any leaks should they occur. With regard to its behaviour and fate, such small quantities are discharged that it is expected to be rapidly diluted by seabed currents.

[1] It is noted that by nature, biocides are intended to harm marine life, but efforts will be made to ensure selection of a Cefas Gold product with no Substitution Warnings (Section 10.7.1.1.2).

10.7.4.1.2 Produced water

10.7.4.1.2.1 Composition of PW

The chemical composition of PW from a particular field can vary considerably depending on the geological characteristics of the surrounding bedrock, the type of hydrocarbons produced, the operating conditions and the age of the field. However, if seawater injection has been practiced (as it will be here), towards the end of the production life of a field, the composition of the PW will more or less resemble that of seawater. Therefore, even if the volumes of produced water increase with time, the total mass of different elements may not increase, due to dilution (Hosseini, *et al.,* 2012).

Nonetheless, while risk-based regulations, 'greener' offshore chemicals and improved treatment systems have reduced the environmental risks of PW, where the PW is discharged, it is still the largest operational source of oil pollution to the sea from the offshore petroleum industry (Beyer, *et al.,* 2020).

Generally, treated PW may contain:

- Production chemicals to assist with:
  - Flow assurance,
  - Oil separation, and
  - Water injection.
- Naturally Occurring Radioactive Material (NORM) (Hosseini, *et al.,* 2012),
- Reservoir hydrocarbon which is separate from the aqueous phase (free oil) and is therefore mostly removed from the water in the separation process,
- Dispersed oil which refers to small droplets of oil which are suspended in the aqueous phase (normally in the range of 10–100 mg/l (Beyer, *et al.,* 2020)), and
- Dissolved oil which comprises of naturally produced low molecular weight organic compounds such as inorganic salts, organic acids, Polycyclic Aromatic Hydrocarbons (PAHs), ketones, phenol / alkylphenols, heavy metals, and volatiles which contribute to its overall toxicity (Yang and Tulloch, 2002, Veil, *et al.,* 2004, Hosseini, *et al.,* 2012; Beyer, *et al.,* 2020).

Most of the free and dispersed oil is removed from the PW in the treatment process leaving a small residue expected to be less than 10 mg/l. Although the removal of dispersed oil droplets in the treatment process removes soluble oils that are contained within the droplets, dissolved oil is not specifically removed by the separation process or by mechanical treatment processes and therefore remains within the PW.

As described in the EMMP (Section 15.7.4), once the field is into production and PW has broken-through, the water will be tested to establish its exact composition as part of the Risk Based Approach (RBA) to PW (Section 10.7.5).

Chemical content

Technological means of ensuring flow assurance and OiW separation are built-in to the Phase 1 & 2 basis of design to minimise reliance on flow assurance and separation chemicals (Section 5.8.4.1). However, some chemical use will be necessary which contributes to the overall toxicity of PW (Holdway, 2002).

The exact chemicals intended for use have not yet been selected from manufacturers and therefore Table 10.46 lists analogous chemicals representative of those that will be used and indicates the potential dosages in the PW in early and late Field Life. The dosages are lower in late Field Life owing to the declining oil production rates over time, the associated increasing water cut and the partitioning co-efficient[60] of the chemicals between the oil and water phases.

To protect commercial information, the names of the chemicals have been omitted, but actual test data for representative chemicals has been used, as shown in the table. In accordance with the legislation (Section 10.7.1.1) all chemicals will be on the approved lists and the majority of the anticipated production chemicals will have:

- An HQ band of 'Gold' (i.e., low aquatic toxicity, readily biodegradable and non-bioaccumulative), or an OCNS rating of 'E',
- No product warnings, and
- No Substitution warnings.

Table 10.46: List of analogous chemicals likely to be used during steady state production

Function	HQ band / OCNS rating	Product warning	Applied dosage into oil, gas and water (mg/l)	Partitioning co-efficient[1]	PNEC[2] (mg/l)	Concentration in water phase after partitioning (mg/l)	
						Early Field Life	Late Field Life
Flow assurance and separation chemicals							
Deoiler	Gold	No	20	-0.1	13.336	24.4	20.4
Solids flocculant	Gold	No	20	-0.1	13.340	24.4	20.4
Demulsifier	Gold	No	19	5.22	0.51	0.0001	0.0011
Oil antifoam	Gold	No	15	-3.3	0.112	127	16.7
Scale inhibitor	Gold	No	25	-0.1	10	30.5	25.5
Injected chemicals							
Wax inhibitor	Gold	No	500	3.86	0.249	55	6.1
Oxygen scavenger	Gold	No	11	-0.1	2.860	1.2	0.1
Calcium nitrate	Gold	No	150	-0.1	0.070	16.5	1.8
Organic biocide	Silver	No	500	-0.33	0.002	55	6.1
Water antifoam	Gold	No	10	0.9	0.218	1.1	0.1
Scale inhibitor	Gold	No	25	-0.1	10	2.8	0.3

[60] Describing whether or not the chemical will partition to the oil-phase or the water-phase of the total fluid.

Function	HQ band / OCNS rating	Product warning	Applied dosage into oil, gas and water (mg/l)	Partitioning co-efficient[1]	PNEC[2] (mg/l)	Concentration in water phase after partitioning (mg/l)	
						Early Field Life	Late Field Life
Solids flocculant	Gold	No	20	-0.1	13.340	2.2	0.2

[1] Indicating whether the chemical mixed into the PW is likely to partition to the oil phase or to the water phase. If it is a positive number the chemical will partition more highly into the oil phase. If it is negative it will partition more highly into the water phase and more of the chemical will thus be discharged if the PW is discharged.
[2] Predicted No Effect Concentration. A lower value means the chemical is more toxic.

NORM

Organisms are exposed to ionising radiation of natural origin as a result of the decay of radionuclides which are found naturally in their habitat. Doses arising from naturally occurring radionuclides in the marine environment will result from natural background levels of these radionuclides as well as from concentrations of naturally occurring radionuclides in PW (along with those from other anthropogenic practices) (Hosseini, *et al.,* 2012).

Several Naturally Occurring Radioactive Materials (NORM) typically occur in PW. The most abundant are usually radium-226 (^{226}Ra) and radium-228 (^{228}Ra) (Eriksen, *et al.,* 2006). Concentrations of ^{226}Ra and ^{228}Ra in PW tend to increase with salinity, although this relationship can vary (Neff, 2002). Radiation levels in PW related to NORM are generally relatively low and are usually representative of chronic low exposure situations (Hosseini, *et al.,* 2012). Further, ^{226}Ra and ^{228}Ra are moderately soluble in seawater and are typically dispersed away from their discharge points by tidal and ocean currents (Gwynn, *et al.,* 2020).

The detailed NORM content of Phase 1 & 2 PW is not yet known, although as the Sea Lion reservoir is of lacustrine[61] origin, the formation water is expected to have low salinity. Gamma rays are emitted by most radioactive decay processes and can therefore be an indicator of general radioactivity of the rocks and fluids. The two most abundant radionuclides, (^{226}Ra and ^{228}Ra), are α and β- emitters respectively and do not directly emit gamma rays. Nonetheless, the activity of these radionuclides can be estimated *via* their gamma emitting parents or daughters when aiming at the particular energy peaks of the gamma spectrum.

Gamma ray logging of the strata around the Sea Lion Field shows that there is no increase in gamma ray detection through the reservoir compared with surrounding rocks, and in fact the oil- and water-bearing sands exhibit significantly lower activity than the surrounding claystone.

Reservoir hydrocarbon content (free and dispersed oil)

OiW will be measured by an approved technique, normally a specific method of infrared absorption correlated against laboratory samples that have been tested using gas-chromatography flame ionisation detection (BEIS, 2022).

As described above, the Phase 1 & 2 philosophy is for zero discharge of PW by using PWRI, however, while the PWRI is being commissioned, and in the event of PWRI downtime or declines in injectivity, it may be necessary to discharge the PW to sea. In that case, in compliance with OSPAR and the UK OPPC regulations (Section 10.7.1.1.1), all PW will be treated, and samples will be taken twice per day to ensure that the OiW concentration in discharged PW does not exceed a monthly average of 30 mg/l and no single sample will exceed 100 mg/l. When the PWRI is online, samples will be taken at least monthly in line with UK legislation (Section 10.7.1.1.1.1)

[61] Formed from freshwater bodies.

However, given that the OiW concentration needs to be as low as 10 mg/l in order to reinject the PW, it is anticipated that the concentration would still be in the region of 10 - 15 mg/l should the PWRI units become unavailable. Further, Navitas will always endeavor to improve upon the legal maximum OiW limits in line with its annual environmental objectives and targets (Chapter 15).

Dissolved oils and naturally produced organic compounds

Naturally occurring organic substances in PW include both volatile and non-volatile compounds which are dissolved in the water and therefore cannot be removed by the OiW separation regime (C-NOPB, 2002). These dissolved oils include PAHs, monocyclic-aromatic hydrocarbons (e.g., BTEX: Benzene, Toluene, Ethyl-benzene and Xylene), metals and high molecular weight phenols e.g., alkyl-phenols (Eriksen, *et al.,* 2006, Hosseini, *et al.,* 2012, Beyer, *et al.,* 2020).

The specific composition of Sea Lion PW is not yet known. Therefore, a review of PW from North Sea reservoirs was carried out to identify a North Sea analogue. Based on this review, the composition of natural components in Sea Lion PW is estimated in Table 10.47 (Genesis, 2015b). The Predicted no-effect (PNEC) concentrations are also shown indicating the concentration below which no harmful effects will occur, as judged by an OSPAR expert panel and documented in OSPAR Agreement 2014/05.

It should be noted however that the composition of Sea Lion PW may differ significantly from North Sea PW, not least because the salinity of the Sea Lion PW is low compared to average North Sea PW. Further, as the Sea Lion oil was formed from freshwater bodies (i.e., is of lacustrine origin) and a certain level of mercury in the oil is assumed. While a low salinity North Sea analogue was used, there is a high degree of uncertainty with the estimates.

From the CEDRE testing (CEDRE, 2017), low levels of PAH were measured in the crude oil and also in water in contact with the crude. It is therefore likely that the PAH levels estimated for the modelling assessment are very conservative. It is noted here that the PAH components comprise the majority of the risk to the water column, and therefore the level of risk estimated is also probably conservative. Once into steady state production, it will be possible to identify the exact composition of the Sea Lion PW and the RBA will be taken (Section 10.7.5).

Table 10.47: Estimation of the Sea Lion PW composition based on an analogous low salinity PW from the North Sea[1]

Component	Type				Concentration in the PW (mg/l)	PNEC[2]	Component	Type				Concentration (mg/l)	PNEC[2]

[1] Note that these estimates are subject to change following the onset of steady state production and the opportunity to test the PW.
[2] Predicted No Effect Concentration.

10.7.4.1.2.2 Behaviour and fate of PW discharges

The environmental impact of PW will depend upon its behaviour and fate following discharge, both of which depend on a number of physical, chemical and biological processes:

- Physical:
  - The duration of the discharge,
  - The volume of water and density of the discharge in comparison to seawater,
  - Depth of the discharge e.g., topside or subsea,
  - Sea state,
  - Wind strength, and
  - Current direction and strength.
- Chemical:
  - The inherent toxicity of the discharge,
  - The OiW concentration,
  - The volatility of low molecular weight hydrocarbons and biodegradation of organic compounds (OSPAR, 2009a), and
  - The concentrations of the components in the water column following natural dilution.
- Biological:
  - The length of time biota are exposed to a given concentration, and
  - The sensitivity of the organisms to the particular component.

Depending upon the above, and as described by Holdway (2002) and the International Association of Oil and Gas (O&G) Producers (OGP, 2005), the potential fate of PW plumes are varied. Ultimately, PW can:

- Sink to the seabed or remain on (or rise to) the surface, depending upon the effects of temperature and salinity on the buoyancy of the discharge plume,
- Volatilise (evaporate) to the atmosphere (low molecular weight organic compounds),
- Be biodegraded by micro-organisms (low molecular weight organic compounds),
- Precipitate (become solid) on discharge (low molecular weight organic compounds),
- Adsorb (attach) onto suspended solids and settle out onto the bottom sediments (higher molecular weight organic particles),
- Be dispersed by water currents, and / or
- Be ingested and metabolised by pelagic and / or benthic marine organisms.

Individually or collectively, these processes tend to reduce concentrations of PW components in the receiving environment and thereby decrease their potential toxicity and bioavailability to marine organisms (OGP, 2005).

10.7.4.1.3 Grey water, black water and food waste

The maceration of the food, discharge concentrations, location and depth of grey and black water should all ensure that waste discharges are dispersed and diluted rapidly by the natural water movement around the vessels, thus minimising the impact of nutrient enrichment. Additionally, the natural activity of bacteria and other marine organisms will rapidly break down organic waste.

