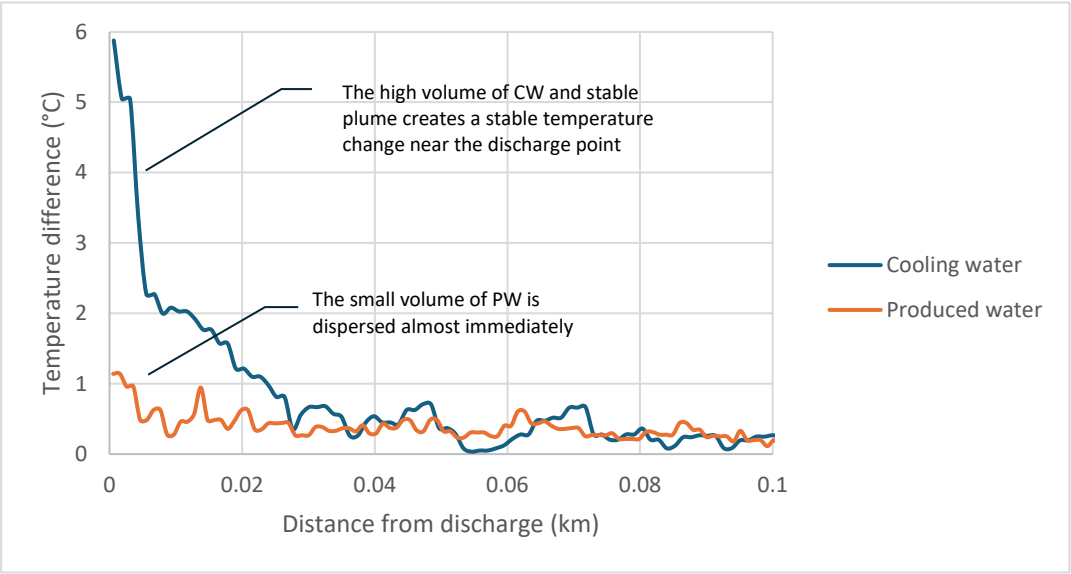
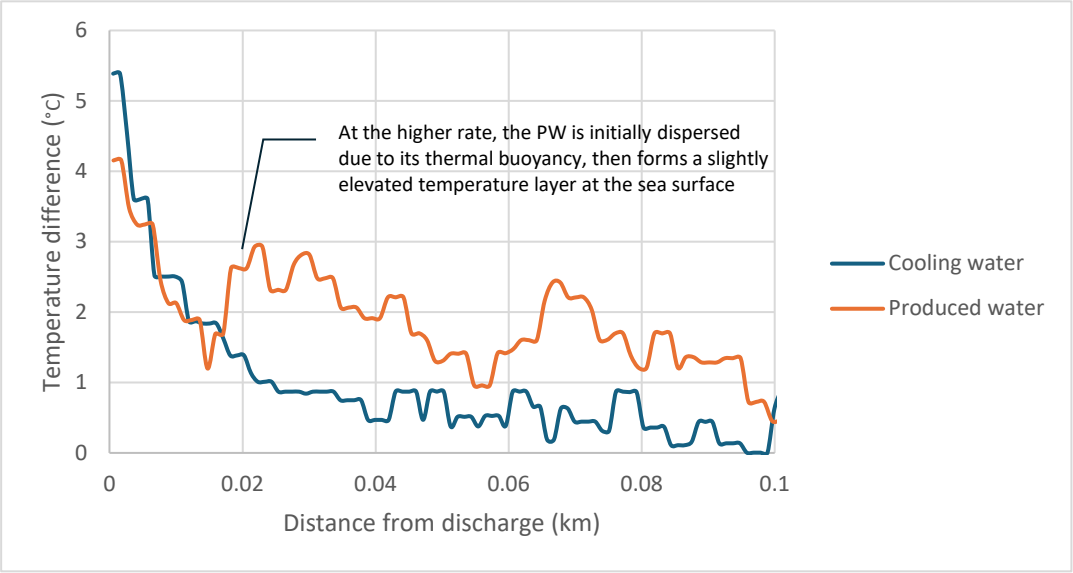
Increases in temperature caused by both CW and PW do not extend below the top 30 m of the water column (Figure 10-38).

Since the CW is a much larger volume than the PW, and is discharged at a lower temperature and is therefore less buoyant, a stable plume remains for longer in the vicinity of the discharge point (4 m below the surface) and maintains a region where the temperature is more elevated (Figure 10-37 a). The PW is discharged at a lower rate forming a smaller plume and it is much hotter, meaning it rises more quickly and moves away from the discharge point, resulting in cooling taking place in a shorter distance (Figure 10-37 a & b), while in Figure 10-37b it can be seen that an slightly elevated temperature layer persists when the plume reaches the sea surface and no longer disperses vertically.

It is also noted that the two plumes have different trajectories in the water column given their different discharge rates, depths and diameters, and the two plumes do not mix until well beyond the range where temperatures are close to the 3°C threshold. Therefore, cumulative effects, that could occur during the daily periods when currents align the trajectories of the two plumes over each other, are insignificant.



a) Early Field Life



b) Late Field Life

a) Early Field Life b) Late Field Life

Figure 10-38: Plots of temperature differences (°C) from ambient seawater for both PW and CW discharges in early and late Field Life. Note: the scale base in the top left corner is 28 m

10.8.5 Industry-standard mitigation measures

No industry-standard mitigation measures exist for the management of thermal discharges, although it is common for discharges to be assessed against IFC standards, as carried out above.

10.8.6 Impact and risk assessment

10.8.6.1 Impact assessment of thermal discharges

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. Assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes is tabulated in Section 10.8.12, which shows the worst-case impact / risk for each activity and receptor.

10.8.6.1.1 Heated subsea infrastructure on the benthos

In the event that the subsea equipment releases sufficient heat to warm the sediment and / or the surrounding seawater, it is possible that this may impact directly upon the benthic fauna in the

immediate area. Given that any populations which may be affected are not of geographical importance however, and the habitat is undesignated, the sensitivity of the receptor is considered to be '**Very Low**'.

Equally, any effect from the heat generated by the subsea equipment is likely to be highly localised such that it is very unlikely that any impacts will be detectable above background levels. Therefore, the severity of effect is considered to be '**Slight**'.

Therefore, the significance of the impact of the temperature of subsea infrastructure is considered to be '**Very Low (1)**'.

10.8.6.1.2 Cooling water discharges on pelagic receptors

As described in Section 10.8.4.1.2, the majority of studies into the impacts of thermal discharge plumes relate to coastal and intertidal regions. Discharges of CW will be to the open ocean and temperature increases of > 3°C are restricted to within 10 m of discharge source. Therefore, these increases will not impact any species of geographical importance at a population level such that the sensitivity of the pelagic receptors is considered to be '**Very Low'**.

The turbulent metocean conditions in the Sea Lion area are such that it is unlikely that impacts will be detectable above background variability. Given that the temperature differences are < 3°C well within the 'edge' of the 100 m mixing zone (Section 10.8.4.3.3), the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of the impact from the planned discharge of CW is considered to be '**Very Low (1)**'.

10.8.6.1.3 Produced water discharges during commissioning

Discharges of PW during commissioning are expected to last for between three and six months only. This will create minimal change in water temperature differences for a short period of time. Discharges of PW will be to the open ocean and temperature increases of > 3°C are restricted to within 10 m of discharge source (Section 10.8.4.3.3.3). Therefore, these increases will not impact any species of geographical importance at a population level such that the sensitivity of receptors is considered to be '**Very Low**'.

The turbulent metocean conditions in the Sea Lion area are such that it is unlikely that impacts will be detectable above background variability. Given that the temperature differences are < 3°C well within the 'edge' of the 100 m mixing zone (Section 10.8.4.3.3), the severity of effect is considered to be '**Slight**'.

Therefore, the significance of the impact for the short-term planned discharge of PW is considered to be '**Very Low (1)**'.

10.8.6.2 Risk assessment of thermal discharges

10.8.6.2.1 Produced water discharges

The modelling results described in Section 10.8.4.3.3, indicate that unplanned discharges of PW will create minimal change with water temperature differences falling below the IFC threshold of 3°C within 10 m of the discharge during early Field Life and 50-60 m in late Field Life. Therefore, the sensitivity of the receptors and the severity of the effect are the same as described in Section 10.8.6.1.3 above). As such, the significance of the impact for the unplanned discharge of PW is the same as that for the planned discharge of CW and is considered to be '**Very Low (1)**'.

Given that the base-case is to re-inject PW using two PWRI units, the likelihood of occurrence of PW being discharged in the event of PWRI downtime 'unlikely'. However to take a precautionary approach, the likelihood is considered to be '**Possible**'.

Therefore, the overall significance of the risk is considered to be '**Very Low (3)**'.

10.8.7 Project-specific mitigation measures

Given that the impacts and risks of thermal discharges are '**Very Low**', no project-specific mitigation measures are required.

10.8.8 Residual impacts and risks

Not applicable.

10.8.9 Cumulative impact

No cumulative effects are anticipated (Section 10.8.4.3.3.3).

10.8.10 Confidence

Confidence in the impact assessment for heated subsea equipment is '**Probable**' owing to the lack of data on the level of heat loss that may occur and the potential impacts.

With regard to CW and PW, while the literature only describes the impacts of thermal discharges on coastal and intertidal regions, the DREAM modelling was used to quantify the distance at which the discharge plume will have returned to ambient levels.

Nonetheless, there is uncertainty around the influence of a continuous heated discharge stream (CW) on algal blooms. Therefore, confidence in the impact assessment for CW discharges is '**Probable**', and the impact and risk assessments for PW discharges are considered to be '**Certain**'.

10.8.10.1 Monitoring required

No specific monitoring over and above any legal or Navitas' corporate standards have currently been identified. However, all monitoring requirements have been established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP which is provided in Chapter 15.

10.8.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

10.8.12 Findings summary

Table 10.58: Summary of the impact assessment for thermal discharges during the Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Insulated subsea infrastructure (passive)	Radiation of heat	Potential to heat surrounding sediment and water with effects on benthic flora	Planned	2a, 2b & 3	Very Low	Slight	n/a	**Very Low (1)**	**n/a**	**Probable**	**Industry-standard:** None **Project-specific:** None proposed
Topside cooling process	Discharge of cooling water (50°C)	Potential for direct and indirect impacts on flora and fauna from heated discharge	Planned	2a, 2b & 3	Very Low	Slight	n/a	**Very Low (1)**	**n/a**	**Probable**	
Production from the FPSO	Discharge of PW (90°C) during PWRI commissioning		Planned	2a	Very Low	Slight	n/a	**Very Low (1)**	**n/a**	**Probable**	
PWRI malfunction or injectivity failure	Discharge of PW (90°C)		Unplanned	2a, 2b & 3	Very Low	Slight	Possible	**Very Low (3)**	**n/a**	**Certain**	

[1] See Chapter 8 for definitions of sensitivity, severity, likelihood and significance.

10.9.1 Introduction

Numerous activities associated with the Phase 1 & 2 Development will generate atmospheric emissions and this was raised as a concern by stakeholders during scoping consultations (Chapter 6).

Atmospheric emissions can result in global and transboundary environmental impacts including global warming, ocean acidification and acid deposition (e.g., acid rain). In an interim update to its Sixth Assessment Report (AR6) in 2023, the Intergovernmental Panel on Climate Change (IPCC) estimated that global surface temperatures increased by 1.1°C (1.98°F) between the latter half of the nineteenth century and the first two decades of the twenty-first century. If global warming continues to increase at the current rate, it is likely to reach a level of 1.5°C over pre-industrial levels between 2030 and 2052.

As described in Navitas' Carbon Strategy, Navitas acknowledges the weight of scientific research indicating the challenges faced in human-induced climate change. Therefore, reduction in emissions is a focus within the project design and a number of emission reduction technologies have been built-in to the basis of design (Section 10.9.2.1) to optimise energy efficiency and minimise outputs. The majority of emissions will arise from the combustion of fossil fuels during the transportation of goods and personnel by sea, air and road and from power generation on the FPSO.

This chapter assesses the global environmental impacts (climatic factors) of atmospheric emissions associated with the Phase 1 & 2 Development. Emissions resulting from offshore, inshore and onshore operations are all included to ensure the worst-case scenario has been assessed. Other impacts related to vessel and helicopter use are described elsewhere in this document, as described in Table 2.2.

Note: As described in Chapter 9, impacts to air quality have been scoped out owing to distance of the offshore location from environmental and social receptors, and owing to the short duration of LTV presence in Berkeley Sound (Section 5.5.1).

10.9.1.1 Relevant legislation

Conventions, legislation and strategies relevant to atmospheric emissions in the Falkland Islands are:

- International protocols, conventions and other agreements:
  - Kyoto Protocol to the United Nations Framework Convention on Climate Change (2005 – 2020) (now superceded by the Paris Agreement but included here owing to its definition of direct and indirect GHGs).
  - Paris Climate Agreement, United Nations Framework Convention on Climate Change (commenced in 2016), including:
    - 'Net Zero'
  - International Convention for the Prevention of Pollution from Ships (MARPOL) 73/78 Annex VI on the Prevention of Air Pollution from Ships.
  - Montreal Protocol 1987.
  - Global Methane Pledge.
  - World Bank Zero Routine Flare Initiative.
- UK Legislation that may be relevant:
  - The Climate Change Act 2008 and The Climate Change Act 2008 (2050 Target Amendment) Order 2019.
  - Offshore Combustion Installations (Prevention and Control of Pollution) Regulations 2013 (as amended).

- Offshore Combustion Installations (Pollution Prevention and Control) (Amendment) Regulations 2018.
- Energy Act 2023.
- The Merchant Shipping (Prevention of Air Pollution from Ships) Regulations 2008.
- Ozone Depleting Substances (ODS) Regulations 2015.
- Fluorinated GHGs Regulations 2015 (**note**: these were being updated in 2024).

- FIG strategies:
  - FIG Islands Plan 2022 - 2026.
  - FIG Environmental Strategy 2021 - 2040 (FIG, 2021a).
  - The Falkland Islands Energy Strategy (FIG, 2023j) and Implementation Plan (FIG, 2023k).

Under the above, there are numerous compliance requirements with regard to emissions.

10.9.1.1.1 Greenhouse Gas Emissions Compliance

The following provides an overview of the relationship between the United Nations Framework Convention on Climate Change (UNFCCC), the Kyoto Protocol, the Paris Agreement, the requirement for 'Net Zero' and the UK Climate Change Act 2008.

In 1992, the UNFCCC was adopted with the objective of stabilising greenhouse gas levels in the atmosphere to a safe level. The Kyoto Protocol was a legally binding international treaty that operationalised the UNFCCC and came into force in 2005 with the key aim of reducing emissions of GHGs and slowing global warming. The Protocol grouped GHGs into those which are considered 'Direct' in that they directly trap heat within the atmosphere, and those which are 'Indirect' and can affect the climate depending on atmospheric chemistry. The Kyoto Protocol set national emissions limits for each contracting party (i.e., each country which is party to the Protocol). These served to limit the total volume of CO_2 and other GHGs which could be emitted by each contracting party over a five-year period.

Under the first Kyoto commitment (2008-2012), countries that were party to the protocol agreed to reduce GHG emissions by an average of 5.2 % by 2012 when compared to 1990 levels. Under the second Kyoto commitment (the 'Doha Amendment') the remaining participants agreed to cut emissions by an average of 18 % by 2020, again compared to 1990 (base year) levels.

The second Kyoto commitment period ran from 2013 to 2020 inclusively. For this second commitment period, the (then) EU Member States and Iceland set an independent and economy-wide emission reduction target of 20 % by 2020 compared with the base year. This was known as 'the EU2020 target'. The EU2020 target was based on the understanding that it would be fulfilled jointly by the (then) EU Member States and Iceland. Under the terms of the Brexit Withdrawal Agreement, the UK remained committed to its shared target and to reporting with the EU under the Kyoto Protocol, including any further requirements for the conclusion of the true up period[76]. The EU2020 target was unconditional and was supported by EU legislation which has been in place since 2009 (The EU Climate and Energy Package). This Kyoto target included the UK, and the relevant Crown Dependencies and Overseas Territories to which the ratification is extended (DESNZ, 2023a).

The Kyoto Protocol has now been superseded by the UNFCCC Paris Agreement which is also a legally binding international treaty on climate change. It was adopted by 196 Parties at the UN Climate Change

[76] True-Up Period means the period beginning on the 'Closing Date' and concluding on the date that is 180 days after the 'Closing Date'. In essence it refers to the additional period of time allowed for fulfilling commitments.

Conference (COP21) in 2015 and entered into force on 4 November 2016, four years earlier than anticipated. Reporting against the Paris Agreement commences in 2024 (DESNZ, 2023a).

The overarching goal of the Paris Agreement is to:

> *'Hold the increase in the global average temperature to well below 2°C above pre-industrial levels.'*

However, the UN IPCC indicates that even breaching the 1.5°C threshold risks severe climate change impacts, including more frequent and severe droughts, heatwaves and rainfall such that there is now increased pressure to limit global warming to 1.5°C by the end of this century. To achieve this, GHG emissions must peak before 2025, at the latest, and decline by 43 % by 2030.

Similar to the Kyoto Protocol, the Paris Agreement works on a five-year cycle of increasingly ambitious climate action and since 2020 it has been a requirement for each country to submit climate action plans, known as Nationally Determined Contributions (NDCs). Each successive NDC is meant to reflect an increasingly higher degree of ambition compared to the previous version.

The Paris Agreement also underlines the need for 'Net Zero' which refers to a state in which the GHGs going into the atmosphere are balanced by their removal out of the atmosphere. Therefore, the Paris Agreement requires states to 'achieve a balance between the emissions from anthropogenic sources and the removal of GHGs by sinks in the second half of this century'. The IPCC concluded that Net Zero must be achieved by 2050 in order to restrict the increase in global temperature to ≤1.5 °C.

In summary, Net Zero is the internationally agreed upon goal for mitigating global warming in the second half of the century.

In the UK, the Climate Change Act 2008 (CCA) is the key instrument for tackling and responding to the above commitments. The CCA requires the UK government to set legally-binding five-yearly 'carbon budgets' to act as stepping-stones towards the 2050 target. The carbon budget is a cap on the amount of GHG emissions permitted in the UK over a five-year period.

In June 2019, the CCA was amended to commit the UK to achieving a 100 % reduction in net emissions by 2050 (Net Zero). The most recent review and update of the Energy and Emissions Projections (EEP) 2019 (EEP, 2019) was published in October 2020. However, since this time, a partial and interim update, the 'Net Zero Strategy (NZS) Baseline', was published in December 2021 and a new reference scenario was published in October 2022.

An independent Committee on Climate Change (CCC) has been created under the CCA to provide advice to the UK Government on these targets and related policies.

Of importance, the UK ratification of the UNFCCC has been extended to the Falkland Islands. However, as yet, none of the UK Overseas Territories (UKOT) have had the Paris Agreement on climate change extended to them. Therefore, while the UKOT emissions are included within the UK reporting of national emissions statistics to the UNFCCC, the NDC and UK Carbon Budgets do not include emissions from the Falkland Islands. At the time of writing there are no budgets assigned to Falkland Islands and there is little guidance on what such allowances may be. However, the 'Information to facilitate Clarity, Transparency and Understanding' (ICTU) report, which accompanies the UK NDC, makes a commitment to:

> *'Updating on the progress made in expanding the territorial scope of the NDC to include the UK's Crown Dependencies and Overseas Territories' (House of Commons Library, 2023).'*

It is anticipated that should the Carbon Budgets be extended to include the UKOTs and Crown Dependencies, they will not be dramatically increased. However, the 8th National Communication (BEIS, 2022) does not suggest an expansion of UK budgets to the Falkland Islands and, therefore, the

UK Carbon Budgets (Section 10.9.4.3.3) as they stand have been used in this EIS as the only point of comparison available at this time (Section 10.9.4.5.5).

10.9.1.1.2 Global Methane Pledge and Zero Routine Flare Initiative

The Global Methane Pledge (GMP) was launched at COP26 in November 2021 to drive action to reduce methane emissions. The Pledge now has 111 country participants who together are responsible for 45 % of global human-caused methane emissions. By joining the Pledge, countries commit to work together in order to collectively reduce methane emissions by at least 30 % below 2020 levels by 2030.

The World Bank Zero Routine Flare (ZRF) Initiative, endorsed by the UK, was launched in 2015 and is linked to the GMP since some methane is emitted unburnt in the operation of flares. Flaring is essentially the burning of gas during steady oil production because of technical, regulatory, or economic constraints that mean the gas cannot otherwise be conserved or utilised. The ZRF initiative seeks to bring GHG emissions from routine operational flaring to an end by 2030. Non-routine flaring, such as for pilot flames or for safety reasons, may still take place.

The UK aims to achieve zero routine flaring and venting targets by 2030 or sooner. Navitas strive to comply with the principles of the Methane Pledge with the target of zero cold venting as part of the Phase 1 & 2 Development basis of design, and similarly with the ZRF initiative to achieve zero routine flaring.

Navitas is aware of the updated GMP 2.0 Framework and that the UK has signed up to this. Once UK legislation has been amended to enact the requirements of the GMP 2.0, Navitas will review the Framework and its commitments, in discussion with FIG.

10.9.1.1.3 MARPOL Annex VI on energy efficiency in shipping

In 1973, the IMO adopted the International Convention for the Prevention of Pollution from Ships, now known universally as MARPOL. The convention has been repeatedly amended and updated by the Marine Environmental Protection Committee (MEPC). Annex VI was introduced in 1997 and is concerned with both energy efficiency and the prevention of air pollution by shipping.

10.9.1.1.3.1 MARPOL: GHG and energy efficiency in shipping

CO_2 emissions from international shipping cannot be attributed to any particular national economy due to its global nature and complex operation such that shipping was not included within the Kyoto Protocol[77]. Therefore, in 2011, the IMO MEPC adopted mandatory technical and operational energy efficiency measures which are expected to significantly reduce the amount of CO_2 emissions from international shipping. Chapter 4 of MARPOL Annex VI (and associated amendments to Chapter 1 and 2) came into force in 2013. Chapter 4 applies to all ships of > 400 gross tonnage and requires the following:

- Mandatory:
  - Energy Efficiency Design Index (EEDI), for new ships, and
  - Ship Energy Efficiency Management Plan (SEEMP), for all ships.
- Voluntary:
  - Use of the Energy Efficiency Operational Indicator (EEOI).

The EEDI aims to promote the use of more energy efficient equipment and engines but as it applies to new ships only, including oil tankers, bulk carriers, general cargo and container ships, it may not apply to vessels used for the Sea Lion project.

[77] As of 2033, once the sixth Carbon Budget starts, emissions from UK international aviation and shipping (IAS) will be included within recorded emissions.

The Ship Energy Efficiency Management Plan (SEEMP) is a management tool and establishes a mechanism for ship operators to improve the energy efficiency of a ship during its operation lifecycle, in a cost-effective manner. It works according to planning, implementation, monitoring and review of a number of energy efficiency measures within a continuous improvement management cycle (IMO, 2016).

The EEOI is a performance monitoring tool used to:

- Measure fuel efficiency in different operational modes (e.g., vessel speed, trim and draft), and
- To gauge the effect of changes in operation such as improved voyage planning, more frequent propeller cleaning and / or the introduction of technical measures such as waste heat recovery systems or a new propeller (IMO, 2016).

By enabling identification of the most fuel-efficient modes of operation, the EEOI may be used to inform Key Performance Indicators (KPIs) within the SEEMP (IMO, 2016). Navitas will ensure the owners of all selected Conventional Trading Tankers (CTTs) use the EEOI when developing KPIs related to their operation (Section 5.10).

10.9.1.1.3.2 MARPOL: Air pollution (ODS, NOx, SOx, PM and VOCs)

The aim of Annex VI is the progressive reduction in global emissions of oxides of sulphur (SOx), oxides of nitrogen (NOx), Ozone Depleting Substances (ODS), Volatile Organic Compounds (VOCs) and Particulate Matter (PM) by shipping, and the introduction of Emission Control Areas (ECAs) to further reduce emissions of the above in designated sea areas.

10.9.1.1.4 Fluorinated Gas compliance

Fluorinated gases (F-Gases) are man-made gases which were designed to replace Ozone-Depleting Substances (ODS) for use within refrigerants, solvents, foam blowing agents, fire-fighting fluids and HVAC (Heating, Ventilation and Air-Conditioning). F-Gases do not deplete the ozone layer, are energy efficient and are safe due to their low levels of toxicity and flammability. However, despite not harming the ozone layer, F-Gases are very powerful GHGs and as such, the emission of F-Gases is prohibited and all unplanned releases must be reported.

The phase-out of F-gases is now being significantly accelerated by a tighter phase-down. Under the F-Gas Regulations 2015, the CCC proposed that F-Gases be replaced by low-carbon alternatives in refrigeration, air conditioning and other uses by 2030. However, under the F-Gas Regulations 2024, this will be tightened again and will continue until 2050 with a ban on all F-gases. Navitas will comply with all relevant FIG / UK legislation regarding the phase out of F-Gases.

10.9.1.1.5 Ozone Depleting Substances (ODS) compliance

Under the Montreal Protocol (which is aligned with MARPOL 73/78 Annex VI), the use of ODSs is being phased out. The phase-out of most ODSs is now complete. Notwithstanding critical use exemptions, the use of virgin and reclaimed / recycled Halon, chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs) in new equipment and during maintenance is now prohibited.

10.9.1.1.6 FIG Islands Plan 2022-2026 and Environmental Strategy 2021-2040

FIG's Islands Plan notes that the government will:

> *'Carry out work to measure and reduce our carbon emissions.'*

While the FIG Environmental Strategy (2021a) has an objective to:

'Conduct the extraction of non-renewable resources, including any hydrocarbon development, in a way that values and conserves our unique biodiversity and ecology, supported by effective regulation'

10.9.1.1.7 The Falkland Islands Energy Strategy and Implementation Plan 2023

At the time of writing FIG has prepared a new Falkland Islands Energy Strategy for which the public consultation period has recently closed.

10.9.2 Sources of atmospheric emissions

The main sources of emissions from the Phase 1 & 2 Development which may impact upon the environment include:

- Gaseous emissions from planned activities:
  - Combustion activities associated directly with the Phase 1 & 2 Development:
    - Fuel combustion by vessels during all operations,
    - Transportation of personnel and equipment *via* vessels, road vehicles, helicopters and fixed-wing flights,
    - Fuel combustion for power generation on the Mobile Offshore Drilling Unit (MODU),
    - Fuel combustion on the Floating Production, Storage and Offload Unit (FPSO) (Section 5.8.2.3). The combustion equipment on the FPSO includes:
      - 3 x dual fuel (fuel gas and diesel) Dry Low Emission (DLE) Turbines which will be available for power generation for all power consumers on the FPSO (Table 10.59). The primary fuel will be associated gas with diesel as a back-up. Details on the power demand of the key consumers are provided in Table 10.59 in order to inform the fuel consumption rates of the turbines,
      - 1 x gas fired steam boiler for heating the injection water in the first year of production for enhanced recovery,
      - 2 x auxilliary steam boilers,
      - 2 x diesel driven essential power generators,
      - 1 x diesel driven emergency power generators,
      - 1 x diesel driven hot oil circulation pump,
      - 2 x diesel driven fire pumps, and
      - 4 x diesel driven Totally Enclosed Motor Propelled Survival Craft (TEMPSC).
    - Contingency for well flow-back / testing to the MODU with associated flaring[78],
    - Commissioning of the gas compression system prior to start-up of gas injection and gas lift systems with associated flaring[79],
    - Maintenance of the High Pressure (HP) flaring pilot light on the FPSO, and
    - Use of diesel generators at the onshore supply base on an 'as needed' basis.

[78] The base-case assumes zero flaring during well clean-up to the FPSO and zero well testing. However, a contingency is held to flow four wells (3 x OP wells and 1 x GI well) back to the MODU. Details are provided in Section 5.4.8. This chapter presents both the worst-case baseline emissions, and those which will result if contingency flow-back to the MODU is carried out.

[79] Associated gas is liberated from the oil producing wells, this released gas generates pressure within the flowline. However, there is no facility for gas storage onboard the FPSO. Therefore, there needs to be sufficient volume of gas liberated to meet with the minimum operating parameters of the gas compression system on the FPSO to allow for a safe startup of the gas compression process. During commissioning, the initial start up of the gas compression system takes longer than a normal start-up as control system and instrumentation systems need to be calibrated and tuned before handing over to normal operations (Section 5.4.9).

- Contingency use of a waste incinerator at the supply base in the event that the FIG municipal waste facility is not yet operational,
- Fugitive emissions during diesel bunkering to LTVs in Berkeley Sound, and
- Fugitive emissions during cargo offloading / transfer from the FPSO to the CTT.

- Gaseous emissions resulting from potential unplanned or emergency events associated with the Phase 1 & 2 Development:
  - Emergency blowdown (the rapid depressurisation of high-pressure vessels and pipelines and flaring of the gas for safety purposes),
  - Venting of hydrocarbon gas blankets used to buffer the FPSO cargo tanks in the event that the Vapour Recovery Package fails, and
  - Accidental release of F-Gases.
- Indirect emissions from the use of purchased municipal electricity for the supply base warehousing and offices etc., and
- Indirect emissions from combustion of the sold product, for example, use of fuels created from Sea Lion crude oil in vessels, vehicle, aircraft etc.

Note: details on the use of vessels, helicopters and fixed wing flights during Stages 1 to 3 of the Development are provided in Section 5.11 of the Development Description.

Note: in compliance with the Montreal Protocol (Section 10.9.1.1.5) no ODSs will be used during the Phase 1 & 2 Development. Therefore, these are not listed as a source of emissions. To ensure compliance with the Montreal Protocol, all vessels will be audited prior to selection in line with Navitas' Contractor Management Strategy (Section 3.2.15). This is also ensured by compliance with MARPOL certification requirements during routine vessel registration.

Table 10.59: Key consumers of electricity generated by the DLE turbines[1]

Consumer	Purpose	Power demand (kW)
1st stage High Pressure (HP) compressor A	Gas compression for gas lift, fuel gas	1,527
2nd stage HP compressor A		1,247
Booster compressor A		826
1st stage HP compressor B		1,527
2nd stage HP compressor B		1,213
Booster Compressor B		826
1st stage HP compressor C		1,527
2nd stage HP compressor C		1,247
1st stage Low Pressure (LP) compressor A		170
2nd stage LP compressor A		102
3rd Stage Medium Pressure (MP) Compressor A	Gas compression for gas lift, fuel gas	173
LP Condensate Pump A	Move liquids from gas Knock Out (KO) drum	0.6
1st stage LP compressor B	Gas compression for gas lift, fuel gas	170
2nd stage LP compressor B	Gas compression for gas lift, fuel gas	102
3rd Stage MP Compressor B	Gas compression for gas lift, fuel gas	173
LP Condensate Pump B	Move liquids from gas KO drum	0.6
Produced Water Pumps	Move produced water forward for further processing	2.1
Produced Oil Pumps	Boost crude oil for further processing and storage	44.4

Consumer	Purpose	Power demand (kW)
Degassed water pumps	Transfer separated water for further processing	72
Recirculation pumps	Transfer off spec fluids for reprocessing	3
Seawater Booster pumps	Supply water for cooling and injection processing	147
Water Injection Pumps	Supply water for reservoir pressure / flood	4,176
Well Fracturing Pump (rental)	Frac when blockages occur	762
Hot oil circulation pump (2nd unit is diesel driven)	Flow assurance of subsea facilities	372
Gel Breaking hot oil pump	Topsides wax facilities assurance	201
LP Electrostatic Coalescer	Oil processing	19
Ships Utilities	Air, Nitrogen, lighting, etc.	2,751
Propulsion	Direction Positioning (DP)	1,175
Offloading	Cargo transfer to CTT	2,749

[1] Please note that a power use profile was not used. Instead, a flat fuel consumption profile was assumed that will be conservative in the related emissions estimates.

10.9.2.1 Base-case mitigations

Numerous base-case mitigations are built-in to the basis of design to minimise outputs from these sources. These are factored into the initial impact assessment (Section 10.9.6) and include:

- The main fuel supply for the FPSO will be produced gas,
- Use of waste heat recovery to reduce the need for active heat generation and therefore to reduce fuel consumption / CO_2 emissions,
- No planned flaring during ongoing well testing throughout Field Life,
- No routine flaring during normal production (notwithstanding the flare pilot light),
- Use of a Flare Recovery Package (FRP) during normal operations,
- No venting from the FPSO during normal production,
- Use of Vapour Recovery Package (VRP) during normal operations,
- Back-up inert gas generator for use as gas blanket in the event that the VRP malfunctions to prevent venting of hydrocarbon gas,
- Use of a vapour balancing system to pass blanket gases from the FPSO cargo tanks to the CTT cargo tanks, when available, during transfer of oil,
- The use of passive heat retention systems wherever possible to maintain working temperatures and flow assurance (Section 5.8.4.1), thereby preventing energy expenditure, and its associated emissions, on active heating systems,
- Follow international standards for piping, valves etc. and best practises for integrity management e.g., UK Step Change Hydrocarbon Toolkit,
- Use of Open Hole Gravel Pack (OHGP) completions which minimise downhole debris and reduce the requirement for well clean-up to the MODU, and thus the likelihood of associated flaring. The base-case is for the wells to be flowed straight back to the FPSO (**Note:** there is a contingency flow / test four wells to the MODU if considered necessary which would require flaring),
- Use of F-Gases with the lowest Global Warming Potential, and
- Use of Marine Gas Oil (MGO) instead of Intermediate Fuel Oil (i.e., a lighter fuel) when operating inshore.

10.9.3 Potential environmental receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts and / or risks of emissions warranted further investigation (Chapter 9). These include the impacts and risks to:

- The global atmosphere and the incremental and transboundary effects on:
  - Global warming (*via* the emission of GHG gases),
  - Oceanic water quality (*via* ocean acidification), and
  - Soil quality, water quality and / or flora and fauna (via acid deposition).

10.9.4 Characterising and quantifying the impacts and risks

When characterising and quantifying the global and transboundary environmental impact of emissions, it is necessary to consider the following:

- The characteristics, sources, composition and behaviour of gaseous emissions,
- The nature of the impacts,
- The existing emissions context:
  - Historic Falkland Islands' emissions,
  - Historic total UK emissions,
  - Recent Oil and Gas (O&G) emissions on the UK Continental Shelf (UKCS),
  - Carbon intensity over different O&G installations,
  - Projected future UK emissions, and
  - Global energy demand.
- Quantification of emissions from (and associated with) Phase 1 & 2 activities including:
  - Detail on the assumptions made during the emissions estimate,
  - Detail on fuel consumption rates,
  - Detail on the emissions factors used,
  - Estimation of worst-case emissions, and
  - Estimation of unplanned emissions:
    - Emergency blowdown,
    - Venting emissions offshore in event of VRP failure, and
    - F-Gas release.
  - Quantification of emissions from the use of municipal electricity, and
  - Quantification of emissions from the combustion of sold product.
- Comparison of Phase 1 & 2 emissions with the existing context:
  - Comparison with recent Falkland Island, total UK, and UKCS GHG emissions,
  - Comparison of the Phase 1 & 2 carbon intensity with other UKCS installations,
  - Comparison with projected future UK GHG emissions,
  - Comparison of NOx and SOx emissions, and
  - Comparison of emissions from combusted product with global emissions.

10.9.4.1 Characteristics, sources, composition and behaviour of emissions

Gases are emitted through the combustion of fossil fuels and the cold venting of gases (Table 10.60), the latter of which will not occur in the proposed Development. All of these gases can impact upon

global warming while CO_2, NOx and SOx also contribute to ocean acidification and NOx and SOx can lead to acid deposition.

Under the Kyoto Protocol, gaseous emissions can be grouped into direct GHGs and indirect GHGs. Each of these GHGs has the potential to contribute to global warming to differing extents and in order to estimate the impact of emissions, it is necessary to understand the Global Warming Potential (GWP) of each gas. The direct and indirect GHGs are described below followed by an explanation of the GWP.

10.9.4.1.1 Direct (Kyoto) GHGs

Direct GHGs include those that directly result in radiative warming of the atmosphere. These include gases that result from combustion (e.g., CO_2, N_2O), venting (e.g., CH_4) and the F-Gases which are used in closed systems e.g., HVAC. Together these make up the Kyoto greenhouse gases (Table 10.60).

10.9.4.1.2 Indirect GHGs

In addition to the direct GHGs, there are four gases that result from combustion and venting of fossil fuels which have an indirect GHG effect by increasing ozone (O_3) concentrations in the tropospheric layer (the lower 5-10 miles of the atmosphere) (Section 7.3.1). Specifically, O_3 in the tropospheric layer is produced when nitrogen oxides (NO_X), carbon monoxide (CO), sulphur dioxide (SO_2) and non-methane volatile organic compounds (NMVOC) react with sunlight such that these gases are known as 'ozone precursors' (Table 10.60).

Ozone is a GHG in its own right with a 100-year GWP of 1,000 (i.e., 1 tonne of O_3 is 1,000 times as powerful as CO_2 in its contribution to global warming (see below)) such that its creation can exacerbate global warming. Generally, however, tropospheric ozone is a short-lived GHG which decays in the atmosphere much faster than CO_2.

In addition to impacts upon global warming, the indirect GHGs are those which react in the atmosphere to produce acid rain (Table 10.60).

10.9.4.1.3 Global Warming Potential

The GWP of a gas is most commonly used to indicate how much heat would be absorbed by a gas over a 100 year period and is determined by understanding:

- How well the gas absorbs heat energy (preventing the heat from escaping to space), and
- How long the gas stays in the atmosphere.

To estimate the impact of each gas, all gases are compared to CO_2, which has a GWP of one (1). Therefore, the higher the GWP, the greater the influence a given gas has on global warming. When the GWP is applied to the estimated emissions for different gases, the result is expressed as the 'Carbon Dioxide Equivalent' (CO_2e); i.e., the equivalent amount of CO_2 that would have to be produced to result in the same degree of global warming.

The IPCC conducts periodic assessments on human-induced climate change and, based on the most recent scientific understanding, publishes the most up-to-date GWPs for each GHG. The Final UK Greenhouse Gas Emissions National Statistics 1990-2021 Report uses the GWP's (*without* climate-carbon feedback[80]) from Working Group 1 of the IPCC Fifth Assessment Report (AR5): Climate Change 2013 (IPCC, 2013). Further, the most recent Energy Emissions Projection Report (BEIS, 2022b) uses the same AR5 (w/o cc fb) GWP. Therefore, these will be used when comparing the estimated Phase 1 & 2 Development emissions with historic and projected UK emissions to enable like-for-like comparisons.

[80] Carbon-climate feedback processes refer to the effect that a changing climate has on the carbon cycle which in turn further changes the climate e.g., thawing permafrost releases soil carbon into the atmosphere, which serves to amplify warming and causes further thawing (Royal Society, 2021).

Of note, the UKCS emissions (Section 10.9.4.3.2.2) are estimated using the AR5 GWP's *with* carbon-climate feedback[59] (with cc fb). Therefore, to enable like-for-like comparisons in Section 10.9.4.5, the corresponding GWP's were used to recalculate the total Phase 1 & 2 Development emissions. The AR5 *without* feedback, and the AR5 *with* feedback GWPs are all presented in Table 10.60 and detail on which is used is indicated in each relevant section below.

Table 10.60: Summary of the Direct and Indirect greenhouse gases, the GWP, emission source and impact as a pollutant

GHG	100-year GWP		Source and behaviour	Impacts upon
	AR5[1] (w/o cc fb)	AR5[2] (with cc fb)		
Direct GHGs				
Carbon dioxide (CO_2)	1	1	CO_2 is emitted through fuel combustion. It serves as the baseline for other GWP values. CO_2 remains in the atmosphere for a very long time and changes in atmospheric CO_2 concentrations persist for thousands of years.	Global warming
				Ocean acidification
Nitrous oxide (N_2O)	265	298	N_2O is typically emitted through fuel combustion. N_2O emitted today remains in the atmosphere for up to 170 years.	Global warming
				Acid rain
				Air quality[3]
Methane (CH_4)[4]	28	34	While some CH_4 is emitted *via* the combustion of fuels, CH_4 is typically emitted through natural gas venting. While CH_4 absorbs more heat energy than CO_2, it is mostly removed from the atmosphere after about 12 years by chemical reaction.	Global warming
F-Gases:				
HFCs[5]	<1 -12,400	-	F-Gases are not emitted during the course of normal operations.	Global warming
PFCs[5]	<1-11,100	-		
SF_6[5]	23,500	-		
Indirect GHGs				
Nitrogen oxides (NO_X)[6]	-	-	NOx are produced during the combustion process when nitrogen and oxygen are present at elevated temperatures. Nitrogen oxides (NOx) consist of nitric oxide (NO), nitrogen dioxide (NO_2) and nitrous oxide (N_2O). Their lifespans in the atmosphere range from one to seven days for NO and NO_2, to 170 years for N_2O. Additionally, NOx are both ozone precursors and are formative in the Development of hydroxyl (OH) groups which destroy CH_4.	Global warming *via* ozone production
				Global cooling *via* destruction of CH_4
				Acid rain
				Air quality[3]
Sulphur dioxide (SO_2)	-	-	SO_2 is produced from the burning of fossil fuels that contain sulphur e.g., coal and oil. SO_2 dissolves easily in water to form sulphuric acid and is also an Ozone precursor.	Global warming *via* ozone production
				Global cooling from aerosol formation
				Acid rain
				Air quality[3]
	-	-	CO is produced by the incomplete burning of fossil fuels, including natural gas. CO is unique among pollutants in the lower atmosphere in that it lasts for approximately one	Global warming *via* ozone production

GHG	100-year GWP		Source and behaviour	Impacts upon
	AR5[1] (w/o cc fb)	AR5[2] (with cc fb)		
Carbon monoxide (CO)			month which is long enough for it to be transported long distances but not long enough to be distributed uniformly. CO is also an ozone precursor and reduces OH thus reducing CH_4 destruction	Air quality[3]
NMVOC[7]	-	-	NMVOCs are organic compounds that easily become vapours or gases. They include non-methane hydrocarbons (NMHC) and oxygenated NMHC (e.g., alcohols, aldehydes and organic acids). Along with carbon, they contain elements such as hydrogen, oxygen, fluorine, chlorine, bromine, sulphur or nitrogen. Many VOCs can react with other air pollutants to produce ground level ozone.	Global warming *via* ozone production

[1] In order to compare the Phase 1 & 2 emissions with the historical, and the projected future, UK emissions, the GWPs (*without* climate-carbon feedback) of Working Group 1 of the IPCC Fifth Assessment Report (AR5): Climate Change 2013 (IPCC, 2013) are used to estimate the project emissions. Note that once into steady state production, the current guidance on GWPs will be applied for all Phase 1 & 2 emissions accounting and reporting.

[2] In order to enable like-for-like comparisons between the Phase 1 & 2 Development emissions and the emissions recorded from the O&G industry on the UKCS (Section 10.9.4.3.2.2), the AR5 GWPs *with* climate-carbon feedback are used (Section 10.9.4.5.3).

[3] As described in Chapter 9, impacts to air quality have been scoped out owing to distance of the offshore location from environmental and social receptors, and owing to the short duration of LTV presence in Berkeley Sound.

[4] The GWP for methane includes indirect effects of tropospheric ozone production and stratospheric water vapour production.

[5] HFC = Hydrofluorocarbons, PFC = Perfluorocarbons and SF_6 = Sulphur hexafluoride.

[6] The short lifetime and complex nature of the impact of NOx on global warming through ozone enhancement, traded against the cooling effect of CH_4 reduction, make calculations of the GWP for NOx emissions uncertain (IPCC, 2007). The net radiative forcing of NOx emissions depends strongly on the location of emission and seasonal and daily timing.

[7] Non-methane volatile organic compounds.

10.9.4.2 Nature of the impact

The potential impacts to the varying receptors result from the following processes:

- Global warming from the emission of combustion-based, and other GHGs,
- Ocean acidification from the emission of CO_2, NOx and SOx, and
- The formation of acid rain from the emission of NOx and SOx.

10.9.4.2.1 GHGs and global warming

While the greenhouse effect is a natural and essential dynamic, which is required to enable life on Earth (Section 7.3.1), the increasing quantity of anthropogenic GHGs in the atmosphere accelerates the process of long-term global warming. According to the IPCC, recent anthropogenic emissions of greenhouse gases are the highest in history and changes in climate have caused impacts on natural and human systems on all continents and across the oceans.

The global consequences of atmospheric emissions include:

- Rising sea levels owing to the melting of Arctic, Antarctic and worldwide glacial ice:
  - Changing coastlines.
- Changing climate zones / weather patterns leading to:
  - Changes to ecosystems and biodiversity, and
  - Economic impacts on infrastructure, agriculture and tourism.

In 2018, the IPCC were commissioned to produce a Special Report comparing the impacts incurred by current day global temperatures with the impacts incurred by an increase of 1.5°C and 2°C (IPCC, 2018). Climate models projected robust differences in regional climate characteristics with increasing global temperature changes. These differences were to the extent of:

- Increases in mean temperature in most land and ocean regions,
- Hot extremes in most inhabited regions,
- Heavy precipitation in several regions,
- The probability of drought and precipitation deficits in some regions,
- Impacts on biodiversity and ecosystems, including species loss and extinction, and
- Risks to health, livelihoods, food security, water supply, human security, and economic growth.

Successfully limiting global warming to 1.5°C compared to 2°C is projected to:

- Lower the impacts on terrestrial, freshwater and coastal ecosystems and to retain more of their services to humans, and
- Reduce increases in ocean temperature as well as associated increases in ocean acidity and decreases in ocean oxygen levels.

Consequently, limiting global warming to 1.5°C is projected to reduce risks to marine biodiversity, fisheries and ecosystems, and their functions and services to humans, as illustrated by recent changes to Arctic Sea ice and warm-water coral reef ecosystems (IPCC, 2018).

It is anticipated that many aspects of climate change, and its associated impacts, will continue for centuries, even if anthropogenic emissions of GHG were to cease now (IPCC, 2014). However, under the Paris Agreement and the target of Net Zero, there is now increasing pressure to prevent the global temperature increase from exceeding 1.5°C over the pre-industrial levels.

A project was carried out by Upson *et al.* (2016) under the TEFRA (Terrestrial Ecosystems of the Falklands – a climate change Risk Assessment) project to consider the impacts of climate change on the terrestrial environment of the Falklands. The following potential impacts are identified:

- Changes in plant pests, diseases and invasive plants,
- Increased drying and erosion of soils,
- Inability of native plants unable to shift ranges or track changes in order to survive predicted warming, and
- Habitat disturbance by extreme events from, for example, increased risk of fires and decreases in soil carbon content.

10.9.4.2.2 Ocean acidification

CO_2 is highly soluble in water and consequently the oceans absorb CO_2 from the atmosphere by direct air-sea exchange making the oceans a global 'carbon sink' (i.e., a natural body which reduces carbon in the atmosphere). The exchange process equilibrates surface water CO_2 to atmospheric levels within a timescale of approximately one year (Doney, *et al.,* 2009). However, while the absorption of CO_2 from the atmosphere into the oceanic carbon sink could be beneficial with regard to global warming, there is an associated cost.

When CO_2 dissolves in seawater it forms carbonic acid (H_2CO_3). Over long timescales this reaches an equilibrium, and the chemical dynamics of carbonic acid in seawater serve to maintain pH in a relatively narrow range. However, recent increases in atmospheric CO_2, and therefore increases in carbonic acid concentrations, are resulting in a change to this equilibrium and a decrease in the pH, thus moving oceans toward a more acidic state. Increasing atmospheric CO_2 concentrations are expected to decrease surface ocean pH by 0.3 – 0.5 units by 2100 (Caldeira and Wickett, 2003; Orr, *et al.,* 2005). This is exacerbated at higher latitudes as CO_2 is more soluble at lower temperatures.

In addition to CO_2, the emission of NOx and SOx from emissions in the form of wet and dry acid deposition can also contribute to global ocean acidification (Doney, *et al.,* 2007). Atmospheric inputs of the dissociation products of nitric acid (HNO_3) and sulphuric acid (H_2SO_4) alter surface seawater pH, and inorganic carbon storage. Acid deposition of this kind does create an interesting dynamic however as the decrease in surface alkalinity drives a net air–sea efflux of CO_2, which actually reduces the surface levels of dissolved inorganic carbon so that the effects can offset each other, and the overall decline in surface pH is small (Doney, *et al.,* 2007).

The main effect of ocean acidification is the lowering of calcium carbonate ($CaCO_3$) saturation states, which impacts upon shell-forming marine organisms from plankton to benthic molluscs (e.g., snails, mussels and alike), echinoderms (e.g., urchins, sea cucumbers, sea lilies etc.), and corals (Doney, *et al.,* 2009). Quantification of the impact of acidification on the ability of individual species to calcify remains elusive. However, reduced skeletal growth under increased CO_2 levels has already been shown for corals, molluscs and many other marine organisms (Rodolfo-Metalpa, *et al.,* 2011). For further detailed reviews, see Mundy *et al.*, 2020 and Caldeira *et al.*, 2003.

While the direct and indirect effects of gradual global warming and subsequent heatwaves have emerged as the most pervasive drivers of observed impact and potent threat across all marine foundation species, the effects from ocean acidification, along with sea level rise and increased storminess, are expected to increase (Wernberg, *et al.,* 2024).

The Southern Ocean is naturally undersaturated with $CaCO_3$ which, along with low temperatures, means shell-forming in Antarctica requires more energy than in other oceans. The Southern Ocean is understood to sequester a disproportionally large share of anthropogenic CO_2 and accounts for *c.* 40 % of the global oceanic uptake. The effects of ocean acidification may therefore be greater in the

Southern Ocean than other oceans if GHG emissions continue on their projected trajectory (CCAMLR report CCAMLR-XXIX/BG/24, 2010) due to decreased $CaCO_3$ as well as the impacts on trace metals (Trimborn, *et al.,* 2017).

10.9.4.2.3 NOx, SOx and acid deposition

Acid deposition is a broad term that describes several ways through which acid falls out from the atmosphere. These emissions can be dry or wet (acid rain). The principal cause of acid rain is the emission of NOx and SOx from the combustion of fossil fuels (Table 10.60 above) which react with water molecules to form sulphuric and nitric acid in the atmosphere (Singh and Agrawal, 2008; OECD, 2013). While dry deposition generally occurs close to the point of emission, depending upon the quantity of emissions, wet deposition may occur thousands of kilometres away from the original source of emission.

The acidification of rain-water is identified as a serious environmental problem of a transboundary nature (WBG, 1998a; Singh and Agrawal, 2008; Beylot and Villeneuve, 2013). According to Singh and Agrawal (2008), the OECD (2013) and Doney *et al.* (2007) the potential impacts of acid deposition and nitrogen oxides include:

- Land-based impacts:
  - Impacts on forest ecosystems which can vary greatly according to soil type, plant species, atmospheric conditions, insect populations, and other factors that are not well understood (WBG, 1998b):
    - Increases in the soil acidity causing a decrease in soil fertility and negative impacts on growth and productivity of forest trees and crop plants, and
    - Direct damage to foliage.
  - Acidification of water bodies causing large scale negative impact on aquatic organisms including fish,
  - Effects on the human population *via* impacts on human health and the eroding of infrastructure, and
  - Eutrophication and subsequent changes in water quality and species richness resulting from NOx emissions (OECD, 2013).
- Oceanic impacts:
  - Lowering of oceanic and coastal pH (Section 10.9.4.2.2 above).

10.9.4.3 GHG emissions context

In order to inform the assessment of the 'severity of effect' of the Phase 1 & 2 emissions, it is necessary to quantify the Falkland Islands and UK emissions to enable comparison.

10.9.4.3.1 Historic Falkland Islands GHG emissions

Atmospheric emissions statistics for the Falkland Islands (as provided by the FIG Environment Department in 2024) indicate that the emissions in 2021 were equal to 0.422 million tonnes CO_2e (Table 10.61). Table 10.62 shows the Falkland Islands' emissions by IPCC sector. It is important to note that, at the time of writing (June 2024), the Falkland Islands' data between 1990 and 2021 do not include:

- Emissions from international aviation and shipping and vessels associated with the fishing industry e.g., reefers etc.,
- Emissions arising from previous Oil and Gas (O&G) exploration campaigns, and
- Emissions of the indirect GHGs (NOx, SO_2, CO and VOC).

These data gaps must be taken into account when making direct comparisons as is carried out in Section 10.9.4.5.1 below as the Phase 1 & 2 estimates include all sources of emissions. All comparisons between the Phase 1 & 2 Development and Falkland Islands emissions must therefore be caveated.

Table 10.61: Summary of historical Falkland Islands' emissions of direct Kyoto GHGs[1]

Emission Year	Direct GHG ($MtCO_2e$) [2]						Total ($MtCO_2e$)
	CO_2	CH_4	N_2O	F-Gases			
				HFCs	PFCs	SF_6	
1990	0.267	0.188	0.099	0.000	0.000	0.000	0.554
1995	0.203	0.178	0.095	0.000	0.000	0.000	0.477
2000	0.191	0.166	0.090	0.000	0.000	0.000	0.446
2005	0.192	0.147	0.079	0.001	0.000	0.000	0.418
2010	0.184	0.120	0.067	0.001	0.000	0.000	0.372
2015	0.277	0.118	0.069	0.001	0.000	-	0.464
2016	0.164	0.117	0.067	0.001	0.000	-	0.349
2017	0.197	0.121	0.069	0.001	0.000	-	0.387
2018	0.206	0.114	0.065	0.001	-	-	0.386
2019	0.200	0.118	0.067	0.001	-	-	0.385
2020	0.188	0.110	0.063	0.000	-	-	0.362
2021	0.233	0.120	0.069	0.001	-	-	0.422

[1] Falkland Islands emissions data provided by FIG Directorate of Policy, Economy and Corporate Services Policy Department in February, 2024.
[2] Note that these estimations are based upon GWPs from the IPPC Fifth Assessment Report (without carbon climate feedback) (Table 10.60 above).

Table 10.62: Summary of historical Falkland Islands' emissions of Kyoto GHGs by IPCC sector[1]

Year	Direct ($MtCO_2e$) [2]					Total [6] ($MtCO_2e$)

[1] Source: Falkland Islands' emissions data provided by FIG Environment Department[ibid] (February, 2024) grouped according to the IPCC categories listed within the UK GHG Inventory, 1990 to 2021 (DESNZ, 2023a).
[2] Note that these estimations are based upon GWPs from the IPPC Fifth Assessment Report (without carbon climate feedback) (Table 10.60 above).
[3] These data exclude previous O&G operations.
[4] These data exclude international aviation and shipping. They include emissions from primary fishing vessels (i.e., Jiggers, Trawlers, Longliners, Potters and Combos but exclude fisheries associated vessels e.g., reefers). Data collected by FIG for these values include number of vessels and volume of fuel (FIG, *pers. comm.*),
[5] LULUCF: 'Land and use, land-use change and forestry', and

[6] Total represents the total of Falkland Islands emissions in CO_2e, not the sum of the columns.

10.9.4.3.2 Historic UK GHG emissions

To inform the assessment on the impact of Phase 1 & 2 emissions on the UK's ability to meet commitments under the Paris Agreement and the CCA, it was considered appropriate to use the total UK emissions (which include the Falkland Islands emissions as a UKOT (DESNZ, 2023a)) as a point of comparison. However, in order to provide a more direct comparison between Navitas and its peers, data are also provided for emissions from the UK Continental Shelf (UKCS) between 2018 and 2022. Additionally, a benchmark for carbon intensity is also provided to enable a point of comparison for the Development.

10.9.4.3.2.1 Total UK emissions

According to the UK GHG Inventory 1990 to 2021 (DESNZ, 2023a) the 2021 UK emissions (including those from UKOTs and Crown Dependencies that are party to the UK ratification of the UNFCCC and therefore including the Falkland Islands) amounted to 430.7 $MtCO_2e$ (Table 10.63). As shown in Table 10.64, emissions from the energy sector (88 .1 $MtCO_2e$) in 2021 specifically accounted for 20 % of all direct GHG emissions. Within the energy sector, 17 % (14.9 $MtCO_2e$) of emissions were from the O&G industry on the UKCS in 2021 (Section 10.9.4.3.2.2 below). Note that emissions of the indirect GHGs are not included in the national totals and do not require reporting. However, indirect GHG emissions (to 2021) are shown below.

Table 10.63: Summary of historical total UK emissions (including the UKOTs and Crown Dependencies) of direct Kyoto GHGs[1]

Emission Year	Direct GHG ($MtCO_2e$) [2, 3]						Total ($MtCO_2e$)
	Net CO_2	CH_4	N_2O	F-Gases			
				HFCs	PFCs	SF_6	
1990	607.3	150.9	44.4	12.1	1.5	1.2	**817.5**
1995	569.2	144.2	35.7	15.6	0.5	1.3	**766.5**
2000	569.7	124.3	26.9	7.0	0.5	1.9	**730.2**
2005	568.4	101.3	23.3	8.7	0.4	1.1	**703.1**
2010	508.6	75.7	20.7	11.5	0.3	0.7	**617.5**
2015	417.9	63.0	20.1	13.3	0.3	0.4	**515.0**
2016	394.8	60.9	19.6	13.4	0.3	0.4	**489.5**
2017	382.4	61.3	20.0	13.3	0.4	0.5	**477.8**

Total UK Indirect GHG emissions

The indirect GHG emissions (to 2021) are shown in Table 10.65.

Table 10.65: Total UK Emissions of indirect GHGs for 1990 to 2021[1]

Emission Year	Indirect Greenhouse Gases (million tonnes)			
	NOx	CO	SO_2	NMVOC
1990	2.861	7.725	3.591	2.76
1995	2.467	6.357	2.541	2.279
2000	1.984	4.888	1.305	1.71
2005	1.752	3.266	0.789	1.241
2010	1.251	1.978	0.467	0.914
2015	1.02	1.608	0.27	0.824
2018	0.848	1.491	0.177	0.842
2019	0.794	1.423	0.157	0.824
2020	0.685	1.292	0.134	0.799
2021	0.689	1.312	0.127	0.783

[1] Final UK greenhouse gas emissions national statistics 1990-2021 (DESNZ, 2023a) including all UK emissions and those from UKOTs and Crown Dependencies.

10.9.4.3.2.2 Recent UKCS emissions

To enable a more direct comparison with the UK O&G industry, emissions data from the most recent OEUK Annual Environmental Report (OEUK, 2023) were used. The report does not provide a breakdown of the individual pollutants and, instead, provides only the total emissions in $MtCO_2e$ over each of the last five years (Figure 10-39). The UKCS emissions include those associated with offshore O&G exploration and production operations and excludes emissions from vessels associated with the construction and installation processes, supply, maintenance and surveys, shuttle tankers or export tankers, aviation, onshore activities and any other offshore industries. Given that the estimated Phase 1 & 2 emissions include emissions from construction, installation, MODU / FPSO transit, vessels and helicopter use it should be noted that comparisons are not like-for-like and the Development emissions may be over-represented.

Further, please note that in estimating the emissions, the OEUK report uses the AR5 GWP *with* carbon feedback whereas the total UK emissions, and the Phase 1 & 2 estimates use the AR5 GWP *without* carbon feedback. The GWPs with carbon feedback are slightly higher than those without feedback and therefore, to avoid under-representing the Development emissions, the Phase 1 & 2 emissions are recalculated using the same GWP as the OEUK data below (Section 10.9.4.5.3).

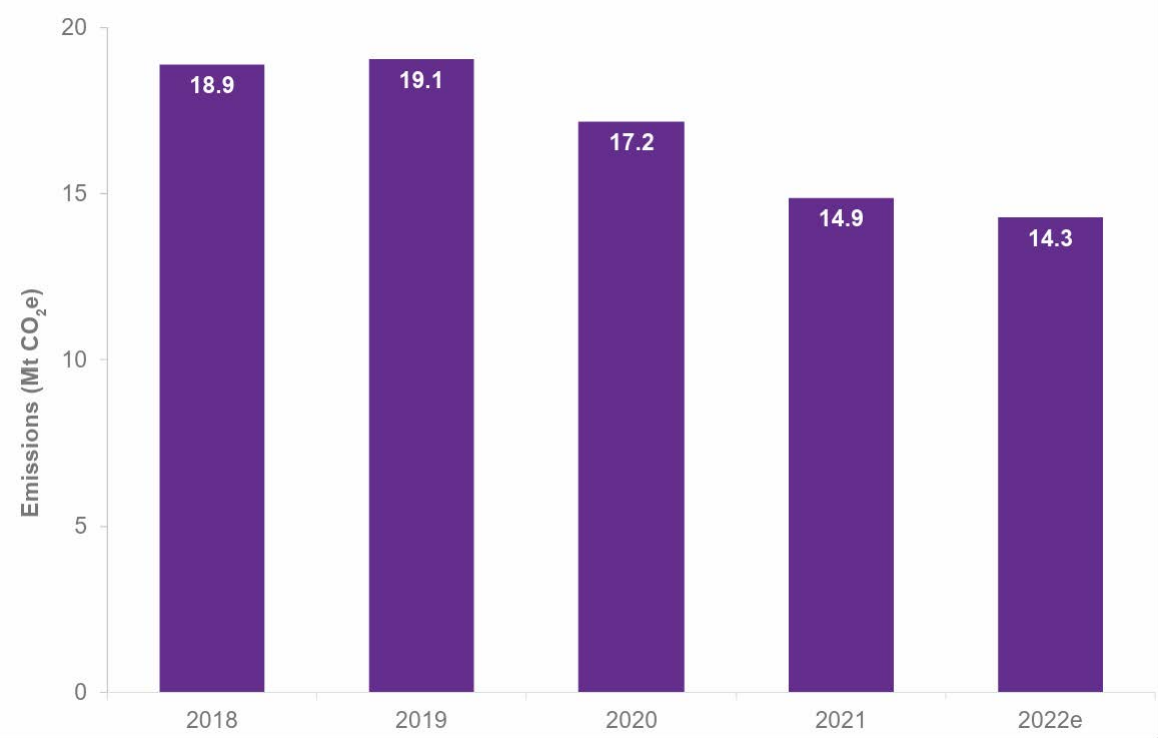

Figure 10-39: Total UKCS emissions

10.9.4.3.2.3 Carbon Intensity

In addition to estimating the absolute emissions associated with a project over a given period of time in order to enable comparison with total UK emissions, it is useful to measure the carbon intensity. Carbon intensity metrics refer to the amount of GHG emissions per unit of output in order to normalise changes in emissions due to changes in project activity. They are also a useful measure of efficiency when aiming to reduce overall emissions.

Table 10.66 indicates the carbon intensity of installations on the UKCS in 2023 based on installation age, type and size.

Table 10.66: Carbon intensity of UKCS installations, 2023 ($kgCO_2e$/boe)

Age / Asset	Small platform	FPSO	Large Platform
0 – 10 years	6	20	12
11 – 25 years	18	36	20
>25 years	33	34	52

(Source: NSTA Emissions Monitoring Report 2024)

10.9.4.3.3 Projected future total UK GHG emissions

It is acknowledged that while the Falkland Island emissions are reported to the UNFCCC as part of the UK emissions totals, UK ratification of the Paris Agreement has not yet been extended to the Falkland Islands as a UK Overseas Territory. Therefore, emissions from all UKOTs and Crown Dependencies are not included within the UK NDC and are therefore not included in the UK Carbon Budget (Section 10.9.1.1.1). At the time of writing there are no budgets assigned to the Falkland Islands and there is little guidance on what such allowances may be. It is anticipated that should the Carbon Budgets be extended to include the UKOTs/Crown Dependencies, they will not be dramatically increased and the UK Carbon Budgets as they stand have been used as the only point of comparison available at this time.

Table 10.67 shows the UK Carbon Budgets set under the UK CCA (Section 10.9.1.1.1) alongside the projected future emissions (EEP, 2019). As shown in Table 10.67, the actual UK emissions were equal to the first carbon budget target and were less than the second carbon budget. The projected emissions for the next two reporting periods (3 and 4) indicate that the emissions will remain below the targets. However, taking into account the ever more stringent targets and the uncertainty around projected data, the projected UK emissions during the future carbon budget periods (5 and 6) are expected to exceed the targets. The UK Government is currently considering ways to reduce emissions toward the goal of Net Zero by 2050 and the Energy and Emissions Projection reports are updated as necessary to take account of the UK Net Zero Strategy.

Table 10.67: Carbon Budgets[1] and actual[2] and projected[3] UK[4] CO_2e emissions and targets

Carbon budget period [1,4]		Allocated UK CO_2e budget ($MtCO_2e$)[5]	Number of years	Average allocated UK $MtCO_2e$ per year [1]	Total projected UK Carbon emissions ($MtCO_2e$)	Average projected UK $MtCO_2e$ per year (over 5 years)	Difference between UK target and projected UK emissions ($MtCO_2e$)
1	2008 to 2012	3,018	5	603.6	3,018[2,5,6]	603.6	Zero
2	2013 to 2017	2,782	5	556.4	2,565[2]	513.0	-217
3	2018 to 2022	2,544	5	508.8	2,181[3]	436.2	-363
4	2023 to 2027	1,950	5	390.0	1,930[3]	386.0	-20
5	2028 – 2032	1,725	5	345.0	1,798[3]	359.6	+73
6[7]	2033 – 2037	965	5	193.0	1,714[3]	342.8	+749
7[7]	2038 – 2042	To be set in 2025	5	-	-	-	-

[1] Climate Change Committee (ww.theccc.org.uk) – the independent, statutory body established under the Climate Change Act 2008

[2] Final UK greenhouse gas emissions national statistics 1990-2021 (DESNZ, 2023a). **Note:** GWPs used are from Working Group 1 of the IPCC Fifth Assessment Report: Climate Change 2013 (without carbon climate feedback) (see also Note 5 below).

[3] **Note:** The most recent previous full update of the Energy and Emissions Projections 2019 - 2040 (EEP, 2019) was published in October 2020. However, a more recent partial interim update, the Net Zero Strategy (NZS) Baseline, was published in December 2021 and a more recent reference baseline was published in 2022. These estimates are taken from Updated energy and emissions projections 2021 to 2040: October 2022. **Note:** Projected emissions provided in the report utilise 100-year GWPs from the Fifth IPPC Assessment Report (AR5 without climate feedback) (See AR5 Table 8.A.1). The projections assume application of all 'EEP-ready' policies (policies that have been implemented and those that are planned where the level of funding has been agreed and the design of the policy is near final) at the time of report publication (2022). EEP-ready policies in this edition include some of the policies and proposals from the Net Zero Strategy, whilst others are yet to reach the required state of development and will therefore be included in later editions. It is notable that with projections based on the current EEP-ready policies, the fifth and sixth carbon budgets will be exceeded.

[4] It is acknowledged that the Falkland Island emissions are not yet included within the UK Carbon Budgets (see narrative above).

[5] Carbon budget periods are as agreed under the Climate Change Act and are not necessarily aligned to the previous Kyoto reporting periods.

[6] **Note:** The actual emissions data vary:

- According to the UK Greenhouse Gas Inventory, 1990 to 2012 (DECC, 2014), the actual emissions for 2008 – 2012 were 2,964 $MtCO_2e$.
- According to the Final UK greenhouse gas emissions national statistics 1990-2018, the 2008 – 2012 were 2,953.7 $MtCO_2e$.
- In the Final UK greenhouse gas emissions national statistics 1990-2021 (DESNZ, 2023a), this figure has changed to 3,018 which directly matches the carbon budget. It is not clear why this change has occurred although it may be due to the use of different GWPs with IPCC AR4 figures used in the earlier estimates. Similar variations exist for 2013 – 2017 also.

[7] The 6th Carbon Budget, and subsequent budgets will include international aviation and shipping (IAS).

10.9.4.3.4 Global energy demand

According to the IEA, global oil demand as of December 2023 was 101.7 MMstb per day and was on track to average 102.8 MMstb per day in 2024 (IEA, 2023; 2024). This figure is driven by several key factors, such as the recovery from the COVID-19 pandemic, geopolitical tensions impacting supply

chains (such as the Russia-Ukraine conflict), and the accelerating transition toward renewable energy sources. While demand continues to grow in emerging economies, particularly in Asia, a structural decline in demand is observed in many advanced economies due to energy efficiency measures and shifts toward cleaner energy technologies.

The Global Energy Outlook 2023 (Raimi, *et al.,* 2023) provides a synthesised analysis from 15 different scenarios for future oil demand. This analysis notes that under most scenarios, global oil demand is considerably lower by 2050 than it is today. Raimi *et al.* (2023) observe that under Reference Scenarios from ExxonMobil, IEEJ, and OPEC, oil consumption plateaus in the 2030s and remains at or above 100 mb/d through 2050, recognising this as a level that is incompatible with achieving international climate targets. Evolving Policies scenarios illustrate a fairly wide range of future consumption, but scenarios that limit global temperature rise to 1.5°C by 2100 project that oil demand falls to roughly 20 to 25 mb/d by midcentury (Raimi, *et al.,* 2023). The large range in future trends underscore a complex interplay between energy security, economic growth, and climate imperatives.

Table 10.68 shows two end-member future scenarios which capture the range of future oil demand forecasts. The IEA STEPS (Stated Policies Scenario) (Table 10.68, Scenario 1) represents a projection of future energy demand based on current government policies and announced commitments, assuming they are implemented as stated. For oil demand, this scenario considers how factors like economic growth, population trends, and technological developments will interact with these policies. It reflects a middle-ground view, where no significant additional climate policies beyond those already planned or pledged are assumed. Under STEPS, oil demand remains resilient in the near term but plateaus and starts to decline from 2035 as energy efficiency improves and alternatives gain traction.

The BP Net Zero scenario (Table 10.68, Scenario 2) envisions a future where the world takes aggressive action to achieve net-zero carbon emissions by 2050. This scenario has been designed to achieve a Net Zero outcome. In this scenario, oil demand declines rapidly as countries prioritise renewable energy, electrification, and energy efficiency while phasing out fossil fuels. This is driven by stricter climate policies than currently exist, shifts in consumer behaviour, and significant advancements in clean technologies. By 2050, oil use in this scenario is dramatically reduced, playing a much smaller role in the global energy mix.

The Sea Lion emissions associated with the combustion of sold product, as they compare to emissions from the above global demand scenarios, are provided in Section 10.9.4.5.7 below.

Table 10.68: Current daily global oil demand (as of December 2023 as reported by IEA) and two future global oil demand scenarios.

Global Oil Demand Scenarios[1]	2023	2030	2035	2050
	Average Daily Global Oil Demand (MMstb/d) - EIA Dec 2023[3]	Average Daily Global Oil Demand (MMstb/d)	Average Daily Global Oil Demand (MMstb/d)	Average Daily Global Oil Demand (MMstb/d)
1. World Oil Demand - Scenario IEA STEPS (MMstb/d)[2]	101.7	101.7	99.1	93.1
2. World Oil Demand - Scenario BP Net Zero (MMstb/d)[2]	101.7	77.5	62.1	18.2

[1] Two end-member future scenarios are presented which capture the range of future oil demand forecasts: IEA STEPS which predicts a relatively small reduction in future global oil demand, and the BP 2023 Net Zero scenario from the Global Energy Outlook (2023) which is one of the most aggressive scenarios in terms of reduction in global oil demand.
World Oil Demand – STEPS Scenario IEA from Table A.9 in 2024 World Energy Outlook (https://iea.blob.core.windows.net/assets/6a25abba-1973-4580-b6e3-ba014a81b458/WorldEnergyOutlook2024.pdf)
World Oil Demand – Scenario BP Net Zero from Resources for the Future Global Energy Outlook (https://www.rff.org/publications/data-tools/global-energy-outlook/)
[2] Note that the source documents express the volumes in mb/d which, in these documents, refers to million barrels of oil per day. The units have been changed here for consistency as in the O&G industry mb/d often denotes thousand barrels of oil per day.
[3] Daily global oil demand from IEA as at Dec 2023 (Oil Market Report - December 2023, IEA, Paris https://www.iea.org/reports/oil-marketreport-december-2023).

10.9.4.4 Quantification of emissions from (and associated with) Phase 1 & 2

All emissions reduction technologies built-in to the basis of design (Section 10.9.2.1) have been factored into the estimation of emissions from planned activities.

As described above (Table 10.60 above), direct and indirect GHGs include those that result from the combustion of fuels (e.g., CO_2, N_2O, NOx, SO_2) and those that result from the direct venting of gas (e.g., CH_4). While F-Gases are also considered to be direct GHG, these are used in closed systems and therefore do not require emissions factors.

The amount of GHG emission resulting from the above activities is calculated as follows (from DESNZ, 2023a):

'Activity (source and amount of fuel/material combusted)' x 'the Emissions Factor for the GHG' = GHG emission'

10.9.4.4.1 Assumptions regarding source activities

Estimation of the emissions associated with a project requires an understanding of the fuel consumption rates of the combustion equipment used for both generation of electricity (the GTGs) and heat (the gas fired steam boiler). Understanding of the fuel consumption requires an understanding of the power demands of the consumers (Table 10.59 above). Emissions also result from other sources such as flaring, vessel use, fugitive emissions etc.

While these can be estimated and itemised according to an expected and best-case scenario, it is prudent to assume a degree of uncertainty and to estimate the emissions based on a worst-case scenario. Table 10.69 indicates the expected base-case with regard to operations alongside the worst-case assumptions used to estimate the emissions associated with the Phase 1 & 2 Development. The emissions estimates provided in Section 10.9.4.4.4 below, and the impact assessment provided in Section 10.9.6 both assume the worst-case as detailed below.

Table 10.69. Indicating the expected Development activity and the worst-case assumptions used for the emissions impact assessment

Source	Currently expected base-case[1]	Worst-case assumptions
Power generation on the FPSO	**The following estimates assume the use, at any one time, of two out of the three available DLE Turbines (9.7MW each) to power the consumer units which are itemised in Table 10.59 above.** **Fuel gas:** • Fuel gas is expected to become available 3 - 4 weeks after First-Oil. • During the first year of operation, fuel gas consumption is expected to average at *c.* 9.5 mmscfd every day with peak days of *c.* 12 mmscfd during offloads. While offloads at peak production are expected to occur every 7 - 10 days, they will be intermittent during the first year of production as the system is commissioned. Therefore, an average fuel gas use of 9.8 mmscfd can be assumed for the first year after First-Oil. o Fuel consumption in the initial months of Phase 1 production and the initial months of Phase 2 production is higher than in subsequent years due to the combustion of fuel gas to heat the injection water (Section 5.8.5.8). Heating this water requires *c.* 2.5 mmscfd of fuel gas to the steam boiler (Section 5.8.2.3). o Heated injection water is required for a total of 12 months across the initial Phase 1 & 2 production operations. After this it is expected that there will be a sufficient volume of hot water already in the reservoir to provide a buffer between the cold injected water and the oil to prevent wax formation. o After cessation of injection water heating, fuel gas consumption will drop down to *c.* 7.3 mmscfd. • The need / uses for power over the life of field decreases as production volumes decline such that fuel gas consumption is predicted to be[2]: o Production year 1: 9.8 mmscfd. o Production year 2: 7.3 mmscfd. o Production years 2 to 15: 6.5 mmscfd o Production years 15 to 30: 4.2 mmscfd	**Fuel gas:** • Assume fuel gas will not come online for up to three months and that diesel will be used for these three months at a rate of 35 mt/d. • Adding a 20 % contingency to the fuel gas usage, the average fuel gas consumption rate is assumed to be 6.6 mmscfd over Field Life. This is an overestimate to account for the worst-case fuel gas use assumptions that: o Injection water requires heating for a total period of 24 months, requiring extended use of the gas fired steam boiler[3], o Even during an extended stabilisation period there would still be periods of fuel gas supply, and o There will be 100 % uptime of the fuel gas system (which effectively means an element of double-counting of emissions given the assumptions below on diesel use but this is assumed to ensure a worst-case[4]). **Fuel gas Conversion rate:** • The conversion rate based on sampling has been estimated at 21.87 t per mmscf of gas[5]. **Diesel:** • Adding a contingency to the diesel use rate, the consumption rate is assumed to be 6.6 mt/d when fuel gas is available, (assumed to be 93 % of the time): o With the addition of a third dual fuel GTG the availability of using fuel gas for power

Source	Currently expected base-case[1]	Worst-case assumptions
	• Based on the above, it is anticipated that over the life of the field, the average fuel gas consumed will be *c.* 5.5 mmscfd. **Fuel gas conversion rate:** • Based on laboratory data of live oil samples recovered from the Sea Lion Field, Navitas estimate the conversion rate for the associated gas to be 1 mmscf gas = 21.87 t. • Of note, POEPL assumed a conversion rate of 1 mmscf gas = 27.8 t, which, based on the samples, Navitas consider to be highly conservative. **Diesel:** • Diesel consumption is estimated at an average of 5.2 mt per day. • Fuel gas is expected to be available for 93 - 95 % of the time. Downtime of the fuel gas relates to times of no production due to planned or emergency shutdowns.	generation increases, thus having 3 GTGs to run or select from for the supply power. Additionally, the volume of oil being produced will see sufficient associated gas being liberated to support fuel gas for longer available periods. Therefore, this buffer is in line with the basis of design reliability of the system. • Adding a contingency to the diesel use rate that may result when fuel gas is offline (e.g., during process or emergency shutdowns, estimated conservatively to occur for 7 % of the time), the use of 55 mt/d of diesel is assumed. • To incorporate the above figures in line with the estimated downtime, a weighted average will be applied: o FPSO active for total of 11,353 days: o 93 % of time @ 6.6 tpd = 10,558.29 days = 69,684.71 tonnes o 7 % of time @ 55 tpd = 794.71 days = 43,709.05 tonnes o Average daily fuel use over full Field Life = (69,684.71 + 43,709.05) / 11,353 = 10.0 tonnes/day diesel use. • [Note also the assumption of teething trouble at startup listed above leading to diesel usage at 35 mt/d for the first three months.]
	Production levels at the expected P50 case (310.5 MMstb): • At the end of Phase 1, seven oil wells will be in production and the throughput of crude is anticipated to be 45,000 bopd (barrels of oil per day),	For the purposes of the credible worst-case assumptions:

Source	Currently expected base-case[1]	Worst-case assumptions
	• At the end of Phase 2, all 16 OP wells will be in operation and throughput will peak at 55,000 bopd. • Production levels will decline over the Field Life as the basin matures and the daily average throughput over Field Life is estimated at 28,356 bopd[6] (Section 5.8.2.2.1). The P50 *and* the P10 and P90 production profiles are presented in Figure 10-40 below for transparency, showing the decline in production rates over field life.	• The emissions estimates are based on power and activity requirements which are not exactly tied to any one production case. • All three production cases (P10, P50 and P90) have been used to present a range of outcomes for both 'combustion of sold product' (Table 10.76) and emissions intensity (Table 10.78).
Use of vessels[7]	Fuel consumption rates by vessel vary according to the activity and are naturally higher when the vessel is in transit *vs*. when they are idle or in-field.	For the majority of the vessels an average of the fuel consumption rate has been taken and applied to the total duration of vessel use. This is expected to provide an over-estimate as the majority of the vessel activity will be in-field, and this will be at the lower fuel consumption rate. For the Large Transport Vessels (LTVs), separate fuel consumption rates have been used for transit time and in-field time as the vessels will be at anchor, running only generators, for the majority of the duration.
Personnel transportation[7]	As described in Section 5.11.3.1.1, charter flights will be used to transfer personnel to the Falkland Islands from the UK on a fortnightly basis. Stage 1 of the Development is expected to last for 31 months (67 fortnights). However, in reality, the charter flights will not commence until one year before First-Oil (approximately 19 months into Stage 1).	The EIA assumes charter flights will occur fortnightly for the full 31 months and this is assumed for the emissions estimates.
	As described in Section 5.11.3.1.1, charter flights may continue to be used for the full duration of stage 3. However, once into steady state production, the reliance on charter flights may diminish in favour of weekly commercial flights.	The EIA assumes the use of fortnightly charter flights for the full duration of Stage 3 and this is assumed for the emissions estimates.
Well clean-up / testing	As OHGP will be used for the well completions (Section 5.4.5.5), rather than cement and perforation, it is anticipated that there will be little solid material debris which minimises the risk of damage to the FPSO facilities. Therefore, it is anticipated that extensive clean-up / flowback operations to the MODU will not be required. As such, the base-case is to leave the wells suspended with a	As described in Section 5.4.8, the contingency is retained for well flow-back or testing to the MODU of up to four wells should circumstances necessitate it. This will involve flaring off of the oil and gas as there will be no other way to safely manage the products.