10.7.4.1.4 MODU / FPSO bilge and drainage discharges

Water from the MODU / FPSO drainage separation and bilge processes may contain emulsified oil and grease, diesel, hydraulic oil, lube oil, and marine fuels. Following separation, the water will be discharged provided it has an OiW concentration <15 ppm.

10.7.4.1.5 Hypersaline water

The volume of hypersaline discharge from each vessel will depend upon the number of crew members on board and any additional operational requirements for potable water. The potential impacts of hypersaline discharges in open ocean conditions are not well understood and the majority of studies report on the impacts to sub-tropical or temperate shallow, nearshore and low-energy marine environments. The desalination plants included in a critical review of published studies on the impacts of hypersaline water by Roberts *et al.* (2010) discharged volumes ranging from 2,000 - 288,000 m^3 per day with salinity concentrations ranging from 37.3 -to 75 psu (practical salinity units) in the nearshore, shallow water environment.

In the majority of cases, the intensity of the plume appeared to diminish rapidly and was usually no greater than 2 psu (or 2 mg/l) above the background salinity of 34 psu (34 mg/l) within 20 m of the outlet, and less than 0.5 psu (0.5 mg/l) when measured hundreds of metres from the outlet.

In a study of the impact potential of hypersaline brines released into the marine environment, Dewar *et al.* (2022) found that dispersion in a hydrodynamically active region like the North Sea acts to dilute disposed brine rapidly such that the potential impact footprint is small and can be measured in tens of metres. This was found to depend on the release scenario and site-specific data, for example the *in situ* conditions such as currents and mixing. The method of brine disposal has a significant influence on dispersal, and brines released nearer the sea surface disperse more rapidly, compared with those released at the seabed. Of note, all hypersaline discharges at the Sea Lion field will be to the surface and into a dynamic environment.

10.7.4.2 Nature of the potential impact

10.7.4.2.1 General operational fluids

All the chemicals which make up the composition of the hydrotest, wellbore clean-up / completion fluid and cooling waters as well as the NADF and hydraulic oils will be listed within the Cefas Definitive Ranked List of Registered Products (Section 10.7.1.1.2). As such, all the chemicals used will have gone through rigorous testing with regard to their biodegradability, toxicity and persistence. The potential impacts to water quality and marine organisms are associated with these factors. In particular, the hydrotest and cooling water will contain biocides that are necessarily intended to have lethal effects. While there is the possibility for acute effects, it is likely that the discharges will be rapidly diluted by seabed and surface currents such that no chronic impacts are anticipated.

With regard to hydraulic oils specifically, the potential impacts to marine organisms are associated with the components in the oil. Historically, hydraulic fluids often had Substitution Warnings (Section 10.7.1.1.2), often due to the low biodegradability of the lubricant components. However, as hydraulic fluids without Substitution Warnings are now available and are intended for use, and as such small quantities are discharged, any environmental impact is expected to be minimal.

10.7.4.2.2 Produced water as a substance

The dilution of PW when discharged to the marine environment has long been considered adequate to mitigate the risks of harmful ecological effects at offshore production fields (e.g., Koons, *et al.,* 1977; Middleditch, 1984; Somerville, *et al.,* 1987; Girling, 1989; Stephenson, 1992, Balk, *et al*., 2011). Produced water discharges will disperse and dilute in the receiving water body according to a number of factors, including:

- The composition of the discharged mixture,
- The flow rate, depth, direction and speed of the discharge jet,
- The prevailing current, tidal and wind conditions at the site,
- The differences in temperature, salinity, density, and buoyancy between the PW plume and the surrounding seawater,
- The stratification of the water column,
- Turbulent mixing conditions; and
- Advection-diffusion processes (Beyer, *et al.,* 2020).

In addition, the PW mixture will be transformed and reduced by the weathering of its constituents, particularly by volatilisation, microbial biodegradation and photodegradation (McFarlin, *et al.,* 2018).

It is known to be challenging to characterise all the possible biological impacts associated with PW discharges. Nonetheless, several earlier summaries of research and monitoring programs have concluded there is little to no evidence that significant impacts occur outside the primary dilution zone downstream of PW outfalls (Beyer, *et al.,* 2020). Modelling studies show that offshore PW plumes dilute rapidly and although the rate of dilution may vary depending on the site-specific factors mentioned above, PW may typically reach a 1,000-fold dilution at a distance of 1,000 m from the PW outfall (Neff, 2002).

However, despite these general assessments, there are still a number of unknowns such that studies continue in efforts to identify the uptake routes, suitable biomarkers[62] and to identify the possible environmental impacts from PW. Some mild acute effects are found in water column biota some kilometres away from large PW outfalls, but whether there are notable chronic (and ecologically adverse) effects occurring in a larger area downstream remains largely unknown.

10.7.4.2.2.1 Uptake routes and biomarkers

Biological uptake of hydrophobic[63] organic contaminants such as those found in PW, and NORM, can occur in numerous ways, including, but not necessarily limited to:

- Passive uptake over gill surfaces,
- Passive and active uptake over digestive linings, and
- Active uptake of contaminated food particles (Hosseini, *et al.,* 2012; Beyer, *et al.,* 2020).

In order to assess the potential impacts of exposure to PW, it is necessary to identify relevant and sensitive biomarkers. In fish, the liver-bile-faeces pathway is the major route for elimination of toxic substances such that bile metabolites are an effective way to test for contamination with, for example, PAHs and alkylphenols (Beyer, *et al.,* 2020).

Other common biomarkers used include, but again are not limited to:

- Liver enzymes used to metabolise contaminants,
- Hormonal changes resulting from xenoestrogenic[64] effects,
- The presence of precursor proteins[65],
- Endocrinology and reproductive systems,

[62] A biomarker is a biological molecule found in blood, other body fluids, or tissues that is a sign of a normal or abnormal process, or of a condition or disease.

[63] Molecules that do not mix with water.

[64] Xenoestrogens are chemicals that mimic oestrogen and can disrupt the body's natural hormonal balance.

[65] Protein precursors are proteins that serve as building blocks for other proteins and perform various cellular functions.

- Cardiac toxicity,
- Impaired development e.g., of fish embryos, and
- The presence of PAH-related DNA adducts[66].

10.7.4.2.2.2 Acute impacts of PW discharge on marine organisms

Numerous studies have been carried out to assess the impacts of acute toxicity of 'whole PW' as a substance and were reviewed by Holdway (2002). The acute effects of the PW discharges studied included:

- Alteration of benthic communities dominated by short-lived opportunistic species up to 100 m from offshore installations (Neff, *et al.,* 1992),
- A decrease in abundance of biofouling organisms on solid platform structures, and
- Increased mortality of filter feeders within 23 m of a PW outfall (Black, *et al.,* 1994a, b), and
- Detectable exposures in caged mussel and fish several kilometres downstream from PW outfalls, (but notably the biomarkers indicated only mild acute effects in these sentinels (Beyer, *et al.,* 2020).

However, within the studies reviewed by Holdway (2002), a large range in results was observed. It was concluded by the respective authors that the range in impacts observed was due to the varying concentrations and types of chemicals in the PW batches tested and distribution models predicted that acute toxicity effects would be negligible outside the immediate mixing zone (Holdway, 2002).

The UK government has summarised the potential impacts of PW in Strategic Environmental Assessment (SEA) work. The SEAs state that most studies of PW toxicity and dispersion, in the UK and elsewhere, conclude that, while under some circumstances (e.g., strong stratification), a plume concentration sufficient to result in sub-lethal effects may persist for >1,000 m, the necessary dilution to achieve a No Effect Concentration (NEC) would usually be reached at <10 to 100 m and always less than 500 m. Indeed, according to Meier *et al.* (2010), liver enzyme biomarker responses were found in fish only when the specimens (Atlantic cod (Gadus morhua)) were exposed to a PW concentration of 1 % oil in water, which realistically would represent a distance of less than 100 m from a PW outfall offshore.

With regard to NORM contamination, the radiobiological effect of ^{226}Ra on Atlantic cod embryonic cells was studied by Olsvik *et al.* (2012). The results of this study suggested that environmentally relevant activities of ^{226}Ra can induce oxidative stress and apoptosis[67] in embryonic cells of the fish. Nonetheless, while follow-up studies were suggested to better understand the link between these short-term effects and possible impacts on growth and survival rates, the authors of this study concluded that radionuclides present in produced water have a relatively low impact on early life stages of fish (Hosseini, *et al.,* 2012).

With regard to chemicals entrained within the PW, the careful selection of chemicals known to have minimal environmental effect (Section 10.7.1.1.2), will aim to ensure the acute toxicity of PW can be considered to be modest (Holdway, 2002).

10.7.4.2.2.3 Chronic impacts of PW discharge on marine organisms

There are less data available regarding the chronic effects of PW (Beyer, *et al.,* 2020). Nonetheless, some of the potential effects seen in the field, and the laboratory during chronic toxicity tests, include:

- Impacts on the surface microlayer surrounding producing installations,

[66] PAH-related DNA adducts are a form of DNA damage caused by covalent attachments of PAHs to DNA.
[67] A type of cell death caused by a series of molecular steps.

- Altered benthic community species composition,
- Altered behaviour and / or physiology e.g., cardiac toxicity syndrome,
- Reduced growth / impaired development,
- Decreased rates of reproduction (fecundity), and
- Damage to DNA (DNA adducts) (Beyer, *et al.,* 2020).

Beyer *et al.* (2020) conducted a review of the environmental effects of offshore PW discharges on the Norwegian Continental Shelf (NCS) which has a depth range of 200 – 500 m.

The review describes increased concentrations of DNA adducts which are found repeatedly in benthic fish populations, (especially in haddock (Melanogrammus aeglefinus), a North Atlantic bottom-feeding species), although it is uncertain whether these are a long-term effect of sediment contamination due to ongoing PW discharges in the region, or earlier discharges of oil-based drilling waste given that O&G operations have been conducted on the NCS for over 40 years. PAH-related DNA adducts are a form of DNA damage caused by covalent attachments of PAHs to DNA. Many studies have shown that fish will develop high concentrations of such adducts in different tissues when exposed to PAH mixtures of pyrogenic[68] or petrogenic[69] origins (e.g., Aas, *et al.,* 2000; Aas, *et al.,* 2001; Holth, *et al.,* 2009; Balk, *et al.,* 2011; Sundt, *et al.,* 2012b; Pampanin, *et al.,* 2017). If not removed by the DNA repair systems of the affected cells, these adducts can cause mutations that eventually may give rise to development of tumors and other cancer-associated diseases. However, Beyer *et al.* (2020) state that the potency for forming DNA adducts varies greatly among PAHs and the most common petrogenic PAHs in PW are generally of low potency. In support of this, caged groups of fish (Atlantic cod) were exposed to diluted PW plumes for 5–6 weeks at fixed positions in the water column and at increasing distances downstream of different PW outfalls. This caged approach provides a semi-controlled *in situ* exposure model, effectively another mesocosm study. Beyer *et al.* (2020) state that these offshore caging exposures generally did not cause increased DNA adduct concentrations, even when caging was performed close to the Statfjord and Gullfaks platforms (i.e., in the platform-dense Tampen area of the NCS) in 2001, 2002 and 2004 and at the Troll field in 2003. Likewise, subsequent surveys in 2006, 2008 and 2009 at the Ekofisk field in the central North Sea, showed no increase in DNA adduct concentrations in cod caged for 5–6 weeks. The absence of adducts was noted even in the groups caged in the diluting plume only 200–250 m downstream of the PW discharge point (Beyer, *et al.,* 2020).

Field surveys in the NCS offshore monitoring program have repeatedly used such caging of fish and mussels to test for accumulation and effects of PW contaminants. The caged sentinels were kept for up to six weeks at fixed positions in the likely path of the diluting PW plume, at least for a certain part of the tidal cycle. In contrast to the above caged studies, these offshore monitoring surveys repeatedly demonstrated that the caged biota did develop exposure signals that were in quite good agreement with their distance downstream of the PW outfall/s. The best exposure markers were two- and three-ring PAHs, with parent PAHs being detected in caged blue mussels (*Mytilus edulis*) and biliary[70] PAH metabolites being detected in the caged fish. The increased concentrations of bile metabolites of petrogenic PAHs and alkylphenols were detected in fish caged as far as 10 km downstream from offshore production platforms in the assumed direction of the PW plume (Beyer, *et al.,* 2020). However, Beyer *et al.* (2020) note that it is uncertain to what extent caged fish are representative of the real-world conditions experienced by wild and free moving fish in offshore waters. In offshore condition monitoring surveys, wild-caught fish species collected in areas relatively close to oil

[68] Of or relating to igneous origin.
[69] Of or relating to the origin or formation of rocks and especially of igneous rocks.
[70] Relating to bile or the bile duct.

platforms have generally shown few indications of exposure of contaminants from PW discharges (Beyer, *et al.,* 2020) and controlled behaviour studies have shown that adult fish will actively avoid environments contaminated with PAH or oil above certain thresholds, (e.g., Claireaux, *et al.,* 2018).