Source	Currently expected base-case[1]	Worst-case assumptions
	completion fluid that can safely be flowed back to the FPSO and no flaring associated with clean-up will be required.	The planned emissions estimate in Section 10.9.4.4.4 below presents the worst-case baseline emissions and also itemises the emissions from four well flow-backs / tests (3 x OP wells and 1 x GI well).
Flaring	Flaring associated with the Development includes the following: • The flare pilot light will be lit from First-Oil and will remain so for Field Life, assuming 0.5 mmscfd. • Commissioning of the gas lift and injection systems. In order to achieve the commissioning operations, it will be necessary to flare produced gas for up to 30 days at a rate of up to 306.2[8] tonnes of gas per day. • Year 1: 19.5 days flaring due to process upsets and emergency blowdowns, • Year 2: 13 days flaring due to process upsets and emergency blowdowns, and • Years 3 - 32: 7 days flaring due to process upsets and emergency blowdowns (per year)	• The flare pilot light will be lit from First-Oil and will remain so for Field Life, assuming 0.5[9] mmscfd • Assume 45 days flaring at 306.2[8] tonnes per day as the worst-case for commissioning the gas system. • Year 1: Assume 25 days flaring due to process upsets and emergency blowdowns, • Year 2: Assume 20 days flaring due to process upsets and emergency blowdowns, and • Years 3 - 32: Assume 10 days flaring due to process upsets and emergency blowdowns (per year).
Fugitive emissions	The methodology for calculating fugitive emissions has been published by several internationally recognised sources (DECC, 2008; API, 2021). The accepted methodology requires documenting both the total number and type of process and utility equipment relevant to the installation, such as flanges, connections, valves, vessels, pumps etc. When *in situ* operational measurements are not available, a specific emissions factor is applied to each component type and summed to derive the total estimated fugitive emissions per year. However, the degree of fugitive emissions from these components depends on the type and nature of the hydrocarbons being produced, the age of the facilities, and the specifications of each component. The Sea Lion FPSO has not yet been confirmed and contracted. However, whichever FPSO is ultimately selected will undergo modification and refitting. Therefore, the level of detail regarding the number and type of components relating to the production system at Sea Lion cannot currently be defined with any precision, making an estimate of potential fugitive emissions at this stage premature. Any estimate made at this point cannot be supported by any project-specific data and may produce an over- or under-estimate that cannot be verified. As FEED work progresses, a calculation of fugitive emissions will be made and refined in later project phases.	
Combustion of sold product	The oil produced from the Sea Lion Field will be sold into multiple markets and will be refined to produce a variety of end products. This will be dictated by the offtaker of each shipment, prevailing market forces, and the refinery that will process the oil such that it is	

Source	Currently expected base-case[1]	Worst-case assumptions
	not possible to predict what the end uses will be. For the purposes of estimating the worst-case emissions associated with use of the sold product, it is assumed that 100 % of the product will be combusted. Such emissions are estimated for Field Life production levels at: • The lower case (P90) - 242.3 MMstb, • The mid (expected) case (P50) – 310.5 MMstb, and • The upper case (P10) – 336.7 MMstb[10].	

[1] These figures represent the currently expected sources of emissions. It is expected that ongoing work during the FEED process will continue to identify further means of reduction.

[2] Power use will reduce over time for the FPSO. As oil production decreases so does associated (produced) gas, potentially requiring less compression power as re-injection gas rates will decrease. Water injection power requirements will remain at approximately the same level until total produced liquid rates fall below the nameplate capacity of the facility and, therefore, voidage replacement requirements decrease.

[3] Navitas estimates that heated injection water will be required for between 12 and 24 months over the life of the field.

[4] This scenario assumes 100 % uptime of gas whereas the downtime is factored in for diesel use i.e., fuel gas and diesel both in use when fuel gas is down, therefore this scenario will likely lead to an overestimate of emissions.

[5] Please note that the fuel gas conversion rate used for the worst-case was changed to 21.87 t per mmscf in accordance with representations during the statutory consultation period. See Chapter 0, Xodus 46.

[6] Average daily production over whole field life is calculated based on the expected total oil production divided by total production period in days. This is a representative average production rate for the life of field, in reality production rates will vary over time and be higher during early production and decline over time as shown in Figure 10-40.

[7] In sections below, comparisons are made between the estimated Sea Lion emissions and those that occur on the UKCS (Section 10.9.4.5.3 and Section 10.9.4.5.4). To ensure like-for-like estimates within these comparisons, the emissions associated with personnel transportation are excluded, as are those associated with drilling and vessels in accordance with the scope defined by the NSTA in their Emissions Monitoring Report 2023.

[8] Navitas has taken a conservative approach to the estimated volume of gas flared at start-up and the flaring rate per day will likely reduce during the FEED process as viable modifications to the selected FPSO are evaluated.

[9] Please note that the post-consultation flare pilot light gas usage was reduced from 0.7 mmscfd to 0.5 mmscfd in the worst-case assessment following representations during the statutory consultation period (see Chapter 0, OPRED 12).

[10] The Conversion factor for Sea Lion oil is 1 barrel oil = 0.1399995 tonnes oil, using specific density of the oil at Stock Tank conditions 1 atm / 60 degF = 880.5 kg/m^3.

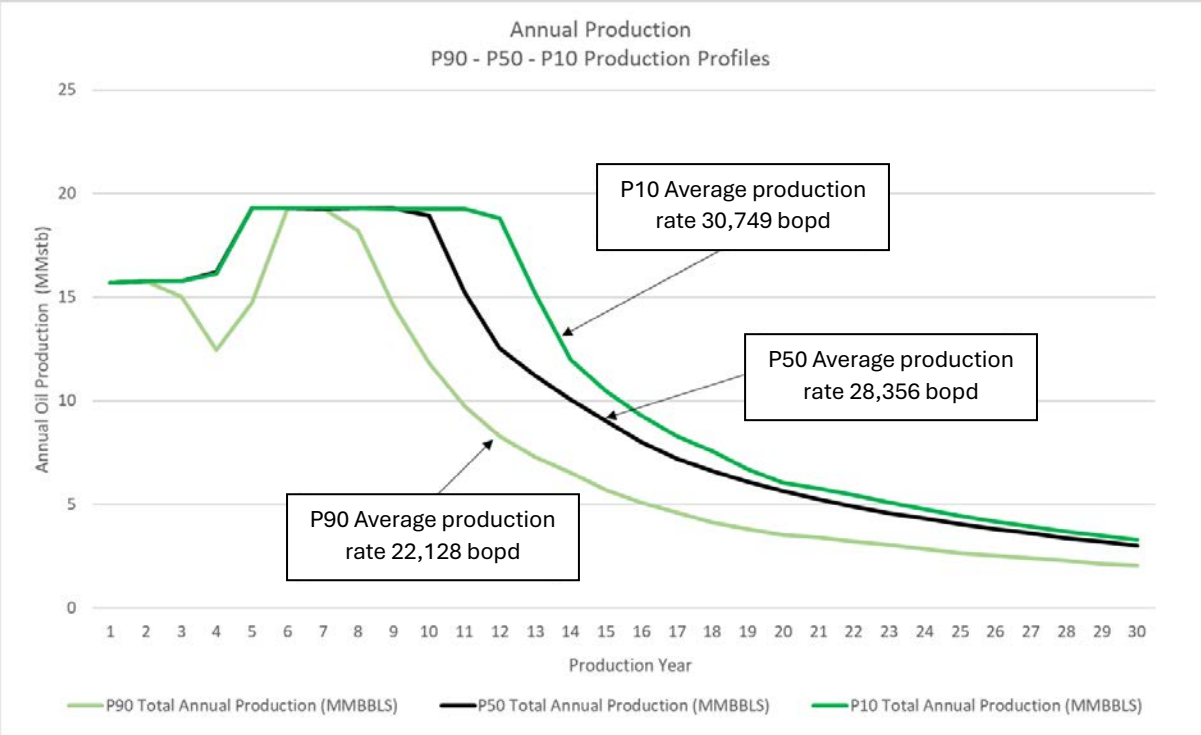

Figure 10-40: Showing the decline in production over field life for the P10 – P90 production profiles

10.9.4.4.2 Activity (source and amount of fuel / material combusted)

Combustion emissions can be estimated by multiplying the total fuel consumption by the published emissions factors (see below) for each fuel type. The total fuel consumption was estimated using the fuel consumption rates in Table 10.70 and the estimated duration of use of each source.

Table 10.70: Consumption rates for each planned source of combustion emissions[1]

Emissions Source	Fuel Type	Fuel Consumption	Fuel Consumption Units	Example Vessel/Vehicle
Drilling[2], GI well commissioning and contingency well clean-up / testing				
Semi-sub MODU - drilling	Diesel	25	tonnes/day	*Stena Don*
Flaring during GI well commissioning	Fuel Gas	306.2[3]	tonnes/day	-
Oil well clean-up/test flaring - Oil	Oil	1,262	tonnes per well	-
Oil well clean-up/test flaring - Gas	Gas	105	tonnes per well	-
Oil well clean-up/test flaring - Base Oil	Diesel	56.3	tonnes per well	-
Gas Injection well clean-up/test flaring - Oil	Oil	76	tonnes per well	-
Gas Injection well clean-up/test flaring - Gas	Gas	751	tonnes per well	-
Gas Injection well clean-up/test flaring - Base Oil	Diesel	42	tonnes per well	-
Production[1]				
FPSO - on location	Diesel	10.0	tonnes/day	*Aoka Mizu*
FPSO - on location	Fuel Gas	144.3[3]	tonnes/day	*Aoka Mizu*

Emissions Source	Fuel Type	Fuel Consumption	Fuel Consumption Units	Example Vessel/Vehicle
Flare Pilot Light	Fuel Gas	10.9[3]	tonnes/day	-
Flaring during commissioning	Fuel Gas	306.2[3]	tonnes/day (during commissioning period only)	-
Vessel Use[2]				
FPSO - sailing	Marine Gas Oil	35.0	tonnes/day	*Aoka Mizu*
Anchor Handling Tugs (AHTS)	Marine Gas Oil	12.0	tonnes/day	*Pacific Centurion*
Offshore Construction Vessel (OCV)	Marine Gas Oil	20.0	tonnes/day	*Island Frontier*
Large Transport Vessel (LTV) - on location & offloading cargo	Marine Gas Oil	5.2	tonnes/day	*Jumbo J-Type Vessel - Jumbo Jubilee*
LTV - sailing	Marine Gas Oil	30.6	tonnes/day	*Jumbo J-Type Vessel - Jumbo Jubilee*
Platform Supply Vessel (PSV)	Marine Gas Oil	7.0	tonnes/day	*Troms Pollux*
Ad hoc Freighter	Marine Gas Oil	7.0	tonnes/day	*BBC London*
Emergency Response and Rescue Vessel (ERRV)	Marine Gas Oil	3.0	tonnes/day	*Esvagt Don*
Onshore				
Car	Diesel	0.004	tonnes/day	*Land Rover Discovery*
Mobile Crane	Diesel	0.008	tonnes/day	*Liebherr 150SWL*
Forklift Truck	Diesel	0.004	tonnes/day	*10mt CAT Diesel*
Truck	Diesel	0.004	tonnes/day	*25mt Volvo cab*
Diesel Generator (supply base)	Diesel	0.184	tonnes/day	80 KW @ 75 % capacity
Personnel transportation[2]				
Helicopter - personnel transport & Search And Rescue SAR)	Aviation Fuel	0.379	tonnes/day	*Sikorsky S-92*
Helicopter - Personnel transport	Aviation Fuel	1.231	tonnes/day	*Sikorsky S-92*
Charter Airplane	Aviation Fuel	15.0	tonnes/day	*A330*
Unplanned events				
Year 1 & 2 Emergency Shut Down (ESD) events	Fuel Gas	45.1[3]	tonnes/day	25 days
Year 2 Shut Down events due to operational disruptions	Fuel Gas	36.0[3]	tonnes/day	20 days
Year 3 onwards Emergency Shut Down (ESD) events	Fuel Gas	18.0[3]	tonnes/day	10 days per year

[1] Please note that the emissions estimate is not based solely on the oil production rate. Power use will reduce over time because, as oil production decreases so does associated (produced) gas, potentially requiring less compression power as re-injection gas rates will decrease. Water injection power requirements will remain at approximately the same level until total produced liquid rates fall below the nameplate capacity of the facility and, therefore, voidage replacement requirements decrease (see Section 5.8.2.2.1 and Figure 5-8).

[2] In sections below, comparisons are made between the estimated Sea Lion emissions and those that occur on the UKCS (Section 10.9.4.5.3 and Section 10.9.4.5.4). To ensure 'like-for-like' estimates as far as possible within these comparisons, the emissions associated with drilling, vessel use and personnel transportation are excluded, in accordance with the scope defined by the NSTA in their Emissions Monitoring Report 2023.

[3] Based upon the conversion rate of 21.87 tonnes per mmscf based on sampling, as explained in Table 10.69 above.

10.9.4.4.3 Emissions factors

The emissions factors used in this assessment are provided in Table 10.71.

Table 10.71: Emissions factors

Activity (source of emissions)	Fuel	Direct GHG			Indirect GHG			
		CO_2	CH_4	N_2O	NOx	SO_2	CO	VOC
Fuel Gas (Turbines)[1]	Fuel gas	2.577	0.000138	0.000004	0.006100	0.000013	0.003000	0.000036

[12] Emissions factor for combustion of crude oil (based on 30.5 API oil), stated in tonnes of CO_2e per tonne crude oil combusted as taken from Appendix 1 of CDP (2022) guidance for estimation of Scope 3 category 11 emissions for oil and gas companies.

[13] Carbon Footprint Limited (30th July 2023) Country-Specific electricity grid greenhouse gas emissions factors – 2023. https://www.carbonfootprint.com/docs/2023_07_international_factors_release_11.xlsx (CFL, 2023).

10.9.4.4.4 Estimation of worst-case Phase 1 & 2 emissions

No direct venting of process gas will occur during routine and planned operations and the emission of F-Gases is prohibited (Section 10.9.1.1.4). Therefore, the only routine emissions that will occur are those that result from combustion throughout the Development (FPSO, vessels etc.) and VOCs emitted during offloading from the FPSO to the CTT. A small amount of gas is inevitably released from seals on process gas equipment, known as fugitive emissions, which are quantified in annual reporting.

The estimated quantities of GHGs emissions from combustion for each Stage of the Phase 1 & 2 Development are provided in Table 10.72 (including flaring that may result from unplanned process upsets and emergency blowdowns once fully operational) and are summarised in Table 10.73. Both tables also itemise the emissions that may result from the contingency well flow-back / testing, should it occur (Section 5.4.8). Therefore, this provides the emissions estimated using the worst-case assumptions outlined in Table 10.69 above.

The total emissions estimated using the worst-case assumptions itemised in Table 10.69 above amount to 7.33 $MtCO_2e$ resulting in a carbon intensity of 23.6 $kgCO_2e$/boe (Section 10.9.4.5.4). This is as compared to the total emissions using the 'currently expected' assumptions, (also listed in Table 10.69), of 5.6 $MtCO_2e$, a reduction of 24 % of the worst-case assumptions, and a carbon intensity of 17.9 $kgCO_2e$/boe. Emissions over the course of Field Life are also presented visually in Figure 10-41.

Of note, when the personnel transportation, drilling and vessel emissions are excluded to enable like-for-like comparison with the actual UKCS emissions reported to the NSTA, the carbon intensity for the 'currently expected' assumptions is estimated to be 14.2 $kgCO_2e$/boe (Section 10.9.4.5.4), although please note that this figure still includes for unplanned process upsets and emergency blowdowns and so is still a likely overestimate.

The average worst-case emissions per annum over Field Life are estimated at 0.2243 $MtCO_2e$ (and 0.2249 $MtCO_2e$ including the contingency well flow-back / tests) (Table 10.73). Table 10.74 shows the percentage contribution of each activity category to the worst-case Phase 1 & 2 emissions. The greatest overall contributor is power generation on the FPSO (62.8 %) followed by non-routine flaring during operational years as a result of process upsets and emergency blowdowns (Table 10.69) at 15.0 %. Following this, all vessels contribute 11.8 % and personnel transport contributes 8.5 % to the overall emissions. It should be noted however that these figures are overestimated as, for example, contingency allowances have been added to fuel use on the FPSO (fuel gas and diesel) and charter flights will not be utilised for the full duration of Stage 1 and may not be used at all in Stage 3 (See Table 10.69 above).

Table 10.72: Estimation of worst-case atmospheric emissions[1] per Phase 1 & 2 Development Stage (using AR5 GWPs w/o cc feedback)

Total Emissions	Total fuel burned	Tonnes emitted

[1] **Note:** To ensure the worst-case estimates, the fuel consumption estimates are based on durations of vessel use which include the mobilisation and demobilisation periods which are *not* included in the vessel use estimates provided in Table 5.24 in Section 5.11.2. The vessel emissions include those that result from the use of all construction vessels.

[2] The supply base estimates include the use of all vehicles (including those associated with the onshore transportation of personnel) as well as the use of electricity generated onshore (including electricity required to pump water to vessels). It is anticipated that the development waste will be incinerated by the FIG municipal waste facility which is expected to be operational by the end of 2026. In the event that the municipal waste facility is *not* ready prior to operations, waste will either be incinerated by a temporary facility at the supply base, or it will be shipped back to the UK on returning vessels which is considered the worst-case for emissions. In terms of in-Falklands waste incineration, whether the waste is incinerated by Navitas or by FIG, the estimated emissions from the development waste would amount to *c.* 18,974 tCO_2 over the course of total Field-Life.

[3] This includes emissions from the MODU during drilling, the FPSO pilot flare, flaring from the FPSO during the worst-case 45-day commissioning and charge-up of the gas injection and gas lift systems and FPSO fuel use in the first month of startup operations, all based on the worst-case emissions assumptions presented in Table 10.69.

[4] This includes emissions from fuel use on the FPSO, the flare pilot and the MODU (when active).

[5] This includes FPSO fuel use, the flare pilot and assumes flaring per year during unplanned process upsets and emergency blowdowns in accordance with the worst-case assumptions in Table 10.69.

[6] Please note that the emissions estimates have reduced since the statutory consultation EIS owing to reductions in the fuel gas conversion rate used, and the fuel gas usage rate estimated for the pilot light. This is in accordance with changes requested during the statutory consultation (see Chapter 0, comments Xodus 46 and OPRED 12 respectively).

[7] Please note that the presented figures are rounded up from many decimal places such that the totals may not exactly match the sum of the separate components.

[8] Including emissions from the flaring of oil, gas and base oil as indicated in Section 5.4.8.

Table 10.73: Summary of worst-case total atmospheric emissions for the whole Phase 1 & 2 Development (32.6 years) (using AR5 GWPs w/o cc feedback)

Emissions	Tonnes						
	Kyoto GHG's (Direct)			Indirect GHG's			
	CO_2	CH_4	N_2O	NOx	SO_2	CO	NMVOC

CO_2e total per annum	**224,318[1]**						
Average contingency Phase 1 & 2 Development (32.6 years) emissions including 4 x well flow-back / test							
CO_2e total per annum	**224,937[1]**						

[1] Please note that the presented figures are rounded up from many decimal places such that the totals may not exactly match the sum of the separate components.

Table 10.74: Showing the percentage contribution of each activity category to the worst-case Phase 1 & 2 emissions

Activity	Percentage contribution to total worst-case emissions
Drilling	1.5 %
All Vessels	10.4 %
Offshore personnel transport	8.5 %
Onshore supply base and personnel transport	0.8 %
FPSO fuel use	62.8 %
Flaring during commissioning (GI system)	0.7 %
Non-routine flaring during process upsets and emergency blowdowns	15.0 %
Flaring during contingency well clean-up (4 wells)	0.3 %

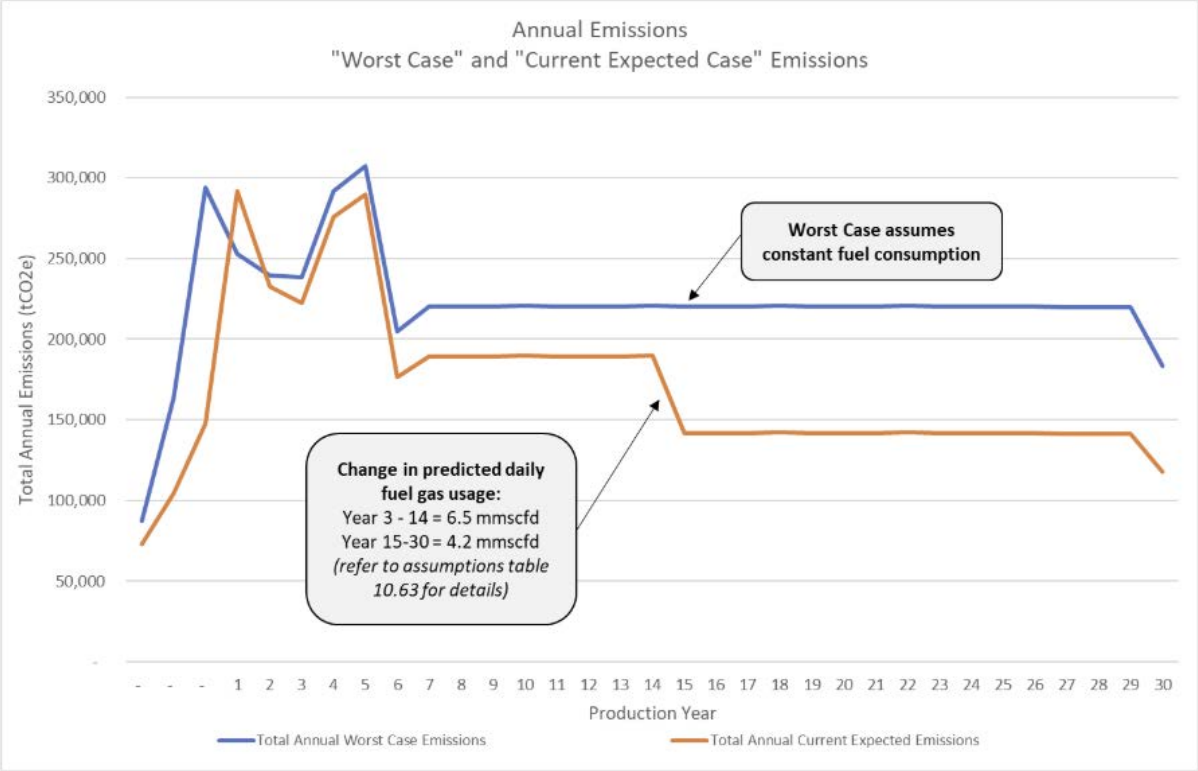

Figure 10-41: Showing the 'worst-case' and 'currently expected' emissions profiles over the course of field life. Note: emissions pre year 1 (i.e., pre First-Oil) are those associated with drilling and construction

10.9.4.4.5 Estimation of unplanned Phase 1 & 2 emissions

Please note that the following unplanned emissions are included within the estimate of the Phase 1 & 2 Development emissions provided in Section 10.9.4.4.4. However, for transparency, they are separated out and further itemised here to indicate the emissions from a single event.

10.9.4.4.5.1 Emergency blowdown

As described in Section 10.9.1.1.2, the Phase 1 & 2 Development is based on a 'zero routine flaring' philosophy during normal production activities. However, it is possible that emergency blowdowns could be required on occasion for safety reasons. Given the nature of such events, it is not possible to estimate accurately how often this would be required but through experience it is possible to estimate overall flaring volumes during operations. During an emergency blowdown it is assumed that the event would take approximately 15 minutes and the gas release rate would be approximately 204 kg/s (amounting to 184 tonnes) of exhaust gas. The CO_2e emissions resulting from a blowdown are estimated in Table 10.75 below using emissions factors listed in Table 10.71 above.

Foreseeable flaring resulting from planned shutdowns, deliberate maintenance and normal levels of unplanned flaring events are factored into Table 10.72 above.

10.9.4.4.5.2 Venting emissions offshore

As described in Section 5.8.4.6, hydrocarbon (HC) gas blanketing will be used on the FPSO to buffer the cargo tanks with a Vapour Recovery Package (VRP) system in place to prevent the release of the HC gas blanket as the cargo tanks fill. Therefore, the only source of venting would be if the VRP system were to malfunction, leading to direct venting.

In the event the VRP is unavailable, inert gas will be generated for use (Section 5.8.4.6). However, there is the potential for some of the HC gas blanket to be vented prior to a change-out to inert gas. This emission would comprise primarily methane (CH_4) and VOCs which could contribute to global warming. As a worst-case estimate, it is possible that a maximum inventory of 38.8 tonnes of HC gas could be released prior to a complete change-out to inert-gas. This assumes the VRP malfunctions when the cargo tanks are empty and that the system remains out of commission for the duration it takes for the cargo tanks to fill. In such a circumstance (albeit unlikely) the full cargo volume of HC gas would be displaced by the crude and vented to the atmosphere. Estimating the frequency of events of VRP malfunction is not tenable but will be examined during the FEED process and associated Reliability, Availability and Maintainability (RAM) studies.

The CO_2e emissions resulting from a single worst-case venting of HC gas are estimated in Table 10.75 using emissions factors listed in Table 10.71 above. However, note that venting estimates are not included in the overall estimates of the Development emissions, or annual average, as it is not possible to credibly estimate how often this may be required.

Table 10.75: Estimated emissions during emergency and unplanned events (per event)

Activity	Total (tonnes)	Tonnes									
		Kyoto GHG's (Direct)						Indirect GHG's			
		CO_2	CH_4	N_2O	F-Gas			NOx	SO_2	CO	VOC
					HFCs	PFCs	SF_6				
Emergency blowdown											
Gas burned	184	515	3.31	0.015	0	0	0	0.22	0.00	1.23	0.37
CO_2e[1]		515.20	92.74	3.95	0	0	0	0	0	0	0
CO_2e		**612**									
VRP malfunction											
Gas vented	38.8	-	19.42	-	-	-	-	-	-	-	19.42
CO_2e		-	543.8	-	-	-	-	-	-	-	-
CO_2e		**544**									

[1] Note: the GWPs used are those from AR5 without carbon feedback as per in Table 10.72 above.

10.9.4.4.5.3 F-Gas release

As described in Section 10.9.1.1.4 above, the release of F-Gases to the atmosphere is prohibited such that zero emission of F-Gases is the base-case.

In the event that an accidental release were to occur, this would be reported to FIG in terms of the CO_2e of the release. Given that this would be an unplanned event, it is not possible to estimate the potential quantities that could be released. However, Navitas will aim to use F-Gases in the lower GWP range wherever possible.

10.9.4.4.6 Estimation of NOx and SOx emissions

At the Sea Lion location the prevailing wind direction, high humidity, frequent showers of rain and the distance to land masses mean that it is extremely unlikely that measurable levels of acidity will occur over land from the FPSO emissions. Indeed, modelling studies undertaken for the project show sea level concentrations of NOx from offshore combustions emissions reducing to near zero over 10 kilometres (Premier, 2017c). Therefore, the potential for direct and localised impacts to air quality from the FPSO were scoped out (Premier, 2017c) and emissions of NOx and SOx from the FPSO are included only within the assessment of ocean acidification.

10.9.4.4.7 Quantification of emissions from the use of municipal electricity

Emissions resulting from the use of municipal electricity generation in the local Navitas offices and warehouses are estimated to be 0.0097 $MtCO_2e$ (9,686 tCO_2e), assuming an average annual usage of

750,000 kWh over the full project lifespan of 32.6 years. A total municipality emissions factor for electricity generation in the Falkland Islands of 0.3962 $kgCO_2e/kWh$[81] has been used (which includes electricity generation and transmission/distribution emissions and is based on a 50:50 fuel mix of renewable and oil). Emissions resulting from worst-case use of back-up diesel generators have been included within the emissions estimates for the Supply Base.

10.9.4.4.8 Quantification of emissions from the combustion of sold product

The oil produced from Sea Lion will be sold into multiple markets and will be refined to produce a variety of end use products throughout the duration of the 30-year production life. The sale and use of the product from Sea Lion will be to independent buyers who will determine the location of the refinery that will process the oil. Therefore, once the oil is produced and sold, it is beyond the ability of Navitas to determine where, when and how the end-use emissions will be created and thus Navitas has very little ability to influence these aspects.

It is unlikely that *all* of the product will be combusted and a proportion of the oil will contribute to products such as plastics and essential petroleum products. Nonetheless, the conservative worst-case emissions estimates, assuming all oil produced from Sea Lion is combusted, are shown below in Table 10.76. This has been calculated utilising the CDP Scope 3 Category 11 Guidance for Oil & Gas, Tier 1 Production Method, using Tier 1 default emissions factor of 3.12 for crude oil (direct-use phase emissions) as stated in Appendix 1 (CDP, 2022).

Table 10.76: Summary of emissions from combustion of sold product

Production Case	Total Oil Production (MMstb)	% of Oil Combusted	Quantity of Combusted Oil (million tonnes)[1]	Emissions Factor Crude Oil[2]	Total Emissions ($MtCO_2e$)
P90	242.3	100	33.9	3.12	105.8
P50	310.5	100	43.5	3.12	135.6
P10	336.7	100	47.1	3.12	147.1

[1] Conversion factor for Sea Lion oil is 1 barrel oil = 0.1399995 tonnes oil, using specific density of the oil at Stock Tank conditions 1 atm / 60 degF = 880.5 kg/m3. Presented figures are rounded up from many decimal places such that the totals may not exactly match the sum of the separate components.

[2] Emissions factor for combustion of crude oil from Appendix 1 of CDP (2022) guidance (based on 30.5 API oil) is 3.12 tCO_2e/tonne crude oil.

10.9.4.5 Comparison of Phase 1 & 2 emissions with the existing context

The following sections compare the Phase 1 & 2 emissions with the following:

- Falkland Islands emissions,
- Total UK emissions,
- UKCS emissions,
- Carbon intensity of other UKCS O&G installations based on NSTA data (2024),
- The projected future emissions, and
- Total UK NOx and SOx emissions.

To ensure data are as comparable as possible, the GWPs used in each comparison are indicated within each section and the results are summarised in Table 10.77 below. It should be noted in all the comparisons below, that the worst-case emissions estimated in Section 10.9.4.4.4 above are likely to be an overestimate owing to contingencies built-in to the assumptions (Table 10.69).

[81] Carbon Footprint Limited (30th July 2023) Country-Specific electricity grid greenhouse gas emissions factors – 2023. https://www.carbonfootprint.com/docs/2023_07_international_factors_release_11.xlsx (CFL, 2023).

10.9.4.5.1 Comparison with Falkland Islands emissions

For comparison with the total Falkland Island emissions, the Phase 1 & 2 CO_2 equivalents (CO_2e) were estimated using the AR5 GWPs *without* carbon climate feedback (Table 10.60 above).

As described in Section 10.9.4.3.1 it is understood that the Falkland Islands dataset is currently incomplete and is therefore an underestimate as it does not include emissions from aviation, shipping, previous offshore O&G activity or the peripheral activities associated with fishing activity e.g. use of reefers etc. [82],.

Based on the worst-case baseline CO_2e emissions (Table 10.69 above), calculated from CO_2, CH_4 and N_2O alone, the average annual emissions of direct GHGs during the Phase 1 & 2 Development (including the contingency well tests) amount to 53 % of the 2021 Falkland Islands emissions (Table 10.77 below).

Of note, when using the UKCS equivalent emissions estimate (i.e., the currently expected Sea Lion baseline emissions (Table 10.69) excluding personnel transportation, drilling and vessels), the Sea Lion emissions estimate amounts to 32 % of the Falkland Island 2021 emissions.

10.9.4.5.2 Comparison with total UK GHG emissions

For comparison with the total UK emissions, the Phase 1 & 2 CO_2 equivalents (CO_2e) were estimated using the AR5 GWPs *without* carbon climate feedback (Table 10.60 above).

Based on the worst-case CO_2e emissions, (with and without the worst-case contingency well test included) the average annual emissions of direct GHGs during the Phase 1 & 2 Development amount to 0.06 % of the total UK 2021 emissions (Table 10.77 below).

Of note, when using the UKCS equivalent emissions estimate (i.e., the currently expected Sea Lion baseline emissions (Table 10.69) excluding personnel transportation, drilling and vessels), the Sea Lion emissions estimate amounts to 0.03 % of the UK total 2021 emissions.

10.9.4.5.3 Comparison with total UKCS emissions

For comparison with the total UKCS emissions, the Phase 1 & 2 CO_2 equivalents (CO_2e) were estimated using the AR5 GWPs *with* carbon climate feedback (Table 10.60 above).

When compared to the 2021 UKCS emissions alone, the worst-case Phase 1 & 2 emissions amount to 1.50 % of the UK O&G emissions (Table 10.77 below), and 1.52 % of emissions if the four contingency well flow-back / tests are carried out. However, it should be noted that, unlike the UKCS data, the Phase 1 & 2 emissions estimated in this EIS include all the worst-case emissions associated with offshore, inshore, onshore and at-shore operations, including all construction and all associated shipping (except the purchaser's CTT) and aviation. As the UKCS data do not include emissions from all equivalent operations, the Phase 1 & 2 emissions as a percentage of the UKCS emissions appear higher than they would on a like-for-like basis. When using the UKCS equivalent emissions estimate (i.e., the

[82] At the time of writing the EIS (June 2024), Navitas was advised that the FIG emissions dataset did not include aviation, shipping, previous offshore O&G activity or fishing activity. As such, it was not considered possible to carry out a meaningful comparison with other industry sectors, as required by the EIA Guidance Note (FIG, 2016e). Subsequent to the public consultation carried out in July 2024, FIG has advised that the dataset *does* include emissions from fishing within the 'Transport' IPCC Category. FIG has specified that 'fishing' includes Jiggers, Trawlers, Longliners, Potters and Combos. Data collected by FIG for these values include the number of vessels and volume of fuel but importantly do not include peripheral emissions associated with the industry sector such as the use of reefer vessels or onshore transshipment of product and onward transport etc. Nonetheless, in order to meet the requirements of the EIA Guidance, Navitas has attempted a sectoral comparison. It can be shown that the total average annual worst-case Sea Lion emissions represent: 2,249 % of the Falklands 'energy' emissions in 2021 (noting that the data exclude previous O&G activity), 111 % of the 'transport' emissions (including small-scale fishing, but excluding international aviation) and 124 % of 'agricultural' emissions. However, it must be noted that these comparisons are considered misrepresentative owing to the data gaps currently within the Falkland Island datasets.

currently expected Sea Lion baseline emissions (Table 10.69) excluding personnel transportation, drilling and vessels), the Sea Lion emissions estimate amounts to 0.91 % of the UKCS 2021 emissions.

Table 10.77: Phase 1 & 2 average annual emissions in the context of Falkland Islands' and UK emissions data[1]

Direct GHG	Emissions of direct GHG ($MtCO_2e$)			Average Phase 1 & 2 emissions per annum ($MtCO_2e$, AR5 *without* cc fb)[3]		Average Phase 1 & 2 emissions per annum ($MtCO_2e$, AR5 *with* cc fb)[3]		Average Phase 1 & 2 CO_2e emissions per annum as a % of:					
								Falkland Islands 2021 emissions[2]		UK 2021 emissions		UKCS 2021 emissions

[1] Note that these compare the direct Kyoto GHGs only and exclude NOx, SOx, CO and VOC

[2] Data do not include aviation, fishing, shipping or offshore oil and gas emissions.

[3] Including emissions from UKOTs and Crown Dependencies. See Table 10.63.

[4] The worst-case (WC) contingency includes the emissions based on the worst-case assumptions in Table 10.69, including emissions from emergency blowdowns and process upsets during steady state production, plus those that will be incurred if the contingency flow-back / testing of four wells to the MODU occurs (Section 5.4.8).

10.9.4.5.4 Comparison of carbon intensity with other UKCS installations

The annual worst-case carbon intensity[83] data for each production profile are presented in Figure 10-42 to Figure 10-44 below. These show that the average carbon intensity estimates per annum, based upon the worst-case emissions assumptions itemised in Table 10.69 above.

Table 10.78 below summarises the carbon intensity for a range of production and emissions scenarios, with comparison to NSTA benchmarks for carbon intensity for floating installations.

Of note, when focusing on the 'currently expected' baseline emissions of 5.6 million tCO_2e:

- The average carbon intensity estimates for Sea Lion range between 23.0 and 16.5 $kgCO_2e$/boe (P90-P10 production cases) (Table 10.78), and
- Removal of the personnel transportation, vessels and drilling emissions to derive a closer like-for-like comparison with UKCS emissions results in a carbon intensity range between 18.2 and 13.1 $kgCO_2e$/boe for the P90-P10 production cases (Table 10.78).

Two North Sea benchmarks for carbon intensity of floating installations are used for comparison to the Phase 1 & 2 development (NSTA 2024). These benchmarks assume a 'lease and operate' FPSO refitted between 11 - 25 years ago, with average carbon intensity of 36 $kgCO_2e$/boe, and an FPSO refitted between 0 – 10 years ago with average carbon intensity of 20 $kgCO_2e$/boe (Table 10.78). When comparing the average carbon intensity for the Development P50 production case (i.e., the most likely volume of oil expected to be produced from the field), the 'current expected' and 'worst-case' NSTA comparable emissions scenarios have an average carbon intensity of 14.2 and 18.6 $kgCO_2e$/boe[84], respectively, which compare favorably to these benchmarks (Table 10.78).

[83] Emissions Intensity ($kgCO_2e$/boe) = (Total emissions in tonnes CO_2e x 1,000 to convert to kg) / (Total oil production in barrels for each production case) e.g., 'worst case' P50 average EI = (7,332,951 tCO_2e * 1,000)/(310.5 MMbbl * 1,000,000) = 23.6 $kgCO_2e$/boe .

[84] The UKCS emissions include those associated with offshore O&G exploration and production operations and excludes emissions from vessels associated with the construction and installation processes, supply, maintenance and surveys, shuttle tankers or export tankers, aviation, onshore activities and any other offshore industries. Therefore, to present a scenario for Sea Lion that is more comparable to reported North Sea O&G emissions, "operational emissions" include fuel consumption of the FPSO during production and non-routine flaring, and exclude emissions from all vessels, drilling, personnel transport and onshore activities.