Endocrine Disrupting Compounds (EDCs) in offshore PW discharges became a concern around the mid-1990s, especially after alkylphenols were identified as a likely cause for xenoestrogenic effects in fish in some UK rivers. As such, more than 30 research studies (many conducted by the Norwegian Institute of Marine Research) to address the effects of PW discharges on the endocrinology and reproduction of offshore fish and fish populations have been carried out. However, a risk assessment based on the results of all these studies concluded that there was no significant risk of adverse reproductive effects on the cod, saithe (*Pollachius virens*) or haddock populations in the North Sea as a result of exposure to alkylphenols from offshore PW discharges (Beyer, *et al.,* 2020).

With regard to NORM, a review of studies on the impacts of NORM on biota was carried out by Hosseini *et al.* (2012). While the review stated the need for further research, the paper concluded that risk to the environment from naturally occurring radionuclides discharged in produced water is considered to be negligible (Hosseini, *et al.,* 2012). However, some studies indicate that the speciation[71], mobility and bioavailability of radium in produced water from O&G installations can vary with the barium concentration of the PW, the mixing with seawater sulphates and the presence of added flow assurance chemicals such as scale inhibitors (Eriksen, *et al.,* 2006).

Two studies conducted off Louisiana in the Gulf of Mexico in scenarios intended to reflect the wide range of activity concentrations of radium that may be present near offshore O&G installations, and the associated impacts upon fish, molluscs and crustaceans were reviewed in Hosseini *et al.* (2012) (see Hamilton, *et al.,*1991; Meinhold, *et al.,* 1996). Making use of an estimated no-effect level for individuals provided by Anderson and Harrison (1986), Hamilton *et al.* (1991) concluded that all resulting dose rates were below the threshold at which any deleterious effects might occur. Similarly, testing the dose rates for finfish and shellfish species living close to platforms, Meinhold *et al.* (1996) found that none of the subjects exceeded the reference limit. According to Neff (2002), concentrations of ^{226}Ra and ^{228}Ra in PW from the Gulf of Mexico are probably higher than other offshore locations in the world such that if no risk was identified here, NORM would be unlikely to pose a risk to marine biota elsewhere.

More recently, Beresford *et al.* (2011) applied screening level assessments for the impacts of radionuclides on three offshore *Natura 2000*[72] sites on the UKCS. Based on the outputs of their assessments, the authors concluded that there is negligible risk to the three considered sites from releases of radioactive substances from marine O&G platforms (Hosseini, *et al.,* 2012).

It is therefore the case that there remains some ambiguity as to the chronic effects of PW discharges on marine life.

Although the specific species and PW compositions in the above studies may be different to the Sea Lion Development which is located in 450 m of oceanic water, the results above show that some biota may be adversely affected by the hydrophobic organic components in PW plumes, even in highly dynamic environments. However, of note, the Sea Lion Development will be operating in isolation of other sources of PW and will be reinjecting, rather than discharging, the PW once the PWRI equipment is commissioned (Section 5.8.5.8).

[71] Radionuclide speciation is the physical and chemical properties of radionuclides, which determine their behavior in the environment and their toxicity.

[72] *Natura 2000* is a network of protected areas covering Europe's most valuable and threatened species and habitats.

The Predicted No-Effect Concentrations (PNEC) used in the DREAM analysis described in Section 10.7.4.5 below are chronic values taken from a large dataset and are included in the latest OSPAR agreed list (Agreement 2014/05, updated *via* OSPAR Working Groups). The DREAM modelling results presented below predict the area that might be at chronic toxic risk. Further, once the PW breaks through in the total fluids, further sampling will be taken and the RBA to PW as a whole substance will be taken, as described further in Section 10.7.5.

10.7.4.2.3 Grey water, black water and food waste

With regard to seawater quality, the discharge of grey water, black water and galley food waste may lead to minor localised impacts on water quality due to nutrient enrichment. This in turn can result in increased numbers of plankton, and therefore a localised increase in Biological Oxygen Demand (BOD) around the discharge point.

As with any vessel at-sea, the MODU, the FPSO and all project vessels are likely to attract a mixed flock of seabirds, including albatross and petrel species which are listed under the Agreement on the Conservation of Albatrosses and Petrels (ACAP) (Section 7.4.5.5.2), many of which rely on scavenging for much of their food.

10.7.4.2.4 Drainage and bilge water

The potential impacts of drainage and bilge water discharges are associated with any chemicals, grease, diesel or oil in the wash-down water collected by the drains or bilge tanks. While there is the possibility for acute effects through sheens, all discharges associated with drainage and bilge are likely to be highly diluted with rainwater and seawater on deck. Further, it is likely any discharges will be rapidly diluted by surface currents such that no chronic impacts are anticipated.

10.7.4.2.5 Hypersaline water

Ecological monitoring studies have found variable effects ranging from no significant impacts to benthic communities, through to widespread alterations to community structure. However, all these are from studies on discharges to poorly flushed and shallow environments (Roberts, *et al.,* 2010) and thus do little to inform an impact assessment on surface saline discharges to the open ocean. According to Dewer *et al.* (2022), little impact is observed in dynamic environments such as the North Sea, or indeed the Southern Ocean (Section 10.7.4.1.5).

10.7.4.3 Potential for oil sheens

10.7.4.3.1 Sources of oil sheens

Oil sheens (and slicks) are most commonly associated with large and small spills of oil and diesel, the impacts and risks of which are assessed in Section 12.1. However, legally compliant operational discharges such as PW, bilge and drainage waters are also recognised as a low-level contributor to chronic oil pollution (NRC, 1985; 2003).

Impact to seabirds from legally compliant discharges arises predominantly from the potential for thin surface oil sheens. While OiW concentrations of discharges are tightly controlled by legislation (Section 10.7.1.1), oil sheens can, in practice, be associated with PW (Fraser, *et al.,* 2006) and may occur at OiW concentrations as low as 25 mg/l when discharged on calm days (Wills, 2000). In the North Sea, it is necessary to report sheens which extend beyond the 500 m exclusion zone. These can occur even when all discharges have been in compliance with regard to OiW concentration and discharge volumes, although their occurrence is rare and normally coincides with extremely calm conditions.

However, OSPAR is concerned with the oiling of seabirds and in an OSPAR-commissioned report, Camphuysen (2005) states that there is good evidence that bilge oil is the main source of oil pollution, with a clear correlation between oiled guillemots and shipping lanes. Therefore, there is the potential

that compliant bilge and drainage discharges could lead to sheens although, as described above, this would require very calm weather. Such weather occurs rarely at the Sea Lion location with wave heights at 0-1 on the Beaufort Scale occurring less than 3 % of the time according to metocean reports for the location.

Nonetheless, the sensitivity of seabirds to oil pollution *via* oiling and / or ingestion is taken very seriously and therefore, to take a precautionary approach, it is necessary to consider the potential contribution of all discharges to chronic oil pollution and the acute and / or chronic impacts upon seabirds.

10.7.4.3.2 Formation of oil sheens

The relationship between the discharge of oil in PW, bilge and drainage water and the occurrence of oil sheens is not well understood. The formation of sheens may be related to the characteristics of the receiving waters, the rate and depth of discharge, the characteristics of the PW such as temperature, quantity of solids, type of hydrocarbon, discharge volume, oil droplet size and / or the presence of certain types of metals such as iron (ERIN Consulting Ltd. and OCL Services Ltd., 2003). Further, while sheens are mostly comprised of the free oil (Section 10.7.4.1.2.1), Veil *et al.* (2004) suggest that the dispersed and dissolved oils (Section 10.7.4.1.2.1), which are not easily removed from the PW, also contribute to sheen formation.

Regardless of why or how sheens form, a surface oil film of <3 µm is referred to as a 'sheen' and an oil film >3 µm is referred to as a 'slick' (ERIN Consulting Ltd. and OCL Services Ltd., 2003). According to O'Hara and Morandin (2010) a light sheen is approximately 0.1 µm thick and has a hydrocarbon volume of approximately 0.1 ml/m^2 of the surface water.

Testing of the Sea Lion crude was undertaken to determine the impact of PW streams on feathers (CEDRE, 2017). Local feathers from nine species of Falkland birds[73] were tested in dispersed oil at a concentration of 100 mg/l, and oil droplets of *c.* 100 microns were produced into the water column. In compliance with legislation (Section 10.7.1.1), and in the event of PW discharge, this is the maximum concentration that would be present at the mouth of the discharge caisson. However, as explained in Section 10.7.2.5, in the event of PWRI malfunction, the Phase 1 & 2 target is OiW concentrations of 10-15 mg/l of oil on a continuous basis. Of note, it is estimated that the PWRI system will be operational 93 % of the time, during which there would be no discharge at all.

Feathers exposed to the dispersed Sea Lion oil at 10 mg/l in the water column showed oil particles adhered to all species of feathers tested, though no structural damage to feathers was observed. However, it was noted that the barbules (the intricate 'feathery' parts in between the feather's structure) were 'messy' following contact with the oil / water solution (CEDRE, 2017). Depending on their distance from the PW caisson, birds exposed to PW would probably be exposed to concentrations two or three orders of magnitude lower than that used in the test.

Bulk crude at 55°C was also released into completely calm seawater at a temperature of 18°C. This test indicated that the Sea Lion crude can form a very thin sheen on completely calm water when a large mass is spilled. When samples of this sheen were observed in outdoor conditions they would correspond to the lower limit of Band 1 in the Bonn Agreement Oil Appearance Code i.e., near 0.04 µm thickness. When samples of the sheen were tested, the amount of oil present was below the limit of detection. This indicates that only in a large spill scenario would Sea Lion crude develop a very thin sheen, and sheens are unlikely to be observed as a result of PW discharges (CEDRE, 2017). Although

[73] The nine species selected were: black-browed albatross, gentoo penguin, king cormorant, thin-billed prion, king penguin, Wilson's storm petrel, South American tern, silver-grey fulmar and sooty shearwater. For the prion, feathers from the back and the stomach were studied, leading to a total of ten feather types (CEDRE, 2017).

the test represents a 'best estimate' on how the oil will manifest i.e., in microscopic particles, the actual nature of the oil in PW will be confirmed once the system is brought online.

10.7.4.3.3 Sheens and seabird contamination

As described in Section 10.7.4.2.3, seabirds tend to be attracted to offshore structures owing to localised enrichment from sewage and food discharges as well as the presence of artificial light (Tasker *et al.,* 1986, Baird 1990, Wiese *et al.,* 2001). Therefore, such birds may be at risk of low-level oil contamination and / or ingestion in the event of a sheen, which may lead to impacts upon:

- Feather microstructure and thus thermoregulation and buoyancy (O'Hara and Morandin, 2010; Fraser *et al.,* 2006; Levy, 1980), and / or
- Reproductive success (Camphuysen, *et al.,* 2005; Rocke, 1999; Butler, *et al.,* 1988).

While it is known that feather fouling with as little as 10 ml of heavy oil can significantly reduce thermoregulation in seabirds and may be lethal (Hartung, 1967; McEwan and Koelink, 1973; Levy, 1980; Lambert, *et al.,* 1982; Jenssen and Ekker, 1989; Burger and Fry, 1993), such a degree of contamination is unlikely to ever occur from a sheen alone. However, laboratory-based experiments determined that exposure to oil sheens at a thickness of 0.1 µm could result in measurable oil transfer to feathers. While the impact of such contamination has not been investigated in practice, the study was able to demonstrate that such contamination does affect the essential microstructure of the feathers (O'Hara and Morandin, 2010).

Additionally, Butler *et al.* (1988) found that contamination of feathers with as little as 0.1 ml of oil significantly reduced hatching success in Leach's storm-petrels (*Oceanodroma leucorhoa*) due to abandonment of the egg by the contaminated bird and / or its mate. While the breeding success of the individuals in the experiment returned to normal the following year, this indicates the potential for small amounts of feather contamination to impact upon seabirds (Butler, *et al.,* 1988).

The level of contamination however will depend upon the level of contact the bird has with the sheen and this is likely to depend upon the foraging modes of different species (King and Sanger, 1979; Camphuysen, 1989; Williams *et al.,* 1994). For example, species that feed by diving below the surface or feeding at the ocean's surface (e.g., the IUCN 'Least Concern' black-browed albatross or the 'Endangered' northern royal albatross, Section 7.4.5.2.2) are at greater risk of plumage fouling than those that pluck prey from the surface while in-flight.

While there are limited data on the level of contact, and the thickness of the sheen, required to affect the microstructure of feathers, or to contaminate the bird sufficiently to impact upon reproduction, it is believed that small quantities of oil contamination could have severe consequences (Butler, 1998; O'Hara and Morandin, 2010).

However, while the data indicate that small levels of contamination may impact upon mortality and reproductive success in seabirds, it is not clear whether or not one-off exposure to sheens translate into impacts on the fitness of individual birds or populations.

10.7.4.4 Volume of planned discharges

10.7.4.4.1 General operational fluid discharge volumes

Where possible, the estimated volumes of the discharges are provided in Table 10.48.

Table 10.48: Estimated volumes of discharge

Discharge	Estimated Volumes
Hydrotest discharges	The volumes and dosages associated with hydrotesting will be defined during the FEED / Detailed Design phase of design, at which time a more detailed assessment will be provided. At this time, it will be possible to conduct 'Osborne-Adams' subsea discharge models to determine the impact upon the benthos.
Wellbore clean-up / completion fluid	It is anticipated that approximately 3,000 bbls (477 m^3) of visibly clean water (under the OEUK Well Clean-up Guidelines, Section 10.7.5) will be discharged per well. Over the Development drilling campaign this will result in a total of 78,000 bbls (12,394 m^3) being discharged in total.
Cooling water	It is anticipated that approximately 70,000 m^3/day of CW will be discharged to sea after being used in the cooling system. While the specific biocide for use has not yet been selected, and the dosages are currently unknown, the application strategy will be optimised to ensure any impact is as low as reasonably practical given the unavoidable need for a biocide in the cooling system.
Hydraulic fluids	Small volumes of hydraulic fluid will be discharged during each valve actuation.

[1] The completion fluid is effectively the fluid in the completed well after well cleanup. On first flowback it will go through the PW system on the FPSO.

10.7.4.4.2 Volumes of planned PW discharges during commissioning

As explained above, under normal and planned operations, the FPSO facilities will be capable of treating all PW for reinjection.

It is anticipated however that there may be discharge of PW when it first starts to appear and the PWRI units are being commissioned. At the time of writing it was not possible to estimate when PW may start to arrive, nor how much may be discharged during the commissioning phase. However, water will start to cut from the production wells at different times and the PWRI commissioning process will commence upon first arrival of water from any one of the production wells. Therefore, all efforts will be made to minimise discharges that follow between the first 'water cut' and full implementation of the PWRI system. Therefore, it is anticipated that PW discharges during the commissioning stage will be low volume and short-lived.

In the event of PWRI downtime such that the PW has to be discharged to sea, all PW will be treated and sampled prior to discharge to ensure that it is compliant with the OSPAR and UK OPPC OiW concentration limits. OiW concentrations of 10-15 mg/l will be targeted at all times. In the event that the OiW concentration exceeds the legal limits, it will be diverted to the off-spec tanks (which have a capacity of *c.* 17,038 m^3) before being re-routed back into the separation process. Off-spec PW will not be discharged (Section 10.7.2.5).

Discharge volumes associated with PWRI downtime (which is unplanned) are estimated below in Section 10.7.4.5.1.

10.7.4.4.3 Volumes of grey and black water

It is estimated that the conventional systems on the vessels will generate 0.2 m^3 / person / day of grey water, and 0.07 m^3 / person / day of black water (Huhta, *et al.,* 2007). Using these data it is possible to estimate the wastewater volumes that will be produced by vessels associated with the three Stages of the project (Table 10.49).

It should be noted here that for vessels > 400 GT or certified to carry >15 persons on board, black water cannot be discharged within 3 nm of the coast (Section 10.7.1.1.6).

Table 10.49: Estimated grey and black water volumes generated by vessels during the Phase 1 & 2 Development[1]

Development stage	Water m^3 / day / person[2]		Volume of grey water (m^3)	Volume of black water (m^3)
	Grey water	Black water		
Stage 1 (31 months)				
Total	0.2	0.07	47,280	16,548
Average per month			1,525	534
Stage 2a & 2b (35 months)				
Total	0.2	0.07	59,568	20,849
Average per month			1,702	596
Stage 3 (27.1 years)				
Total	0.2	0.07	276,014	96,605
Average per month			688	241
Cumulative over whole project				
Total for 32.6 years			**382,862**	**134,002**
Average per month over 32.6 years			**979**	**343**

[1] Please note that the numbers are correct but cannot be exactly replicated in the word document due to rounding in the excel spreadsheet.
[2] The numbers of personnel used to calculate grey and black water volumes are based on an average worst-case (maximum number) of offshore personnel during each Stage and this is applied throughout that stage. Stage 1 max offshore personnel = *c.*250, Stage 2a & b = *c.* 280, Stage 3 = *c.* 140. Please note these numbers are averaged over a long period of time and are subject to rounding discrepancies.

10.7.4.4.4 Volumes of MODU / FPSO bilge and drainage water

The amount of water passing through the drains pumps will depend on the volume of precipitation received. It is therefore not possible to estimate the quantity of water (and thus oil) that may be discharged. In the event that drainage or bilge water exceeds 15 ppm however, discharges will cease. Operational discharge records will be kept in line with the current legislation (Section 10.7.1.1) and reporting will be carried out in accordance with current FIG requirements.

10.7.4.4.5 Volumes of hypersaline discharge

The volume of desalination discharge water will depend upon the demand for potable water on any given vessel (e.g., the number of people on board) and the volume of water required for operations. Typically, to generate sufficient volumes of potable water, the volume of desalination discharge water is approximately 0.3 m^3 / person / day which results in an average of 5,154 m^3 per month over the course of the Development (Table 10.50).

Operational discharge records will be kept in line with the current legislation (Section 10.7.1.1) and reporting will be carried out in accordance with current FIG requirements.

Table 10.50: Estimated hypersaline discharge volumes during the Phase 1 & 2 Development

Development stage	Water m^3 / day / person[1]	Water m^3 / day for operations	Volume of saline water (m^3)	
			For consumption	For operations
Stage 1 (31 months)				
Total	0.3	n/a	70,920	0
Average per month			2,288	0
Stage 2a & 2b (35 months)				

Development stage	Water m^3 / day / person[1]	Water m^3 / day for operations	Volume of saline water (m^3)	
			For consumption	For operations
Total	0.3	138[2]	89,352	146,913[3]
Average per month			2,553	4,198
Stage 3 (27.1 years)				
Total	0.3	138[2]	335,399	1,372,583
Average per month			1,032	4,223
Cumulative over whole project				
Total for 32.6 years			**495,670**	**1,519,495**
Average per month over 32.6 years (391 months)			**1,268**	**3,886**
Total average per month over 32.6 years			**5,154**	

[1] Volumes of hypersaline discharge water from generating potable water for consumption are estimated at 0.3 m^3 / person / day.
[2] Figure provided by Navitas as an estimate of the daily hypersaline discharge expected to result from the creation of 30 tonnes / day of potable water, to cover all FPSO freshwater requirements (including water for personnel).

10.7.4.5 Estimation and modelling of unplanned PW discharges

It is anticipated that even in the event of successful PWRI operations, the PWRI facilities may be shutdown for up to 7 % of the time (25.5 days per year). During such times, it will be necessary to divert PW to the off-spec tank for reprocessing or to discharge it to sea. In some O&G developments PWRI is not successful, and in the event of significant issues with injectivity the project may need to use seawater only for reservoir management, meaning that all PW would be disposed of overboard. In the event of abnormal conditions requiring that the PW be discharged, the effluent will be treated and sampled prior to discharge in order to ensure the OiW content is within the legal limits (Section 10.7.1.1.1.1). As stated above, PW with OiW concentrations that are higher than 10-15 mg/l will be diverted to the off-spec tank (Section 10.7.2.5).

To predict the risk to the water column from PW discharges during PWRI downtime, Genesis was commissioned to carry out the following modelling, which has been updated by Navitas:

- DREAM (Dose-related Risk and Effect Assessment Model) and EIF (Environmental Impact Factor) (DREAM/EIF) modelling to assess the risks associated with PW discharges to sea.

The aims of the model were:

- To simulate anticipated realistic worst-case PW discharges during early and late Field Life using the estimated flow rates and PW composition (based on a North Sea analogue (Section 10.7.4.1.2.1)),
- To compare the predicted concentrations of substances within the PW discharges with the known 'no-effect concentrations' published by OSPAR for discharges to the marine environment, and
- To assess the overall risk to the marine environment from the discharges of oil, low molecular weight organic compounds and chemicals.

10.7.4.5.1 Potential volumes of unplanned PW discharges

The quantity of PW generated by the Phase 1 & 2 Development will increase over time as the oil reservoir becomes depleted and the water cut increases. Therefore, in the event that the PWRI units are down, the potential daily volume of PW discharge would be higher in late Field Life than it would be in early Field Life.

The anticipated volumes of oil and PW are shown in Table 10.51. These values reflect both high oil volumes, which tend to increase concentrations of chemicals in PW, and high water volumes, which can result in the minimum rate of dispersion upon discharge.

Table 10.51: Flow rates and volumes of PW and oil production

Produced fluid	Early Field Life[1]	Late Field Life[1]
Oil Production	8,390 m^3/d	2,016 m^3/d
PW	1,626 m^3/d	16,796 m^3/d
Total produced fluids	10,016 m^3/d	18,812 m^3/d
7 % downtime	25.5 d/yr	25.5 d/yr
PW discharge in 25.5 days	41,461 m^3	428,294 m^3

[1] From 'High' case production profile

10.7.4.5.2 The DREAM / EIF modelling approach

The DREAM / EIF modelling approach is an accepted method for assessing PW and chemical discharges in the North Sea and, according to the UK RBA Guidance (BEIS, 2020), is one of the tools accepted for demonstrating levels of risk within the RBA framework (Section 10.7.1.1.1.2).

DREAM consists of both a 'dispersion model', based on wind and 3D current data, and a 'component-specific fate model' whereby the physiochemical, toxicological and biodegradation properties of the compounds within a discharge are modelled. From these combined models, overall toxicity risks to the environment are calculated.

To enable brevity in this section, the following describes only the information required to ensure appreciation and understanding of the modelling results.

10.7.4.5.2.1 Discharge parameters used in DREAM

Table 10.52 shows the discharge parameters that were used in DREAM to assess the risk associated with Phase 1 & 2 PW discharges.

Table 10.52: PW discharge parameters used in DREAM

Parameter		Value	Comments
Discharge location	Latitude	49° 16' 21.9912" S	These co-ordinates relate to an earlier proposed location of the FPSO but are sufficiently close that results remain reliable
	Longitude	59° 5' 53.0042" W	
Discharge depth (m)		8 m	A discharge 8 m below the surface has been assumed, representative of the FPSO type
Discharge temp (°C)		75°C	Process temperature may be higher but PW will cool in pipework during flow to discharge point
Discharge orientation		Vertically downwards	-
Discharge rate	Early Field Life	1,626 m^3/d	From production profiles
	Late Field Life	16,796 m^3/d	
Discharge salinity (mg/l)		6.4	From Basis of Design document (Premier, 2015a)
Discharge duration modelled		7 % downtime in a year = 25.5 days	Model duration is 42 days to allow up to two weeks for the plume to reach a steady state followed by 28 days discharge in accordance with the UK RBA Guidance (BEIS, 2020). The model assumes that PW discharges will occur continually rather than intermittently through the year.

10.7.4.5.2.2 Understanding the model, the PEC:PNEC ratio and the Environmental Impact Factor (EIF)

The risk assessment is based on a comparison of the:

- PEC (Predicted Environmental Concentration) i.e., the concentrations of different components in the water column resulting from PW discharge as predicted by the model (Table 10.53), and
- PNEC (Predicted No Effect Concentration) i.e., the highest theoretical concentration of the same components at which no harmful effects are expected to occur to marine organisms (Table 10.53).

In other words, the model assesses whether or not the concentrations resulting from Phase 1 & 2 PW discharges will exceed the concentrations which marine organisms can 'tolerate' to determine whether or not the impacts will be likely to cause significant harm (i.e., PEC:PNEC >1) (Table 10.53).

An EIF (Environmental Impact Factor) of 1 is defined as a cuboid volume of water equal to 100 m x 100 m x 10 m (0.0001 km^3) in which the calculated PEC exceeds the PNEC. In practice, an EIF of 1 signifies that within this volume (0.0001 km^3), there is a risk to >5 % of the most sensitive species present (i.e., the Potentially Affected Fraction (PAF)). Therefore, an EIF of, for example, 100, indicates that there is a risk to >5 % of the PAF in 0.01 km^3.

The model therefore uses the volume of seawater affected by PW discharge plumes as a measure for quantifying environmental risk and the results are expressed as the volume of water (km^3) in which >5 % of the PAF may be significantly impacted. Of note, there is no threshold for the EIF above or below which discharges may be permitted and the EIF is primarily a comparative tool.