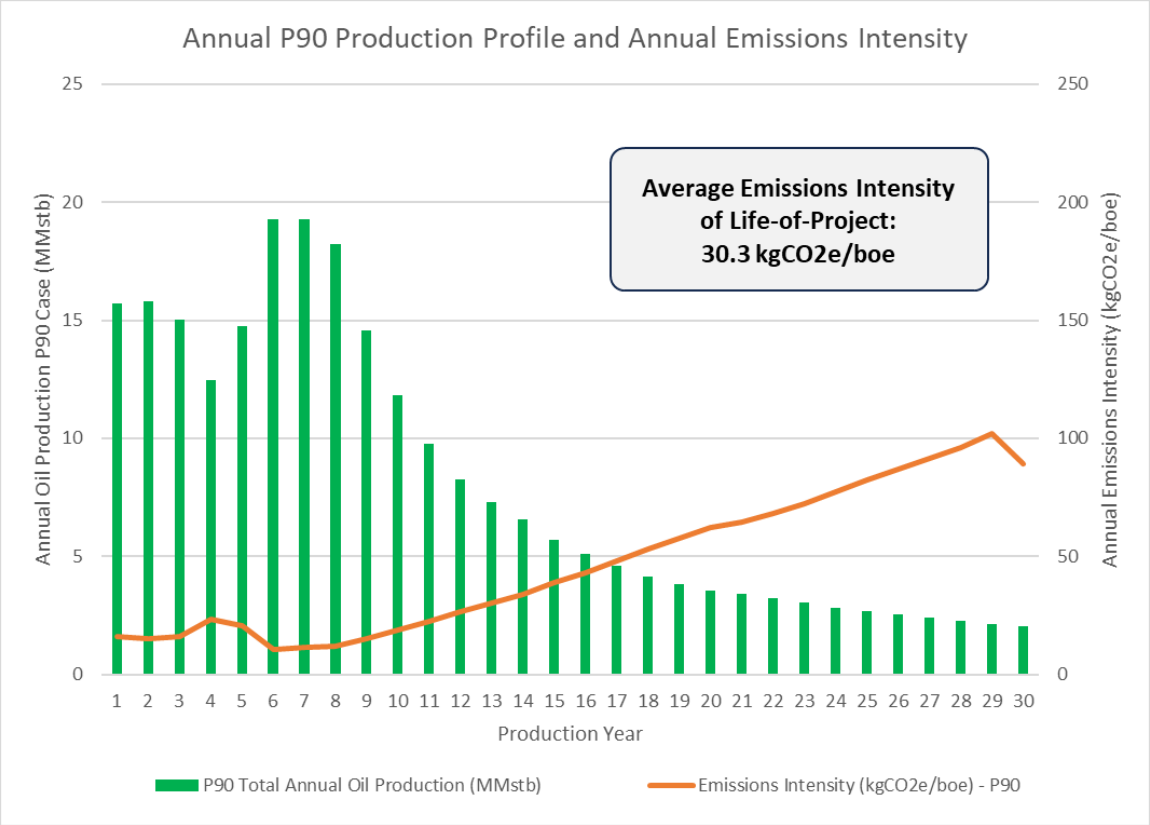

Figure 10-42. Indicating the worst-case carbon intensity, per annum, for the lower production rate (P90, 242.3 MMstb)

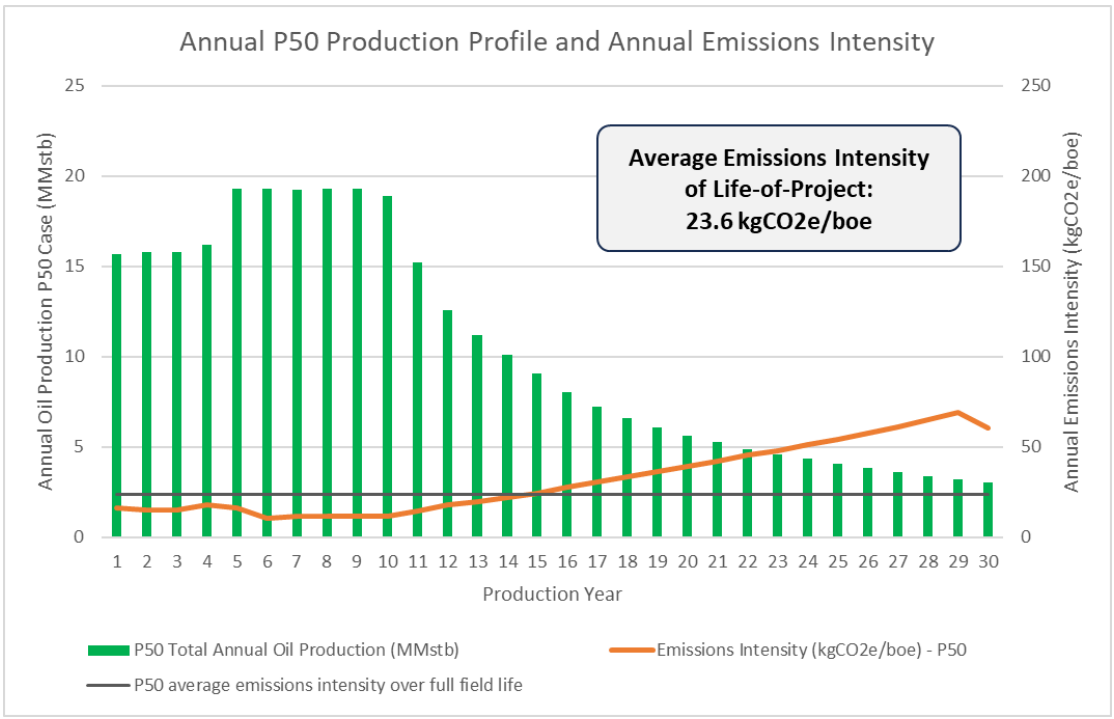

Figure 10-43. Indicating the worst-case carbon intensity, per annum, for the medium (and expected) production rate (P50, 310.5 MMstb)

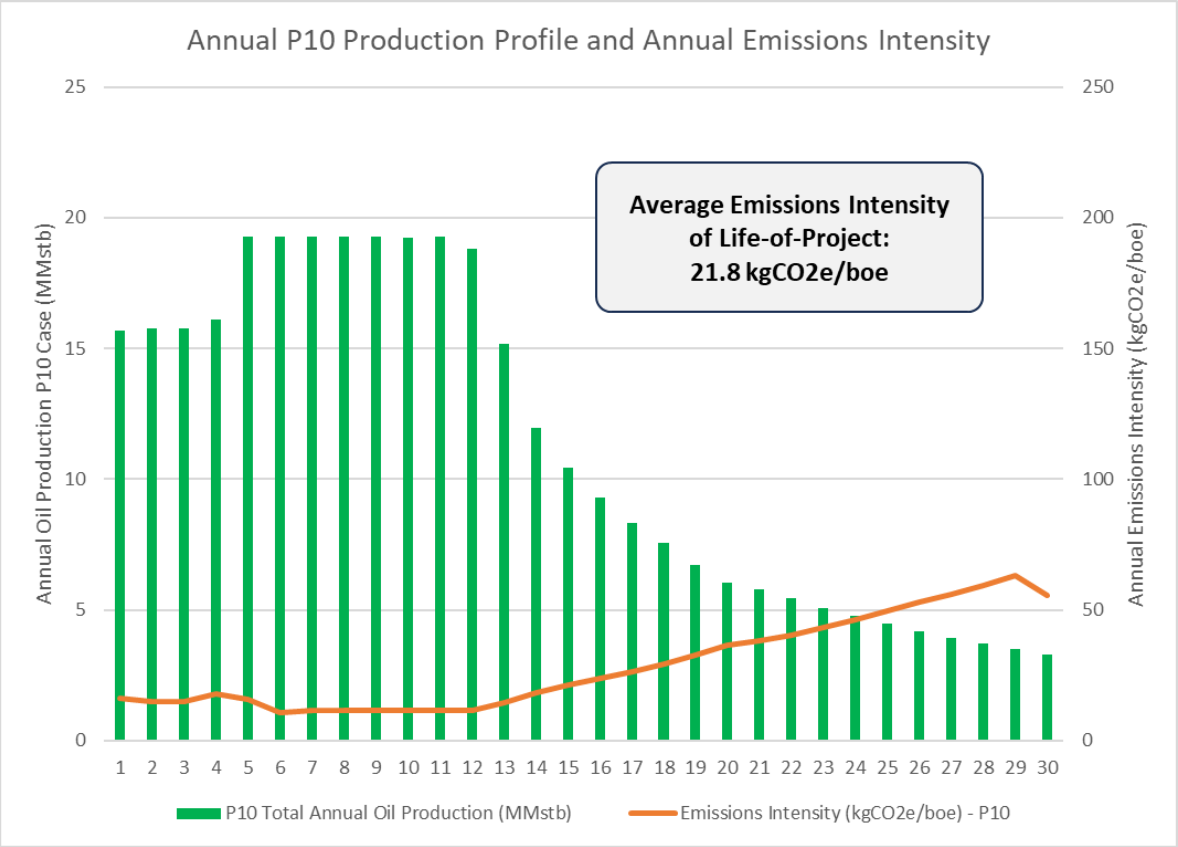

Figure 10-44. Indicating the worst-case carbon intensity, per annum, for the upper production rate (P10, 336.7 MMstb)

Table 10.78. Summary of the Sea Lion carbon intensity estimates and the NSTA benchmarks

Emissions	Carbon intensity ($kgCO_2e/boe$)		
	P90 Production Case 242.3 MMstb	P50 Production Case 310.5 MMstb	P10 Production Case 336.7 MMstb
Sea Lion 'worst-case' emissions (including contingent well flow-back/testing) (Table 10.73)	30.3	23.6	21.8
Sea Lion 'currently expected' emissions (including emergency blowdowns and process upsets)	23.0	17.9	16.5
Sea Lion worst-case emissions with the personnel transportation, vessels and drilling emissions removed to enable meaningful comparison with NSTA benchmark data (NSTA, 2024)	23.8	18.6	17.2
Sea Lion 'currently expected' emissions with the personnel transportation, vessels and drilling emissions removed to enable meaningful comparison with NSTA benchmark data (NSTA, 2024)	18.2	14.2	13.1

Emissions	Carbon intensity ($kgCO_2e$/boe)		
	P90 Production Case 242.3 MMstb	P50 Production Case 310.5 MMstb	P10 Production Case 336.7 MMstb
2024 NSTA benchmark for FPSO at 0 – 10 years old	20		
2024 NSTA benchmark for FPSO at 11 - 25 years old	36		

10.9.4.5.5 Comparison with projected total UK GHG emissions

The Phase 1 & 2 emissions were compared with the projected future UK emissions to provide a context within which to assess the 'severity of effect'. The AR5 GWPs (w/o cc fb) (IPPC, 2013) were used.

Comparing the direct Kyoto emissions alone, the estimated annual Phase 1 & 2 emissions will amount to 0.028 % of the UK emissions during the fourth carbon budget period (2023 - 2027), 0.077 % during the fifth period (2028 - 2032), and 0.113 % of the sixth carbon budget allowance (Table 10.79). Emissions will be higher during Stages 1, 2a & 2b than in steady state production (Stage 3) due to drilling and installation activities. During the Carbon Budget Periods six and seven, the Development will be into Stage 3 so the annual emissions will stabilise. However, due to the reducing the UK Carbon Budget allocation, the percentage contribution of Phase 1 & 2 emissions will increase.

Table 10.79: Comparison between the Phase 1 & 2 direct GHG emissions and the projected future UK direct GHG emissions[1]

UK Carbon Budget Period[2]		Number of Years	Carbon Budget ($MtCO_2e$)	Sea Lion Worst-case Scenario Emissions ($MtCO_2e$)[3]	Sea Lion Worst-case Emissions as % of UK Carbon Budget
1	2008 - 2012	5	3,018	-	-
2	2013 - 2017	5	2,782	-	-
3	2018 - 2022	5	2,554	-	-
4	2023 - 2027	5	1,950	0.545	0.028 %

7	2038 - 2042	5	To be set in 2025	1.102	-

[1] BEIS (now DESNZ) Energy and emissions projections (BEIS, 2022b).
[2] Carbon budget periods are as agreed under the Climate Change Act.
[3] Using AR5 GWPs without carbon climate feedback and including the contingency well tests. Emissions estimated for 5-year periods relative to the UK Carbon Budget periods, assuming the Sea Lion development starts in 2025 with production starting in 2028.

10.9.4.5.6 Comparison of NOx and SOx emissions

As can be seen in Section 10.9.4.3.1, the raw data for the emissions of NOx and SOx by the Falkland Islands are not provided. Those for the UK are provided in Section 10.9.4.3.2.1. Therefore, while the worst-case estimates of NOx and SOx emissions from the Phase 1 & 2 Development are estimated (Table 10.72 above), it is only possible to compare these to the total UK indirect emissions.

Using the data in Table 10.65 above, which indicates a decline in indirect GHG emissions, it is estimated that the worst-case average annual baseline Phase 1 & 2 NOx emission (i.e. 967 tonnes, Table 10.73 above) will amount to approximately 0.14 % of the 2021 UK total. That of SOx is estimated to 0.04 % of the 2021 UK total.

10.9.4.5.7 Comparison of emissions from combustion of sold product with global emissions

As shown in Section 10.9.4.4.8, the conservative worst-case emissions estimate for the P10 production case, assuming all the oil produced from Sea Lion is combusted, is 147.1 million tCO_2e based upon the production of 336.7 MMstb over Field Life. To put this in context, global oil demand as of December 2023 was 101.7 MMbbl per day (IEA, 2023; Section 10.9.4.3.4).

Table 10.80 shows a comparison of the daily emissions associated with the combustion of sold product (oil) from Sea Lion against those associated with projected global oil demand. Looking at the worst-case scenario (highest Sea Lion production (P10) and lowest future oil demand (Scenario 2)), the percentage contribution to global emissions ranges from 0.059 - 0.087 %. However, it should be noted that Scenario 2 is a projection based on more aggressive moves toward Net Zero than are currently expected under existing policies (Section 10.9.4.3.4). When compared with Scenario 1, which is based on oil demand expected under existing climate change policies, the contribution ranges from 0.014 – 0.055 %. As can be seen in the two selected scenarios, there is a considerable range in the future oil demand projections reflecting the uncertainty in estimating such ongoing demand. When comparing the overall average daily emissions (calculated on a like-for-like basis), emissions from combustion of the expected P10 Sea Lion production per day represents 0.031 % of global daily emissions from oil, assuming all globally produced oil is similarly combusted (Table 10.80).

Table 10.80. Showing a comparison of estimated emissions from combustion of sold product between Sea Lion[1], current global oil demand (as at December 2023 as reported by IEA) and two future demand scenarios[2]

[1] Refer to Section 10.9.4.4.8 for description of quantification of emissions from combustion of sold product. Assumes all produced oil from the three production cases is combusted so as to represent a worst-case scenario.

[2] Two end-member future scenarios are presented which capture the range of future oil demand forecasts (refer to Section 10.9.4.3.4, **Error! Reference source not found.** for additional details).

[3] Emissions factor for combustion of crude oil from Appendix 1 of CDP (2022) guidance (based on 30.5 API oil) is 3.12 tCO_2e/tonne crude oil. Conversion factor for Sea Lion oil is 1 barrel oil = 0.1399995 tonnes oil, using specific density of the oil at Stock Tank conditions 1 atm / 60 degF = 880.5 kg/m^3.

[4] The same methodology that was used for Sea Lion has been used to estimate emissions from total daily global oil demand, assuming all oil is combusted. Emissions factor for combustion of crude oil from Appendix 1 of CDP (2022) guidance (based on 30.5 API oil) is 3.12 tCO_2e/tonne crude oil. General conversion factor for oil of unknown properties is 1 barrel oil = 0.1364 tonnes of oil (BP Conversion Factors 2021: https://www.bp.com/content/dam/bp/business-sites/en/global/corporate/pdfs/energy-economics/statistical-review/bp-stats-review-2022-approximate-conversion-factors.pdf). Refer to Section 10.9.4.3.4, **Error! Reference source not found.** above for corresponding daily oil demand figures.

[5] Emissions calculated based on daily global oil demand from IEA as at Dec 2023 (Oil Market Report - December 2023, IEA, Paris https://www.iea.org/reports/oil-marketreport-december-2023) assuming all oil is combusted and using the same methodology described above in footnote 4.

10.9.5 Industry-standard mitigation measures

10.9.5.1 Combustion emissions

The industry-standard mitigations as applied by Navitas include:

- Use of Best Available Techniques (BAT) in the Development basis of design (as described in Section 10.9.5),
- Regular monitoring and inspection of all combustion equipment and use of a Management Maintenance System with Planned Maintenance Routines to ensure all combustion equipment runs as efficiently as possible,
- Testing of fuel gas to enable analysis of composition thus improving emissions estimates,
- Metering of fuel gas used and recording of diesel use,
- Monitoring, recording and reporting all emissions,
- Auditing of third parties as part of the selection and pre-mobilisation processes, and
- Ongoing ALARP reviews throughout the Field Life which will take account all emissions monitoring outcomes.

Navitas also carries out all of its activities in line with its OMS Framework (Section 3.2). Within this, and as part of its Carbon Strategy, Navitas is committed to reducing its GHG emissions to a level that is 'As Low As Reasonably Practicable' (ALARP) and will set SMART (Specific, Measurable, Achievable, Realistic and Time-based) environmental objectives and targets each year.

10.9.5.2 F-Gas emissions

Owing to the high GWPs of many F-Gases (Table 10.60 above), all F-Gas containing equipment is subject to preventative maintenance (e.g., level checks and leak checks in accordance with legislation) to prevent losses of even small quantities of F-Gases by fugitive emission or by leaks. The frequency of maintenance and leak checks is determined by the quantity of the F-Gas contained within the equipment and the GWP of a full release. The leak test thresholds are governed by the tonnes of CO_2e of a release. The leak testing requirements are as follows. Where the release could lead to the emission of:

- <5 tonnes of CO_2e, there is no need to check the equipment for leaks,
- 5 - <50 tonnes of CO_2e, the equipment should be checked every 12 months,
- 50 to 500 tonnes of CO_2e, the equipment should be checked every six months, and
- > 500 tonnes of CO_2e, the equipment should be checked every three months.

10.9.6 Impact and risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. The assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes for this Development is tabulated in Section 10.9.12, which shows the worst-case impact / risk for each activity and receptor and details are provided below.

10.9.6.1 Impact assessment

10.9.6.1.1 Global warming and GHG emissions

As described in Section 8.5.2.1.1, the sensitivity of the global (transboundary) atmosphere as a receptor is considered to be '**Very High**'.

The worst-case average baseline annual CO_2e emissions of Kyoto GHGs during the Phase 1 & 2 Development is anticipated to be 53 % of the declared 2021 Falkland Islands emissions, 0.06 % of 2021 UK emissions and 1.50 % of the 2021 UK offshore O&G (UKCS) emissions (Table 10.77 above).

The Phase 1 & 2 emissions amount to a significant percentage of the annual Falklands Islands emissions. However, it is acknowledged that the Falkland Islands data is incomplete (Section 10.9.4.3.1) such that, after including aviation, fishing, shipping and previous offshore emissions on a like-for-like basis, the Development will comprise a much smaller percentage-increase to Falkland Islands emissions than is currently estimated. Further, it should be noted that the Phase 1 & 2 estimates (Section 10.9.4.4.4) include the worst-case and non-routine requirement for emergency flaring during process upsets and emergency blowdowns such that the emissions estimate can be considered highly conservative (see assumptions in Table 10.69).

When comparing the estimated annual Phase 1 & 2 emissions to the projected future UK emissions (2023 - 2037) (which do not, as yet, include any allowance for the Falkland Islands emissions), the conservative percentage contributions range from 0.02 - 0.11 % (Section 10.9.4.5.5). The increased contribution over the years reflects the fact the future UK NDC emissions are expected to decrease in order to meet the reducing UK emissions targets and Net Zero (Section 10.9.4.5.5).

Nonetheless, in the context of the future UK total emissions, the Phase 1 & 2 annual emissions contribution is very small. While the UK Government is currently aware that its projected future emissions are expected to exceed the carbon budget beyond 2028 (Section 10.9.4.3.3), the Phase 1 & 2 Development is a new operation and incorporates current BAT to ensure efficiency and reduce emissions per unit gain with an efficient carbon intensity (Section 10.9.4.5.4). Assuming the expected (P50) production profile, including all potential non-routine emissions and those associated with drilling, vessels and personnel transportation, the worst-case carbon intensity is 23.6 $kgCO_2e$/boe, which is less than the UKCS actual reported carbon intensity for 2023 of 24 $kgCO_2e$/boe (which does not include drilling, vessels and personnel transportation, NSTA 2023). Further, the worst-case like-for-like Sea Lion emissions intensity (i.e., with transportation, drilling and vessel emissions excluded) is 18.6 $kgCO_2e$/boe which also compares favourably to the NSTA benchmark for an FPSO of 0-10 years old (20 $kgCO_2e$/boe) (Section 10.9.4.5.4).

Therefore, the Phase 1 & 2 Development is considered to be comparatively efficient with actual emissions intensity expected to be below the UKCS average (Section 10.9.4.5.4), and it is not expected that the Phase 1 & 2 emissions will compromise the current or future UK targets and, therefore, the severity of the effect is considered to be '**Minor**'.

Therefore, the overall significance of impact from the emission of GHGs is considered to be '**Moderate (10)**'.

10.9.6.1.2 Water quality and ocean acidification

The sensitivity of water quality as a receptor is usually considered in terms of whether the receiving body of water is 'closed with no flushing' or is 'open ocean', reflecting its ability, or otherwise, to flush pollutants received from a single point source. In this context, the sensitivity of oceanic water quality as a receptor could be considered to be 'Very Low'. However, the impact of ocean acidification is directly related to the emission of CO_2 which persists for centuries in the atmosphere, is absorbed by the surface of the ocean (and so is not a single point source of release) and has a long-lived effect

(Section 10.9.4.2.2). Therefore, on balance, the sensitivity of the global (transboundary) ocean as a receptor to atmospheric emissions is considered to be '**High**'.

The amount of CO_2, NOx and SOx generated as a result of the proposed operations is very low in relation to overall UK emissions and would, in its own right, have a negligible effect on the oceans' pH. For example, the average annual Phase 1 & 2 CO_2 emission amounts to only 0.06 % of the 2021 UK CO_2 emissions (Table 10.77). Given this, and the fact that the Phase 1 & 2 Development is inherently designed to minimise emissions, the severity of the effect on water quality is considered to be '**Minor**'.

Therefore, the overall significance of the impact from the emission of CO_2 with regard to ocean acidification is considered to be '**Moderate (8)**'.

10.9.6.1.3 Emissions associated with the combustion of sold product

As described in Section 8.5.2.1.1, the sensitivity of the global (transboundary) atmosphere as a receptor is considered to be '**Very High**'.

Emissions from the use of the product once it is sold are beyond the ability of Navitas to control and are difficult to estimate accurately owing to the number of variables which may affect the end use. To ensure a worst-case estimate, it has been assumed that the entire inventory of Sea Lion crude will ultimately be combusted and the range of emissions presented in Section 10.9.4.4.8 reflects the range of potential total production (P10 – P90). The potential emissions resulting from the use of the sold product are significantly higher than the emissions which are directly within Navitas' control and influence, namely those that are directly associated with the production of the Sea Lion Field, Phase 1 & 2.

While the global community transitions to more sustainable and renewable sources of energy with the ultimate goal of Net Zero, global demand for fossil fuel is still relevant. If all 336.7 MMstb (P10, and therefore worst-case in this context) of Sea Lion oil were to be produced at once, the volume would be sufficient to meet the current global demand for three days (based on global daily oil demand of 101.7 MMstb as of December 2023 (Section 10.9.4.3.4)).

When emissions resulting from the sold Sea Lion product (assuming P10) are compared with the estimated global emissions based on two projections of future oil demand (Section 10.9.4.3.4), the estimated daily contribution made by Sea Lion over Field Life ranges from 0.014 - 0.055 % in the IEA STEPS scenario that considers current policies and announced commitments. In the more aggressive BP Net Zero scenario that considers the actions required to reach the net zero goal, the estimated daily contribution made by Sea Lion ranges from 0.059 - 0.087 %. These are based on estimates of two very different future projections, both of which will have a high level of uncertainty and assumption. When compared with the currently known global demand as at December 2023, the average Sea Lion contribution is 0.031 %. All the above estimates assume all globally produced oil is similarly combusted (Section 10.9.4.5.7).

Nonetheless, the impact of GHG emissions continues to be of concern and it must be recognised that while the average 0.031 % is a small percentage, in absolute terms the maximum (P10) estimate of emissions from combusted product is a sizeable contribution. While it is extremely unlikely that 100 % of the end product will be combusted (as assumed in this assessment), a precautionary approach must be taken and the severity of effect of emissions associated with the use of the sold product is considered to be 'Moderate'.

Therefore, the overall significance of the impact of indirect emissions resulting from the combustion of the sold product is considered to be '**Upper Moderate (15)**'.

10.9.6.2 Risk assessment

10.9.6.2.1 Emergency blowdowns and VRP failure

As described in Section 8.5.2.1.1, the sensitivity of the global (transboundary) atmosphere as a receptor is considered to be '**Very High**'.

The incremental increase resulting from combustion of gas during blowdowns and / or the venting of the HC gas blanket in the event of VRP failure is anticipated to be small such that the severity of effect of added emissions is considered to be '**Slight**'.

The significance of the impact is therefore considered to be '**Low (5)**'.

The VRP will be considered to be an environmentally critical piece of equipment within the Maintenance Management System and the likelihood of occurrence of blowdowns and VRP failure is '**Possible**'.

Therefore, the overall significance of the risk is considered to be '**Low (6)**'.

10.9.6.2.2 Release of F-Gases

As described in Section 8.5.2.1.1, the sensitivity of the global (transboundary) atmosphere as a receptor is considered to be '**Very High**'.

In the event that F-Gas containing equipment fails, there is the potential for an F-Gas to leak. Any such emissions would be one-off, finite and very limited in volume. Therefore, the severity of effect of atmospheric emissions to the global atmosphere is considered to be '**Slight**'.

The significance of the impact is therefore considered to be '**Low (5)**'.

While the F-Gas containing equipment will be subject to standard maintenance, the likelihood of the equipment malfunctioning is considered to be '**Possible**'.

Therefore, the overall significance of the risk associated with the VRP malfunctioning is considered to be '**Low (6)**'.

10.9.7 Project-specific mitigation measures

All mitigation measures intended to reduce GHG emissions to ALARP are built-in to the Phase 1 & 2 basis of design (Section 10.9.2.1) and are factored into the quantification of emissions (Section 10.9.4.4.4) albeit based upon worst-case assumptions (Section 10.9.4.4.1). These, along with the Navitas OMS, are factored into the initial impact and risk assessment. Therefore, the impacts and risks, as determined from the initial assessment, are considered to be ALARP.

An additional mitigation considered 'reasonably practicable' at this stage is to ensure tanker owners use the EEOI when developing Key Performance Indicators (KPIs) related to the CTT. However, this does not materially change the initial impact assessment at this stage.

Nonetheless, Navitas remains committed to exploring opportunities to further reduce its emissions as is indicated in the Emissions Reduction Action Plan (ERAP) for the FPSO. These investigations will occur during the Front End Engineering and Design (FEED) project and associated Reliability Availability & Maintainability (RAM) studies. Further, continual improvement will be sought throughout the life-cycle of the Sea Lion Field.

10.9.7.1 Potential mitigation measures that will be considered during FEED

The FEED process contract has been awarded to a Norwegian based company which has proven experience in reducing environment emissions in O&G projects. The investigated measures shall include, but not be limited to:

- Onshore measures as follows:
  - Exploration of electric transportation opportunities, although close dialogue will be required with FIG to ensure that the municipal power generation could accommodate an increase in the number of electric vehicles and whether or not this has a net environmental benefit,
  - The tenders for all new infrastructure (e.g., the TDF causeway upgrade, supply Base, accommodation (both housing and 'hotel')) shall request the use of:
    - Light Emitting Diode (LED) Lighting in place of higher voltage alternatives,
    - Energy efficient construction methods,
    - Energy efficient housing systems (to include but not be limited to insulation types, heating and power storage solutions), and
    - Supplementary small wind turbine units and / or solar paneling (with the understanding that this will need to be considered / approved by FIG.)
- Offshore measures as follows:
  - Review and monitoring of the technology for a ballistic ignition system for Flare Gas Recovery (FGR), allowing the pilot light to be removed while providing a reliable spark. This does, however, require a safe and robust flare monitoring system,
  - Exploration of new technologies, for example evaluating additional and novel technology for GTG Waste Heat Recovery Unit heat generation,
  - Exploration of the use of combined cycle power generation,
  - Review and challenge of the requirement for the additional steam boiler,
  - Review of the total power demand for the facility to reduce the amount of energy created to only meet with what is needed for processing fluids,
  - Review of the type of thermal insulation and its selection for process and utility pipework and vessels, and
  - Modification of the cargo oil tank steam heating system to use the most modern design and material to bring about an increased efficiency.

Please note that the above measures cannot be included within the residual impact assessment until RAM studies have proven they will be feasible.

10.9.8 Residual impacts and risks

The initial assessment takes account of all the mitigation measures which are built-in to the basis of design and while SMART goals and ALARP reviews may serve to reduce emissions in future, at this time, they cannot change the initial assessment. Therefore, the residual impact and risk assessments remain the same such that the impacts to global warming and ocean acidification remain '**Moderate**'.

Project specific mitigation measures are not applicable to the emissions associated with the combustion of sold product as these emissions are beyond the ability of Navitas to control or influence. As such, the residual impact remains '**Upper Moderate**'.

10.9.9 Cumulative impact

While no O&G activities are currently expected to occur in the NFB alongside the Phase 1 & 2 Development, both POEPL and Noble Energy Falklands Ltd. (NEFL) conducted exploration drilling campaigns in 2015. Further, the NFB supports numerous shipping activities all of which will emit GHGs from combustion which all may lead to cumulative impacts from increased 'concentration' and increased 'extent and proportion' (Section 8.9.1). It is therefore necessary to consider the Phase 1 & 2 emissions in the broader context.

Given that the key impacts of concern with regard to emissions are global warming and ocean acidification, both of which are long-term and transboundary in nature, it is not relevant to break these emissions down into yearly units when assessing the cumulative input. One measure of overall emissions over comparable timescales can be made by adding the total emissions of all known O&G activities that will have occurred in the NFB between 2015 and 2040 (Table 10.81), in addition to those of the different Falkland Islands sectors (Table 10.62). However, it is not possible to quantitatively assess cumulative impact including emissions from other Falkland Island industries due to the immaturity / incompleteness of the data noting that these do not include aviation, fishing or shipping on a like-for-like basis.

It is acknowledged that emissions from the combustion of sold product will contribute to cumulative impacts on the global receptor. However, it is difficult to quantify the extent of this without a fuller understanding of the actual uses of the sold product. In the absence of control or influence over the end uses of the product, or knowledge of any mitigation applied, the current estimates provided in Section 10.9.4.4.8 are based on the worst-case assumption that 100 % of the raw product is combusted which, in reality, is considered very unlikely.

Table 10.81: Estimated total atmospheric emissions resulting from O&G operations in the NFB during Field Life

Emissions source	Tonnes						
	CO_2	CH_4	N_2O	NOx	SO_2	CO	VOC
NEFL[1] and POEPL[2] exploration drilling campaigns CO_2e	155,605	3,187	15,694	95,741	0	1,416	766
Phase 1 & 2 Total CO_2e (32.6 years)[3]	7,101,115	181,430	30,235	-	-	-	-
O&G CO_2e total (2015 - 2040)	**7,487,266**						

[2] As estimated in the NEFL Rhea exploration well EIS (NEFL, 2015a).
[3] As estimated in the POEPL exploration campaign EIS (Premier, 2014d).
[3] See Table 10.73

10.9.10 Confidence

The duration of the Phase 1 & 2 Development is known and the associated transport for equipment, supplies and crew have been estimated on a conservative basis to provide worst-case estimates. Where possible, up-to-date emissions factors and GWPs have been used to calculate the emissions arising from the project activities.

The relationship between emissions and global warming, ocean acidification and regional air quality are well researched and documented. Therefore, level of confidence in the predictions of these impacts is considered to be '**Certain**'.

With regard to the assessment of emissions associated with the combustion of sold product, there is a great deal of uncertainty as the end uses are beyond Navitas' ability to influence (Section 10.9.4.4.8). Further, it is extremely unlikely that the entire inventory will be combusted, as has been assumed for the purposes of the worst-case assessment. Therefore, the confidence here is considered to be '**Uncertain**'.

10.9.10.1 Monitoring required

At all times, Navitas will monitor its emissions to enable reporting, which is set out by regulation and Navitas' corporate reporting standards. The Navitas monitoring strategy for emissions will be set out in the Environmental Monitoring and Management Plan (EMMP).

All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 EMMP (an outline EMMP is provided in Chapter 15).

Please note: while it is acknowledged that the impact associated with the combustion of sold product is considered to be '**Upper Moderate**' and '**Uncertain**' and thus triggers the need for inclusion within the EMMP, this impact is also considered to be beyond the ability of Navitas to influence such that no viable EMMP actions are considered (Table 15.2). Navitas is aware of the draft guidance issued by the UKs DESNZ for consultation in October 2024 proposed as a supplement to the UK EIA Regulations (2020) for assessing the effects of Scope 3 emissions on climate change. Upon finalisation of these guidelines, and any amendment to the FIG EIA Guidance Note (FIG, 2016e), any potential measures regarding the monitoring and management of Scope 3 emissions will be identified and discussed with FIG and the EMMP governance board and advisors (Section 15.5).

10.9.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

Of importance it is beyond Navitas' ability to influence the use of the product once it has been sold or to monitor and manage emissions, thus the end user's emissions will be their responsibility to monitor, manage and offset.

10.9.12 Findings summary

Table 10.82: Summary of the impact assessment for emissions during the Phase 1 & 2 Development

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Fuel combustion throughout Development	Emission of direct and indirect GHG	Contribution to global warming	Planned	1, 2a, 2b & 3	Very High	Minor	n/a	**Moderate (10)**	**Moderate (10)**	**Certain**	**Industry-standard:** Use of BAT in project design, Monitoring and measuring of emissions, Selection and pre-mobilisation auditing, Optimisation of operations, MMS, SMART objectives and targets, and Ongoing ALARP reviews. **Project-specific:** Use of EEOI in developing tanker KPIs, and Investigation of pilot-free flare design using automatic ignition systems. **Note:** The 'as sold' emissions are outwith Navitas' control.
	Emission of CO_2, NOx and SO_2	Contribution to ocean acidification			High	Minor	n/a	**Moderate (8)**	**Moderate (8)**	**Certain**	
Combustion of sold product	Use of product	Emissions from combustion of Sea Lion product	Planned	n/a	Very High	Moderate	n/a	**Upper Moderate (15)**	**n/a**	**Uncertain**	
Emergency blowdown / Venting of full HC gas blanket	Emissions of CO_2, NOx, SO_2, CO, VOCs and/or CH_4	Contribution to global warming and ocean acidification	Unplanned	2a, 2b & 3	Very High	Slight	Possible	**Low (6)**	**n/a**	**Certain**	
Malfunction of HVAC and fire-fighting equipment	Release of F-Gases	Contribution to global warming	Unplanned	1, 2a, 2b & 3	Very High	Slight	Possible	**Low (6)**	**n/a**	**Certain**

10.10.12 Findings summary 918

10.10.1 Introduction

Every activity during the Phase 1 & 2 Development will generate waste which must be managed in a safe and environmentally responsible way in accordance with the Waste Hierarchy (Figure 10-45). The Waste Hierarchy is an established principle in waste management worldwide and is part of Navitas' corporate environmental standards. The hierarchy emphasises minimisation and beneficial endpoints for waste, with disposal to landfill considered the option of last resort that is only suitable when managed in accordance with international good practice.

The disposal of waste to sea is prohibited under the London Convention (1972) and MARPOL Convention (1973/78). There are a few exceptions allowing the discharge of non-hazardous liquids (Section 10.7) but inevitably, some waste must be transferred to shore. Once ashore, modern disposal and recycling techniques can be employed to minimise the impact of waste on the environment. However, such techniques and accompanying resources are currently limited in the Falkland Islands, and waste management was identified as a concern for stakeholders during the scoping consultations (Chapter 6). The hope for improved waste management facilities in the future, both for Oil and Gas (O&G) operations and more widely, was also communicated. Navitas (formerly POEPL) has taken, and continues to take, a collaborative approach with FIG in helping to determine the most environmentally sound in-country solutions for the Phase 1 & 2 waste in as short a timescale as practicable.

This chapter assesses the impacts and risks associated with the management of solid and hazardous liquid waste streams only (Table 10.83). Waste management associated with decommissioning (Development Stage 4) will be covered in a dedicated EIA, which will be prepared in support of the decommissioning programme (Section 5.12).

Note: In the previous iteration of the project (Section 2.1.1), it was likely that an incinerator, operated by (then) POEPL's contractors, would be necessary at the onshore supply base for an initial period to observe, as far as possible, the Waste Hierarchy (see below). In the intervening period, the Falkland Islands Government's (FIG) plans for a municipal waste incinerator have progressed and there is confidence that a waste incineration plant will be operational and will have sufficient capacity for the incinerable wastes resulting from the Sea Lion Phase 1 & 2 Development. Therefore, the possibility of an incinerator at the onshore supply base is now an unlikely contingency. Should this become necessary for any reason, plans will be developed for such a plant *via* the onshore planning regime. Nevertheless, as a potential, albeit unlikely, contingency, incineration at the onshore supply base is discussed where necessary in this chapter.

Note: The impacts of discharges to sea including drill cuttings, produced water, bilge water, drainage water, grey water, galley discharges, sewage and ballast water are described elsewhere in this document, as shown in Table 10.83.

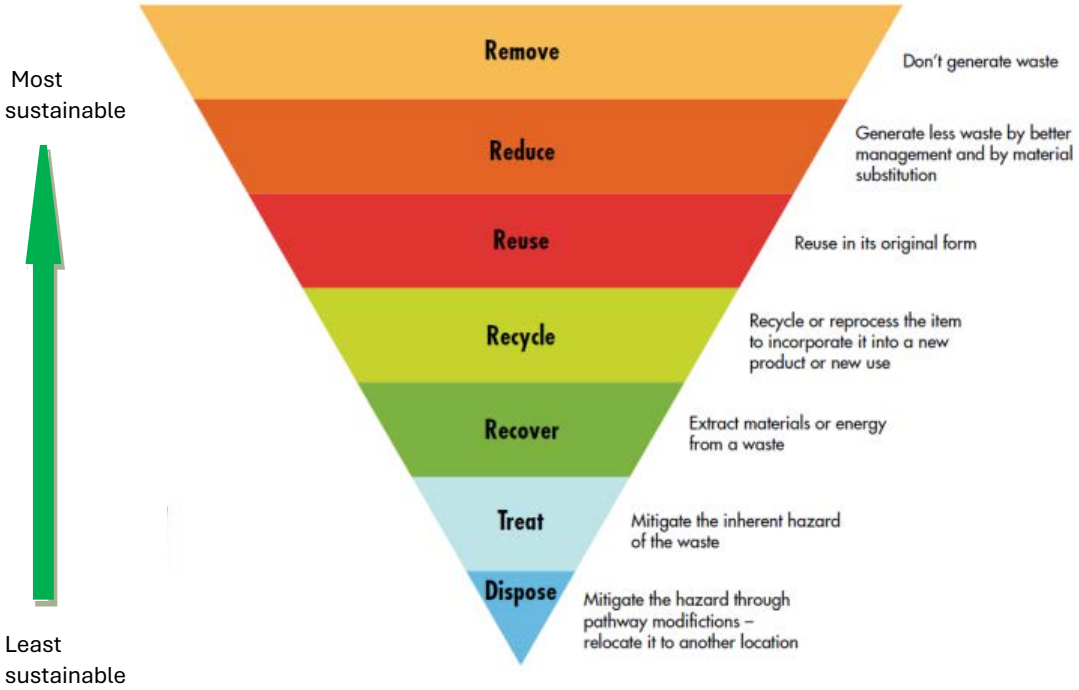

Figure 10-45: Waste Hierarchy

Table 10.83: Summary of waste streams generated by the Phase 1 & 2 Development, showing where they are assessed within this EIS

Waste stream	Generated during Stage:			Discharge to sea	Where addressed in EIS
	1	2a & b	3		
Offshore and onshore waste streams including: Containers and empty Intermediate Bulk Containers (IBCs), Metal, gas cylinders, Waste oil, including contaminated oil and oily rags, Rubber, Glass, Food waste (generated or arriving onshore), Wood, paper, cardboard, Flammable liquids, Bulk hoses, chemical sacks, Medical waste, Plastics, Low-hazard chemicals e.g., barite, Oil-based mud, Hardened cement, Non-hazardous filters, hazardous filters, Electrical waste including hazardous electrical waste, Aerosols, chemicals, Paints / solvents	✓	✓	✓	X	This chapter

Waste stream	Generated during Stage:			Discharge to sea	Where addressed in EIS
	1	2a & b	3		
Batteries, light bulbs, Tank washings, oily water, oily well-cleanup fluids, and Potential oil spill-related waste.					
Water-based mud and associated drill cuttings	✓	✓	X	✓	**Section 10.6**
Appropriately treated drill cuttings generated during drilling with NADF	✓	✓	X	✓	
Hydrotest water and well completion water (visibly clean)	✓	✓	X	✓	**Section 10.7**
Hydraulic fluids	X	✓	✓	✓	
Produced water (containing oil, heavy metals, iron etc.)	X	✓	✓	✓	
Cooling water	X	✓	✓	✓	
Domestic wastewater e.g., grey water and black water (sewage)	✓	✓	✓	✓	
Food waste	✓	✓	✓	✓	
Deck drainage water e.g., precipitation run-off	✓	✓	✓	✓	
Bilge water	✓	✓	✓	✓	
Hypersaline water from the desalination plants, which creates potable water	✓	✓	✓	✓	
Ballast water	✓	✓	✓	✓	**Section 10.12**

10.10.1.1 Relevant legislation

Currently there is limited waste-related legislation enacted in the Falkland Islands, although The Planning Ordinance 1991 has provisions for dealing with the storage, treatment or removal of any deposit or waste material. In 2023, FIG published the Falkland Islands Pollution Prevention and Waste Management Policy for consultation (FIG, 2023o). This includes the principles of Integration, Prevention, Rectification at Source, Polluter Pays, Precaution and Duty of Care, in line with the Waste Hierarchy, and sets out that a Pollution Prevention and Waste Management Ordinance will be developed.

In compliance with this Policy (under consultation) and with FIG Guidance Note 02/13 and the FIG EIA Guidance notes (FIG, 2016e), Navitas (formerly POEPL (Section 2.1.1)) has developed a Waste Management procedure which will be used to develop a project specific Waste Management Plan (WMP) for operations, to ensure that all waste is processed, stored, transported and disposed of responsibly.

Key legislation and agreements which inform the management of waste and the Development of the WMP include:

- International agreements:
  - International Convention for the Prevention of Pollution from Ships (MARPOL) 1973/78, which provides regulation on the different types of pollution and specifies whether discharge to sea is permitted:
    - Annex I - Regulations for the Prevention of Pollution by Oil,
    - Annex II - Control of pollution by noxious liquid,

    - Annex III - Prevention of pollution by harmful substances carried by sea in packaged form,
    - Annex IV - Prevention of pollution by sewage from ships, and
    - Annex V - Prevention of Pollution by Garbage from Ships.
  - The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal, the protocols of which apply to the onward processing of waste from the Falkland Islands to the UK. Note that the Falkland Islands are not party to the Basel Convention but a bilateral agreement is in place.
  - OECD Council Decision C (92)39/FINAL on the Control of Transfrontier Movements of Wastes Destined for Recovery Operations.
  - The London Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter 1972, and the London Protocol 1996 amended 2006.
  - The OSPAR Convention 1992, which incorporated the Oslo Convention 1972 for the prevention of marine pollution by dumping from ships and aircraft and the Paris Convention for the prevention of marine pollution from land-based sources.
- Key UK (and retained EU) legislation:
  - Waste Shipments Regulation EC No 1013/2006 as amended by The International Waste Shipments (Amendment) (EU Exit) Regulations 2019 and The International Waste Shipments (Amendment of Regulation (EC) No 1013/2006) Regulations 2020.
  - Transfrontier Shipment of Waste (amendment) Regulations 2014.
  - Environmental Protection Act 1990.
  - The Waste (England and Wales) Regulations 2011 (as amended), and The Waste (Scotland) Regulations 2012.
  - The Controlled Waste (England and Wales) Regulations 2012 (as amended) and The Controlled Waste Regulations 1992 (as amended).
  - The Special Waste Regulations 1996 (as amended).