Table 10.53: Explanation of the PEC, PNEC and the EIF and how these are calculated and used by DREAM

Factor	Definition	Calculated by
Predicted Environmental	The concentration of PW	DREAM calculates the fate of each component by modelling the influence of:

Factor	Definition	Calculated by
Concentration (PEC)	components in the water column resulting from the discharge of Phase 1 & 2 PW	Currents (tidal, residual, meteorological forcing), Turbulent mixing (horizontal and vertical), Density (difference through salinity and temperature), Evaporation at the sea surface, and Reduction of concentration due to biodegradation.
Predicted No Effect Concentration (PNEC)	The highest theoretical concentration of the same components at which no harmful effects are expected to occur to marine organisms	The PNEC value is derived from the: EC_{50} (i.e., the half maximal effect concentration) which is the concentration at which 50 % of test organisms experience growth inhibition when compared to a control, (LC_{50}) (i.e., the median lethal concentration) which is the concentration at which 50 % of the sample population of a specific test-animal in a specified period die from exposure, and NOEC (i.e., the No Effect Concentration) which is the highest concentration at which there is no observed effect to test animals when compared to a control. The EC_{50}, LC_{50} and NOEC are divided by an assessment factor in order to arrive at the expected chronic PNEC. An additional assessment factor is used to reflect any uncertainties in the representativeness of the laboratory results. An assessment factor of 1,000 was applied in this study in line with the RBA guidance issued by BEIS (2020).
PEC:PNEC > 1	PEC:PNEC > 1 means there is a risk to > 5 % of the most sensitive species present.	The DREAM model calculates an individual PEC:PNEC ratio for each of the components in the PW and applies a species sensitivity distribution to each. This allows the model to combine and compare the contribution of different PW components to the overall risk to species present, known as the Potentially Affected Fraction (PAF). The level of 5 % risk to the PAF (corresponding to a PEC/PNEC ratio of 1) is a generally-accepted risk level representing the concentration below which no adverse effects on organisms are expected (EC, 2003).
Environmental Impact Factor (EIF)	A volume of water equal to 100 m x 100 m x 10 m (i.e., 0.0001 km^3) in which the PEC:PNEC > 1. An EIF of 1 means that there is a risk to >5 % of the PAF in 0.0001 km^3.	DREAM predicts the PEC across the model domain and each cuboid of water within that domain in which the EIF = 1. The model then effectively adds together each cuboid to give the overall EIF for that particular release. Three EIFs for early Field Life and late Field Life were predicted: The **maximum EIF** i.e., the largest EIF value derived throughout the model run duration. This instantaneous EIF is sensitive to small changes in environmental inputs, such as wind and currents, throughout the modelling period, The **time-averaged monthly EIF** which is more stable, presenting an average EIF of the modelling period once stable conditions have been established, and The **'annualised' EIF** which takes account of the intermittent nature of any PW discharges given that 25.5 days (7 %) worth of discharge will not be continuous (as is considered acceptable in the RBA). The value of the EIF denotes the volume (expressed in km^3) over which risk to the PAF exceeds 5 %.

10.7.4.5.2.3 DREAM Results

Figure 10-32 shows the 'combined maximum instantaneous EIF' values over the entire model duration of 42 days during both early and late Field Life.

The 'combined instantaneous' element means time is not taken into account in this plot. In other words, where the model indicates there is a risk to >5 % of the PAF in one place on day one of the discharge and a risk of >5 % to the PAF in a different place on day 25 of the discharge, *all* of these maximum EIF values are plotted in Figure 10-32. Therefore, this figure indicates the maximum risks as if they were all happening at the same time. However, in reality these areas would not all be affected to the same extent at the same time.

The cross-sections below these risk plots show that the discharged water does not descend significantly into the water column due to the temperature and salinity of the plume. The PW plume is confined to the top 80 m of the water column in early Field Life, and 120 m in late Field Life (Figure 10-32).

Figure 10-33 plots the distribution of the maximum instantaneous EIF on a single day during both early and late Field Life, thus incorporating the reality that the PW plume will disperse over time. Day 23 (early Field Life) and day 26.75 (late Field Life) were chosen as the days giving the highest EIFs during the month of July 2011, which in turn was chosen as the least dispersive month in the metocean record. These plots demonstrate that on any given day, the volume of water in which there was a risk to >5 % of the PAF is less than the cumulative volume indicated in Figure 10-32. Here it can also be seen in the cross-sections that in early and late Field Life, the effect of the plume on a single day does not descend significantly below 60 m into the water column (Figure 10-32) although this varies from day to day.

In order to take account of the changing metocean conditions and to provide a more stable and realistic result for comparison in line with SINTEF and DESNZ guidelines, the average EIF for the duration of the model run was calculated using the daily EIFs shown in Figure 10-34. The time-averaged EIFs for both early and late Field Life are provided in Table 10.54.

Similarly, during PWRI downtime, it is unlikely that PW discharges will occur continuously as is assumed by the model. It is more likely that any discharges will be intermittent throughout the year. Therefore, it is useful, as advised in the RBA Guidance (BEIS, 2020), to determine the 'annualised' EIF which averages the 25 day discharge over the year (Table 10.54).

As is shown in all representations of the data, the EIF is far higher in late Field Life than in early Field Life owing to the volume of PW which may be discharged.

Finally, Figure 10-35 shows a breakdown of the main components which contribute to the overall EIFs in the late Field Life case (the early Field Life case has almost identical contributions). Wax inhibitor was the main contributor to the risk given its low PNEC. The other main contributors to the EIF were the naturally produced PAHs (which are expected to be higher in the analogue used than in the actual Sea Lion PW (Section 10.7.4.1.2.1)) and alkyl-phenols. Dispersed oil, conservatively modelled here as 30 mg/l, poses no significant toxic risk. In later life, the added chemicals become less important and the natural components dominate the predicted effect.

b) Late Field Life (day 26.75)

Figure 10-33: Instantaneous EIF for early and late Field Life cases at time of maximum EIF (yellow equals 1 - 5 % risk)

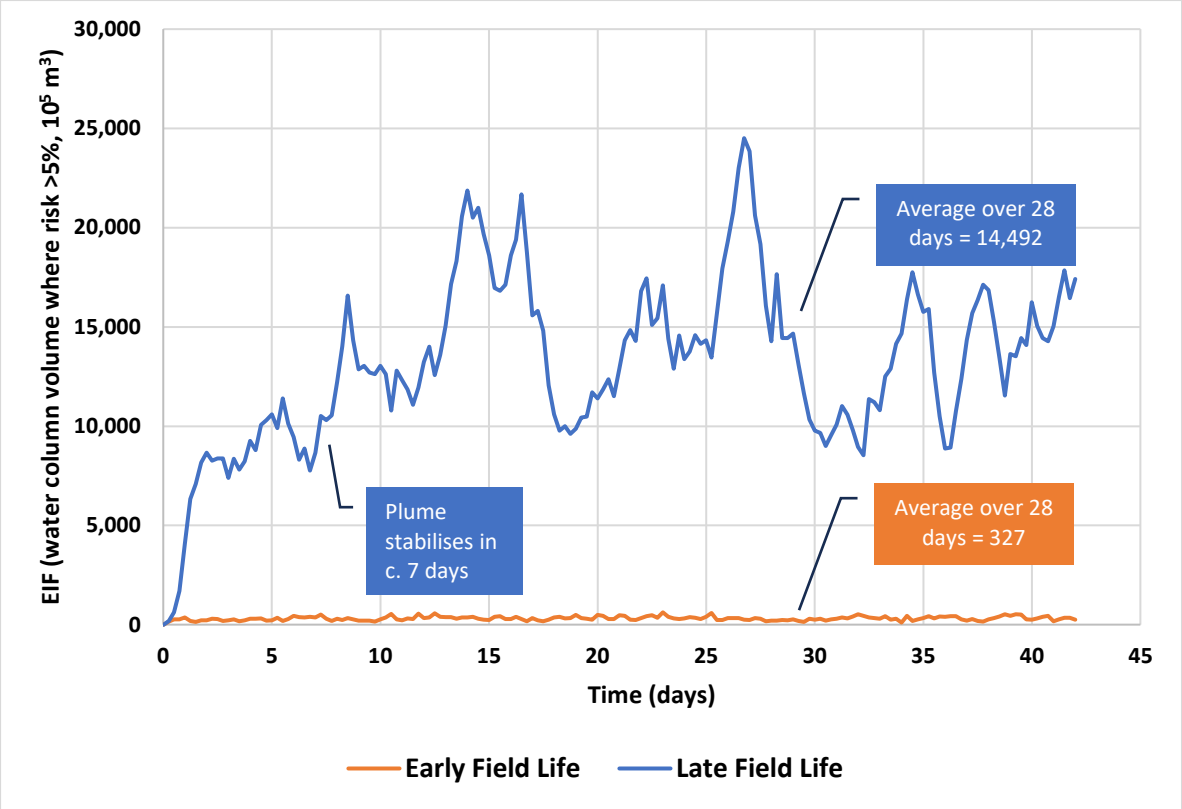

Figure 10-34: Daily EIFs over model duration (Note: the model duration is 42 days to allow up to two weeks for the plume to reach a steady state followed by 28 days discharge in accordance with the UK RBA Guidance (BEIS, 2020))

Table 10.54: Time averaged and annualised EIFs for early and late Field Life

Model result	Early Field Life		Late Field Life	
	EIF	Representing	EIF	Representing
Time averaged EIF	327	0.0327 km^3 of water in which there is a risk to > 5 % of the most sensitive species	14,492	1.45 km^3 of water in which there is a risk to > 5 % of the most sensitive species
Annualised EIF [1]	23	0.0023 km^3 of water in which there is a risk to > 5 % of the most sensitive species	1,012	0.101 km^3 of water in which there is a risk to > 5 % of the most sensitive species

[1] The annualised EIFs shows the EIF of the 25.5 days (i.e., the 7 % of the time that the PWRI units are down) averaged over the year

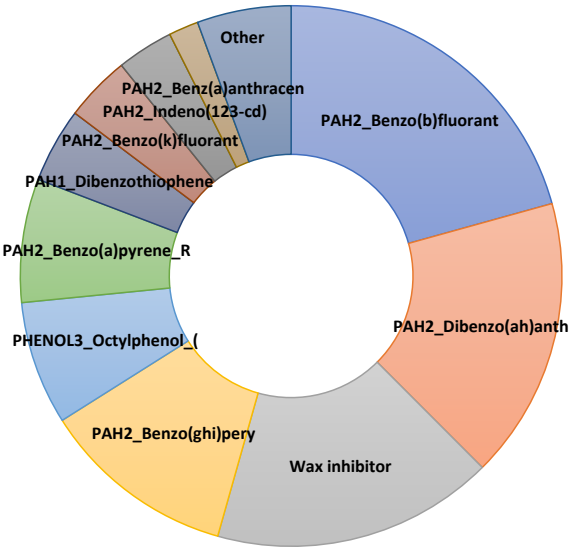

Figure 10-35: Contribution of the main components to the EIF value (late life case)

10.7.4.5.2.4 Comparison with North Sea EIFs

While it can be useful to compare the EIFs for PW from different installations, there is little published data on PW modelling studies under the OSPAR RBA process (Section 10.7.1.1.1.2).

Nonetheless, some installations on the Norwegian Continental Shelf (NCS) underwent RBA modelling in 2008, the results of which were published in Smit *et al.,* 2011[74]. Of all the installations reviewed, the maximum annualised EIF observed was 1,200 (equating to a volume of 0.12 km^3 in which the risk was >5 % to the PAF), which is slightly higher than the late Field Life EIF for the Sea Lion Field of 1,012 (Table 10.54 above). However, direct comparisons are very approximate at this stage because:

- The estimated Sea Lion PW composition (Table 10.47 above) may be very different from the real composition, which is as yet unknown,
- The analogue North Sea data used were chosen owing to the low salinity of the PW while the NCS RBA data are not from low saline PWs such that the comparison is not like-for-like,
- It is not possible from Smit *et al.* (2011) to check the basis of the calculations used for the NCS installations, and
- The EIF may have been calculated differently due to revised PNEC values.

Nevertheless, the RBA is founded on refining and reducing risk, and this can take the form of reducing all of the uncertainties in the analysis, be they compositional values, assessment factors, metocean data or other parameters, in conjunction with examining obvious risk reduction opportunities presented by choices of chemicals, availability of PWRI, physical dispersion etc. (Smit, *et al.,* 2024).

10.7.5 Industry-standard mitigation

In addition to the legal requirements of MARPOL etc. (Section 10.7.1.1), industry-standards include:

- Selection of the most environmentally benign chemicals available on the Cefas list of registered products where possible (notwithstanding the need for optimal operational performance),

[74] This 2011 paper is still regarded as the most recent compilation of EIF values.

- The use of BAT to minimise PW discharge volumes and / or OiW concentrations e.g., by using PWRI and the project target of 10-15 mg/l,
- Daily sampling of PW samples. Automatic detection devices will be available on the FPSO that measure oil in water, and other discharges and laboratory technicians will also be onboard the FPSO to undertake analysis,
- Development of an on-Island laboratory if necessary for PW analysis,
- Seabed surveys conducted every five years,
- The RBA to PW as a product, and DREAM / ParTrack modelling (or any updated model) be repeated once the exact composition is known[75], to assess the potential impact of PW as a whole substance and to determine forward actions to manage risks (Section 10.7.1.1.1.2):
    - The key rationale for using RBA in PW management is to focus mitigation actions on discharges and substances that represent the greatest risk to the environment. The RBA requires that risks of PW discharges are assessed with either a Whole Effluent Toxicity (WET) approach, a Substance Based (SB) approach, or a combination of the two (Beyer, *et al.,* 2020), and
    - The need for further sampling / monitoring of PW upon discharge will be evaluated following RBA assessment to see if it is necessary / justified (noting that this is rarely the case on the UKCS).
- That the Energy Institute (2016a) Guidance on the management of subsea hydraulic fluids is followed,
- That a Maintenance Management System (MMS) be used to ensure that all equipment is sufficiently maintained,
- Compliance with the ISO14001 certified (or equivalent) OMS working procedures and OiW objectives and targets, and
- Compliance with the O&G UK Good Practice Well Clean-up Guidelines.

10.7.6 Impact and risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. Assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes is tabulated in Section 10.7.12, which shows the worst-case impact / risk for each activity and receptor.

10.7.6.1 Impact assessment of operational discharges

10.7.6.1.1 General operational fluids

While individual marine organisms may be impacted at the point of subsea or surface discharges, any impact is anticipated to be short-lived and localised such that there will be no impact at the population level and no species or habitats that are of conservation importance will be affected. With regard to biocide discharges in particular, it is assumed that the only marine organisms likely to be impacted are those which cannot actively remove themselves from the mixing zone e.g., plankton. Further, the discharges will be to the open ocean and any effects will be localised with no potential to transmit

[75] Please note that Navitas is committed to having appropriate laboratory facilities and equipment available. If necessary, on island facilities will be developed.

contaminants to nearby sensitive receptors. Therefore, the sensitivity of the receptors (water quality and marine organisms) is considered to be '**Very Low**'.

While the specific volumes of the hydrotest, wellbore clean-up / completion fluids, cooling water discharges and hydraulic fluids, and the chemicals dosed within them, are not yet known, the chemicals will be compliant with the OCNS (Section 10.7.1.1.2) and will be selected to minimise environmental impact (Section 10.7.5). It is therefore anticipated that any impacts will not be detectable above background variability and will be rapidly and fully reversible once the activity ceases and / or outwith the mixing zone of surface discharges. Therefore, the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of the impact from the planned discharge of hydrotest water, wellbore clean-up / completion fluids, cooling water and hydraulic fluids is considered to be '**Very Low (1)**'.

10.7.6.1.2 Produced water discharges during commissioning

While individual marine organisms may be impacted at the point of PW discharges, any impact is anticipated to be short-lived and localised such that there will be no impact at the population level and no species or habitats that are of conservation importance will be affected. Further, the discharges will be to the open ocean and any effects will be localised. Therefore, the sensitivity of the receptors (water quality and marine fauna) is considered to be '**Very Low**'.

The DREAM modelling described in Section 10.7.4.5 was carried out to model the impact of unplanned discharges during PWRI downtime during early and late Field Life. However, the early life outcomes can be used to assess the severity of effect of discharges of PW during the commissioning phase.

While the exact composition of the Sea Lion PW is unknown at this time (Section 10.7.4.1.2.1), all of the components within PW have the potential to cause both acute and chronic impacts to marine organisms (Section 10.7.4.2.2), although there is a great deal of ambiguity in the outcomes of the studies cited. Of those studies which indicated the potential for impacts to marine life, the majority were based on mesocosm studies with fauna held in cages in one location downstream of significant and consistent PW plumes (Section 10.7.4.2.2).

The most appropriate modelling result to 'transfer' to the commissioning PW discharge is the Time-Averaged early-life EIF (Table 10.54). The EIF of 327 indicates that there is a risk to >5 % of the most sensitive species present over a volume of 0.0327 km^3. However, there are two key differences that should be noted. Firstly, commissioning discharges are likely to last for longer than 25.5 days overall and secondly, the volumes of discharge during commissioning are likely to be lower as the production wells will only just have started to cut water and the volumes of water will be sporadic. However, on balance, it is assumed that the result can be used to assess the commissioning discharges.

Given that this area is relatively small, and that the nature of the impact is mostly restricted to the immediate mixing zones (Section 10.7.4.2.2) the discharge is expected to have a localised effect for the duration of the discharge with fully reversible effects once activity ceases. Moreover, the DREAM model assumes a discharged OiW concentration of 30 mg/l while in reality, the concentration is anticipated to be in the region of 10-15 mg/l (Section 10.7.5). On balance, given that the discharge may occur for longer than 25.5 days while the PWRI system is commissioned, albeit with lower volumes, the severity of the effect is considered to be '**Moderate**'.

Therefore, the overall significance of the impact is considered to be '**Low (3)**'.

10.7.6.1.3 Grey water, black water and food waste

The offshore habitat in the vicinity of the Sea Lion Field is undesignated and ubiquitous in nature and, given that the discharges will be into open ocean conditions, the extent of eutrophication from the

discharge of grey and black water (Section 10.7.4.2.3) is expected to be very small. For grey water, black water and food waste, the sensitivity of water quality, and plankton, as receptors is therefore considered to be '**Very Low**'.

While the discharge to sea of grey water, black water and food waste may cause slight eutrophication of the surrounding waters, wave action will rapidly disperse and dilute effluent and the action of micro-organisms will breakdown additional nutrients (Section 10.7.4.2.3). Taking account of compliance with MARPOL Annex IV, the impacts of the discharges are expected to be rapidly reversible and barely detectable above background variability. Therefore, the severity of effect has therefore been assessed as '**Slight**'.

The overall significance of direct impacts of the discharge of grey water, black water and food waste is therefore '**Very Low (1)**'.

10.7.6.1.4 Discharge to sea of drainage and bilge water

With regard to water quality, discharges will be to the open ocean where wave action will rapidly dilute any oil remaining in the discharged water. Therefore, the sensitivity of water quality as a receptor to this level of oil contamination is considered to be '**Very Low**'.

Equally, at this concentration, any effect on the water quality will be localised, short-term and reversible and the severity of effect of drainage and bilge water discharges is therefore considered to be '**Slight**'.

The overall significance of the impact of the discharge of deck drainage and bilge water is therefore assessed as '**Very Low (1)**'.

10.7.6.1.5 Discharge of hypersaline water

The Sea Lion Field is located in the open ocean, in waters over 450 m in depth, with currents sufficient to rapidly dilute and disperse hypersaline discharges. Therefore, few flora or fauna are likely to be exposed to high saline conditions and there are no populations that are considered to be of geographical importance. Therefore, the sensitivity of the receptors is considered to be '**Very Low**'.

As described in Section 10.7.4.2.5, discharges of hypersaline water to dynamic environments are expected to have little environmental effect. Given that the Phase 1 & 2 discharges will be to the open ocean, any impacts are expected to be 'rapidly and fully reversible with highly localised effects' such that the severity of effect is considered to be '**Slight**'.

The overall significance of direct impacts of the discharge of hypersaline water is '**Very Low (1)**'.

10.7.6.2 Risk assessment of unplanned events

10.7.6.2.1 PW discharge during PWRI downtime

The sensitivity of receptors is as described above for commissioning discharges of PW and is therefore considered to be '**Very Low**'.

As described above, the DREAM model indicated that, on average, in early Field Life, there is a risk to >5 % of the most sensitive species in only 0.0327 km^3 around the FPSO. In late Field Life this volume increases to 1.45 km^3 (Table 10.54). However, all of these results assume that 25.5 days' worth of PW will be discharged continuously when, in reality, any discharges resulting from PWRI downtime would most likely be spread over the year. Taking account of the PWRI uptime of 93 %, the annualised EIFs are reduced such that in early Field Life, there is a risk to >5 % of the most sensitive species in only 0.0024 km^3 around the FPSO and 0.101 km^3 in late Field Life (Table 10.54). Given that this area, which better represents the reality, is relatively small, and that the nature of the impact is mostly restricted to the immediate mixing zones (Section 10.7.4.5.2.3) the impact is expected to have a localised effect

for short periods with fully reversible effects once activity ceases. Moreover, the DREAM model assumes a discharged OiW concentration of 30 mg/l while in reality, the concentration is anticipated to be in the region of 10- 5 mg/l. Therefore, the severity of the effect is considered to be '**Minor**'.

Therefore, the overall significance of the impact is considered to be '**Very Low (2)**'.

Given that the PW will only be discharged in the event that both PWRI units malfunction, and an off-spec tank will be used to store and re-clean any water that does not meet the discharge specification, the likelihood of occurrence of PW being discharged is '**Unlikely**'.

Therefore, the overall significance of the risk is considered to be '**Very Low (2)**'.

10.7.6.2.2 Oil sheens from PW or bilge/drainage water

Seabirds are attracted to offshore installations owing to light and the discharges of macerated food and sewage (Section 10.7.4.3.3). Of those that may be feeding in the area, it is likely that some of these species will be classed as 'Vulnerable' or 'Endangered' by the IUCN (which equates to 'High' sensitivity). Further, many of the scavenging / diving species of seabird that associate with vessels in Falkland Islands waters are also listed as ACAP species which are considered to be under wider threat (largely from fisheries related mortality). Therefore, overall, the sensitivity of the seabird receptors is considered to be '**Very High'**.

In the event that the PW needs to be discharged, all water will be treated and sampled to ensure that the OiW concentrations are low enough to secure a worst-case monthly average concentration of <30 mg/l and no PW will be discharged in the event that a sample exceeds 100 mg/l. As described in Section 10.7.2.5, it is anticipated that the OiW concentration will range between 10-15 mg/l. Regular monitoring will identify any drift in quality (Section 10.7.5) and the off-spec tank will be used for non-compliant PW (Section 10.7.2.5). The tank will be used for long enough to enable stable conditions to be achieved.

Testing of the Sea Lion crude showed that a large spill of crude can form a sheen in very calm waters and there may be the potential for sheens from the lower volume bilge and drainage discharges. However, the discharge of PW is unlikely to form a sheen owing to the low concentrations likely to discharged at the PW caisson and the minimal sheen forming behaviour observed during the CEDRE PW tests (Section 10.7.4.3.2). The tests showed that oil particles did adhere to feathers at a concentration of 10 mg/l, although no structural damage was observed (Section 10.7.4.3.3).

In practice, the impacts of contamination from sheens on long-term fitness are, as yet, unknown and the impacts may either be reversible or lethal depending on the amount of fouling (Section 10.7.4.3.3). Further, the metocean conditions in the region are such that any sheen resulting from PW discharge, bilge and drainage is likely to be temporary (Section 10.7.4.3.2). Nonetheless, given that a sheen of even 0.1 µm has the potential to reduce fitness, and to take a precautionary approach, the severity of effect is considered to be '**Moderate**'.

The overall significance of the impact of seabirds being oiled by a sheen is therefore considered to be '**Upper Moderate (15)**'.

With regard to the likelihood of occurrence, given that both PWRI units would need to malfunction before PW is discharged, that sheens are not expected at all for the PW discharge given the oil properties and that drainage and bilge will only be discharged if the OiW concentration is <15 ppm the likelihood of a persistent sheen forming and seabirds becoming oiled is considered to be '**Very Unlikely**'.

Therefore, the overall significance of the risk of a sheen oiling seabirds is considered to be '**Low (4)**'.

10.7.7 Project-specific mitigation measures

All mitigation measures are built-in to the basis of design and the OMS and are therefore taken into account in the initial impact assessment. OiW concentrations and PWRI uptime will be included within the Navitas environmental objectives and targets (Chapter 15) which are designed to ensure compliance with the Health, Safety and Security (HS&S) and Environment and Biodiversity (E&B) policies and continual improvement. At all times, Navitas will endeavour to improve upon the legally compliant OiW limits with anticipated concentrations as low as 10-15 mg/l.

Given that all the impacts and risks associated with operational discharges are considered to be '**Low**' or below, there is no need for project-specific mitigation measures over and above those which are built-into the basis of design and the use of environmental objectives and targets.

10.7.8 Residual impacts and risks

Not applicable.

10.7.9 Cumulative impact

10.7.9.1 General operational fluids

Hydrotesting and hydraulic fluid discharges will occur in the same area where drill cuttings may have disturbed the seabed. However, it is not anticipated that this will change the predicted impacts in any significant way.

Further, owing to the degree of dispersion and the fact that no other O&G installations are operating in the Sea Lion area, no cumulative impacts are anticipated from the use of compliant operational chemicals.

10.7.9.2 Produced water, drainage and bilge discharges

Details on the potential for cumulative and chronic impacts of oil discharges from all sources are provided in Section 12.1.