10.10.1.1.1 Waste management Duty of Care

'Duty of Care' is an established international principle whereby waste producers have a Duty of Care to store, transport and dispose of 'controlled waste' without harming the environment. In UK law, for example, 'controlled waste' is described in Part II of the EPA (1990) to mean household, industrial and commercial waste or any such waste, although it is not currently enacted in Falkland Islands specific legislation.

Applying the Duty of Care means it is necessary to:

- Segregate, store and transport waste appropriately and securely, making sure that no pollution or harm to human health is caused,
- Check that waste is transported and handled by people or businesses that are authorised to do so,
- Ensure completion of the appropriate paperwork to accompany the waste,
- Ensure that waste is disposed of responsibly, and
- Ensure that waste service providers are authorised.

10.10.1.1.2 Transfrontier shipments of waste

The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal provides the framework for a global system that controls the movements of hazardous wastes

between countries to ensure they are managed in an environmentally sound manner. The Basel Convention was also amended in 2021 to expand on the controls for exporting plastics, stating that, in summary, certain plastics can only be exported as Green List waste if destined for recycling, and providing that such shipments are consented by the receiving government. As noted in the FIG Pollution Prevention and Waste Management Policy (FIG, 2023o), in January 2023, the Government of the United Kingdom and the Falkland Islands Government entered into a bilateral agreement for the shipment of hazardous and other wastes from the Falkland Islands to the UK. As the Falkland Islands is not party to the Basel Convention, any transboundary movements of hazardous wastes and other wastes between the Falkland Islands and the UK will be managed and regulated *via* the bilateral agreement and any relevant national legislation in force. The EIS takes this position as being the proposed solution for the project, i.e., that any wastes that cannot be disposed of in the Falkland Islands will be exported to the UK. If disposals to any other countries are proposed, this would require a separate discussion between Navitas and FIG and assurance that equivalent environmental controls were in place in line with Duty of Care principles.

In the UK, the Transfrontier Shipment of Waste Regulations (2007, as amended) includes both hazardous and non-hazardous wastes. The 'UK Plan for Shipments of Waste' (Defra, 2021) sets out the UK Government policy on the shipment of waste to and from the UK, and other countries, and takes into account the UK's obligations under international, retained EU and national legislation. Generally, shipments of waste to and from other countries for disposal (as opposed to re-use, recycling or recovery) are prohibited. However, in line with Defra (2021), imports to the UK from UK Overseas Territories (UKOT) are potentially allowed, by exemption, if there are no suitable methods of disposal available in the UKOT. This is subject to the processes laid out in Title V of the retained EU Regulation (1013/2006) and discussion with the appropriate Environmental Protection Agency.

Transfrontier waste shipment controls are expected to follow UK norms which are set out in the retained Waste Shipments Regulation EC No 1013/2006 as amended by The International Waste Shipments (Amendment) (EU Exit) Regulations 2019 and The International Waste Shipments (Amendment of Regulation (EC) No 1013/2006) Regulations 2020.

10.10.2 Sources and categories of waste

10.10.2.1 Sources of waste

Waste generation can be categorised by the following project sources:

- The Mobile Offshore Drilling Unit (MODU),
- Installation vessels,
- The Floating Production, Storage and Offloading (FPSO) Unit,
- Other offshore support vessels including (but not limited to):
  - Multi-Role Support Vessels (MRSVs),
  - Anchor Handling Tug Supply (AHTS) vessels,
  - Large Transport Vessels (LTVs) / Offshore Construction Vessels (OCVs),
  - Offshore Support Vessels (OSVs) / Platform Supply Vessels (PSVs) and,
  - Emergency Response and Rescue Vessels (ERRVs).
- Onshore operations.

10.10.2.2 Categories of waste

All industrial waste falls under the category of 'controlled waste' and can be categorised as:

- Non-Hazardous Waste which includes the following (provided they have not been cross-contaminated with hazardous wastes):
  - Paper, plastics, cans, food waste, scrap metal, rubber and wood.
- Hazardous Waste which includes any material that shares the properties of a hazardous material, for example:
  - Oily waste including waste oil, used oil filters and oily rags,
  - Waste NADF,
  - Waste chemicals i.e., those that are surplus to requirement but cannot be re-used,
  - Waste Electrical and Electronic Equipment (WEEE),
  - Empty oil / chemical containers,
  - Asbestos, batteries, paints, radioactive materials, and
  - Medical wastes.

Wastes anticipated during the Phase 1 & 2 Development, and described in this chapter, include:

- Hazardous liquid wastes:
  - Waste oil that has been separated from bilge, drainage and well completion water.
- Hazardous and non-hazardous solid wastes:
  - Office wastes e.g., paper, light bulbs, batteries, cups, ink cartridges,
  - Packaging materials e.g., wooden pallets, cardboard, dunnage, plastics, packaging bands,
  - Oil contaminated materials,
  - Scrap metals,
  - Fabrication wastes e.g., paint tins,
  - Chemical drums and containers, and
  - Ash generated from waste incineration (if the FIG incinerator is not operational and a temporary incinerator is required at the onshore base).
- Oil spill waste (only generated in the event of a spill).

Note: other waste streams e.g., drilling fluids and cuttings and operational discharges to sea & ballast water are covered in separate chapters as described in Table 10.83 above.

10.10.2.2.1 Hazardous liquid wastes

Bilge and drainage water will be passed through an oil separator before being discharged to sea in accordance with the requirements of MARPOL (Section 10.10.1.1). The oil separated from the drainage and bilge water will typically be returned to the processing facilities on the MODU and FPSO. However, occasionally the recovered oil may be sufficiently ‘off spec’ that it will not be suitable for processing offshore and in these instances it will be collected and stored in drums / transit tanks and will be shipped back to the onshore supply base. At the time of writing it is understood that the FIG Stanley incinerator will be operational by the end of 2026, which aligns with Navitas' operational schedule, and this would be the first option for accepting ‘off spec’ recovered oil. Should the FIG Stanley Incinerator not be available, in the instance of ‘off spec’ recovered oil, Navitas would:

1) Store the waste in suitable containers onshore until the FIG incinerator is once again available,
2) Store the waste in suitable containers onshore until offshore treatment on board either the MODU or FPSO is available, or

3) Store the waste in suitable containers onshore until a suitable volume is ready for export to the UK.

Similarly, during wellbore clean-up between drilling and completion phases when each well is displaced from NADF to brine, the NADF contaminated water returning to the MODU is put through a separation process. Water that has been treated to minimise oil content (such that the oil concentration is <30 mg/l and is 'visibly clean' and will produce no sheen), can be discharged offshore (Section 10.10.1.1) and any residual oil (free-oil) from the separation process will be sent to the supply base or combusted in the cuttings processing equipment if feasible.

Waste oils from the above that are returned to the shore base will be candidates for re-use, with incineration being a secondary solution (Section 5.11.1.2.2).

In the event of equipment failure offshore on the MODU / FPSO, oily waste from the MODU / FPSO may be sent onshore. This waste would be stored at the onshore base and then shipped back offshore for treatment once equipment is fixed. This backloading of waste would be done in discussion and agreement with FIG.

There will be some oily wastewater from the onshore mud plant. Such water will be decanted / stored in a bunded area away from the sewerage network. This will then be treated, incinerated or dealt with in alignment with Navitas' Waste Management Procedure. There is an option for this wastewater to be sent offshore for processing on the MODU / FPSO / *via* vessels, which would be discussed and agreed with FIG.

10.10.2.2.2 Solid wastes

All waste that is not eligible for discharge to sea will be segregated offshore, shipped back to the Temporary Dock Facility (TDF) and taken to the laydown yard in the supply base which will be designed to include a waste reception facility (Section 5.11.1.2). If necessary, the wastes will be further identified, categorised and segregated. Following this process, the waste will either be stored prior to its shipment to the UK for re-use, recovery or disposal, or, if the FIG incinerator is not operational, it will be thermally treated in-country using a temporary incinerator located in the base (Section 5.11.1.2.2).

10.10.2.2.2.1 Incinerator ash

The base-case is that project waste will be incinerated at a new Falkland Islands municipal facility, which will include suitable facilities for the disposal of ash. In the event that the new facility is not completed in time, the project will provide a temporary portable incinerator and waste ash will be temporarily securely stored at the supply base and periodically sent back to the UK along with other waste returns.

10.10.2.2.3 Oil spill waste

In the event of a spill, clean-up operations inevitably generate multiple contaminated waste streams, sometimes in great quantities. Indeed, studies undertaken by ITOPF (2012) have shown that the volume of oil clean-up materials and other debris is typically ten times the volume of oil that is spilled. Management of the waste up to the time of its final disposal, and the complete restoration of all sites, can cause major problems for response coordinators. In the highly unlikely event that a spill incident should occur, Navitas would be supported by international oil spill response contractors who have significant expertise and resources in the appropriate management of oil spill response waste. These response contractors would be deployed to the Islands in the event of a Tier 2 or 3 oil spill event.

A range of different scenarios have been modelled to gain an understanding of the likely behaviour and impact of oils spilled at sea (Sections 12.1, 12.2 and 12.3). These modelled scenarios also estimate the potential quantities of waste materials that may arise. Analysis of the crude oil has shown that it

possesses a high pour point with a high wax content (Section 5.3). Given this viscous consistency, upon contact with cold seawater, the oil solidifies and forms mobile rafts. It may also lead to the formation of tar balls. This tendency means that should any oil wash ashore, it may be more easily separated from the substrate and collected using only rudimentary techniques and equipment (CEDRE, 2017)[85].

The goal of oil spill response is to restore all sites to their previous condition as soon as possible and, to meet this goal, approaches to waste management following any spill will be consistent with:

- The Falkland Islands National Oil Spill Contingency Plan (NOSCP),
- Navitas' strategic waste management objectives, and
- The Phase 1 & 2 Development operational OPEPs which will define the agreements between Navitas and specialised service providers where necessary.

Typical methods and approaches used for the retrieval of oil spill wastes in remote and difficult-to-access areas are:

- Keep oil spill waste to a minimum,
- Avoid contaminating the surrounding environment,
- Prevent overflow, congestion and hold ups, and
- Sort waste as soon as possible.

However, the particular challenges that are faced by a clean-up operation along the Falkland Islands coastline arise as a result of the relative inaccessibility of the foreshore and the nature of the rocky shoreline. Further, where spilled materials come ashore and remain, it is likely that that the residues will be mixed with pebbles and cobbles and organic matter such as kelp.

It is intended that, in the event of a spill:

- Any oily waste that can be recovered at sea or from the shoreline will be stored on the offshore support vessels (OSVs), which will have oil spill response and waste storage capability, at the TDF (Tier 1) and in the onshore supply base facility. An appropriate dedicated bunded area for the storage of oily waste is planned within the supply base yard.
- All oily materials retrieved from the foreshore will be placed initially on lined temporary storage areas. These areas will:
    - Be in line with the requirements of the Falkland Islands NOSCP arrangements and located in an area agreed with FIG,
    - Be surfaced with an impermeable membrane and covered to ensure that no loss to the ground can occur and also to prevent rainwater ingress,
    - Provide interim storage for all recovered oil spill response materials and equipment including shoreline booms,
    - Ensure that the waste will be in a form that can be easily managed for onward transportation to other intermediate, or final, storage areas, and
    - Be easily accessible from the beach to allow rapid and daily evacuation of collected waste ensuring that:
        - Impacts to sensitive coastal areas are minimised, and
        - Manpower and resources can be focused on the initial clean-up effort.
- All wastes will be logged so that the quantities and types of materials that require further intermediate storage, or final disposal, can be readily assessed,

[85] Note that the oil spill modelling indicates a very low likelihood of shoreline oiling as described in Section 12.

- Various techniques will be used (including washing of contaminated kit) to ensure removal of the free-oil from the waste and it is envisaged that the remaining oily water fraction would be contained in drums and IBCs, and
- Final waste storage sites will also be identified as part of the contingency planning.

More details on the oil spill waste clean-up and management are detailed in Navitas' Waste Management Procedure, and will also be detailed in the project-specific WMP.

10.10.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts and / or risks of waste warranted further investigation (Chapter 9). These include the impacts and risks to:

- Global atmosphere (Section 7.3.1),
- Water quality (groundwater) / seabed / soil quality,
- Marine and terrestrial biodiversity, i.e., flora and fauna including:
  - Plankton (Section 7.4.1),
  - Invertebrates and fish (Sections 7.4.3 and 7.4.4),
  - Seabirds (Section 7.4.5), and
  - Marine mammals (Section 7.4.6).
- Landfill resources (tangible property) (Section 7.7.4.5.6),
- Landscape and seascape (Section 7.7.4.6),
- Designated sites (Section 7.5.2), and
- Human population (Section 7.7.2).

The above may be impacted owing to the transport and storage of waste, waste incineration, the disposal of unrecoverable waste to landfill and by waste mismanagement, should it occur.

Note: Impacts of all emissions are assessed in Section 10.9.

10.10.4 Characterising and quantifying the impacts and risks associated with waste

When characterising and quantifying the impacts and risks associated with each waste stream, it is necessary to consider the:

- The nature of the impacts and risks associated with waste:
  - The nature of the impact of waste:
    - Shipping of waste, and
    - Use of regulated landfill.
  - Risks associated with waste management:
    - Loss of containment, and
    - Improper segregation and cross-contamination.
- Existing waste management facilities in the Falkland Islands,
- Phase 1 & 2 Development waste management:
  - Waste management objectives, and
  - Waste management options.
- Quantification of Phase 1 & 2 waste:

- Type and volumes of operational waste.
- Phase 1 & 2 waste estimates in the context of UK waste.

10.10.4.1 Nature of the impacts and risks associated with waste

10.10.4.1.1 Impacts of waste

10.10.4.1.1.1 Shipping of waste

Waste being returned to the UK[86] will be transported *via* the returning *ad hoc* freighter vessels, and, when possible, the MoD Falkland Islands Resupply Service (FIRS) freighters, the emissions of which have been assessed in Section 10.9. Although it is not anticipated that the all the *ad hoc* freighters will be under hire to Navitas on the return trip, the emissions from all freighter return trips have been assumed to ensure a worst-case assessment.

When shipping waste to the UK, Navitas will adhere to the relevant Conventions, Agreements and the Transfrontier Shipment (TFS) of waste controls (Section 10.10.1.1).

10.10.4.1.1.2 Use of regulated landfill

The potential environmental impacts of waste disposed of to landfill include:

- Direct impacts:
  - Use of a finite and unsustainable resource.
- Indirect cumulative impacts:
  - Creation of irritants such as dust, pests, noise and odour,
  - Contamination of groundwater, aquifers and soil, and
  - Production of methane as organic materials (e.g., food scraps and paper etc.) decompose.

With regard to the use of a finite resource, landfill sites in England, for example, are estimated to have a remaining capacity of 349 million cubic metres (EA, 2023). In Scotland, landfill sites had 29 million tonnes of capacity in 2022. It was estimated that 2.4 million tonnes of waste were landfilled in that year (SEPA, 2024) and many sites have lifespans of 20 years or more at their current rates of filling, though clearly other sites have shorter lifespans and ongoing new capacity is required to meet demand. While new landfill space opens every year, available space is in overall decline and forecasts to 2030 point out shortfalls expected in some areas of the UK (Suez, 2017).

The vast majority of O&G wastes in the UK are landed and disposed of in Scotland, as were wastes from the exploration drilling campaign in 2015. Waste management is an area devolved to the Scottish Government and data show that landfill capacity can be managed in the medium term. It is noted that binding targets and changing behaviours to reduce waste to landfill have reduced the quantities going to landfill year on year, reducing quantities landfilled by 50 % from 2008 to 2021 (SEPA, 2023a).

With regard to the indirect impacts, Navitas has no control or influence over the impacts of landfill any more than any other consumer. However, it will aim to minimise the amount of waste that goes to landfill and will ensure that only regulated landfills are used.

[86] At the time of writing this EIS it has been assumed that non-incinerable waste will be returned to the UK in compliance with all transfrontier shipment of waste conventions and regulations (Section 10.10.1.1). As the project matures it may prove viable to ship waste to a closer OECD country, again in accordance with relevant legislation, for re-use, recycling and / or use of regulated landfill sites. For the purposes of this assessment, the UK provides a worst-case with regard to shipping emissions and the assessments for regulated landfill use are unlikely to be affected by the site location as landfill is fundamentally an unsustainable resource (Section 10.10.6.1.2).

10.10.4.1.2 Risks associated with waste management

Both hazardous and non-hazardous waste products have the potential to impact upon the environment if they are not handled, stored, treated and recovered or disposed of appropriately. Mismanaged wastes have the potential to impact upon soil, water and groundwater quality, marine and terrestrial wildlife, resource use and human health. Navitas employs strict controls on waste management in its operations and requires any lost objects to be reported, recovered if at all possible, and corrective actions to be put in place to prevent reoccurrence.

Mismanagement of waste includes:

- Improper storage leading to loss of containment of waste, and
- Improper segregation of waste during generation offshore, transportation and storage onshore leading to cross-contamination.

10.10.4.1.2.1 Loss of containment

The potential environmental impacts of a loss of containment are:

- Loss of solid waste to sea or land which could:
  - Create unsightly litter and may impact upon landscapes / seascapes and therefore, indirectly, upon the local community and visitors to the Islands with regard to wellbeing and 'quality of experience', and
  - Be ingested by terrestrial / marine fauna or cause entanglement thus affecting the animal's fitness.
- Loss of hazardous liquid wastes to sea.

Loss of containment leading to the above impacts would be an unplanned event and as such, it is not possible to quantify the amount of waste that may be released. The industry-standard mitigation measures (Section 10.10.5) will be utilised at all times to minimise the likelihood of an incident.

Nonetheless, the loss of solid wastes to sea, plastic litter and other objects is recognised as a major source of marine pollution (Waluda and Staniland, 2013). In the event of a loss of waste, such materials are very slow to degrade and the impacts are described below.

The loss of hazardous liquids wastes to sea would be treated as a spill and reported to FIG as well as *via* Navitas' internal loss of containment and processes. Spill prevention is managed by good practice in storage, containers, tankage, pipework and bunding and also by the selection of lower hazard chemicals in operations (Section 10.7). Navitas will follow industry good practice in spill prevention such as is documented in the Energy Institute Guidelines for bunding of temporarily stored liquids offshore (Energy Institute, 2016b). Any incidents will be investigated with root causes established and addressed, and any trends tracked *via* Navitas' Key Performance Indicators (KPIs) for environmental management. Small-scale oil spills are discussed in Section 12.1.2.2 and the mitigation measures apply equally to other hazardous liquids. The prevention and mitigation of onshore losses of hazardous liquids are addressed in Section 12.3.4.3.

Impacts of waste loss and litter on landscape and human population

The Falkland Islands are very scenic and wind-blown 'litter' would be damaging visually and ecologically. While it is not possible to estimate the quantities of waste that may be blown away in the event of waste mismanagement, or to predict the destination of lost material, the Falkland Islands are suffused with beauty spots and many around Stanley, where the onshore supply base is likely to be located, could be affected. Many of these areas are highly sensitive owing to their importance for local wildlife, and in some cases, for tourism e.g., Cape Pembroke which is a National Nature Reserve (NNR) and an Important Plant Area (IPA).

Littering of these areas with lost waste is more likely to occur in the event of losses from the onshore waste laydown yard than from waste lost at sea, and may impact upon the 'quality of experience' of both the local population and visitors to the area.

Impacts to wildlife

Buoyant debris remains suspended on the sea-surface while negatively buoyant debris sinks and may remain on the seabed for years. As many man-made materials are not biodegradable, litter and lost debris has the potential to cause damage to wildlife time and again (Laist, 1987, Baulch and Perry, 2014). Therefore, all fauna may be exposed to the wastes over a wide area and over a long time (Laist, 1987). The threats of such debris are often mechanical and, in particular, the ingestion of, and entanglement or capture in, man-made debris is a potentially significant cause of injury and death in Crustacea, fish, seabirds and marine mammals (Derraik, 2002; Fowler, 1987; Laist, 1987; Huin and Croxall, 1996; Gregory, 2009; Waluda and Staniland, 2013; Baulch and Perry 2014). Entanglement can lead to drowning, injury, impaired mobility and ability to catch food or to avoid predators, leading ultimately to mortality (Laist, 1987; Weir and Prieto, 2024). The ingestion of debris may block digestion, cause internal damage or compromise feeding, leading to malnutrition, disease and reduced reproductive output, whilst exposing animals to an additional source of toxins (Laist, 1987; Baulch and Perry, 2014).

Cetaceans, from small dolphins to large baleen whales, are vulnerable to entanglement in, and ingestion of, waste materials. Weir and Prieto (2024) note three instances of live entanglement of sei whales from 2013 to 2020 in US waters, including one animal with plastic strapping around its rostrum (mouth). When entanglements 'limit the mouth opening to feed, or are sufficiently severe to limit mobility, they are highly likely to cause mortality' (Weir and Prieto, 2024). As lunge-feeders, Sei whales are more likely to accidentally ingest non-target items such as plastics and other debris.

To date ingestion of debris has been documented in 48 (56 % of) cetacean species (Baulch and Perry, 2014). Padula *et al.* (2023) record instances of marine debris ingestion in large odontocete species in southern Brazil and northern Argentina. They found 8 % of individuals studied (representing nine different species) had ingested marine debris, of which 68 % of ingested items that were made of plastic.

Further, microplastics may be present within whales' prey species, such as fish (Burkhardt-Holm and N'Guyen, 2019). Plastic ingestion may be an increasing threat, with plastic debris being recently identified in a sei whale faecal sample in Chile (Buchan, *et al.,* 2021). Stranded sei whales have been found with plastic in their stomachs in both the UK and USA (Baulch and Perry, 2014; Henry, *et al.,* 2020), with the ingestion directly contributing to mortality in the USA case. Additionally, microplastics may be trapped within baleen plates where they are a fouling risk that prevents whales feeding efficiently (Werth, *et al.,* 2019). While the above examples focus on sei whales, it should be noted that these or similar impacts have been recorded across many marine mammal species (Baulch and Perry, 2014).

Pinnipeds (such as sea lions) are particularly vulnerable to becoming entangled in loops of rope, packing bands (Page, *et al.,* 2004; Waluda and Staniland, 2013) and plastic sheeting or netting, which generally becomes stuck in the fur around the neck and slowly strangles the animal. It is generally less likely that birds will become entangled but instead may ingest small floating objects which can cause chronic impact by reducing fitness (long-term survival) and potentially breeding success. Indeed, an assessment of the impact to the local population of turkey vultures (*Cathartes aura*) in Stanley was conducted by Augé (2016). The turkey vultures feed around Eliza Cove and were investigated to determine the amount of anthropogenic debris in their diets. This was done by assessing the percentage of anthropogenic debris in the regurgitated pellets. It was found that on average, 16.1 % of the mass of each pellet was anthropogenic (mostly plastics) indicating that the birds are regularly

ingesting waste materials. Seabirds are amongst the marine vertebrates with the highest known ingestion rate of plastic and other marine debris, and this is particularly true for albatrosses and petrels. Marine debris, however, is recorded in stomach samples of many individuals of numerous seabird species. Impacts include reduced body mass and wing length of chicks, potential impacts of toxins from plastics ingested, partial endocrine disruption, and the more plastic ingested, the higher the risk of associated mortality. Nonetheless, the authors note that current plastic loads studied seem unlikely to have an impact at the population level (Phillips and Waluda, 2020).

Where a species or population is already threatened, such impacts upon fitness may have a significant effect. For example, the population of wandering albatross breeding on South Georgia, and foraging in part around the Falklands, has shown a long-term decline (Poncet, *et al.,* 2006), such that any additional pressure could exacerbate their decline.

It is understood that in recent years, the impacts of debris from the fishing industry around South Georgia, and within other CCAMLR (Commission for the Conservation of Antarctic Marine Living Resources) waters, has lessened owing to additional fishing license conditions and strict enforcement regimes (Waluda and Staniland, 2013). However, a significant number of animals are still impacted suggesting that debris also originates from outside the controlled areas. As improvements such as this can be evidenced, it is essential that any new industry in the region manages its waste responsibly.

10.10.4.1.2.2 Improper segregation and cross-contamination

In the event that wastes are not properly segregated on the MODU / FPSO at the point of waste generation and / or that waste is mixed during transportation or onshore storage, there is the risk of non-hazardous wastes becoming contaminated with hazardous wastes. Should cross-contamination occur, non-hazardous waste may need to be treated as hazardous wastes and the potential for waste recovery may be lost. The main impact of this is the loss of opportunity for waste recovery and an increase in the use of landfill.

10.10.4.2 Existing waste management facilities in the Falklands

Waste management facilities in the Falkland Islands are currently very limited. Further details on waste management options in the Falklands were documented in Smethurst (2013) and the FIG Waste Management Action Plan 2015-2017 (FIG, 2014b), while the Falkland Islands Pollution Prevention and Waste Management Policy (FIG, 2023o) recognises that a waste management framework and new facilities need to be developed. A municipal waste facility that meets the relevant regulatory standards is being developed which will allow Navitas to meet its Duty of Care commitments for the Phase 1 & 2 Development waste streams.

10.10.4.2.1 Recycling and re-use

Municipal recycling facilities are currently not available in the Falkland Islands although there is now a monthly can collection and glass is collected and recycled in Stanley. Batteries may also be recycled at collection points in local supermarkets.

10.10.4.2.2 Waste recovery (waste-to-energy)

Currently, some waste fuels are converted into heat for the hydroponics system at the Stanley Growers' site near the proposed onshore supply base and TDF in Stanley. During the last exploration campaign (under POEPL), the facility received waste oils from the drilling programme for energy recovery. This route, however, has a finite capacity and the use of waste oils from the Phase 1 & 2 Development would be subject to specific discussion and agreement with FIG. It illustrates, however, that there may be scope for waste-to-energy in the Islands.

10.10.4.2.3 Waste treatment

A new waste incineration facility that meets the relevant regulatory standards is being developed in Stanley and will be operated by FIG. This will allow Navitas to route a significant fraction of its wastes collected onshore to incineration, thereby reducing the demand on other disposal routes in line with the Waste Hierarchy (Section 10.10.1). Discussions between Navitas and FIG confirm that it is planned to be available towards the end of 2026 and will have sufficient capacity to meet the forecast incinerable waste volumes from the project.

10.10.4.2.4 Landfill facilities

The current municipal landfill sites in the Falklands, namely Eliza Cove and Mary Hill Quarry, are not suitable for landfilling of Navitas' solid wastes. It is understood from FIG that a new landfill facility that meets the relevant regulatory standards will be developed in the Islands. When this is available, it is expected to accommodate the local landfill of wastes which have no other disposal route, other than shipment overseas. This will serve to ensure compliance with the Waste Hierarchy and proximity principle on the minimisation of atmospheric emissions associated with transportation.

10.10.4.3 Phase 1 & 2 waste management

10.10.4.3.1 Waste management objectives

As a responsible operator, and in line with its OMS (Section 3.2), Navitas will implement the necessary measures to ensure that waste management is carried out without endangering human health and safety, and without harming the environment.

In line with the industry-standard, Navitas will follow the Waste Hierarchy (Section 10.10.1) to minimise waste produced throughout the Development.

- Specifically, Navitas seeks to:
- Identify, quantify and characterise all waste streams, and their volumes over the 3 Stages of the Development,
- Promote waste minimisation and segregation,
- Identify appropriate disposal options for the various waste streams and the timings required in the context of operating in the Falkland Islands, and
- Detail options and outline feasibility for the layout and specifications of potential facilities at Navitas' laydown yard.

In order to achieve this, Navitas has developed a forecast of waste quantities based on analysis of analogous projects (Section 10.10.4.4.1). Waste treatment techniques in line with the Waste Hierarchy have been identified (Section 10.10.4.3.2) with consideration given to key legislative sources and the Waste Hierarchy. Collaborative discussion will be undertaken with FIG on the most suitable waste solutions for the Phase 1 & 2 Development in the Falkland Islands context.

Navitas will develop a project-specific Waste Management Plan for operations as described Section 10.10.5.1 below.

10.10.4.3.2 Waste management options assessment

The fundamental principles of waste disposal are based on returning waste materials to the environment in a form which will have the minimal environmental impact. However, in practical terms, while there are many innovative ways to handle and process waste, there are few ultimate disposal solutions as most give rise to residues and secondary wastes that require subsequent management.

Further, waste management in a remote location without sufficient facilities to cope with the waste streams is challenging. When assessing the options, it is important to consider the varying 'trade-offs'

that exist. For example, shipment of the waste to another location will incur emissions to air and while some waste streams, such as wood or paper, may be reusable or recyclable, it is not necessarily best environmental practice to ship these a great distance for the purposes of doing so. Equally, while incineration would also result in emissions, these are offset by the reduction in emissions from waste shipment while also reducing the volume of waste that requires landfill.

A review of available options was undertaken (Filkin & Co., 2017) and the conclusions are presented in Table 10.84 below.

During the review (Table 10.84), waste management techniques and options were scoped out when:

- They were not commercially available or proven,
- The technique was energy intensive,
- They required a high order of operator competence, and / or
- There was an uncertain cost-benefit relationship.

As shown in Table 10.84, while every effort will be made to remove, reduce and re-use waste, the key options that emerged from the review were:

- Thermal treatment to mitigate the hazard of the waste, for example:
  - Treatment of NADF cuttings in line with legislation so they can be discharged to sea, and
  - Incineration of all combustible wastes to minimise waste shipments to the UK and waste to landfill.
- Use of new local municipal landfill resource when available, and
- Shipment of waste for re-use, recycling, recovery, treatment or disposal to landfill in the UK.

Shipment of waste for management in the UK has been undertaken in previous O&G operations where appropriate treatment and / or disposal infrastructure does not exist locally, and all shipments will be made in compliance with the Basel Convention and the Transfrontier Shipment of Waste Regulations (Section 10.10.1.1.2). Nonetheless, it should be noted that, the export of non-recyclable waste for disposal is not a preferred option for Navitas owing to the impact of emissions, cost and reliance on the return trips of existing commercial shipping routes and *ad hoc* freighter vessels etc. However, as this is currently the only assured means of waste disposal for the life of field, it is proposed as the base-case for disposal of all Phase 1 & 2 wastes that cannot be incinerated in the Islands.

Nonetheless, Navitas will continue to explore other options for waste management in the medium to long-term. This will include exploring the export of waste to another, geographically closer, OECD (Organisation for Economic, Co-operation and Development) country.

Table 10.84: Waste management options assessment indicating the methods that were considered both viable and in line with Navitas' objectives

Waste Hierarchy solution	Definition	Location	Navitas options	Viable option?
Remove	Don't generate waste	Falkland Islands and UK	The first way to minimise waste generated is to not create it in the first place. This will be done through consideration of waste in contracting and minimising packaging.	✓
Reduce	Generate Less waste by better management and material substitution			✓
Re-use	Re-use the material in its original form	Falkland Islands	In order to minimise the volumes of waste drilling muds, muds that have been returned to the MODU and cleaned of cuttings will be reused on subsequent wells. Should opportunities be identified to locally re-use waste materials in future, Navitas will support any suitable in-country initiatives.	✓
Recycle	Recycle or reprocess the item to incorporate it into a new product or new use	Falkland Islands	Presently there is little processing infrastructure and / or demand for the types of recyclable waste materials identified during the waste forecasting (Section 10.10.4.4). Therefore, the number of credible options for recycling in the Falklands is currently very limited. Where an opportunity is identified to locally recycle waste material in future, Navitas will support any suitable in-country initiatives.	✗
		UK	Recycling facilities are available in the UK for materials that are shipped out. It should be noted however, that for large developed economies such as the UK, many wastes collected for recycling are exported for processing abroad which then incurs further emissions.	✓
Recovery	Extract material or energy from a waste	Falkland Islands	Waste-to-energy refers to the process of generating other forms of energy (e.g., electricity and / or heat) from the primary treatment of waste. These processes include: Recovery of heat from the combustion of incinerable wastes, Combustion of oils as a fuel source e.g., the free-oil that is separated from oily waters offshore, and Use of organic wastes for composting which is a process of controlled decay enabling aerobic bacteria and other micro-organisms to decompose organic matter. If a temporary incinerator is required, Navitas will investigate the potential for waste heat recovery, with the use of this route being subject to specific discussion and agreement. Nonetheless, should any other opportunities for waste recovery emerge in the future, Navitas will support initiatives where they are considered feasible and safe and where sufficient competence can be demonstrated.	✗
		UK		✓

Waste Hierarchy solution	Definition	Location	Navitas options	Viable option?
Treat	Mitigate the inherent hazard of the waste	Falkland Islands	Thermal treatment of cuttings: A key decision is to thermally treat drill cuttings generated with NADF so that the cuttings can be discharged to sea in line with OSPAR Decision 2000/3. This greatly reduces the amount of material that would otherwise be brought onshore for treatment and disposal. Further, and as stated above, the process also enables the re-use of the base-oil in the next batch of NADF and tests have shown that the base-oil remains of sufficiently good quality through the process.	✓
	Incineration	Falkland Islands	Incineration of waste: Current facilities do not have the capacity to manage the volume of Phase 1 & 2 Development waste (Section 10.10.4.2.3), but FIG are planning to provide new incineration facilities that will meet the project requirements. If this is not possible, as a contingency, the project proposes the use of a portable incinerator at the onshore supply base. Incineration is a means of: Reducing the volume of waste that requires disposal, thus mitigating against landfill impacts, and Reducing the number of shipments of waste back the UK. Navitas recognise that incineration is not a complete management solution as it gives rise to ash and flue gases, as well as a range of maintenance wastes. These will be managed in an environmentally sound manner *via* FIG. Atmospheric emissions are somewhat offset by the fact that incineration of the waste reduces the overall volume of waste and thus reduces the number of waste shipments to the UK.	✓
		UK		✓
Dispose	Landfill	Falkland Islands	As disposal to an in-country landfill is not currently an option (Section 10.10.4.2.4), all materials that cannot be incinerated and require landfill will be returned to the UK. There are two types of landfill that may be required for the unrecoverable Phase 1 & 2 Development waste streams: Hazardous landfill for the deposit of hazardous wastes onto, or into, the land in such a way that pollution or harm to the environment is minimised, and Stable, non-reactive landfill for the deposit of inert waste that is incapable of reacting with other wastes when placed in a designated area within a landfill.	✗
		UK		✓

10.10.4.4 Quantification of Phase 1 & 2 waste

10.10.4.4.1 Type and volumes of planned waste expected

When assessing the original Sea Lion Development, POEPL commissioned a waste study and forecast (Filkin & Co., 2017) to estimate the waste streams and volumes that may result from the Development. Data sources for this study included:

- Data on wastes produced during the previous Falkland Islands exploration well campaigns,
- Data on actual waste arisings from analogous activities both onshore and offshore,
- 2020 UK waste production data, obtained from Defra (2023), and
- UKCS O&G production waste figures, obtained from UK EEMS[87] Report Data (reported in OEUK, 2023), to determine the average quantity of waste produced by all North Sea installations.

While the currently proposed Sea Lion Development has evolved slightly since the original proposal, e.g., reduced number of wells, increased Field Life etc., (Section 2.1.1) the data used in the forecast, which is benchmarked on duration of activities and personnel numbers, remains valid and provides an overview of the solid and hazardous liquid waste arisings in terms of:

- What waste types are forecast to be produced,
- What volumes of these wastes can be expected, and
- When, during the project life-cycle, can these waste types be expected to arise.

In addition to projecting the waste arising throughout the entire Field Life, the forecast was used to group wastes together that share the same, or similar, waste management characteristics. It should be noted that a large proportion of these totals will be discharged to sea, including cuttings, sewage, grey water, treated oily water and food waste, and therefore, will not require onshore treatment or disposal. These are covered in the drill cuttings and operational discharges chapters (see Sections 10.6 and 10.7 respectively).

Figure 10-46 below shows the waste that requires onshore treatment arising throughout the life of the Development, and from which activity. Figure 10-47 indicates the quantities of wastes going to the varying endpoints. The detailed waste forecast and associated disposal options are summarised in Table 10.85 and Table 10.86.

[87] The Environmental and Emissions Monitoring System (EEMS) is the environmental database of the UK O&G industry.

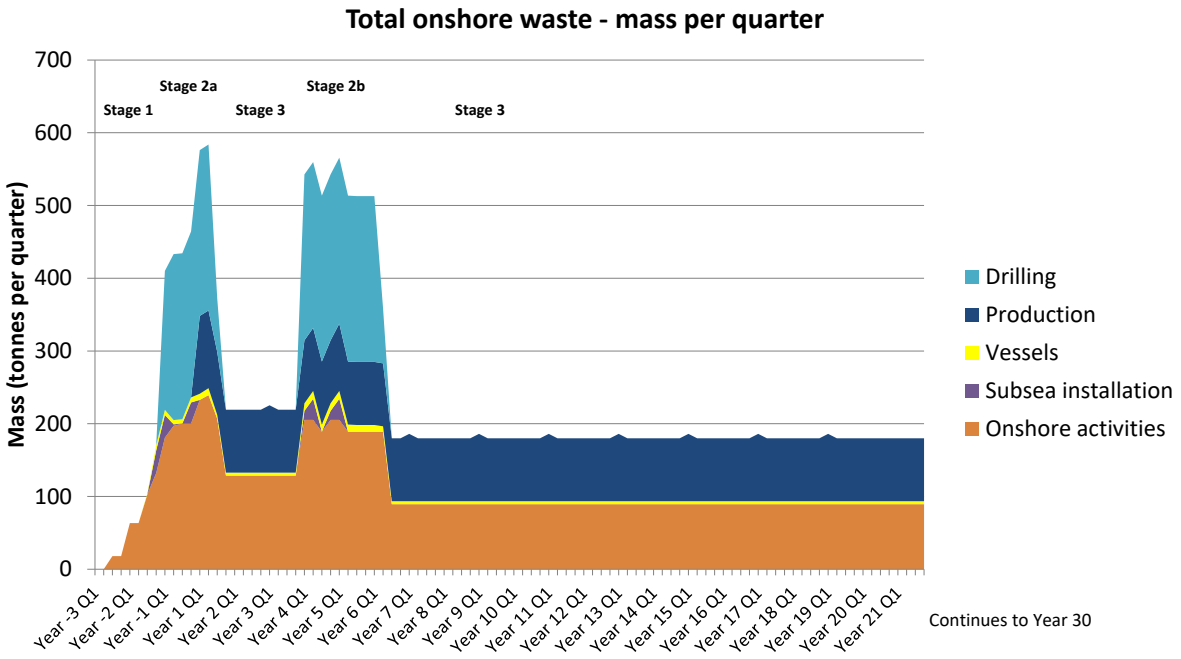

Figure 10-46: Phase 1 & 2 Development wastes managed onshore split by activity generating the waste

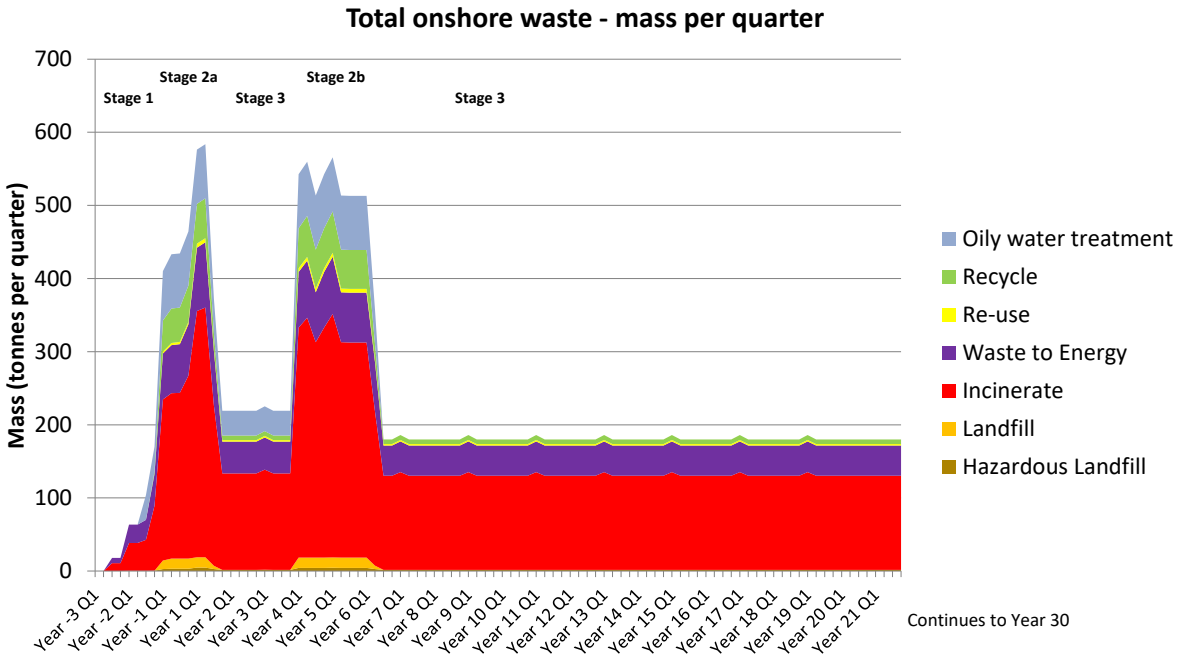

Figure 10-47: Phase 1 & 2 Development wastes managed onshore split by endpoint

Table 10.85: Forecast of hazardous and non-hazardous waste quantities that require onshore treatment, broken down by activity at different stages of the project[1]

Activity	Field life total (tonnes)	% of total	Stage 1	Stage 2a	Initial Stage 3	Stage 2b	Remaining Stage 3
Drilling	3,424	12%	1,071	293	0	2,061	0
Production	10,559	37%	108	194	789	877	8,595
Subsea installation	285	1%	154	0	0	138	0
Vessels	571	2%	42	15	36	97	386
Onshore activities	13,698	48%	1,402	442	1,153	1,941	8,743
Total	**28,537**	**100%**	**2,777**	**944**	**1,978**	**5,114**	**17,724**
% by Stage			**10%**	**3%**	**7%**	**18%**	**62%**

[1] These figures do not include the ash from the incinerator that will be operated by FIG. This waste stream, totaling 1,888 tonnes over the course of the Development, is included in Table 10.86.