10.7.9.3 Grey and black water and food discharges

All vessels discharge grey and black water and food waste at sea in line with MARPOL regulations such that there is the potential for Phase 1 & 2 discharges to lead to cumulative impacts from increased 'concentration' and increased 'extent and proportion' (Section 8.9.1).

The volumes discharged are related to the number of persons on board at any given time. During the Phase 1 & 2 Development, the combined disposal of grey and black water and food waste from the MODU, FPSO and vessels will add to that produced by existing users of the marine environment.

The number of fishing vessels operating within Falkland Islands waters varies considerably throughout the year. The highest peak in number of vessels is associated with the *Illex* fishing season (Section 7.7.3.1.1.1), when the number of vessels at sea can rise to over 130. A second smaller peak is associated with the second fishing season, which comprises loligo and finfish trawlers, with a maximum of about 40 vessels (Figure 10-36). Over the course of the year, the weekly mean number of vessels fishing within Falklands waters in 2023 was 36 (data from FIFD, 2024).

While the number of crew on each fishing vessel varies, with an assumption of 40 crew per vessel, the total number of crew at-sea on fishing vessels peaks for a short-term at about 5,200. The addition of 140 crew on the rig, 80 on the FPSO and up to 300 on the support vessels represents a small increase (approximately 5 %) in the total number of people at-sea in the busiest period in these waters. Additional discharges to sea therefore amount to <5 % of those generated by fishing vessels per month. With the volumes estimated, these waste streams are not regarded as an environmental threat.

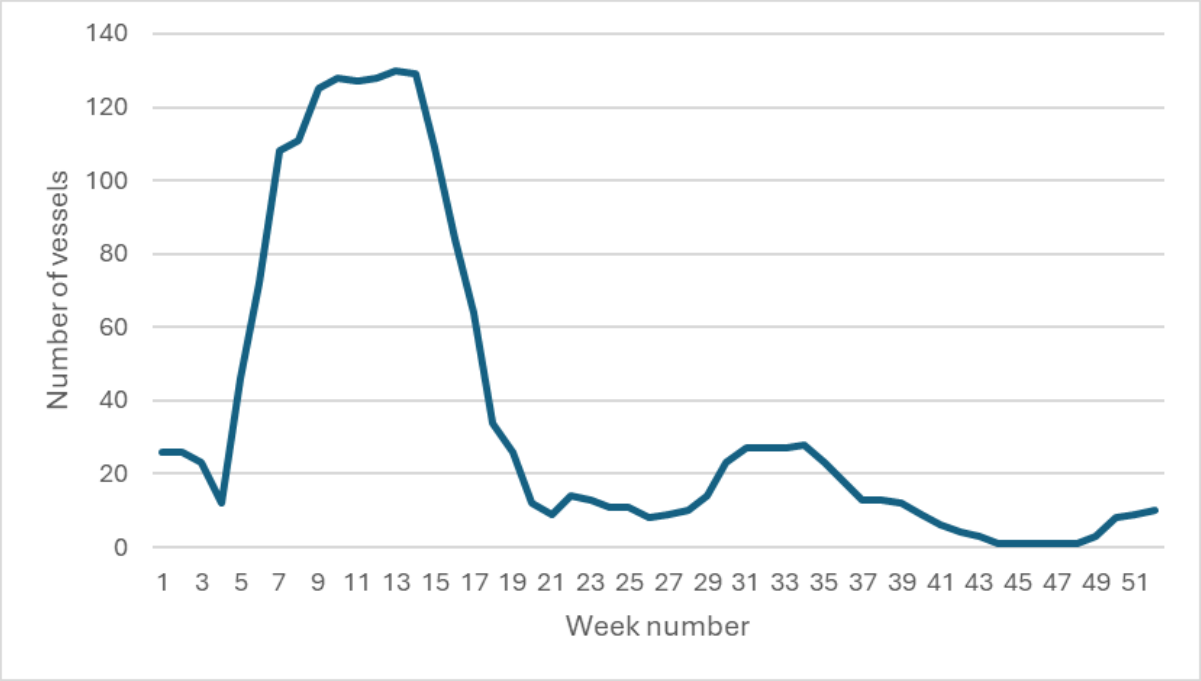

Figure 10-36: The mean number of fishing vessels operating within Falkland Islands waters on a weekly basis throughout 2023

10.7.9.4 Hypersaline discharges

Although some fishing vessels carry desalination plants, many do not such that discharges of hypersaline water from the MODU and the FPSO are not expected to add to significant existing discharges. Also, owing to the degree of dispersion and the fact that no other O&G installations are operating in the Sea Lion area, no cumulative impacts are anticipated from hypersaline discharges in the area.

10.7.10 Confidence

Given that the volume of hydrotest water, and the dosages of biocide in CW are as yet unknown, the confidence in both impact assessments is considered to be '**Probable**'. Similarly, while the clean-up and completion fluids will be 'visibly clean' (Section 10.7.2.2) and the concentration of NADF in the clean-up fluids is currently unknown, the confidence in the assessment is considered to be '**Probable**'.

PWRI has proven effective in certain reservoirs in the North Sea. However, the efficacy of the PWRI units with Sea Lion crude / reservoir conditions has yet to be assessed in practice. Therefore, the confidence in the impact assessment of PW discharges is considered to be '**Probable**'.

Confidence in the assessment of impacts from other discharges to sea (grey water, black water, food waste, drainage and bilge water, hypersaline discharge and clean-up fluids) and in the risk assessment is '**Certain**'.

The risks associated with PW discharges in the event of PWRI downtime were quantified with the DREAM model. However, a number of uncertainties in the model need to be considered with regard to the assumptions made (Table 10.55). Further, the data available in the literature with regard to the known impacts largely pertains to coastal rather than the 'open ocean'. Therefore, the confidence in the risk assessments is '**Uncertain**'.

Initial testing indicated that while Sea Lion PW is unlikely to form a sheen, feather contact with the PW does result in oil particles becoming attached to feathers, though no structural damage was observed. Therefore, on balance, confidence in the assessment of oil sheen risks is considered to be '**Probable**'.

Table 10.55: Modelling uncertainties

Uncertainty	Description
Flow rates	The Phase 1 & 2 production profiles were used for the modelling of the PW and the oil flow rate was used to calculate the partitioning of the chemicals based on their partitioning coefficients (the LogPow). While the dosages were provided by Navitas, the actual chemicals and dosages may differ when it comes to production. The volumes should be representative and the modelling has applied the best available information.
PW composition and parameters	Data on the natural composition of the Sea Lion formation water, in terms of the parameters normally used for assessing water column risk, are unavailable. The composition of a low salinity North Sea analogue was used in the model. However, as the reservoirs and geology are very different to the North Sea, the composition from the lacustrine Sea Lion reservoir could vary significantly. A review of potential PW risks is recommended at a point when Sea Lion PW composition is better understood and when PW first appears in production.
Metocean data	Three years of detailed metocean data has been analysed to identify average current speeds in the Sea Lion area. Conditions used in the modelling were chosen to be the most quiescent month of the available dataset, in order to create the calmest water and thus the least dispersion. The conclusions are conservative in this respect.

10.7.10.1 Monitoring required

Oil in PW concentrations will be monitored as standard with samples taken twice daily during any periods where it is necessary to discharge PW. Also, despite the indication that Sea Lion crude will not form a sheen, vigilance will be maintained with regard to the formation of sheens and any sheens will be reported to FIG. Further monitoring measures, such as satellite surveillance, could also identify any sheens from other sources e.g., bilge, drainage discharges or wellbore clean-up fluid to ensure that actions, if required, are correctly focused. Other monitoring measures include:

- The placement of SMMOs (Seabird and Marine Mammal Observers) on vessels with the identification of oiled or dead birds offshore included in their scope. Fingerprinting of the Sea Lion crude will also allow testing of oiled birds to help determine the source of oiling,
- All chemical use and discharge will be tracked and reported to FIG,
- All vessels will use an Oil Record Book to record all oil discharges from drainage and bilge water and a Waste Disposal Log, and
- All discharges of wellbore clean-up fluid will be conducted in line with O&G UK Guidelines (Section 10.7.5). A minimum of five representative samples spaced across each well operation will be sent onshore for analysis and duplicate samples retained on the rig.

Detailed monitoring requirements have been established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline EMMP is provided in Chapter 15.

10.7.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

10.7.12 Findings summary

Table 10.56: Summary of the impact assessment for operational discharges during the Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Chemical discharges	Discharge of hydrotesting, well clean-up fluid, cooling water and hydraulic fluids	Impacts on water quality and potential for acute and chronic impacts on marine organisms,	Planned	1	Very Low	Slight	n/a	**Very Low (1)**	n/a	**Probable**	**Industry-standard:** Selection of benign chemicals where possible, OiW target of 10-15 mg/l, RBA of PW, EI (2016) Guidance, Maintenance Management System, OMS, Off spec tank, and O&G UK Well Clean-up Guidelines **Project-specific:** None proposed.
Production from the FPSO	Discharge of PW during PWRI commissioning		Planned	2a, 2b, 3	Very Low	Moderate	n/a	**Low (3)**	n/a	**Probable**	
MODU, FPSO and vessel activity	Discharge of grey water, black water and food waste	Impact to water, plankton and seabirds	Planned	1, 2a, 2b & 3	Very Low	Slight	n/a	**Very Low (1)**	n/a	**Certain**	
	Discharge of drainage / bilge water	Impact on water quality	Planned	1, 2a, 2b & 3	Very Low	Slight	n/a	**Very Low (1)**	n/a	**Certain**	
	Discharge of hypersaline water	Impact to flora and fauna	Planned	1, 2a, 2b & 3	Very Low	Slight	n/a	**Very Low (1)**	n/a	**Certain**	
PWRI unavailability	Discharge of PW	Impact to flora and fauna	Unplanned	3	Very Low	Minor	Unlikely	**Very Low (2)**	n/a	**Uncertain**	
Off-spec discharge of PW / bilge / drainage	Formation of a sheen	Impacts to seabirds	Unplanned	2a, 2b & 3	Very High	Moderate	Very Unlikely	**Low (4)**	n/a	**Probable**

10.8.1 Introduction

Owing to its waxy nature, Sea Lion crude solidifies at low temperatures and it is therefore necessary to ensure that the oil remains fluid by maintaining the correct temperature. The crude has to remain hot enough to flow, but cool enough to prevent damage to flowlines and process equipment. Flow assurance is managed with flow assurance chemicals, such as wax inhibitors, and engineering solutions, such as heating and cooling systems (Section 5.8.4.1). The latter can result in the discharge of waste heat to the environment.

Although produced water reinjection (PWRI) is built into the design, Produced Water (PW) may need to be discharged to sea during PWRI system downtime. Additionally, once the produced water treatment system is required there will be a period of commissioning where PW may be discharged for between 3 - 6 months at the beginning of the Field Life. In such cases, the PW will also be at an elevated temperature and will produce a thermal plume.

Cooling water systems are also used to control the temperature of engines and turbines in order to run optimally towards efficient, safe and reliable operations. The Floating Production, Storage and Offloading vessel (FPSO) in particular has turbines, compressors and pumps that require continuous cooling when operating, which is achieved by constantly pumping seawater through heat exchangers that carry heat away from the machinery. All continuous cooling water from machinery is co-mingled and discharged *via* the crude oil cooling water outlet and is included in this assessment. Some machinery, such as fire pumps, are used occasionally and have a dedicated discharge but such discharges are small and very intermittent and have been scoped out of this assessment.

As described by Langford (1990), cooling systems that use seawater, and the associated discharges, can lead to environmental impacts via:

- The abstraction of large volumes of seawater,
- Entrainment of organisms on seawater intake filters,
- Entrainment and passage of organisms through the cooling system,
- The addition of biocides to the cooling water to control biofouling in the system, and
- The discharge and dispersal of heated seawater.

Many of the above were scoped out during the ENVironmental Impact IDentification Workshop (ENVIID) owing to the low significance of the impacts (Chapter 9), and the impact of biocides in cooling water is assessed in Section 10.7.

This chapter specifically assesses the potential impacts associated with the introduction of thermal energy to the marine environment.

Note: the impacts associated with other liquid discharges are described elsewhere in this document, as described in Table 2.2.