Table 10.86: Disposal options for Sea Lion waste streams

Waste stream	Final destination (UK or Falklands)	Disposal method	Estimated quantity over Field Life (tonnes)	Percentage contribution over Field Life
Aerosols and gas cylinders	UK	Recycle / treatment	147	0.5 %
Aluminium and metal	UK	Recycle / re-use	1,450	5.1 %
Batteries	UK	Recycle	20	0.1 %
Bulk hoses	Falkland Islands	Incinerate [1,2]	199	0.7 %
Cardboard, paper and packaging	Falkland Islands	Incinerate [1,2]	793	2.8 %
Chemical sacks	Falkland Islands	Incinerate [1,2]	201	0.7 %
Chemicals	UK	Treatment / hazardous landfill	48	0.2 %
Containers and empty IBCs	UK	Re-use	299	1.0 %
Filters (hazardous)	UK / Falkland Islands	Hazardous landfill / incinerate [1,2]	167	0.6 %
Filters (non-hazardous)	Falkland Islands	Incinerate [1,2]	138	0.5 %
Food[3]/ packaging	Falkland Islands	Incinerate [1,2]	2,887	10.1 %
Flammable solids and solvents	Falkland Islands	Incinerate [1,2]	5,224	18.3 %
General garbage, non-hazardous	Falkland Islands	Incinerate [1,2]	4,755	16.7 %
Glass	Falkland Islands	Re-use	57	0.2 %
Hazardous electrical waste	Falkland Islands	Recover / re-use / recycle	4	0.0 %
Hazardous waste, aerosols, pipe dope	Falkland Islands	Incinerate [1,2]	133	0.5 %
Light bulbs	UK	Recycle	5	0.0 %
Medical	Falkland Islands	Incinerate [1,2]	6	0.0 %
Non-hazardous electrical	Falkland Islands	Recover / re-use / recycle	32	0.1 %

Waste stream	Final destination (UK or Falklands)	Disposal method	Estimated quantity over Field Life (tonnes)	Percentage contribution over Field Life
Oily rags, oily sludge, oily wastes, oily water and WBM washings	Falkland Islands	Incinerate [1,2]	6,510	22.8 %
Other	UK	Landfill	815	2.9 %
Plastics	Falkland Islands	Incinerate [1,2]	952	3.3 %
Printer cartridges	UK	Recycle	16	0.1 %
Slings	Falkland Islands	Incinerate [1,2]	404	1.4 %
Wood	Falkland Islands	Incinerate [1,2]	1,704	6.0 %
Oily water	Falkland Islands	Treat / incinerate	1,571	5.5 %
Total waste			**28,537**	-
Total re-used (UK)			**299**	**1.0 %**
Total recycled (UK)			**1,507**	**5.3 %**
Total incinerated or waste-to-energy (Falkland Islands)			**24,698**	**86.5 %**
Total to landfill (UK)			**462**	**1.6 %**
Total oily water treatment (Falkland Islands)			**1,571**	**5.5 %**
Secondary waste - incinerator ash to landfill[1,2]			**1,888**	-

[1] Ash from the incineration process is the responsibility of FIG.

[2] It is generally expected that ash residues from static hearth incinerators of the type proposed here can vary between 3-10 % of the mass of the input waste (Filkin & Co., 2017). As a worst-case, this assessment assumes 10 % of the mass of waste incinerated is left as ash.

[3] The majority of food waste will be discharged offshore in compliance with MARPOL (Section 10.13.5.1.2) but any food waste returning to the supply base, for example if offshore macerators are not working, would be incinerated unless future opportunities arise in collaboration with FIG for composting of such resources.

10.10.4.5 Phase 1 & 2 waste in the context of the UK

FIG plan to establish a new municipal waste facility that will take the majority of waste from the project. Waste in categories that cannot be managed in the Islands will be shipped to an international location. This section discusses the waste footprint of the entire project in the context of the UK's waste management system.

The UK generated 191.2 million tonnes of total waste in 2020, 20.6 % of which was generated by Commercial and Industrial (C&I) activities (Defra, 2023). The recycling rate was 52.3 % over the UK in 2020, and the proportion sent to landfill was 24.2 % (Defra, 2023).

A summary of the estimated Phase 1 & 2 waste is provided in Table 10.87, alongside the most recent applicable UK waste data (2018-2021 depending on the data). The Phase 1 & 2 Development is predicted to generate a total of 28,537 tonnes of waste (excluding incinerator ash which is secondary to the initial waste volume produced) over the course of the Field Life, with the relative contributions of each Stage also shown in Table 10.87. Notably, the total quantity of waste generated throughout the life of the project (c. 30 years) amounts to 0.01 % of the amount of waste generated in the UK in a single year (2020). Similarly, the Sea Lion waste which may be sent to landfill over the life of the project (462 tonnes) equates to 0.001 % of UK waste which went to landfill in 2020. Assuming that the UK 2020 waste production was to remain consistent over the life of the project, the total Phase 1 & 2 waste would amount to 0.0005 % of the total UK waste tonnage generated in 32 years. When compared to the UK C&I waste alone (Table 10.87) the total Phase 1 & 2 waste generated over 32 years amounts to 0.07 % of the amount of C&I waste generated in the UK in a single year (2020).

Detail on the fate of the North Sea O&G industry wastes is provided in Table 10.88 (OEUK, 2023). These data show 66 % of all waste was reused or recycled, with 9 % of all UK O&G wastes going to landfill as opposed to only 1.6 % of Phase 1 & 2 waste. However, it should be noted in this comparison that the O&G waste industry figures reflect a mature and well established industry so waste options that are

feasible and well-used in the UK may not be directly applicable to the same waste streams generated in the Falklands.

Table 10.87: Summary of wastes produced during the Phase 1 & 2 Development Stages 1 to 3 in comparison to total UK waste, total UK C&I waste and total UK waste to landfill

Waste source		Total Quantity (tonnes)	Average quantity per year (tonnes/year)[1]	Percentage contribution
Stage 1	Drilling, onshore construction, installation (31 months)	2,755	1,066	10 %
Stage 2a	Drilling, installation, First-Oil and initial production (7 months)	956	1,639	3 %
Stage 3 (initial)	Steady production (28 months)	1,979	848	7 %
Stage 2b	Drilling, installation, ongoing production (28 months)	5,135	2,201	18 %
Stage 3 (remaining)	Steady production (*c.* 27 years)	17,711	654	62 %
Totals		**28,537**	-	-
Total UK waste 2020[2]		**191,200,000[1]**		
Total UK commercial and industrial (C&I) waste 2020[2]		**40,400,000**		
Total UK waste that went onto or into land in 2018[2]		**46,270,400**		

[1] Note: Stage 2a is less than one year, so the total for Stage 2a is less than this figure.
[2] Note: these data are as is reported by Defra (2023).

Table 10.88: Comparison of the fate of O&G industry wastes

Fate of waste	North Sea O&G industry waste in 2022[1]		Quantity (t) of Phase 1 & 2 Development waste (excl. incinerator ash)		
	Quantity (t)	As a percentage of the North Sea 2013 total	Total waste over project life	Average waste per year	As a percentage of Sea Lion total waste for one averaged year
Re-use and Recycling	92,000	66 %	1,806	55.4	6.3 %
Waste to energy[2]	7,500	5 %	5,818	178.5	20.4 %
Incinerate	500	0.4 %	18,881	579.0	66.2 %
Landfill	13,000	9 %	462	14.2	1.6 %
Other route[3]	26,000	19 %	1,571	48.2	5.5 %
Total	**139,000**	-	**28,537**	**875**	-

[1] As extracted from OEUK HSE Report rounded to 500 tonnes (OEUK, 2023).
[2] Waste-to-energy refers to the process of generating energy in the form of electricity and / or heat from the primary treatment of waste.
[3] Other disposal routes include but are not limited to: land treatment, specially engineered landfill, biological treatment, injection. Other recovery routes include but are not limited to: use as a fuel, used oil refining, land treatment resulting in benefit to agriculture or ecological improvement (EC Regulation No 1013 / 2006 on the Shipment of Waste, Annex 1a).

10.10.5 Industry-standard mitigation

Industry-standard mitigations available include:

- Development of a voluntary 'Environmental representative / steward' (E-Rep) role among the offshore and supply base personnel,
- Waste awareness training and inclusion of a clear message in all personnel inductions,
- Segregated and coloured / clearly labelled bins,
- Signage,
- Contained waste receptacles,
- Use of netting over open skips,
- Dedicated waste laydown areas, and
- Reporting of loss of waste incidents to FIG.

An example of an educational poster is shown in Figure 10-48 which encourages the containment of waste and, in particular, the cutting of packaging bands so that they do not entangle seals and sea lions in the event that they are lost to sea.

There are also a number of standard management practices which will be followed. These are:

- Compliance with the Navitas OMS with regard to contractor management, auditing, performance monitoring and the setting of waste objectives and targets,
- Development of, and adherence to, the Waste Management Plan (see below),
- Minimisation of waste through contracting and logistics strategy,
- International Finance Corporation (2007) Environmental, Health, and Safety General Guidelines, and
- UK HSE guidance HSG71 for storage of wastes.

Figure 10-48: Example of an educational poster for placement around the MODU and FPSO

10.10.5.1 Waste Management Plan

In compliance with the FIG Guidance Note (02/13), a Waste Management Procedure has been developed, which will be used to develop the project-specific WMP has been developed and will be further refined for operations. It will provide guidance on efficient working practices for the safe handling, storage, transportation and disposal of waste generated during the Phase 1 & 2 Development.

Specifically, the WMP will detail:

- Key roles and responsibilities of Navitas personnel and contractors with regard to waste management,
- The regulatory and EMS guidelines upon which the WMP is based,
- The Waste Hierarchy used to minimise the amount of waste disposal and maximise recovery (Figure 10-45 above),
- Definition of waste types, and
- Guidance on all aspects of waste management.

10.10.6 Impact and risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. Assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes is tabulated in Section 10.10.12 which shows the worst-case impact / risk for each activity and receptor.

10.10.6.1 Impact assessment of waste generation and management

10.10.6.1.1 Shipment of waste

Arrangements for the temporary storage of waste awaiting transhipment in the Falklands will be agreed with and approved by FIG. Navitas will collaborate with FIG and other stakeholders to plan all shipments, thus maximising their efficiency. While the use of the FIG municipal incinerator should reduce the number of waste shipments to the UK, thus reducing the emissions, it has been assumed that all *ad hoc* freighter vessels will remain on hire to Navitas to return the waste to the UK to assume a worst-case. The impact of all emissions resulting from the Phase 1 & 2 Development is assessed in Section 10.9.

10.10.6.1.2 Use of regulated landfill

Landfill occupies the lowest rank in the Waste Hierarchy and it is understood that this method of waste management is ultimately unsustainable. However, as waste that cannot be incinerated in-country will be returned to the UK, and most likely Scotland which has consented landfill space available for 10-20 years (Section 10.10.4.5), the sensitivity of UK landfill sites as a receptor (tangible property) is considered to be '**High**'.

It is currently uncertain how long shipping waste back to the UK will be necessary and / or permissible. However, as is shown in Section 10.10.4.5, only 1.6 % of Phase 1 & 2 waste is expected to go to landfill, which is less than the 9 % of waste from the UKCS as a whole (Table 10.88). In addition to the efforts made to reduce and recover waste, this percentage volume has been lessened due to the incinerator which aims to minimise the volume of materials being returned to the UK. Overall, the total estimated quantity of waste from the Phase 1 & 2 Development that will be sent to landfill amounts to only 0.001 % of the UK waste sent to landfill in 2020 alone (Section 10.10.4.5), and 0.07 % of the UK C&I waste

produced in 2018. As such, this landfill use falls within the category of 'Minimal use of a finite resource throughout lifecycle of project or moderate use for finite stages of the project' and, on balance, the severity of effect on landfill resources for the duration of the Development is considered to be '**Minor**'.

Therefore, the overall significance of the transboundary impact of large amounts of waste over the Project lifetime on tangible property in the UK is assessed as '**Moderate (8)**'.

10.10.6.2 Risk assessment of unplanned and accidental events

10.10.6.2.1 Loss of containment

Given that waste mismanagement and loss of containment would be an unplanned event, it is not possible to estimate which of the potential receptors may be affected by any given event. Therefore, for the purposes of the assessment below, the most sensitive receptor is described to ensure a worst-case assessment has been made.

10.10.6.2.1.1 Impacts to landscape

Assessment of the impacts on landscapes / seascapes, and the indirect impact upon the 'quality of experience' of the human population, is very subjective and almost impossible to quantify. The sensitivity of the receptor will ultimately depend upon the volume of waste accidently lost to the environment, the waste type and the path and final destination of the waste. However, with regard to landscape and seascape, impacts of losses are only likely to result from waste mismanagement at the supply base such that the range of probable destinations would be limited (Section 10.10.4.1.2.1).

Nonetheless, waste could reach areas which are 'partially developed with non-industrial infrastructure which are used for recreational purposes and tourism' and therefore litter could 'conflict with the current use of the area'. The sensitivity of the landscape / seascape as a receptor is therefore considered to be '**High**'. Similarly, with regard to the human population as a receptor, the littering of valued and / or sensitive areas may be considered 'unacceptable to a majority of stakeholders'. Therefore, to assume the worst-case, the sensitivity of the receptors is considered to be '**High**'.

Given the transient nature of litter, the impact of lost materials in any given place may not be permanent as the material may move from place to place under the influence of wind, tide, scavenging fauna and / or may be picked up by a passer-by. Despite the temporary location of the litter however, unless it is collected and appropriately disposed of, the litter itself may be permanent unless it is biodegradable and may impact upon the view from close range. Therefore, the severity of effect in any given time and place is considered to be '**Minor**'.

The worst-case overall significance of the impact of waste mismanagement to landscape / seascape is be considered to be '**Moderate (8)**'.

Once accidentally released into the environment, it is not realistic to suggest that the lost materials can be immediately recovered and it is therefore key to prevent its release. Implementation of the WMP and the use of closed skips (Section 10.10.5) will minimise the likelihood of losses. Additionally, the implementation of the measures described in Section 10.10.5 to achieve early and sufficient containment of waste will hopefully ensure that all personnel are informed and trained on the importance of effective waste containment. The likelihood of loss of containment is considered '**Unlikely**'.

Therefore, the overall significance of the risk to landscape / seascape associated with loss of containment is therefore considered to be '**Low (6)**'.

10.10.6.2.1.2 Impacts to wildlife

As with the impacts to landscape and seascape, it is not possible to predict the fate of litter and which animals it may impact upon, or how many times. However, given that impacts may occur to a protected

species and / or those within a globally important population, which may also be long-lived species with a slow reproduction rate, or during a vulnerable life stage (e.g., during breeding), it has been estimated that the sensitivity of the receptor could be '**Very High**'.

While the effect of litter on wildlife can be fatal (Section 10.10.4.1.2.1), the impacts are likely to affect individual animals rather than groups of animals such that, in most cases, the impact would be unlikely to be detectable above background variability, or to impact upon population fitness. Therefore, the severity of effect to most receptors is likely to be 'Slight' and the overall impact significance 'Low (6)'. However, in the event that a long-lived, slow breeding species was impacted by ingestion or entanglement, such as albatross sp., there is the possibility that this could impact upon the population fitness. To take a precautionary approach therefore, the severity of effect is considered to be '**Minor**'.

Therefore, the worst-case significance of the impact of waste mismanagement is assessed to be '**Moderate (10)**'.

As described above regarding the way waste may be lost, the likelihood of loss of containment occurring is considered to be '**Unlikely**'.

The overall significance of the risk to wildlife associated with loss of containment is therefore considered to be '**Low (6)**'.

The risks of unplanned release of hazardous liquid waste are considered in Section 12.1.

10.10.6.2.2 Improper waste segregation

Assuming that normally recoverable waste was cross-contaminated with hazardous waste through poor segregation, and thus had to be disposed of (rather than recovered), this may have an effect on resource use, such as landfill. Therefore, to take a precautionary approach and assume the unnecessary use of this finite resource, the sensitivity of the receptor is considered to be '**Very High**'.

It is not possible to estimate the extent of any impact as cross-contamination may affect one piece of scrap metal, which could be cleaned, or an entire skip full of plastic packaging or wood. However, given that improper segregation would be an unplanned event and that waste management will be regularly audited in line with the OMS, it can be assumed that the quantities of cross-contaminated waste will be relatively small. Therefore, it is likely that disposal to landfill as a result of cross-contamination will have 'no or negligible use of finite resource throughout lifecycle of project' and therefore the severity of effect is likely to be '**Slight**'.

Therefore, the worst-case significance of the impact of improper segregation could be considered to be '**Low (5)**'.

Implementation of the WMP (Section 10.10.5.1) will ensure that sufficiently labelled waste skips and bins will be in place on the MODU / FPSO. Nonetheless, taking a precautionary approach given that such an incident could occur through negligence by an individual, the likelihood of the event occurring is '**Possible**'.

The overall significance of the risk associated with improper segregation is therefore considered to be '**Low (6)**'.

10.10.7 Project-specific mitigation measures

While some environmental impacts are 'Low' or 'Very Low' such that no further mitigation measures are considered necessary, the following impacts and risks were all considered to be '**Moderate**', and therefore require further mitigation efforts where possible:

- The use of landfill resource in the UK.

10.10.7.1 Mitigating impacts to landfill

Although landfill space may be available over the life of the field (Section 10.10.4.5), landfill is inherently unsustainable and occupies the lowest level in the Waste Hierarchy.

It is therefore necessary to determine ways to further reduce the volume of waste that may be destined for landfill. While the use of an incinerator has been proposed and is included within the initial impact assessment, it will always be necessary for responsible operators to identify other reasonably practicable means for reducing the waste to landfill, and indeed the overall impacts of waste.

Industry-standard practises and the OMS requirements, which aim to ensure continual improvement, are such that no additional mitigation measures are considered reasonably practical in reducing waste quantities at this time.

Note: even in the event that new landfill facilities became available in the Islands, this would not lessen the sensitivity of landfill as a receptor as disposal to landfill, wherever it is located, will always be fundamentally unsustainable.

10.10.7.2 Mitigating impacts from loss of containment

Industry-standard practises and the OMS requirements, which aim to ensure continual improvement, are such that no additional mitigation measures are considered reasonably practical in reducing risks from the loss of containment of waste at this time.

10.10.8 Residual impacts and risks

10.10.8.1 Residual impact of landfill use

There will always be some wastes that cannot be incinerated, e.g., some recyclable wastes and specialty wastes which have to go to landfill, and whether these are transported to the UK, or taken to a new in-country facility in the future, landfill will always be fundamentally unsustainable in the long-term such that the sensitivity of the receptor (landfill) must remain 'High'. The only way to reduce the impact of landfill use is to find opportunities for waste management which sit higher up in the Waste Hierarchy, thus reducing the reliance on landfill and the severity of effect.

Since there are no current plans for new landfill capacity on the Falkland Islands, the residual impact remains '**Moderate (8)**'.

10.10.8.2 Residual risk of loss of containment

Not applicable.

10.10.9 Cumulative impact

10.10.9.1 Landfill use

While application of the Waste Hierarchy will maximise the reduction, re-use, recycling and recovery of waste (including waste-to-energy), the use of landfill sites in the UK, for a proportion of the waste will still be required which may have a cumulative effect in terms of concentration, extent and duration of waste (Section 8.9.1). While the contribution to landfill from the Phase 1 & 2 Development in isolation is relatively low in the UK context (Section 10.10.4.5), and is lower than the average waste to landfill from UKCS operations, the impact significance is considered 'Moderate', primarily owing to the sensitivity of the receptor, i.e., the unsustainability of the resource.

While Navitas will endeavour to reduce this impact by minimising waste to landfill, it has very limited control over the cumulative and indirect impacts caused by landfill e.g., methane gas production from

decomposition. However, all landfill sites in the UK are governed by numerous pieces of legislation to ensure that they are managed in accordance with best practice.

10.10.9.2 Incinerator use

As stated above, FIG have approved plans for a new municipal waste facility and the project will only provide stand-alone incineration in the event that the FIG site is not available. However, with regard to air quality, the siting of the supply base incinerator is not considered to add cumulatively to any impacts already present from the FIMCO incinerator due to their relatively distant locations.

10.10.10 Confidence

The magnitude, extent, reversibility, duration and frequency of the impact of waste generation and management are well understood from previous projects.

One uncertainty in the assessment of the onshore disposal and recovery of waste is that the waste quantities are estimated based on development wells and production in the North Sea. It is also recognised that whilst the exact incinerator product to be used is not yet defined, representative proven models of the type proposed have been used for assessment purposes. To take a precautionary approach confidence in the assessment of all the impacts is considered to be '**Probable**'.

Confidence in the risk assessments for waste mismanagement is '**Certain**'.

10.10.10.1 Monitoring required

Monitoring of waste and compliance with the WMP will occur via:

- Pre-hire audit, and ongoing audits of the MODU and other project vessels to ensure tanks and pits provide flexibility for managing fluids to minimise pit cleaning or other liquids and to ensure waste segregation is being managed,
- Ensuring the contracting strategy with key suppliers incentivises waste minimisation and features in Key Performance Indicators (KPIs) e.g., *via* ISO14001 compliance,
- Weekly inspection of storage facilities in line with the WMP inspection checklists and use of the Navitas Corrective Action list where non-conformances cannot be immediately remedied,
- Monitoring of performance by the E-Rep on the MODU and FPSO and supporting ongoing waste initiatives,
- Internal Navitas waste reporting e.g., monthly provision of the Waste Disposal Logs, reporting of non-conformances or spills and corporate waste reporting and monitoring *via* KPIs,
- Waste reports will be made available to the appropriate regulatory bodies as required,
- The requirement to audit / assess waste contractors (Section 3.2.13) and track actions in corporate systems,
- Reporting any losses of waste to the environment, and
- Transfrontier shipment of waste notification controls.

Detailed monitoring requirements were established during the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the EMMP. An outline EMMP is provided in Chapter 15.

10.10.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

10.10.12 Findings summary

Table 10.89: Summary of the impact assessment for waste management during the Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance a		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Offshore, inshore, onshore and at-shore operations and activities	Waste generation for disposal to landfill in the UK (worst-case)	Use of a finite resource, risks to groundwater, aquifers and soil, production of methane	Planned	1, 2a, 2b & 3	High	Minor	n/a	**Moderate (8)**	**Moderate (8)**	**Probable**	**Industry-standard:** Compliance with the Navitas OMS with regard to contractor management, auditing, performance monitoring and the setting of waste objectives and targets **Project-specific:** Use FIG facility
	Loss of containment	Impact to landscape / seascape, and quality of experience of valued sites	Unplanned	1, 2a, 2b & 3	High	Minor	Unlikely	**Low (6)**	**n/a**	**Certain**	**Industry-standard:** As above, and E-Reps scheme, waste awareness training, segregated bins, signage, netting, dedicated waste laydown areas. **Project-specific:** None proposed.
Offshore, inshore, onshore and at-shore activities	Loss of containment	Impacts to wildlife, ingestion of waste by marine fauna or entanglement	Unplanned	1, 2a, 2b & 3	Very High	Minor	Unlikely	**Low (6)**	**n/a**	**Certain**	
	Improper waste segregation	Loss of opportunity for waste recovery and increased use of landfill	Unplanned	1, 2 & 3	Very high	Slight	Possible	**Low (6)**	**n/a**	**Certain**

10.11.1 Introduction

Numerous vessels will be used throughout the three Stages of the Phase 1 & 2 Development and while the use of vessels is planned, it is necessary to consider the risk of collision with cetaceans (whales and dolphins). Internationally, it is believed that collisions between cetaceans and vessels are more frequent than previously suspected (WDCS, 2006). Such an increase in the risk of collisions is linked to a general increase in the density of shipping traffic, the number of large fast-moving vessels (Silber, *et al.,* 2009) and the continuing recovery of large cetacean populations following the cessation of whaling.

Concern about vessel collisions with marine animals is increasing worldwide. However, most publications focus on larger whales. While Schoeman *et al.* (2020) found that smaller animals are also affected and recommend the establishment of a species-specific necropsy protocol and a database for smaller species, there is a paucity of documented evidence / data on vessel collisions and smaller cetaceans generally. In the Falklands Islands, recent collisions have been reported with sei whales and a Commerson's dolphin (Falklands Conservation, 2020). However, there is little detail on the circumstances. Anecdotally the collision with the dolphin was with a fast-moving launch. According to van Waerebeek *et al.* (2007), most collisions between small cetacean and vessels tend to occur in enclosed inshore, estuarine or freshwater environments where there is a high-density of smaller fast-moving vessels. Navitas will use large ocean-going vessels in Berkeley Sound and in the Sea Lion Field and for this reason, collisions with small cetaceans are not considered further in this chapter.

This chapter specifically assesses the risk of collision between the Phase 1 & 2 Development vessels and large cetaceans. Specifically, the risk of collisions between cetaceans and vessels during the offshore operation and during transit to and from Stanley. Few vessels will visit other inshore waters e.g., Berkeley Sound. These are limited to the arrival and departure of up to four Large Transit Vessels with only two *in situ* at any one time, both of which will be stationary for the majority of the duration, and infrequent visits (*c.* 11) to the Large Transport Vessels (LTVs) by the Offshore Construction Vessels (OCVs) over the course of Stages 1 and 2.

Note: The other impacts associated with vessel use are described elsewhere in this document, as described in Table 2.2.

10.11.1.1 Legislation and guidelines regarding collision with marine mammals

Currently, there is no dedicated legislation in the UK or the Falkland Islands to protect cetaceans from ship-strike specifically. However, marine mammals are protected from deliberate harm by the:

- UK Offshore Marine Conservation (Natural Habitats & Conservation) Regulations 2001.
- Falkland Islands Marine Mammals Ordinance 1992.
- Conservation of Wildlife and Nature Ordinance (1999).
- Cetacean code of conduct for the Falkland Islands (Falklands Conservation, 2020).

10.11.2 Sources of potential risk

10.11.2.1 Shipping and collision risks

During the Phase 1 & 2 Development, shipping traffic will increase as a result of:

- Arrival and positioning of the Mobile Offshore Drilling Unit (MODU),
- Delivery and installation of the subsea moorings and production facilities,
- Arrival and positioning of the Floating Production, Storage and Offloading vessel (FPSO),
- Hook-up and commissioning of the FPSO,
- Emergency support for the MODU and FPSO,

- Supply of cargo to the Falkland Islands,
- Supply of cargo to the MODU and FPSO,
- The arrival and departure of the Large Transit Vessels (LTVs) to Berkeley Sound,
- The transit of OCV's between the LTVs in Berkeley Sound and the Sea Lion Field, and
- Conventional Trading Tankers (CTT) receiving crude oil from the FPSO at the Sea Lion Field.

A summary of vessel use during Stages 1, 2 and 3 is given in Table 10.90. A full inventory of the vessels used during Stages 1 to 3 of the Development is provided in Section 5.11.2.

The behaviour of these vessels will depend upon their specific roles e.g., cargo delivery *vs.* emergency support *vs.* oil export and the frequency of vessel movements will vary depending on the Stage of Development.

Table 10.90: Summary of the vessels to be used during each stage of the Phase 1 & 2 Development

Stage 1	Stage 2a/2b	Stage 3
MODU transit to field Anchor Handling Tug Supply (AHTSs) Vessels Multi-Role Support Vessels (MRSVs) Platform Supply Vessels (PSVs) Emergency Response and Rescue Vessel (ERRV) *Ad hoc* freighters FPSO transit to Sea Lion Field (towed by 3 tugs) Positioning and presence of FPSO on location with 1,275 m radius exclusion zone Large Transport Vessels (LTVs)[1] Offshore Construction Vessels (OCVs)[1]	MODU transit in-field AHTSs ERRV *Ad hoc* freighters PSVs FPSO on location with 1,275 m radius exclusion zone Oil export vessels: Purchaser's Conventional Trading Tanker (CTT) MRSV ERRV LTVs OCVs	FPSO on location with 1,275 m radius exclusion zone Oil export vessels: Purchaser's Conventional Trading Tanker (CTT) MRSV ERRV PSVs *Ad hoc* freighters

[1] These vessels arrive in Berkeley Sound in the final month of Stage 1 in preparation for Stage 2a.

10.11.2.2 Entanglement risks

Entanglement with marine mammals may result from the:

- Use of anchor chains offshore for the FPSO / MODU,
- Presence of risers in the water column, and
- Use of anchor chains inshore for the LTVs.

There is a good deal of literature involving cetacean entanglements, however much of this involves fixed and static fishing gears, such as various types of nets and the cables used to attach floats to lobster and crab traps (e.g., van der Hoop, *et. al*., 2016; Frisch-Jordán and López-Arzate, 2024). One of the key properties with fishing lines is that there is usually a considerable amount of slack in the lines and they are generally of a small gauge. This slack enables the lines to wrap around whale body parts, which ultimately leads to entanglement and often drowning.

However, the various mooring lines, chains and cables associated with large ships, the MODU / FPSO and subsea engineering would be taut under most circumstances and would not have enough slack to allow cetaceans to become entangled. It is understood that there are no records for entanglements with large anchor chains or indeed flow lines from sub-sea engineering to FPSOs such as risers. In addition, reviews conducted on mooring systems for offshore renewable installations have found a lack of information on entanglement (Kropp, 2013). Harnoise *et al.* (2015) defines a methodology to

compare different offshore renewable energy mooring configurations in terms of the risk of entanglement they present to marine megafauna and conclude that the absolute risk of entanglement is low, regardless of the mooring configuration. They concluded that that the taut configuration has the lowest relative risk.

Considering the gauge of anchors chains for ships (Berkeley Sound) and the MODU / FPSO (at the Sea Lion Field), and the risers to the FPSO coupled with the lack of evidence for entanglement in the literature this risk is not assessed further within this chapter.

10.11.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify the specific receptors to which the risk of collision warranted further investigation (Chapter 9). The receptors that may be subject to the risk of collision during the Phase 1 & 2 Development include a wide range of large cetacean species that are known to occur within Falkland Islands waters (Section 7.4.6).

Small cetaceans (dolphins) are fast moving and agile enough to avoid vessels travelling at moderate speed and are likely to be at greater risk from small fast-moving craft rather than those associated with the Development. Indeed, some species, such as Peale's dolphin (*Lagenorhynchus australis*) and Commerson's (*Cephalorhynchus commersonii*), are attracted to large vessels to bow-ride. There is only one mention of a collision between a vessel and a Commerson's dolphin in the 'Cetacean code of Conduct for the Falkland Islands' (Falklands Conservation, 2020) and therefore such collisions are likely to be a rare event. In addition, FIG do not maintain a cetacean collisions database and thus there are no records. For these reasons, small cetaceans are not considered further in this assessment, which explores only the risk of collisions between Phase 1 & 2 vessels and large cetaceans (whales).

10.11.4 Characterising and quantifying the risk of collision

When characterising and quantifying the risk of collisions between large cetaceans and vessels during the Phase 1 & 2 Development, it is necessary to consider:

- The history of cetacean collisions in the Falkland Islands,
- The potential impacts of vessel and cetacean collisions,
- Cetacean behaviour, population and distribution,
- Vessel size, speed, behaviour and distribution, and
- Overlap between Phase 1 & 2 vessel traffic and cetacean distribution.

10.11.4.1 History of cetacean collisions in the Falkland Islands

The Falkland Islands Species Action Plan (SAP) for Cetaceans[88] identifies a number of potential threats to cetaceans. The old SAP (FIG, 2008b) did not regard ship-strike to be a problem in the Falklands and there are no known records of fatal collisions between vessels and cetaceans in the region. However, anecdotal records of collisions (e.g., those described in Weir, 2017; Sei Whale CMP, 2024) will be considered within the new cetacean SAP which is currently being developed.

Although there are numerous records of beached cetaceans (of 26 species) (Augé, *et al.,* 2018), the likely cause of death is not recorded and it is not known how many of these animals were examined for signs of ship-strike. Equally, it is unlikely that all cetaceans that die at-sea in Falkland waters strand on Falklands beaches and given the prevalence of ship-strike elsewhere in the world, it seems likely that there will have been some incidents in the past that have gone undetected, or have not been reported.

[88] Note that this document (FIG, 2008b) expired in 2018 and a new draft is currently under development and will provide more data on collisions.

10.11.4.2 Potential impacts of vessel and cetacean collisions

Globally, collision between marine mammals and vessels has become an increasingly important issue (WDCS, 2006) with the potential to impact upon individuals and / or populations.

In the event that a collision was to occur, the individual animal may suffer:

- Lethal injury (Figure 10-49a),
- Injury leading indirectly to death e.g., owing to an inability to feed, loss of impulse to feed,
- Injury with unknown longer-term impact (Figure 10-49b), or
- Injury leading to reduced fitness e.g., breeding success.

Depending upon the health of the population, all of the above may ultimately impact upon the population of a species, and for a rare species, loss of an individual may be a significant contributor to population decline.

For example, the impact of collisions with vessels is thought to be threatening the survival of the northern right whale (*Eubalaena glacialis*), which is an IUCN (International Union for the Conservation of Nature) 'Critically Endangered' species (NMFS, 2005). Further, interactions between fin whales and ships in the Mediterranean Sea are also causing concern (Vaes and Druon, 2013) and Berman-Kowalewski *et al.* (2010) report interactions between blue whales and shipping off the coast of California.

10.11.4.3 Cetacean behaviour, abundance and distribution

The behaviour, abundance and distribution of individual species all affect both the impact that collisions can have, and the likelihood of occurrence. For example, where a population size is in decline, an individual strike will be of greater significance than for a population with high abundance. With regard to behaviour and distribution, a range of factors are thought to influence the likelihood of a collision (Table 10.91).

Therefore, when assessing the impact and the likelihood of cetacean collisions it is important to consider:

- The size and trends of the relevant whale populations and whether or not they are in decline, thus influencing the impact of a single collision at the population level, and

- The known behaviour of different species which can make individuals of a particular species more likely to be involved in a collision.

Large cetaceans, albeit at lower densities, can be encountered anywhere within Falkland Islands waters (White, *et al.,* 2002). However, the number of large cetaceans encountered within Falkland Islands waters varies on a seasonal basis, with highest densities encountered in the coastal waters during the summer and autumn for sei whales and winter for southern right whales.

Although the evidence is anecdotal, the number of large cetaceans in Falkland Islands waters, and elsewhere in the south-west Atlantic, appears to be increasing (Frans and Augé, 2016). While all marine mammals in Falkland Islands waters are protected and have been identified as priority conservation species (FIG, 2008a), two species that are encountered in the coastal waters of the Falklands are most likely to be susceptible to collision. These are:

- Southern right whales, due to their behaviour and abundance, and
- Sei whales owing to their abundance.

Table 10.91: Summarising the effect of cetacean behaviour and distribution on the likelihood of collision

Factor	Description
Age and condition	A high proportion of the recorded incidents relate to young animals or females with calves.
Swimming speed	Each species will display characteristic behaviour in terms of swimming speed and time spent on the surface.
Congregation	At certain times, animals may congregate in areas to feed or breed. The risk of colliding with an animal where high densities occur is increased.
Distribution	Where animals show a tendency to distribute themselves in areas which are also used by shipping traffic, the risk of colliding may increase.
Feeding / mating behaviour	Animals engaged in feeding or mating behaviour are less likely to respond to an approaching vessel. Also, many large whales feed on planktonic organisms in the surface layers of the water. Therefore, feeding animals may spend longer on or near the surface than those that are travelling. Most planktonic organisms perform a daily vertical migration, being closer to the surface at night. Therefore, cetaceans may be more vulnerable at night when feeding near the surface and undetectable by watch keepers on vessels.
Vessel habituation	Animals that are constantly subjected to vessel noise may become habituated and not respond to an approaching vessel.

10.11.4.3.1 Southern right whale

The size of the southern right whale population that breeds off the Argentine coast is well studied and tripled since 1999 to 2006. The rate of increase decreased from near 7 % in 2007 to 0.06 % and 2.30 % for total number of whales and number of calves, respectively for 2016 (Crespo, *et al.,* 2019). Until the winter of 2017, in the Falklands, southern right whales were only occasionally seen in inshore waters and even in Stanley Harbour (A. Black, *pers. obs.*; Baines and Weir, 2020). Although right whales were known to be present within Falkland Islands waters throughout the year, acoustic and visual surveys indicated that their numbers were highest in the spring and summer months, However, during the winter of 2017 an influx of southern right whales was witnessed (Section 7.4.6.3.1.1). It should be noted however, that 2017 was the year that empirical survey effort started and therefore it is difficult know what their abundances were in preceding years.

With regard to their behaviour and distribution, right whales appear to be particularly vulnerable to collision strike because they:

- Aggregate in nearshore waters around the Falklands coast during winter (but occur offshore year-round),
- Spend prolonged periods near the surface,
- Are particularly buoyant and slow moving, so can be slower to react to approaching vessels than many other whales, and
- Tend not to react to approaching vessels when engaged in some behaviours (especially mating and socialising winter aggregations).

10.11.4.3.2 Sei whales

Although the occurrence of this species has been erratic in the past (showing considerable inter-annual variation), the sei whale is by far the most numerous species of large whale in coastal waters near Stanley during the summer and autumn months (White, *et al.,* 2002; FIG, 2008b; Thomson and Munro, 2014; Weir, 2017; Baines and Weir, 2020; Weir, *et al.,* 2021; Cerchio and Weir, 2022). While the results of photo-identification are emerging (Weir, 2022) there is not sufficient survey data to determine an accurate population estimate, although there is anecdotal evidence that the number within Falklands' waters, and more generally within the south-west Atlantic, is increasing (Iñíguez, *et al.,* 2010).

Sei whales are currently listed as 'Endangered' on the IUCN Red List and are also afforded conservation status and management under CITES (Convention on the International Trade in Endangered Species) and CMS (Convention on Migratory Species).

The International Whaling Commission (IWC) indicate that mortality of >2 % of any population would be unacceptable and the loss of 1 % of the population estimate would be cause for concern (IWC, 2014b). The size of the population in Falkland Islands waters is unknown however and therefore local incidental mortality limits cannot be set.

With regard to their behaviour, while there are records from around the world of collisions between sei whales and vessels (IWC database, 2014b) they are considered to be at lower risk than most other large whale species (e.g., fin whales, sperm whales and southern right whales) (Vanderlaan and Taggart, 2007). This is primarily because they:

- Appear to respond to approaching vessels,
- Are relatively fast swimmers, and
- Tend to swim just below the surface leaving a clear trail of 'fluke prints' in their wake, which are conspicuous in calm weather (Sea Watch Foundation, 2012).