10.8.1.1 Legislation regarding thermal discharges

No legislation is in place to govern the impacts of thermal discharge. While such local legislation as the Conservation of Wildlife and Nature Ordinance (1999) could be considered relevant, no harm or threat of harm is anticipated as a result of thermal discharges given that the heat will disperse so rapidly. However, perhaps of greater relevance, the International Finance Corporation (IFC) Environment, Health and Safety Guidelines on Wastewater and Ambient Water Quality recommend that the:

> *'Temperature of wastewater prior to its discharge does not result in an increase greater than 3 °C of ambient temperature at the edge of a scientifically established mixing zone which takes ambient water quality, receiving water use and assimilative capacity into account.'* (IFC, 2007b)

The IFC Guidelines are mainly intended for freshwater and coastal protection. However, the intent of the guideline remains useful for offshore discharges (Genesis, 2015b). The 3 °C temperature increase reflects a threshold above which impacts on aquatic biota may occur and is also referred to in SEPA (2023b) as a 98%ile threshold for marine waters of good ecological status. The 'mixing zone' describes an area within which a 3 °C temperature increase can be tolerated, provided it does not significantly impact the larger ecological unit or the overall success of species that traverse the area (IFC, 2007b). The mixing zone is therefore site-specific and detailed guidelines are published by the US Environmental Protection Agency on how to designate such a zone (e.g., USEPA, 1991).

10.8.2 Sources of thermal impact

The potential sources of thermal impacts during the Phase 1 & 2 Development include:

- Insulated (and thus passively heated) subsea infrastructure including insulated Subsea Production Systems (SPS) and Subsea Umbilicals, Risers and Flowlines (SURF) on the seabed.
- Periodic active heating of subsea infrastructure in certain circumstances (e.g., the circulation of hot oil for flow assurance during shutdowns (Section 5.8.4.1),
- Heated surface discharges:
  - Continuous and planned cooling water discharges,
  - Potential discharge of PW during commissioning of the PWRI units (three to six months),
  - Bilge and slop water discharges, and
  - Unplanned PW discharges (under abnormal conditions only).

10.8.2.1 Heated subsea infrastructure

The produced fluids will already be at an elevated temperature. This heat is retained as much as possible using insulation to passively maintain flow assurance in the SPS and SURF. Nonetheless, during production, some heat loss at the seabed will occur.

In the event that the production process undergoes a planned or unplanned shutdown, there is a risk that the oil in SPS and SURF could cool and cause blockages. To prevent this, active flow assurance techniques are used to keep the oil at an appropriate temperature (Section 5.8.4.1), again which may result in the loss of heat at the seabed or in the water column *via* the risers.

10.8.2.2 Surface discharges of heated water

The topside cooling system will use cold seawater to absorb heat from a closed loop cooling medium circuit. The cooling medium absorbs heat from the process *via* a series of heat exchangers and is then re-cooled with the seawater; the warm seawater is then discharged back to sea. These cooling water (CW) discharges will be at an elevated temperature, with a maximum of around 50°C and all discharges will be planned.

A separate marine cooling system located in the engine room will use cold seawater to cool several marine systems including a closed loop cooling medium circuit for marine equipment, steam condensers for the closed loop steam system, and the freshwater generator package. All seawater will be discharged back to sea from several overboard discharge locations located in the engine room at a temperature in the region of 28°C. The discharged seawater capacity will increase during crude offloading periods to meet the additional cooling requirement from the steam turbines of the cargo offloading pumps.

Any discharges of PW will be at a temperature of approximately 90 °C. However, as is described in detail in Section 10.7, the target is that PW will be reinjected into the reservoir such that no discharges will occur during steady state production. However, there may be the need to discharge the PW for three to six months while the PWRI units are commissioned. Beyond this, any discharge of PW would

be due to equipment downtime or reservoir injectivity issues. In the event that both of the PWRI units fail simultaneously, it may be necessary to discharge the PW, at 90 °C, for a short duration. In the event that PWRI provides adequate reservoir pressure management, as a worst-case, it is estimated that PW discharges due to PWRI downtime may occur for up 7 % of each year (or 25 days per year).

10.8.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts and / or risks of thermal discharges warranted further investigation (Chapter 9). These include the impacts and risks to:

- Plankton (Section 7.4.1),
- Fish and cephalopods (Section 7.4.4.2),
- Benthic marine flora and fauna (including water quality and sediment) (Section 7.4.3.2),
- Seabirds (Section 7.4.5), and
- Marine mammals (Section 7.4.6).

The above may be affected as the native marine flora and fauna normally inhabit sea temperatures ranging between 5 - 11 °C (Genesis, 2015b), although the seas in this area are fed by strong currents from both the Circumpolar Antarctic Current (via the Falklands Current) and the Brazil Current where larger extremes exist (Section 7.3.3). Of note, to avoid repetition, the impacts to these receptors are not assessed individually below and instead they are grouped and assessed as 'marine organisms'.

10.8.4 Characterising and quantifying the impacts of thermal discharges

When characterising and quantifying the potential impacts of thermal discharges it is necessary to consider:

- The behaviour and fate of thermal plumes resulting from:
  - Insulated subsea infrastructure, and
  - CW and PW discharges.
- The nature of thermal impacts, and
- Quantification of the impacts and risks of thermal discharges:
  - Heated seawater resulting from subsea equipment, and
  - Modelling of the discharge plumes.

10.8.4.1 The behaviour and fate of thermal plumes

10.8.4.1.1 Heated subsea infrastructure and seawater

While heated SPS and SURF may elevate the temperature of surrounding water which will rise and dissipate, some heat may be transferred to the sediments directly beneath infrastructure. Local pockets of warmer water may develop adjacent to the pipelines.

10.8.4.1.2 Surface discharges of heated water

While the ambient seawater temperature may vary with season, the temperature of CW and PW will be significantly higher than the ambient temperature year-round. Nonetheless, the heat in discharges will dissipate in the marine environment as the plume mixes.

The rate at which heat is dissipated will depend on the extent and rate of mixing between the discharge plume and the receiving body of water. Continuous thermal discharges to semi-enclosed bodies of water, such as estuaries, can result in a net increase in the temperature of the water column or in stratified layers of different temperatures. However, in open ocean conditions, the plume is likely to

mix more homogenously and thermal dissipation is expected to be rapid, particularly in turbulent metocean conditions.

In the event that the discharge plume is very buoyant such that it remains at the surface, some heat energy may also be lost to the atmosphere.

10.8.4.2 Nature of the impact

Both direct and indirect impacts can result from thermal discharges both at the surface and subsea.

The direct effects of thermal discharges on the marine environment are those that may affect the success of species present. These effects include:

- Alteration of the temperature regime of the water column or sediment (Langford, 1990; UKSAC, 2015), including changes to:
  - The mean temperature,
  - The maximum temperature,
  - Temperature fluctuations and the rate of change,
  - Lethal and sub-lethal responses of marine organisms to changes in temperature regime,
  - Stimulation in productivity in a range of organisms, and
  - Reduction in the dissolved oxygen saturation.

The indirect effects of thermal discharges on the marine environment include those which may affect the larger ecological unit and include changes in the distribution and composition of communities of marine organisms.

The majority of studies into the effects of thermal energy on marine flora and fauna explore the impacts in coastal and intertidal regions receiving discharges from power generation plants. In such regions, it is recognised that discharges over a number of years can serve to increase the ambient temperature of the receiving environment (Scheil, *et al.,* 2004; UKSAC, 2015). However, the results presented varied. Some studies showed significant changes to community structure and species abundance in key taxa, albeit with no influx of warmer-water species (Scheil, *et al.,* 2004). Other studies concluded that heated effluent did not change assemblage structure or the spatial distribution of the study taxa over and above background variability (Lardicci, *et al.,* 1989).

With regard to the potential for impacts in the open ocean however, few data are available although it is unlikely that thermal discharges would alter the temperature of the water column in any sustained way. The British Antarctic Survey (BAS) was commissioned by the previous operator (POEPL) to estimate marine growth (see Section 10.3.4.2.1.3) and noted in its report that the discharge of large volumes of warm water may change local microalgal production, which has the potential to contribute to algal blooms (BAS, 2014). However, algal blooms tend to form seasonally when the combination of photoperiod and nutrient mixing is optimal. While sustainable temperature changes may impact upon the proliferation of algal blooms, the thermal discharges associated with the Sea Lion field will disperse rapidly and will not be sustained. Nonetheless, should such unexpected impacts become apparent, these will be recorded and monitored, not least as blooms could impact the seawater intakes.

With regard to the impact of heated subsea equipment, again there is a paucity of data. While it is possible that subsea sources of heat may stimulate growth in the immediate area, it is unlikely that the equipment and surrounding environment could reach lethal or sub-lethal temperatures or change the temperature of the surrounding environment in any significant way.

10.8.4.3 Quantification of the impacts and risks

10.8.4.3.1 Heated subsea infrastructure

The aim of the insulated infrastructure is to prevent heat loss. However, whilst some heat loss from the insulated subsea infrastructure will occur, the external temperature is not expected to be much higher than the ambient temperature due to the high levels of insulation.

10.8.4.3.2 Volumes of planned PW discharges during commissioning

See Section 10.7 above.

10.8.4.3.3 DREAM Modelling of surface CW and PW discharge plumes

The DREAM (Dose-Related Risk and Effects Assessment Model) model incorporates a temperature simulation model that is capable of predicting changes in temperature in the receiving environment based on the temperature of discharged substances, the ambient conditions and thermal advection in dispersion (Genesis, 2015b). While CW discharges are planned and PW discharges, once into steady state production (Stage 3), would be unplanned, the discharges of both were modelled together to capture any accumulated effect.

The following describes only the information required to ensure appreciation and understanding of the modelling results. Full details with regard to the DREAM/EIF methodology and metocean data used are given in Premier (2017c).

10.8.4.3.3.1 Discharge parameters

The discharge parameters of the CW and PW are shown in Table 10.57.

Table 10.57: Discharge parameter inputs to DREAM

Parameter		Cooling water	Produced water	Description
Discharge location	Latitude[1]	49° 16' 21.9912"S	49° 16' 21.9912"S	CW discharge is assumed to be 50 m from the PW discharge as this is the width of the FPSO.
	Longitude[1]	59° 5' 50.5"W	59° 5' 53.0042"W	
Discharge depth and diameter (m)		4 m depth 0.457 m	8 m depth 0.3556m dia.	Typical values for FPSO discharges of these types
Discharge orientation		Vertically downwards	Vertically downwards	-
Discharge temp (°C)		50	90	Conservative – discharge temperatures may be lower than these values
Discharge rate	Early Field Life	70,000 m^3/d	1,626 m^3/d	CW discharges will be planned and Outwith the first three to six months, PW discharges will be unplanned, occurring for an estimated 7 % of the time
	Late Field Life		16,796 m^3/d	
Discharge salinity (PSU)		34 (seawater)	6.4	-

[1] This modelling was performed for updated discharge parameters (i.e., Produced water temperature and discharge depth) at the original FPSO location *c.* 2km to the north to the revised location presented in this EIS. This distance change is not considered to have a material impact on the modelling conducted.

10.8.4.3.3.2 Understanding the model

The model results are interpreted in accordance with the IFC Guidelines which require that ambient temperature of the receiving environment is not increased by > 3°C at the edge of the 'scientifically established mixing zone' (Section 10.8.1.1).

With regard to establishing the size of the mixing zone, it is necessary to consider the context of the receiving environment (USEPA, 1991). In the context of offshore thermal discharges in the OSPAR area, the edge of a 500 m radius zone around the installation is often considered an area of mixing outside which risks should be reduced to an acceptable level, and this is one way of applying the 3 °C temperature increase threshold.

In other situations, it is the point at which rapid, dynamic mixing processes give way to slower, passive mixing e.g., at the edge of a 'surface boil' when considering an outfall. Other measures quoted are the water depth applied as a distance, or simply a 100 m distance as a screening tool. In the absence of precedents in the North Falkland Basin (NFB), the distance of 100 m can be applied as a conservative test, such that if the threshold were not met in this distance, it would warrant more detailed consideration. Therefore, an increase of 3 °C within 100 m of the discharge point has been applied as a zone to reflect the IFC standard.

The results of the model are expressed as the temperature difference between the water within the mixing zone and the yearly average ambient temperature (which in the NFB is assumed to be 8 °C) near the sea surface.

10.8.4.3.3.3 Model results

The maximum temperature differences between the mixing zone (as opposed to the exact point of discharge) and ambient seawater at increasing distance from the discharge point are plotted in Figure 10-37 for early and late Field Life. Of importance, the outcomes of the model show the temperature difference over tens of meters and the discharge rates are such that rapid cooling occurs almost instantaneously. Figure 10-38 shows the instantaneous temperature difference at a single moment in time between the mixing zone and ambient water during early and late Field Life. Cross sections through the water column of both the CW and PW plumes are shown below the plots in Figure 10-38. To present the worst-case modelling results, these plots indicate the temperature differences during quiescent metocean conditions which would result in the poorest dispersion of the discharge.

Results of the model indicated that:

- The CW plume cools down rapidly after release and drops to <3 °C above ambient within 10 m during both early and late Field Life (Figure 10-37), and
- The PW plume cools down rapidly after release and drops to <3 °C above ambient within 10 m during early Field Life and within 50-60 m in late Field Life, allowing for transient fluctuations caused by turbulence (Figure 10-37) owing to the differences between the daily PW flowrates at these times (Table 10.57 above) and the subsequent increase in volume.