Nonetheless, the risk of collision can be increased when they:

- Occur in high densities in nearshore waters during summer and autumn, including in Berkeley Sound,
- Use nearshore waters as a foraging habitat, where their focus on feeding may make them less responsive to vessel, and
- When they surface skim- and lunge-feed (Segre, *et al.,* 2021) and spend prolonged periods moving slowly near the surface.

It should be noted that elsewhere in the world sei whales are considered to be an offshore species; however, in the Falklands this species is associated with relatively shallow inshore waters.

The initial results of observations recording the dive behaviour of sei whales (Weir, *et al.,* 2018) indicate that this species is highly mobile with estimated average speeds of 3.5 - 8.3 km/hr. Combined with relatively inconspicuous behaviour on the surface, these parameters make sei whales relatively

difficult to detect visually, which supports observations made by other observers regarding the difficulty of seeing these animals at-sea (A. Black, *pers. obs.*).

Much of Falkland Islands inshore areas are registered as a Key Biodiversity Area (KBA) (Section 7.5.2.3.4). Two major assessments have occurred to assess whether particular areas of the Falkland Islands inshore marine environment contain populations of species which trigger the global KBA criteria. This work occurred as of September 2021. The assessments were for sei whales and breeding seabirds. This process concluded that 10 species have populations which trigger global KBA criteria and, notably within this context, sei whales. For full details about the assessments for sei whales please see Weir (2020).

10.11.4.4 Vessel behaviour

10.11.4.4.1 Effect of vessel size and speed on collision impact and likelihood

In varying combinations, both the size and speed of vessels can affect the impact of a collision and the likelihood of avoiding whales once sighted.

A number of authors have investigated the lethality of ship strike. Most recently Kelley *et al.* (2020) investigated this using biophysical models. They concluded that vessels of all sizes can yield stresses that likely result in impact. Analysis by Vanderlaan and Taggart (2007) updated by Conn and Silber (2013) found a direct relationship between vessel speed and the outcome of a collision with increasing speed shown to increase the probability of lethal injury (Figure 10-50). The Conn and Silber (2013) analysis includes more incidents and shows that impacts are more likely at lower speeds than is indicated in the Vanderlaan and Taggart (2007) study. With regard to likelihood, vessel speed and size both have implications for the detection of marine mammals and the ability, or otherwise, to take effective avoidance action if a cetacean is seen ahead of a vessel (Clyne and Leaper, 1999). As shown in Figure 10-51, it can be seen that:

- Large vessels such as tankers and container ships are unable to respond quickly enough to significantly reduce the likelihood of a collision, and
- Decreased speed reduces the likelihood (and severity) of a collision in vessels of all sizes.

These data corroborate the findings of Laist *et al.* (2001) who reviewed the available data regarding collisions between vessels and cetaceans and made several interesting observations:

- Although all types and sizes of vessels may hit whales, most lethal and serious injuries to whales are caused by relatively large vessels (>80 m in length),
- Most severe and lethal injuries caused by ship-strikes appear to be caused by vessels traveling at >14 knots,
- Ship collisions probably have a negligible effect on the status and trend of most whale populations, but may have a significant effect on very small populations or discrete groups, and
- The available accounts of real events suggest that most whales hit by ships are not seen beforehand or are seen only at the last moment (Laist, *et al.,* 2001).

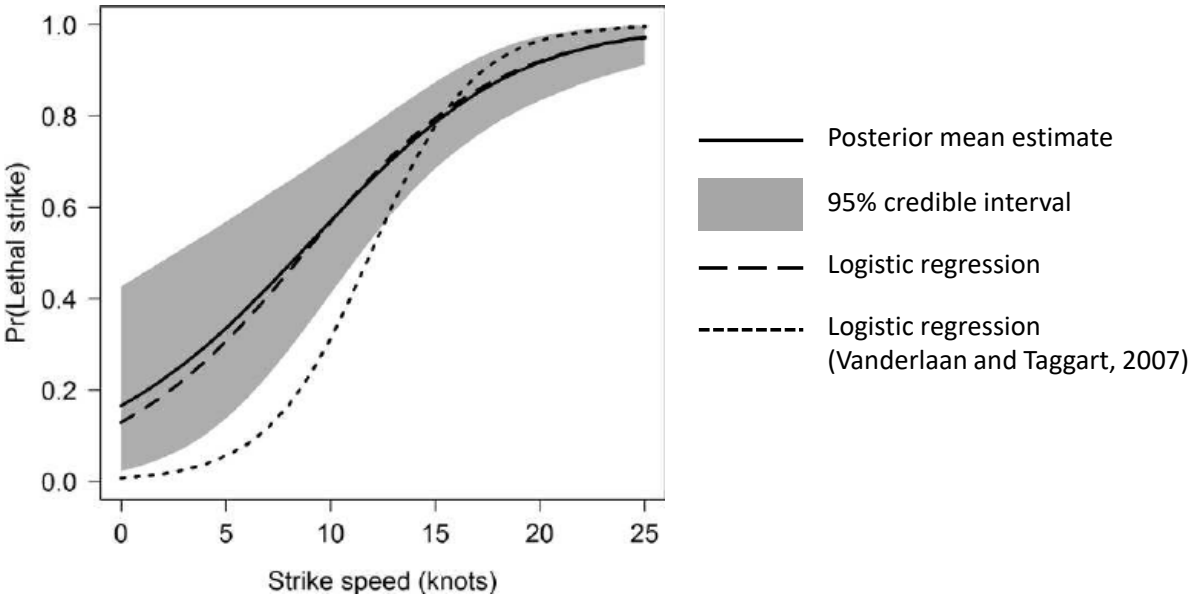

Figure 10-50: Probability of a lethal injury resulting from a vessel strike to a large whale as a function of vessel speed ***(Source: Conn and Silber, 2013)***

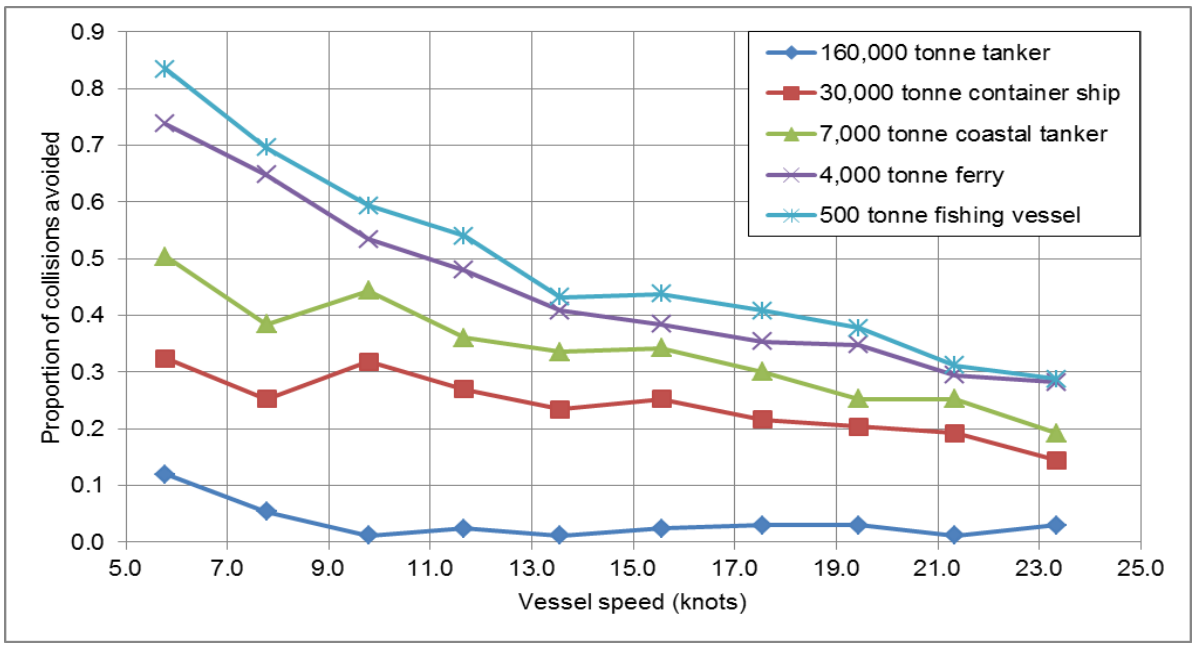

Figure 10-51: Proportion (out of one (1)) of collisions that were successfully avoided as a proportion of the total that would have occurred if no avoidance action was taken ***(Source: Clyne and Leaper, 1999)***

10.11.4.4.2 Effect of vessel distribution on collision likelihood

The location, route and behaviour of vessels influence the likelihood of a collision with regard to congregations and distribution of marine mammals. Wherever high densities of cetaceans and shipping coexist there is the potential for collisions (see Williams and O'Hara, 2010; Vaes and Druon, 2013). Where information regarding both vessel movements and cetacean populations is available, it is clear that geographic bottlenecks occur. While there are limited, but growing, data regarding cetacean distributions around the Falkland Islands, there is some very detailed information regarding shipping movements, although this has only been recorded since June 2014.

As shown in Figure 10-52 (an example of a busier fishing year), several routes are regularly used by vessels and mostly converge in Port William, Stanley and Berkeley Sound (in the north-east corner of the Islands) such that geographic bottlenecks of vessel traffic occur in these coastal waters. The band of heavy vessel activity near the 200 m isobath to the south and east of the Falklands is due to the activity of the loligo trawl fleet (Section 7.7.3.2.1.1).

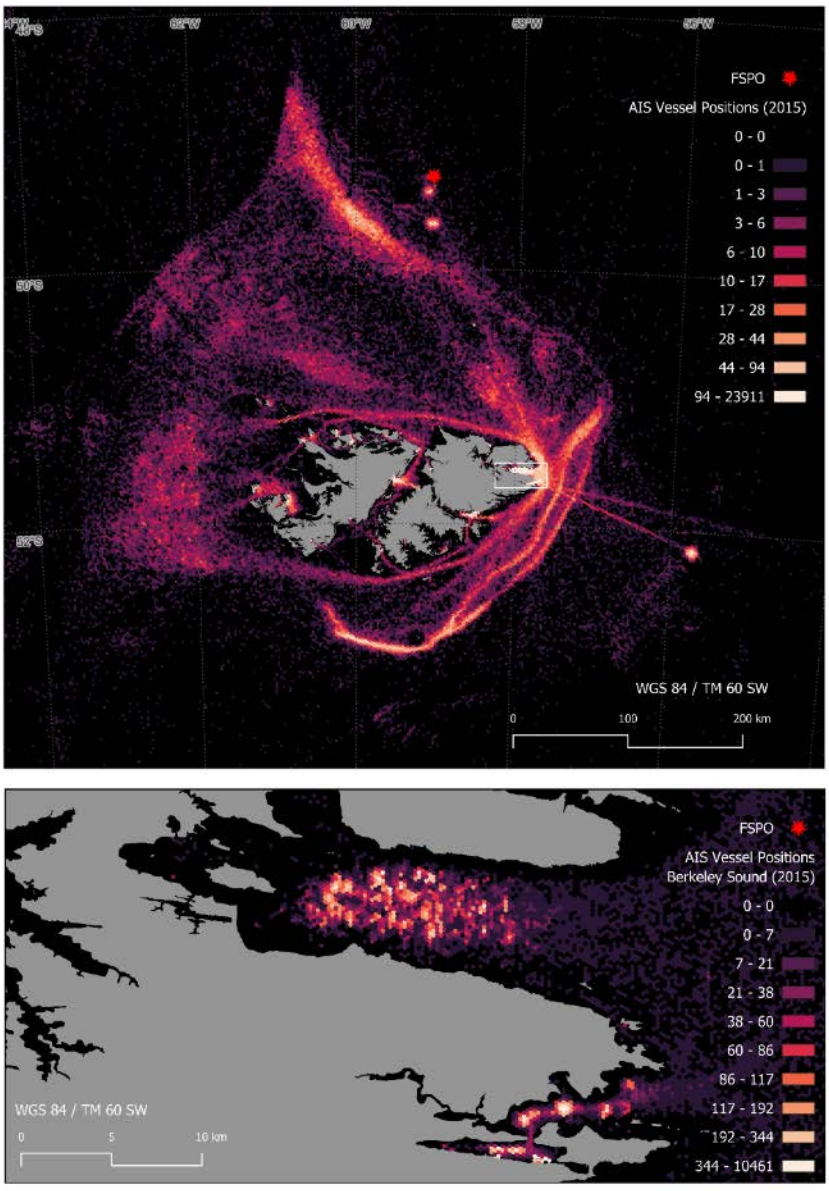

Figure 10-52: Distribution of vessel activity between June 2014 and June 2015

10.11.4.5 Overlap in Phase 1 & 2 vessel traffic and cetacean distribution

With regard to the above information, it is necessary to consider the specification and behaviour, route and location of vessels associated with the Phase 1 & 2 Development.

The exact number, type and likely routes of vessels used in the Phase 1 & 2 Development are yet to be finalised. However, specifications of typical vessels likely to be used, and their behaviour is provided in Table 10.92. The highest number of vessels will be used during Stage 1 (Table 10.92) and based upon this, the risk of collision to marine mammals will be greatest in this Stage. However, some of the vessels

(e.g., installation vessels) will be in place for a relatively short duration whereas Stage 3 (steady state production and associated vessel activity) will last for around 27 years.

With regard to the overlap in vessel activity and cetacean distribution, the distribution of right and sei whales in particular is not well understood outside of Berkeley Sound, and the north Falklands coast (Section 10.11.4.3). However, the fact that both are sighted within the NFB, Berkeley Sound and near Stanley Harbour year-round highlights that these species have spatial and temporal patterns of distribution, which overlap with shipping activity.

Table 10.92: Summary of vessel use during the Phase 1 & 2 component of the Sea Lion Development

Stage	Total number of vessels at sea at any one time in the NFB	Range of vessel lengths (m)	Mean vessel length (m)	Mean vessel speed (kn)	Main vessels locations
Vessels associated with the offshore component of the Development (drilling, installation and production)					
Stage 1	16	61 - 250	89.0	9	In-field and in transit between UK, Sea Lion Field and Falkland Islands
Stage 2a/2b	6	61 - 250	111.0	11	
Stage 3	3	61 - 250	98.0	11	
Vessels associated with the oil export component of the Development					
Stage 1	n/a	n/a	n/a	n/a	In-field and in transit
Stage 2a/2b	7	50-250	103	8	
Stage 3	7	50-250	103	8	

10.11.5 Industry-standard mitigation measures

No industry-standard mitigation measures are in place to minimise the impact or likelihood of collision with marine mammals in UK waters, or those of UK Overseas Territories. Though there are 'Guidelines' issued by the National Oceanic and Atmospheric Administration (NOAA) providing guidance on collision reduction.

Off the eastern seaboard of the U.S., this issue has posed a threat to the survival of the northern right whale and mariners are legally bound by the US Marine Mammal Protection Act (MMPA) 1972 to follow area- and time-specific measures.

Guidelines issued under the MMPA by the NOAA (2009) include:

- 'Compliance Guide for Right Whale Ship Strike Reduction Rule' which require that vessels greater than 19.8 m entering dense shipping areas reduce their speed to 10 knots,
- 'Guidelines for Mariners' detailing precautionary measures which should be taken to avoid northern right whales,
- 'Mandatory Ship Reporting System for North Atlantic Right Whales' which are relevant to key areas known to be of importance to northern right whales, and
- The measures outlined in the above include:
  - The re-alignment of traffic separations schemes,
  - The creation of areas to be avoided,
  - Mandatory ship reporting systems,
  - Advisories to mariners, and

- Speed restrictions.

As part of Navitas' operating procedures, speed restrictions will be applied to vessels entering the boundary of the Inshore KBA (Section 7.5.2.3.4); as vessels approach the inshore KBA boundary line the maximum speed permitted will be ≤10 knots.

Additionally, vessels generally will only transit the Sound during daylight hours, with daylight-only berthing and night-time departure by exception only.

10.11.6 Risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor', the 'Severity of Effect' and the 'Likelihood of Occurrence' to determine the overall 'Risk'. A summary of the impact and risk assessment outcomes is tabulated in Section 10.11.12, which shows the worst-case risk for each activity and receptor.

Given the difference in the behaviour and location of the vessels used during installation, drilling, production and oil export, it is considered appropriate to assess the risk of collision between cetaceans and each vessel type (grouped by location and behaviour) separately.

10.11.6.1 Risk of collision during drilling, installation and production (offshore)

Given that, for varying lengths of time, drilling, installation and production will occur over all seasons, the use of vessels will coincide with periods of highest abundance of both right whales, sei whales, and other cetacean species, in Falkland Islands waters. With regard to the sensitivity of each receptor, southern right whales are considered to be susceptible due to their behaviour (Section 10.11.4.3.1). Although the number of animals utilising Falklands waters appears to be increasing, in line with the population in the South Atlantic as a whole, and this species is listed as 'Least Concern' by IUCN. However, the SW Atlantic population *is* of regional conservation concern (IWC-CMP, 2023). The sei whale population in the south-west Atlantic is also believed to be increasing and relatively high numbers of sei whales have been encountered in inshore waters around the Falkland Islands for a number of years (Section 10.11.4.3.2). However, sei whales are listed as an IUCN 'Endangered' species. In addition sperm whales are known to occur in the NFB and are listed as an IUCN 'Vulnerable' species. Despite the differences in the international conservation status of these species, all marine mammals are conservation priority species in the Falkland Islands and therefore, the sensitivity of the receptor is considered to be '**High**'.

As shown in Section 10.11.4.5 above, the number of vessels will be highest during Stages 1 and 2a/2b of the Development which is to last for 35 months in total, with 10 months of this time being the highest levels of overlapping vessel activity. Nonetheless, while the number of vessels decreases in Stage 3, the mean vessel lengths increase and Stage 3 will last for 27.1 years (Section 10.11.4.5). Further, many of these vessels are >80 m in length and are capable of maximum speeds of >14 knots, both of which are thresholds noted by Laist *et al.* (2001) (Section 10.11.4.4.1). While it is unlikely that vessels will be operating at their maximum speeds when in-field or approaching inshore waters, a 50 % probability of lethal injury is still likely at only 9 knots (Section 10.11.4.4.1, Figure 10-50). Additionally, the larger vessels used (e.g., the LTV) would only be able to manoeuvre to avoid a collision in less than 50 % of scenarios even if the animal was observed at low speed (Figure 10-51).

Although a whale may be better able to avoid a slow-moving vessel, the kinetic energy (proportional to mass x speed) of the largest vessels employed during the Development will be higher than that of smaller vessels moving at considerably faster speeds. Therefore, the potential for injury or lethal impact is higher for the largest vessels and following a precautionary approach it is considered that any collision will lead to lethal injury.

Given the long generation time of the species concerned, any collision that could result in mortality would have a 'moderate effect in the local area'. Nonetheless, given that the populations of sei and southern right whales are believed to be increasing (Section 10.11.4.3), it anticipated that there would be a 'temporary and reversible impact on the species'. The severity of effect of collisions between ships and cetaceans is therefore considered to be '**Moderate**'.

The overall significance of the impact of collisions between vessels and cetaceans therefore is assessed as **'Upper Moderate (12)**'.

With regard to the likelihood of collision, vessels used during the offshore component of the Development (e.g., installation vessels in Stage 1 and 2, and supply vessels throughout), are most likely to be operating at very slow speeds in the field. Nevertheless, vessels will be travelling between the offshore Sea Lion Field and Stanley Harbour throughout the project and it is while steaming through inshore waters that the likelihood of encountering cetaceans is highest. However, vessel speed will decrease and watch-keeper vigilance will be heightened as vessels approach land in response to the increased risks of navigating in coastal waters, which increases the likelihood of detecting and avoiding cetaceans. Despite the lack of documented records, it is assumed that whale-strikes have occurred around the Falklands, although without further evidence these are considered to be very rare events. Given the competence standards that are required as part of the contractual process within the O&G industry, the overall likelihood of a collision has been assessed as **'Unlikely'**.

Therefore, the overall significance of the risk associated with the offshore component is considered to be **'Moderate (8)'**.

10.11.6.2 Risk of collision in Berkeley Sound (inshore)

The sensitivity of the receptor and severity of effect are as described above (Section 10.11.6.1). Therefore, the overall significance of the impact of collisions between vessels and cetaceans therefore is considered to be **'Upper Moderate (12)'**.

With regard to likelihood, some vessels (LTVs and installation vessels) are required to transit to, and manoeuvre in, inshore areas (Berkeley Sound) where there is a seasonally high likelihood of encountering large whales. However, vessel speed will be limited to ≤10 knots when they reach the inshore pMMA boundary as the vessels are heading inshore.

In addition to the lookouts posted on the forecastle of the vessels as already referred to in Section 10.11.7, all vessels will be in a state of heightened awareness due to the risks associated with mooring operations, which will aid early detection of hazards to navigation, such as non-project vessels or cetaceans. The relatively slow vessel speed (10 knots) somewhat reduces the likelihood of collisions, and the impact energy. Therefore, the overall likelihood of a collision during the inshore operations is considered to be **'Possible'.**

Therefore, the overall significance of the risk associated with vessels operating in Berkeley Sound is considered to be **'Upper Moderate (12)'.**

10.11.7 Project-specific mitigation measures

Collisions within the Falkland Islands waters between vessels and whales is considered **'Unlikely'** for offshore vessels and **'Possible'** for inshore vessels**,** and the overall significance of the risk is **'Moderate (8)'** and '**Upper Moderate (12)'**. A precautionary approach was taken during the assessment because, while collisions have not historically been a recorded around the Falkland Islands (Section 10.11.4.1), oil production and export developments and all the incumbent vessels, have not been in the area for any extended period of time either. It is therefore necessary for project-specific mitigation measures to be implemented.

The introduction of a 10 knot speed limit for the Falklands pMMA and Port William, in line with NOAA guidelines, is already considered as industry standard mitigation (Section 10.11.5) and included in the initial assessment (Section 10.11.6). To further reduce the risk of collisions in inshore waters, Navitas will limit vessel speeds to under eight (8) knots within Berkeley Sound.

Additionally, during transit in Berkeley Sound, there will be two qualified Seabird and Marine Mammal Observers (SMMOs), most likely posted to the OSVs and they will advise the Ship's Master on the bridge of the need for evasive action. The OSVs are the most common vessels transiting Berkeley Sound to pick up equipment from the LTVs.

While the US MMPA is not relevant to the waters of the Falkland Islands, a number of common-sense precautions, based on the NOAA Guidelines (2009), should also be taken to reduce the likelihood of collisions with cetaceans, as follows:

- Mariners should be made aware of the issue and how it relates to the Falkland Islands, educational materials, such as posters, will be produced to be displayed on the bridge of contracted vessels (see IFAW (2013) and Figure 10-53 below for example),
- Along with the usual duties of a watch-keeper, additional vigilance is required to detect cetaceans in inshore waters and all cetacean sightings will be logged and collated annually,
- On all vessels a lookout should be posted while transiting areas of high cetacean abundance, and
- If whales are spotted, speed should be reduced and animals given a wide berth.

While these measures may be effective in hours of daylight and calm seas they become less effective as sea state rises. Furthermore, mitigation based on visual observations is not possible during the hours of darkness when feeding baleen whales may be nearer the surface (Section 10.11.4.3, Table 10.91 above). Additionally, even where these measures can be applied, modelling suggests that collision avoidance strategies dependent on detecting and avoiding whales are ineffective for large ships with limited manoeuverability (Section 10.11.4.4.1).

Equally, to prevent collisions going unrecorded the IWC encourage mariners to report all collisions with cetaceans.

The objectives of collecting this information are to:

- Lead to more accurate estimates of the incidence of mortality and injuries, to help detect trends over time,
- Allow better modelling of risk factors (for example, vessel type, speed and size), and
- Identify high risk or unsuspected problem areas.

In addition to Navitas incident reporting and investigation, any incidents of collisions with marine mammals will be reported to FIG and the IWC via:

- FIG Environment Department, and
- The IWC web portal for reporting ship strikes - https://portal.iwc.int (see also: https://iwc.int/management-and-conservation/ship-strikes).

In addition to a programme of environmental awareness for all personnel contracted to Navitas, the use of qualified SMMOs will ensure that observations from vessels are recorded and analysed. Although it might not always be possible to take evasive action due to the slow response of a large vessel (Section 10.11.4.4.1), these observations will help to determine whether an issue exists and inform further mitigation, if required.

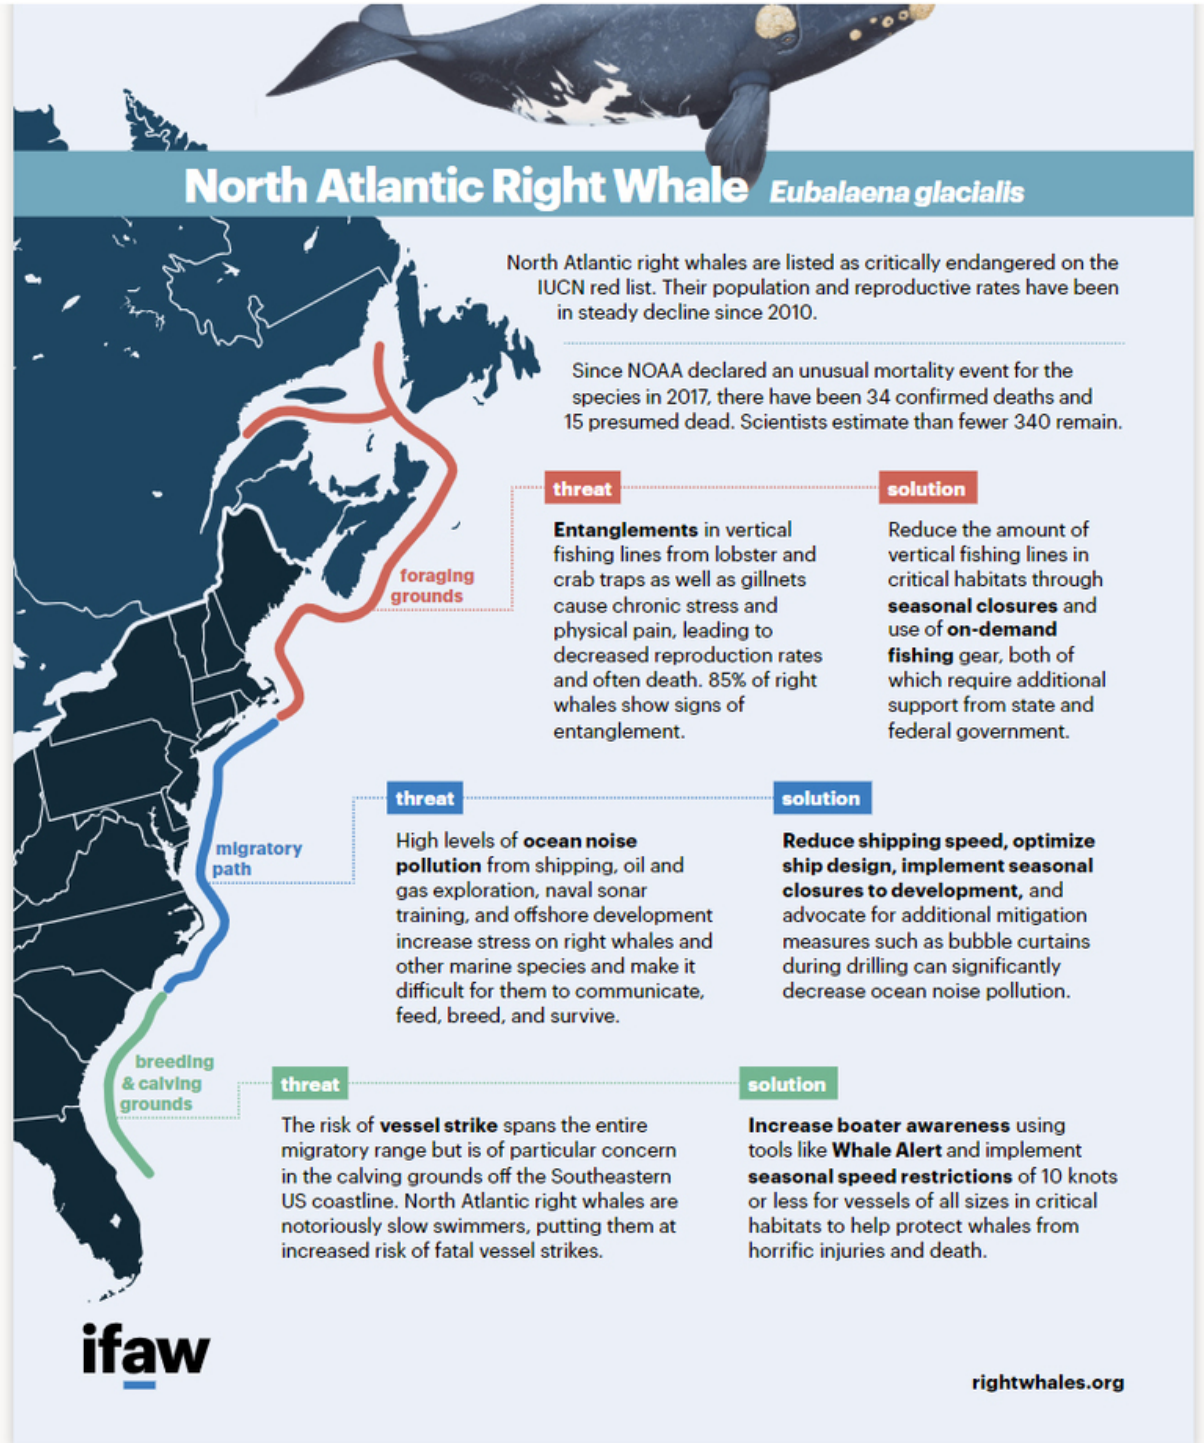

Figure 10-53. Example of educational poster on whale strikes ***(Source: IFAW, 2024)***

10.11.8 Residual impacts and risks

10.11.8.1 Risk of collision during drilling, installation and production

Increased awareness and vigilance should help to reduce the risk of collisions between vessels and cetaceans. However, there are concerns that measures that rely on visual observations are ineffective in poor observation conditions and are open to human error. Therefore, it is doubtful that the likelihood of collisions will be reduced sufficiently enough to warrant downgrading, and therefore the

likelihood remains **'Unlikely'.** The overall significance of the risk associated with the offshore component remains **'Moderate (8)'**. Vessels will be requested to report any incidents, which will help to quantify the scale of the impact and better inform future impact assessments.

10.11.8.2 Risk of collision during inshore operations

SMMOs coupled with the reduction to eight (8) knots within Berkeley Sound will reduce the likelihood of collisions between cetaceans and vessels from **'Possible'** to **'Unlikely'**. Vessel speed within Berkeley Sound will be well below that recommended in the US MMPA, however, lethal injury remains a possibility. Therefore, overall residual risk reduces to **'Moderate (8)'** for Inshore vessels.

Along with increased awareness of all personnel, the presence of qualified SMMOs will help reduce the likelihood of collisions but perhaps more importantly will provide information to better assess the interactions between vessels and cetaceans. Although there is no evidence to suggest that a problem exists around the Falklands, uncertainty surrounding the issue has resulted in this very conservative assessment.

10.11.9 Cumulative impact

As described in Section 7.7.3.2, there are already a reasonable number of fishing and other commercial vessels using Berkeley Sound, Port William and Stanley Harbour (close to 1,800 port visits in 2014, which was an unprecedented year (Figure 7-119)). Therefore, there is the potential for cumulative impacts due to increased 'concentration' and increased 'extent and proportion' (Section 8.9.1).

Existing vessel numbers peak between February and June, which also coincides with the period of highest large cetacean density (Section 7.4.6.3.3). It is estimated that the Phase 1 & 2 Development will increase the amount of vessel traffic in and out of Stanley by less than 5 % at this time. The percentage increase in vessel activity within Berkeley Sound is highly variable due to fluctuations in *Illex* catches and therefore transhipment activity.

The percentage increase in the number of vessels is not the only important factor; size, speed and behaviour of vessels is also important. Vessels associated with the Phase 1 & 2 Development within Berkeley Sound are similar in size to the largest vessels that currently use the Sound; however, the speed of project vessels in Berkeley Sound (maximum of eight knots) and their movements will be tightly controlled. Combined with vigilant observers, this should limit the risk of collisions with cetaceans.

10.11.10 Confidence

Data gaps exist regarding the inter-annual variation in density of the environmental receptors. Sei and right whales are a common sight throughout the inshore waters of the Falklands during the summer, as well as autumn for sei whales and winter for right whales. Reports of southern right whale presence around the Falklands indicate a change from previously understood spatial and temporal behaviour in Falkland Island waters. Additionally, data regarding vessel movements is not collected systematically and therefore it is not possible to accurately quantify the risk of collisions between cetaceans and vessels. It is clear that not all incidents of collisions between marine mammals and vessels are reported or even evident to the crew of the vessel. For these reasons, confidence in the risk assessment is **'Uncertain'.**

10.11.10.1 Monitoring required

The loss of cetaceans to collision with vessels is a global issue that requires further research in order to better understand and model the potential impact on the populations of cetacean species (IWC, 2011). Although it is not thought that a significant problem exists in the Falklands at present, with the advent of O&G production in the region, further investigation to establish the causes, consequences and provisions for risk management is required.

SMMOs will be based on Navitas' vessels (most likely the OSVs). The information gathered will help to verify the accuracy of this assessment and refine future policy and procedures.

A review of all SMMO reports will be carried out every six months and after the first three years of SMMO deployment to validate the EIA and to inform decisions on whether ongoing monitoring is necessary.

In addition to reporting *via* Navitas internal incident reporting systems, all vessels will be instructed to report any collisions with marine mammals to FIG and the IWC via:

- FIG, and
- The IWC web portal for reporting ship strikes - https://portal.iwc.int (see also: https://iwc.int/management-and-conservation/ship-strikes).

Detailed monitoring requirements have been established during the Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 EMMP (an outline EMMP is provided in Chapter 15).

10.11.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

10.11.12 Findings summary

Table 10.93: Summary of the risk assessment for collision with marine mammals during the Phase 1 & 2 Development

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Collision between vessels and cetaceans	Collision with small cetaceans	Lethal injury	Unplanned	1, 2 & 3	n/a	n/a	n/a	**n/a**	**n/a**	**n/a**	**Industry-standard:** The premise of the NOAA (2009) guidelines will be followed Increased vigilance by officer of the watch in high-risk areas, Reduced vessel speed to 10 kn at the KBA boundary **Project-specific:** Awareness training for vessel crews, Reduced vessel speed to max 8 kn in Berkeley Sound Seabird and Marine Mammal Observers on vessels All collisions will be reported to FIG and the IWC via: https://portal.iwc.int.

10.12.1 Introduction

Remote islands, such as the Falkland Islands, harbor a unique biodiversity. Yet their small size and remoteness lead to vulnerability resulting from small population sizes and limited genetic variation, limited options for dispersal, narrow ecological niches, and behavioral naivety (Dawson, *et al.,* 2022). The introduction of non-native marine species to 'new' environments is a global phenomenon and is considered to be a major threat to island biodiversity (Dawson, *et al.,* 2022). In remote locations like the Falkland Islands, where the vast majority of equipment, materials and vessels have to be sourced from overseas, there is a risk of non-native marine species 'hitch-hiking' from one biogeographical region to another. If a non-native species is released into a 'new' environment, reproduces and spreads it will be regarded as invasive. Marine invasive species are difficult to detect and once established, are almost impossible to remove.

The International Union for the Conservation of Nature (IUCN) has identified the introduction of non-native species as one of the major threats to native biological diversity. Further, in 2015, a review of the Falklands Biodiversity Framework upgraded invasive species and biosecurity from a medium to high priority threat (FIG, 2016a).

Numerous vessels will be used throughout the Phase 1 & 2 Development and while the use of vessels is a planned event, the introduction of marine invasive species would be an unplanned event. It is therefore necessary to consider this as a risk. Notably, the potential for the introduction of non-native species was raised as a concern by stakeholders during scoping consultations (Chapter 6).

The Phase 1 & 2 inshore activities include the entry and anchorage of up to two Large Transport Vessels (LTVs) at any one time in Berkeley Sound, the intermittent entry of a construction vessel and supply vessels and periodic *ad hoc* freighter vessels arriving in Stanley. This chapter assesses the potential for the vessels used during the Phase 1 & 2 Development to introduce non-native marine species to the Falklands' marine environment that could, in time, become invasive.

Note: there is also a risk that native species will be transported elsewhere when vessels depart from the Falklands. However, the impact on the ecosystem of remote islands, where species have evolved in isolation, is deemed to be of greater significance than the impacts of non-native species in regions that adjoin continental land masses. Therefore, the risk of exporting species from the Falkland Islands is not considered further.

Note: the other impacts associated with vessel use are described elsewhere in this document, as described in Table 2.2.

10.12.1.1 Legislation and guidelines regarding the risk of marine species invasion

Falkland Islands strategies and framework relevant to the risks associated with the introduction of non-native species include:

- FIG Biodiversity Framework 2016-2030 (FIG, 2016a).
- The Environment Strategy (FIG, 2021a).

However, currently, specific legislation relating to the management and control of invasive species has not been established for the Falkland Islands. However, the issue of biosecurity is becoming more significant and dedicated legislation to govern marine and terrestrial biosecurity is likely to be drawn-up and enforced in the near future (D. Baigorri (Biosecurity Officer), *pers. comm.*).

Nonetheless, there is a range of international legislation and conventions relevant to invasive marine species management either through general environmental management, biodiversity protection requirements, or through more specific management requirements. These include:

- International Maritime Organisation (IMO) – International Convention for the Control and Management of Ships' Ballast Water and Sediments (the Ballast Water Management Convention).
- IMO International Convention on the Control of Harmful Anti-fouling Systems (AFS) on Ships (2001) - The AFS Convention does not address the prevention of introducing invasive aquatic species directly but focuses on the AFS used on ships and on the prevention of adverse impacts from the biocides they may contain.
- United Nations Convention on Biological Diversity (CBD) and the Kunming-Montreal Global Biodiversity Framework (GBF) which supports the achievement of the CBD Sustainable Development Goals and builds on the Convention's previous Strategic Plans.
- United Nations Convention of the 'Law of the Sea', specifically on the 'protection and preservation of the marine environment'.
- Department for Environment, Food and Rural Areas (Defra), Great Britain Non-native Species Secretariat – Invasive Non-Native Species Framework Strategy for Great Britain.
- United Kingdom Overseas Territories (UKOTs) – Biodiversity Strategy.

Under the above, there are numerous compliance requirements which will be applied within Falkland Islands waters, as described below.

Note: the IMO has also developed non-legislative guidelines for the 'Control and Management of Ships' Biofouling to Minimise the Transfer of Invasive Aquatic Species'. These are guidelines for industry-standard best practice that will be followed by Navitas and are described below in Section 10.12.5.2.

10.12.1.1.1 Ballast water exchange

IMO's Ballast Water Management (BWM) Convention came into force in September 2017. Further, the provisions of the BWM Convention are reflected in the UK by Marine Guidance Note 363 (M+F) (MCA, 2007) and at the IMO level in Marine Environment Protection Committee (MEPC) Resolution 127 (53), (IMO, 2005).

The Convention provides performance standards for the discharge of ballast water, namely standards D1 and D2 for ballast water treatment and standard D3 for a ballast water management system. Historically, vessels have normally used a D1 standard of treatment, however the BWM Convention requires all qualifying vessels to have a D2 standard of ballast water treatment by September 2024, allowing time for vessels to have an opportunity to have equipment installed in dry dock if necessary. All the vessels set out in the EIS would qualify for the D2 standard, and given the project schedule, all vessels arriving in the field will be fitted with a D2 standard ballast water treatment system, operated within a ballast water management system compliant with standard D3. Standards D1, D2 and D3 are all described below for completeness.

10.12.1.1.1.1 Regulation D1 - IMO BWM - ballast exchange

The D1 standard is for ballast water exchange and specifies the volume of water to be replaced. The standard requires that ballast water be exchanged with local water prior to entry into inshore waters as a mitigation against the introduction of non-native species.

Specifically, all ships using ballast water exchange should:

- Conduct a ballast water exchange at least 200 nautical miles from the nearest land and in water at least 200 metres in depth, taking into account the suite of Guidelines developed by the IMO to support the BWM Regulations, or

- Where the ship is unable to conduct ballast water exchange as above, the exchange should occur as far from the nearest land as possible, and in all cases at least 50 nautical miles from the nearest land and in water at least 200 metres in depth.

Ballast water exchange can either be *via* a 95 % exchange of volume or, where the tanks are continuously flushed through, by a volume equal to three times that of the tank, to take account of incomplete displacement of water during flushing.

10.12.1.1.1.2 Regulation D2 - IMO BWM - ballast water treatment

The D2 standard specifies levels of viable organisms which may be left in the ballast water after treatment and specifies approved ballast water treatment systems.

The standards for ballast water cleanliness are:

- No more than 10 viable organisms per cubic metre greater than 50 µm in size and no more than 10 viable organisms per millilitre between 10 - 50 µm in size, and
- Indicator microbes, as a human health standard and expressed as colony forming unit (cfu), shall not exceed:
  - Toxigenic *Vibrio cholerae* (serogroups O1 and O139): with less than 1 cfu per 100 millilitres or less than 1 cfu per 1 gram (wet weight) zooplankton samples,
  - *Escherichia coli*, less than 250 cfu per 100 millilitres, and
  - Intestinal Enterococci, less than 100 cfu per 100 millilitres.

In order to meet the standards described above, ballast water treatment will be required. According to the Marine and Coastguard Agency (MCA, 2012) ballast-water treatment options may include:

- Mechanical filtration and separation,
- Treatment methods such as sterilisation,
- Chemical treatment, or
- A combination of these methods.

Compliance with D2 will take time (up to five years from September 2019) to cascade through the global fleet, but, by the time of Sea Lion First-Oil, it is expected that the vast majority of vessels will have the treatment systems installed and Navitas will contract with those vessels that have the system in place.

10.12.1.1.1.3 Regulation D3 - IMO BWM - ballast water management systems

In the event that a BWM System is used to comply with the BWM Convention, Regulation D3 requires that:

- The management system must be approved by the IMO Administration taking into account the 'Guidelines for approval of ballast water management systems' (MEPC, 2008a), and
- The use of active substances shall be approved by IMO in accordance with the 'Procedure for approval of ballast water management systems that make use of Active Substances' (MEPC, 2008b) to ensure that the ballast water management system does not pose unreasonable risk to the environment, human health, property or resources.

Compliance with the above will lead to the award of the International Ballast Water Management Certificate.

10.12.1.1.2 Biodiversity

The UK ratification of the UN CBD was formally extended to the Falkland Islands on the 29th June 2016. The CBD is effectively an agreement on environmental management and best practice and originated from the 1992 Rio Conference on environment and development.

Historically the CBD set out a plan for achieving 20 targets, known as the 'Aichi Targets', which were grouped under five strategic goals. However, the Kunming-Montreal GBF is an international agreement which was developed after a long negotiation process to address weaknesses in the Aichi Targets. The GBF was adopted in December 2022 and ultimately replaces both the Aichi Targets and the Strategic Plan for Biodiversity 2011-2020 under the CBD. The GBF aims to be more ambitious than previous agreements, with a broader implementation approach that includes the private sector.

The Kunming-Montreal GBF lists targets which range from the maintenance and restoration of ecosystems through to the encouragement of sustainable consumption choices but 'Target 6' is of most relevance to this chapter and aims to reduce the introduction of invasive alien species by 50 % and minimise their impact.

More specifically Target 6 aims to:

> *'Eliminate, minimise, reduce and or mitigate the impacts of invasive alien species on biodiversity and ecosystem services by identifying and managing pathways of the introduction of alien species, preventing the introduction and establishment of priority invasive alien species, reducing the rates of introduction and establishment of other known or potential invasive alien species by at least 50 % by 2030, and eradicating or controlling invasive alien species, especially in priority sites, such as islands.'*

The CBD, and now the GBF, are supported by the FIG Biodiversity Framework 2016-2030 (FIG, 2016a), the Environment Strategy (FIG, 2021a) and supporting strategies. This Biodiversity Framework was formally endorsed by FIG in January 2016 and identifies priority conservation objectives for the Falkland Islands. Importantly, the Biodiversity Framework is a threat-based document which outlines the priorities required with regard to the wider Falkland Islands' environment. The introduction of non-native species was identified as a high priority threat.

10.12.2 Sources of marine invasive species

Throughout the different development stages, numerous vessels will be used (see Section 5.11.2) which have the potential to introduce non-native species. These include:

- Vessels contracted to Navitas:
  - Mobile Offshore Drilling Unit (MODU),
  - Anchor Handling Tug Supply (AHTS) vessels,
  - Floating Production, Storage and Offload vessel (FPSO),
  - Multi-Role Support Vessels (MRSV),
  - Emergency Rescue and Response Vessel (ERRV),
  - Offshore Construction Vessels (OCV),
  - Platform Supply Vessels (PSV),
  - *Ad hoc* freighter vessels, and
  - LTVs, used as temporary floating logistics vessels.
- Third-party vessels:
  - The purchaser's Conventional Trading Tanker (CTT).

A full inventory of the vessels used during Stages 1 to 3 of the Development is provided in Section 5.11.2.

10.12.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify the specific receptors upon which the impact / risk of marine invasive species warranted further investigation (Chapter 9). The specific receptors that may be impacted include:

- Marine flora, fauna and biodiversity of the region, and designated sites (Section 7.4).

Note: Navitas acknowledge that an unplanned introduction of marine invasive species could impact upon commercial fisheries. This is an economic impact and is considered within the Sea Lion Northern Development Area Phase 1 & 2 Socio-economic Impact Assessment which is currently being carried out by Navitas.

10.12.4 Characterising and quantifying the risk of marine invasive species

When characterising and quantifying the risk of introducing marine invasive species, it is necessary to consider the:

- Process of marine species introduction and invasion,
- Potential consequences of marine species invasion:
  - Case studies of marine invasive species.
- Factors influencing the introduction and invasion of species:
  - Origin and activity of Phase 1 & 2 Development vessels.
- High-risk invasive non-native species.

10.12.4.1 The process of marine species introduction and invasion

Two steps are involved in the process by which a non-native marine species may become invasive and impact upon an existing ecosystem:

- The species has to be transported into the region, and
- The species has to find a niche, become established and spread.

10.12.4.1.1 Species introduction

There are two main pathways by which non-native marine species are transported and introduced into new environments:

- In vessel ballast water, and / or
- Biofouling on the surfaces of vessels.

While the species that may be introduced by these routes differ, the process by which they can be introduced and / or become invasive is similar and is summarised in Table 10.94 at the end of this section. Both routes are recognised as serious issues by the IMO, which has developed guidelines to guard against such introductions (Section 10.12.4.4).

10.12.4.1.1.1 Ballast Water

Ballast is taken on-board or discharged, as necessary, to trim and stabilise a vessel. When a vessel is not carrying any cargo, it is necessary to compensate by taking on ballast water, and equally, it will be necessary to discharge ballast water when cargo is taken on board. Therefore, ballasting operations are most often required in coastal or inshore waters where cargo is loaded and unloaded. Typically, a crude tanker is ballasted with 30-35 % of its cargo capacity carried as water in the ballast tanks that are located between the inner and outer hulls in the double-hull design. Ballast water and cargo are therefore carried in separate tanks so there is no risk of cross contamination of ballast water with oil.

Ballast exchange practices are specific to each vessel but, in all vessels, planktonic organisms, larval stages, eggs, cysts and micro-organisms can be transported from one location to another in the ballast tanks. To combat the spread of non-native species, the IMO BWM Regulations (Section 10.12.1.1.1.2) will require all vessels to have D2 standard Ballast Water Treatment Systems (BWTS) in place by September 2024. Most BWTS include a primary filtration step to remove organisms larger than 20–55 µm in size, such as eggs, larvae and adults of many benthic or pelagic plankton, that are likely to survive secondary treatments such as UV irradiation, ozonation or electro-chlorination (Grob and Pollet, 2016). Regardless of the BWTS used, there is sufficient evidence to say that there is not one ballast water treatment method, or even a combination of primary and secondary methods that can guarantee a 100 % kill of all marine organisms (Grob and Pollet, 2016). However, ballast water treatment methods work to prevent unreasonable risk of introduction e.g., through a reduction in concentration of organisms.

10.12.4.1.1.2 Biofouling

Biofouling is the growth of marine organisms on man-made structures (Figure 10-54) and can be divided into:

- Hard (calcareous) fouling types e.g., barnacles, encrusting bryozoans, tube worms, mussels and other molluscs, and
- Soft (non-calcareous) fouling types e.g., seaweed, hydroids, algae and biofilms (i.e., any group of micro-organisms in which the cells stick to each other to create a 'slime' on a surface).

Together, and untreated, these two groups can encrust the hulls of vessels. Biofouling organisms can have deleterious impacts on industry; such as blocking of water intakes or increasing drag on a vessel, which then increases fuel consumption. While biofouling is often prevented with anti-fouling coatings or is mechanically removed from vessels to miminise these impacts, fouling organisms are likely to remain in 'nooks and crannies' such as the sea chest on vessels or around propeller shafts (Figure 10-55).

Therefore, these animals remain on the vessel as it transits to other regions where they can then be introduced by falling off the vessel (sometimes *via* hull cleaning) or by maturing and spawning into the new environment. Further to this, where vessels are travelling slowly (such as MODUs), mobile organisms such as fish have been known to follow a vessel to new regions (Wanless, *et al.,* 2010).

The IMO's requirements for managing biofouling organisms (Section 10.12.4.4) will greatly reduce the likelihood of introducing non-native species; however, as stated above, these guidelines do not guarantee 100 % removal of non-native species. Recently, there has been a growing recognition that biofouling is a major pathway in the introduction of non-native species, some of which may become invasive. For example, it is estimated that biofouling is responsible for approximately 75 % of non-native marine invertebrates in Hawaii and 78 % of non-native marine species in Port Phillip Bay, Australia (OGP/IPIECA, 2010).

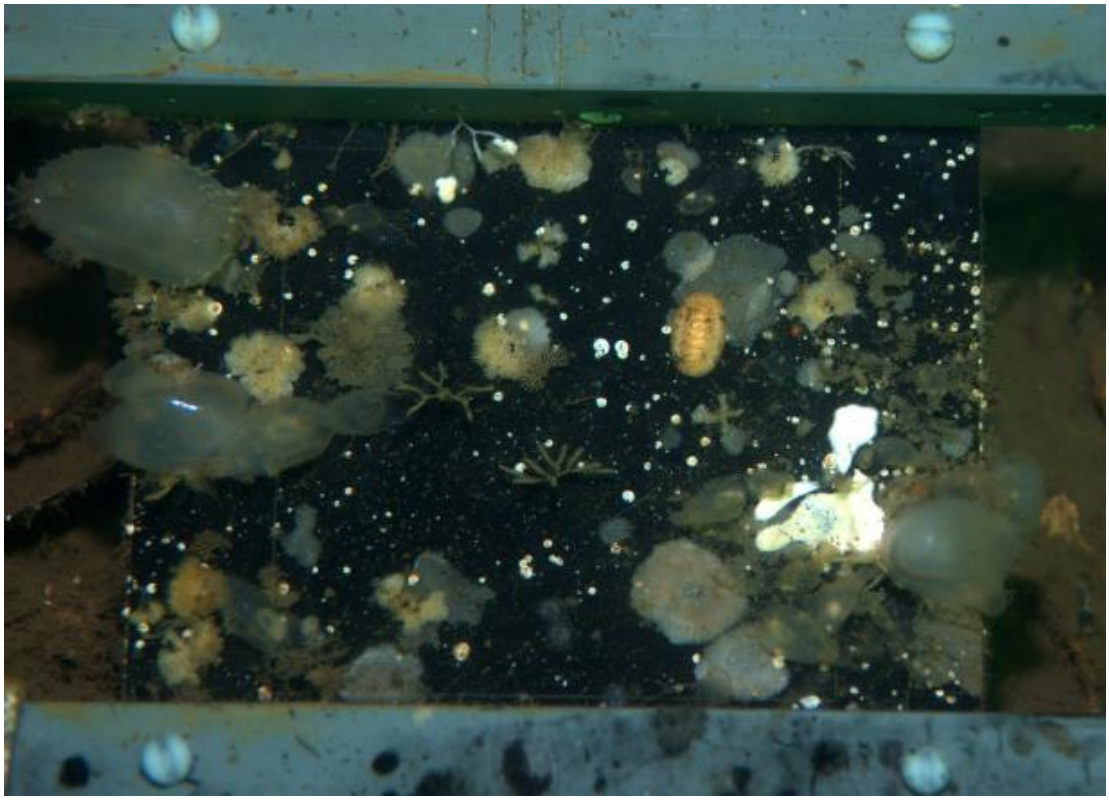

Figure 10-54: Biofouling on a settlement plate used to monitor for non-native species; note the presence of the invasive vase tunicate (*Ciona intestinalis*), transparent balloon like organisms ***(Source: SMSG)***

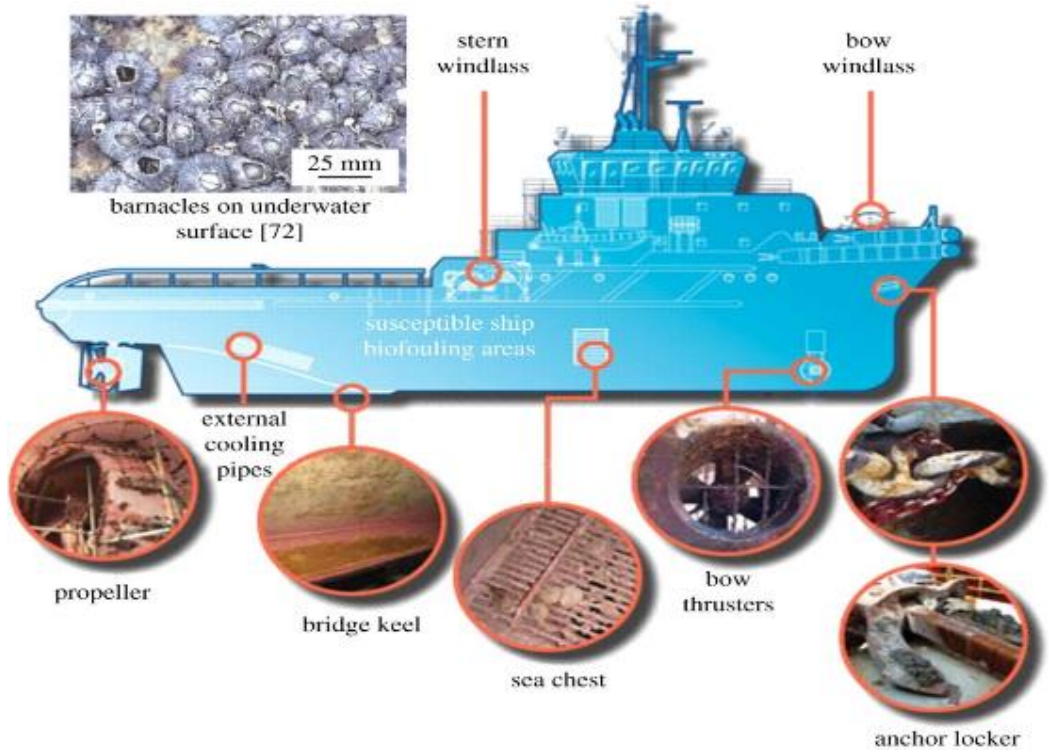

Figure 10-55: Regions on a ship that may remain fouled following mechanical cleaning ***(Source: rsta.royalsocietypublishing.org)***

10.12.4.1.2 Species invasion

Not all non-native species that arrive in the Falklands are able to survive, reproduce and spread to the point that they become invasive. For a non-native species to become invasive it is necessary for it to gain a foothold (Table 10.94), which is more likely when the recipient region is similar to the donor region with respect to parameters such as salinity and temperature.

However, many of the most prevalent invasive species can become established in many different regions of the world and share biological characteristics such as rapid reproductive capacity and fast growth, which enable them to out-compete native species. Additionally, non-native species may not have any natural predators in the receiving environment, which further aids survival and growth.

Table 10.94: The process of non-native species introduction and invasion[1]

Region	Process	Key factors	
		Ballast water	Biofouling
Donor	Colonisation of vessel	Quantity of ballast water uptake, Salinity (fresh or seawater), and Location from which ballast water is taken.	Presence or absence of anti-fouling, Age and type of anti-fouling, Hull location, and Residency period (inshore waters).
Translocation		Ballast water exchange *en route*, and Treatment of ballast water.	Voyage route, Voyage duration, and Vessel speed.
Recipient	Transfer	Ballast water exchange (inshore waters).	Residency period (inshore waters), and Defouling activity (e.g., in-water cleaning).
	Colonisation	Availability of suitable environmental conditions, Availability of suitable substrate, Biotic resistance, and Water currents.	
	Establishment	Availability of suitable substrate, Environmental conditions, Predation pressure and Control measures.	

[1] Adapted from Lewis and Coutts (2010)

10.12.4.2 Potential consequences of invasive marine species

Invasive species may impact upon biodiversity by:

- Outcompeting native species for space and resource and therefore exclude native species,
- Predating upon native species,
- Causing indirect changes to the ecosystem e.g., smothering by plankton blooms, and / or
- Causing toxicity for native species e.g., Harmful Algal Blooms (HAB).

The impacts of the above can be immense and are often irreversible (Hilliard, 2004; OGP/IPIECA, 2010). Further, impacts to biodiversity tend to be disproportionately worse for islands as compared to continents (Russell, *et al.,* 2017) and in remote island ecosystems like the Falklands, where native species have evolved in biological isolation, they can be particularly severe. Although there are cases where planktonic invasive species such as dinoflagellates or salps can impact offshore waters e.g., by HAB, most marine invasive species impact upon inshore benthic communities of native species, and the extent of the impact is often difficult to detect and monitor.

In addition, there are many examples from around the world where marine invasive species have had serious economic impacts (e.g., Lowe, *et al.,* 2004; Cuthbert, *et al.,* 2021) and OGP / IPIECA (2010)

provides a comprehensive review of the risks that the Oil and Gas (O&G) industry poses regarding the introduction of non-native species.

While there is little commercial exploitation of inshore marine species or industries such as aquaculture in the Falklands, some species that are exploited offshore do spawn in inshore waters. The species of greatest concern off the east coast of the Islands is loligo (*Doryteuthis gahi*; Section 7.7.3.2.1.1). A loss of spawning habitat (e.g., kelp beds[89]) or predation of eggs could have socio-economic impacts for the human population. While this direct impact would require the introduction of species likely to use kelp beds[1] or predate on the eggs, the introduction of any species that became invasive would impact biodiversity overall, with indirect impacts for many species.

10.12.4.2.1 Case studies of marine invasive species

Human trade and travel have frequently introduced alien species to areas like the Falklands where the native species are not adapted to the new threat. On the nearby central Patagonian coast, for example, most marine ecosystems have been modified by invasive species (Orensanz, *et al.,* 2002).

The Falkland Islands have been a strategic point for international shipping traffic for over 200 hundred years and human activity has seen both the deliberate introduction of non-native species, such as the brown trout, and unintentional introductions. Until recently however, there were no baseline environmental surveys of the Falklands, so determining those species that are native and those that are invasive is not always straightforward.

Nonetheless, it is clear that several invasive species are already established within Stanley Harbour and Mare Harbour, such as the tunicate (*Ciona intestinalis*) and the parchment tubeworm (*Chaetopterus variopedatus*, Figure 10-56), both of which have the potential to out-compete and smother native species. The 2011 Shallow Marine Surveys Group (SMSG) survey looked at a number of sites around the Falklands to determine the presence of the parchment tubeworm and results are shown in Figure 10-57 below. Results showed the species was present island-wide, although concentrations are markedly higher nearer ports of entry (SMSG, 2011). Recently (March 2023), *Undaria pinnatifida* has been found in Stanley Harbour and is one of only two seaweeds included in the Invasive Species Specialist Group list of the 100 most invasive species of the world (IUCN ISSG, 2024). Native to cold-temperate areas of the north-west Pacific (e.g., Japan, Korea, Russia, China), *Undaria* is now established across four continents. Within the San Jose Gulf (Argentina), only four years after its introduction, *Undaria* had spread across approximately 100 km of coastline where it is mixed with *Macrosystis pyrifera* kelp forest (SMSG, unpublished data).

Elsewhere in the world, the impact of invasive species has been far more dramatic. For instance, the European shore crab (*Carcinus meanus*) has been transported all over the world. Once established, they displace native species of crab and predate upon native invertebrates resulting in both the loss of native biodiversity and impacts upon crab and shellfish industries (CABI, 2014).

Another example is the sea walnut (*Mnemiopsis leidyi*) which is a stingless jellyfish-like animal (a comb-jelly) native to the Atlantic coasts of North and South America. This organism was transported to the Black Sea by ballast water and spread to the Caspian Sea. In both places, this species multiplied to form immense populations which, because they feed on zooplankton that commercial fish also consume, contributed to the collapse of local fisheries (Pang and Martindale, 2008). This comb-jelly has now also been discovered in the Mediterranean, Baltic, and North Seas (Pang and Martindale, 2008).

[89] Although kelp beds are a known spawning location for loligo, the spatial / bathymetric distribution and habitat characterisation of loligo spawning areas are not yet fully understood (Section 7.4.4.3.2.1).

10.12.4.3 Factors influencing the introduction and invasion of species

In order to conduct an assessment of the risk posed by Phase 1 & 2 vessels introducing non-native species, and these species becoming invasive, three main factors need to be considered:

- The origin of the vessel,
- The activity of the vessel when in the region, and
- Whether or not the vessel is 'new' to the Falkland Islands.

With regard to the origin of the vessel, the geographical location of the last vessel deployment is of great importance as this will affect the likelihood of any introduced species becoming invasive. Vessels coming from temperate regions with similar climates pose the greatest risk to the Falkland Islands as the species that may be introduced are most likely to be able to survive, become established, and thus become invasive. Importantly however, the origin of the vessel can also present natural barriers to the introduction of non-native species. For example, with regard to biofouling, where vessels are travelling from a northern hemisphere temperate climate to a similar climate in the southern hemisphere, the vessel will pass through the Tropics such that the gradual changes in salinity and temperature may help to remove many biofouling organisms (Minchin and Gollasch, 2003). Although this may serve as a natural barrier to effective translocation, there are instances of species flourishing in both tropical and Falklands waters. As such, the temperature barrier is no guarantee and should not be relied upon as a means of preventing introduction. With regard to ballast water, the time that water is held in the tanks is significant such that the distance of the vessel origin from its destination is a factor. Many organisms may die *en route* while other, mostly micro-organisms, may reproduce and multiply (Gollasch, *et al.,* 2000; Grob and Pollet, 2016).

With regard to activity, vessels that spend long periods of inactivity in coastal waters (wherever these may be) are more prone to biofouling than those that are active offshore and ballast water taken onboard in coastal waters is likely to contain a far higher density of planktonic organisms than water taken onboard in offshore waters. While the risk of introducing ballast organisms is less dependent upon the location of the discharge as micro-organisms may colonise anywhere, the risk of biofouling organisms becoming established in the Falklands is greatly increased when vessels are inshore, as most biofouling species require hard substrates to attach to. Another consideration with regard to the activity of vessels is the volume of ballast water carried. Vessels arriving laden with a cargo e.g., *ad hoc* freighter vessels and LTVs, will be carrying less ballast water, while those arriving empty, or partially full, and awaiting receipt of a cargo e.g., the OCV and PSV vessels, will be carrying a larger volume of ballast water.

Finally, the greatest risk of marine species introduction is associated with the first arrival of potentially contaminated vessels which are 'new' to Falkland Islands waters. Vessels that have been in the region for extended periods of time are more likely to carry native species in their ballast water. However, biofouling organisms may continue to grow *in situ* where conditions are conducive and may eventually fall off or spawn into the environment of the recipient region

Those vessels that repeatedly leave the region and exchange ballast waters elsewhere, or have the opportunity for the hull to become recolonised elsewhere before returning to the Falklands, will be considered 'new' each time they return.

10.12.4.3.1 Origin and activity of Phase 1 & 2 Development vessels

A summary of the Phase 1 & 2 vessels' origin and behaviour is provided in Table 10.95. While all vessels pose a risk, those vessels that are 'new' each time and which come inshore (particularly for prolonged periods) are those that pose the greatest risk. Therefore, the periodic *ad hoc* freighter vessels and the LTVs are expected to pose the greatest risks (Table 10.95).

The *ad hoc* freighter vessels will arrive laden with cargo and will not be 'in-ballast' such that the greatest risk with these vessels is species introduction *via* bio-fouling. The *ad hoc* freighter vessels pose a risk because:

- They will be 'new' to the Falkland Islands on each visit having been in other biogeographical regions where they may have become colonised with flora and fauna local to the donor region,
- They will most likely originate in Europe / USA which is a compatible donor region,
- They will spend time passing thorough the Tropics, which may provide a natural barrier to the introduction of bio-fouling species, but cannot be relied upon, and
- They will spend time at the Temporary Dock Facility (TDF) and / or Falklands Interim Port And Storage System (FIPASS) to the east of Stanley while cargo is transferred and while they refuel, allowing opportunity for the transfer of bio-fouling organisms.

Similarly the LTVs are considered to pose a risk with regard to species introduction from bio-fouling because:

- They will be 'new' to the Falkland Islands, on each visit, having been in other biogeographical regions where they may have become colonised with flora and fauna local to that region,
- Regardless of their origin, they may harbour viable organisms, while those from dissimilar climates may be less able to thrive, some tropical organisms are known to be able to flourish in temperate climates, and
- The LTVs will enter Berkeley Sound where they will anchor for a period of weeks to several months, allowing time for the potential translocation of bio-fouling organisms to the substrate in the Sound.

Table 10.95: Factors that may influence species introduction and / or invasion from Phase 1 & 2 vessels

Vessel	Donor region	Influencing factors						
		Donor / recipient climates similar	Passing through dissimilar climates *en route*	Activity of vessel	Carrying ballast on arrival	Time spent inshore	'New' to region:	
							Once	Each time
MODU	Europe / Asia	Y / Unknown[1]	Y	Drilling offshore	Y	-	✓	-
FPSO	Middle East / Asia	Unknown[1]	Y	Production offshore	Y	-	✓	-
Ad hoc freighter vessels	Europe / USA	Y	Y	Delivery of cargo to TDF in Stanley	N[2]	✓	-	✓
Anchor Handling Tug Supply (AHTS) vessels	Europe	Unknown	Y	Tow of MODU to region and MODU support, may need to refuel inshore at TDF	Y	✓	✓	-
Multi-Role Supply Vessels / Emergency Rescue and Response Vessel	Europe	Unknown[2]	Y	Supply vessels operating between field & TDF, on standby for FPSO and MODU, may need to refuel inshore at TDF	Y	✓	✓	-
Offshore Construction Vessel (OCV) and Platform Support Vessels (PSV)	Norway / Europe	Y	Y	Transit back and forth between field and LTVs in Berkeley Sound to collect cargo for installation in field	Y	✓	✓	-
Large Transport Vessels	Europe / USA	Y	Y	Arrival and standby in Falkland Islands for use as floating logistics barges in Berkeley Sound	N[2]	✓	-	✓[3]
Conventional Trading Tanker	Unknown	Unknown	Unknown	Arrival and standby offshore Falkland Islands	Y	-	-	✓[4]

[1] The initial location is unknown at the time of writing and it is not possible to estimate which donor region could be considered to be worst-case as numerous factors influence the process.
[2] Vessels arriving laden with cargo are assumed to be carrying little or no ballast.
[3] Note that the individual LTVs may be changed out for other LTVs and therefore, each LTV could be 'new' to the Islands.
[4] The same CTT may make repeat trips under a long-term contract, but a variety of vessels is likely over Field Life.

10.12.4.4 High-risk invasive non-native species

Dawson *et al.* (2022) applied a 'horizon scanning' approach to identify high-risk invasive non-native species in UKOTs. High-risk species were identified according to their potential for arrival, establishment, and likely impacts on biodiversity and ecosystem function, economies, and human health. Across the UKOTs (which ranged in location and therefore local climates), 231 taxa were included on high-risk lists. The highest-ranking species were:

- The Asian green mussel (*Perna viridis*),
- Little fire ant (*Wasmannia auropunctata*),
- Brown rat (*Rattus norvegicus*), and
- Mesquite tree (*Prosopis juliflora*).

Shipping containers were identified as the introduction pathway associated with the most species.

While some of the above may not be high-risk to the Falkland Islands owing to the difference between the donor and recipient climates, the outcomes of the exercise provide a guide for remote islands and archipelagos to focus ongoing biosecurity and surveillance aimed at preventing future incursions (Dawon, *et al.,* 2022), and managing them *via* application of, for example, dedicated and project-specific Biosecurity Management Plans

10.12.5 Industry-standard mitigation measures

The most cost-effective way to avoid the adverse impacts associated with the introduction of invasive non-native species is prevention. This is most effective when high-risk non-native species are identified before arrival and introduction is prevented through biosecurity measures (Dawson, *et al.,* 2022).

In line with the legal compliance requirements and published IMO guidelines, the following will be in place for all vessels, to prevent, or minimise, the introduction of non-native species:

- Ballast Water Management Plan (BWMP), and
- Biofouling Management Plan (BFMP), and
- Biosecurity Management Plan (BMP).

Further, in line with its Contractor Management Standard (Section 3.2.15), Navitas will carry out pre-selection and / or pre-mobilisation audits. These audits will be used to ensure that all contracted vessels arriving in the Falklands are compliant with the current expectations under IMO (Section 10.12.1.1).

The use of these plans is factored into the initial risk assessment below. However, it should be noted that while the measures in the above plans will reduce the likelihood of non-native species introductions, neither can completely eliminate the risk.

Lastly, it should also be noted that FIG will implement its own biosecurity inspection and management processes and may refuse visits, or quarantine assets if it believes the biosecurity risk is too high.

10.12.5.1 Ballast Water Management Plan

The IMO BWM regulations came into force in 2019 (Section 10.12.1.1.1.3) and the requirements within are industry-standard best practice. The BWMP is key to the safe and effective exchange of ballast water. BWMPs are specific to each vessel and include a detailed description of the actions to be taken to implement the BWM requirements and supplemental practices.

The BWMP should describe:

- The duties of key shipboard control personnel undertaking ballast water exchange at-sea:

- Such personnel should be fully conversant with the IMO BWM and the safety aspects of ballast water exchange and, in particular, the method of exchange used on-board their ship.

- The need for a Ballast Water Record Book (BWRB) to record the following (in compliance with the IMO BWM Regulation D1 (Section 10.12.1.1.1.1)):
  - When and where ballast water is taken on board, circulated or treated for BWM purposes and discharged to sea,
  - When ballast water is discharged to a reception facility,
  - Accidental or other exceptional discharges of ballast water, and
  - When sediment in ballast tanks should be removed and how it is disposed of.
- Detail on the ballast water treatment (in compliance with the IMO BWM Regulation D2 (Section 10.12.1.1.1.2):
  - The method will be class-certified under the MEPC (2008a) (**Note:** Navitas will discuss with the Harbour Authority whether alternative methods would also be acceptable).

Although not a requirement of the IMO, Navitas has committed to taking samples of ballast for analysis from all vessels coming inshore and arriving 'in-ballast' as detailed in Section 10.12.10.1.1. Ongoing review of sampling results will be drawn into the EMMP (Chapter 15).

10.12.5.2 Biofouling Management Plan

The IMO Guidelines for the Control and Management of Ships' Biofouling to minimise the Transfer of Invasive Aquatic Species do not describe legal requirements but are considered to indicate best practice. These guidelines were adopted by the MEPC in 2011.

The purpose of the BFMP is to outline measures used to control and manage biofouling on vessels to minimise the transfer of non-native aquatic species.

The BFMP should provide details on:

- The AFS and operational practices or treatments used, including those for niche areas and sea chests,
- The hull locations susceptible to biofouling, schedule of planned inspections, repairs, maintenance and renewal of AFS,
- The recommended operating conditions suitable for the chosen AFS and operational practices,
- The safety of the crew, including details on the AFS used,
- The need for the use and maintenance of a Biofouling Record Book (BRB), and
- The documentation required to verify any treatments recorded in the BRB (see MEPC, 2011 - Appendix 2).

10.12.5.2.1 Antifouling coatings

Until relatively recently, the majority of the world shipping fleet used tributyltin (TBT) based antifouling treatments, which proved to be very effective but had serious environmental side-effects. Since 2008, TBT coatings have been banned (IMO, 2001) and alternative treatments are now used to prevent biofouling (see Yebra, *et al.,* 2004 for a review). One of the most effective inhibitors of marine growth is copper, which is inherently toxic to marine organisms. Copper based coatings slowly release copper into the marine environment and are effective long-term solutions to prevent biofouling (Brooks and Waldock, 2009). Although there is potential for a localised elevation in the concentration of copper,

the overall amounts released from antifouling paint are small in comparison to natural inputs (mostly runoff from sources on land).

The potential impacts of copper anti-fouling on non-target organisms have been the subject of debate (see Brooks and Waldock, 2009). Overall, copper toxicity from an antifouling source only becomes a problem in the marine environment in isolated water bodies, such as enclosed marinas and harbours that experience little water exchange, with high levels of boating activity.

An anti-fouling coating philosophy for semi-stationary and long-term objects (e.g., the FPSO and Turret Buoy) will be developed (as is indicated in the EMMP, Chapter 15) and all project vessels will be treated with IMO-compliant antifouling treatments, such as slick self-polishing polymer paints. Many of these systems include copper to inhibit marine growth, which is released slowly and is deemed compliant under the IMO standards, which consider environmental risks. Therefore, the small quantities of copper released into dynamic marine conditions are considered to pose no risk to non-target marine organisms and are not assessed further in this EIS.

10.12.5.3 Biosecurity Management Plan

An integrated management approach will be implemented and will include:

- Prevention:
  - Preventative measures include identifying potential pathways and implementing controls to minimise the impact of invasive species (e.g., through ballast water and biofouling management).
- Monitoring, detection and elimination:
  - Settlement plates will be placed in Berkeley Sound and at the TDF / Stanley Harbour prior to and during the construction phase of the project, and
  - Vermin attraction / containment / detection devices will be used on vessels to monitor pest populations and activity. Visual inspections of the devices will identify specific areas of infestation, if any, and assess the need for further action.
    - Rat guards will be used when vessels are berthed at the TDF in Stanley Harbour.
- Management and controls:
  - If a potential new marine species is detected a pathway analysis will be conducted to attempt to determine where / how the species had been brought to the Islands. If appropriate, safe and feasible, efforts will be made to eradicate the invasive species.
  - In the event of a biosecurity incident, FIG Biosecurity will be informed and asked to advise on required treatment and disposal (if practicable), and
  - Awareness campaigns and training will be used to highlight biosecurity risks.
- Regulatory inspections:
  - If a vessel with an observed / documented fouled hull arrives to be offloaded at the TDF, the TDF Operator will coordinate the relevant governmental agencies / regulatory bodies to ensure appropriate measures are taken. However, under the BMP and vessel vetting process, a vessel berthing at the TDF with a fouled hull is considered unlikely.

10.12.6 Risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect'. Assessment of unplanned events includes an assessment of the overall impact followed by an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the risk assessment outcomes for this Development is tabulated in Section 10.12.12, which shows the worst-case impact / risk for each activity.

As identified in Section 10.12.4.3 (and Table 10.95), not all vessels present an equal risk of introducing invasive species and the *ad hoc* freighter vessels and the LTVs are those considered to pose the greatest risk with regard to bio-fouling. Nonetheless, for the purposes of the risk assessment, the Phase 1 & 2 vessels can be broadly split into four groups:

- Sea Lion in-field vessels that visit the Falklands once and work within the Falklands Conservation Zones e.g., the MODU, FPSO, MODU / FPSO offshore support vessels, etc.,
- *Ad hoc* freighter vessels that may visit the Falklands several times a year from varying donor regions and will enter inshore waters, but carry little or no ballast water,
- Semi-stationary floating storage vessels (LTVs) that visit the Falklands once and anchor temporarily in inshore waters (for a combined period of up to 13 non-consecutive months), and
- CTT vessels that will visit the offshore FPSO multiple times per year carrying large quantities of ballast water.

The impact of marine invasive species would be the same for all the vessel types above, however the likelihood of introducing the non-native species differs depending upon the influencing factors described in Section 10.12.4.3 above such that the associated risks may differ. Therefore, the impact of species introduction is assessed once for all vessels while the likelihoods, and therefore the risks, are considered separately below.

10.12.6.1 The impact of introducing invasive species, all vessels

With regard to the sensitivity of receptor, the immediate impact may be to one species only, however broader impacts could exist for the biodiversity and ecosystem as a whole which are difficult to estimate with so many variables in the process. Equally, it is not easy to determine the zone of influence of the Development as this would depend upon the proliferation of the invading species. While the impact would greatly depend upon which species were introduced (Section 10.12.4.1), the potential for impacts to marine biodiversity as a whole could be such that the sensitivity of the receptor is considered to be '**High**'.

If invasive species were introduced during the Phase 1 & 2 Development the impact on the ecology of the Islands may not be evident for a number of years. However, the long-term implications for the Islands' marine ecology could be severe and irreversible (Section 10.12.4.2). Given the potential impact of invasive species, as seen in previous case studies around the world (Section 10.12.4.2.1), there is the possibility that invasive species could have an 'extensive effect over a large (regional) area with the potential for long-term irreversible damage to species / regional population / habitat / ecosystem'. Therefore, following the precautionary principle, the severity of the impact is considered to be '**Major**'.

Therefore, overall the significance of the potential impact is assessed as '**High (20)**'.

10.12.6.2 Likelihood of occurrence

Given the number of vessels that visit Stanley from all around the world (e.g., fishing vessels and cruise ships) and the apparently few invasive species in the Harbour (SMSG, 2011), the introduction of invasive species appears to have been an uncommon event thus far. However, introduction of invasive species has happened both in the Falklands a number of times and by the O&G industry elsewhere.

The following assessment of the likelihood of the introduction of marine invasive species by different vessels assumes that industry-standard IMO guidelines are followed (Section 10.12.4.4). Phase 1 & 2

vessels will comply with the BWMC and the associated culture change across the whole shipping industry will reduce the overall likelihood of introducing non-native species in ballast water.

Nonetheless, when assessing the likelihood of marine species invasion, it is important to consider:

- The process by which species become invasive (Section 10.12.4.1),
- The factors that influence the likelihood of species introduction / invasion (Section 10.12.4.3), and
- How these apply to the Phase 1 & 2 vessels (Section 10.12.4.3.1).

After all, not all species that are introduced *via* biofouling or ballast water will become invasive and therefore, the likelihood of species introduction is not the same as the likelihood of species invasion and both outcomes must be taken into account. However, it is important to note that while these influencing factors are taken into account for each of the assessments below, the likelihoods rarely differ enough to justify a lower category of likelihood according to the definitions provided in the EIA methodology (Section 8.6.2).

10.12.6.2.1 Risk of invasive species introduction by Sea Lion in-field vessels

As described above, the significance of the impact of species introduction is considered to be '**High (20)**'.

The origin of some of the in-field vessels remains unknown but it is likely that they will arrive with cargo and therefore little ballast water (Table 10.95 above) although there is a risk that vessels could be carrying bio-fouling organisms on arrival. However, as these vessels will be under direct charter to Navitas the maintenance history of biofouling and hull cleaning will be known. Importantly, these vessels will remain within Falklands waters while supporting the Development and therefore the risk of transporting non-native species is further reduced. However, while these influencing factors may somewhat reduce the likelihood (Section 10.12.4.3), some potential does remain and therefore, to take a precautionary approach, the likelihood of in-field vessels introducing potentially invasive species is considered to be '**Unlikely**'.

Therefore, the overall significance of the risk of introducing non-native marine species *via* Sea Lion in-field vessels, which may then go on to become invasive is considered to be '**Moderate (10)**'.

10.12.6.2.2 Risk of invasive species introduction by ad hoc freighter vessels

As described above, the significance of the impact of species introduction is considered to be '**High (20)**'.

It is likely that *ad hoc* freighter vessels will be shipping from temperate climates of northern Europe / USA throughout all three Stages of the Phase 1 & 2 Development such that the 'donor climate' may be compatible with the Falkland Islands climate (Table 10.95 above). While these vessels will travel through the potential natural barrier of the Tropics and will be carrying little ballast, each vessel will be 'new' to the Islands with each return trip. Therefore, the *ad hoc* freighter vessels can present multiple pathways for the introduction of non-native species, especially in regard to biofouling organisms. While these influencing factors may, on balance, reduce the likelihood (Section 10.12.4.3), some potential does remain and therefore, to take a precautionary approach, the likelihood of coaster vessels introducing marine non-native species that go on to become invasive is considered to be '**Unlikely**'.

Therefore, the overall significance of the risk of introducing non-native marine species *via ad hoc* freighters, which may then go on to become invasive is considered to be '**Moderate (10)**'.

10.12.6.2.3 Risk of invasive species introduction by Large Transport Vessels (LTVs)

As described above, the significance of the impact of species introduction is considered to be '**High (20)**'.

Up to four LTVs (and a maximum of two at any one time) will be used inshore in Berkeley Sound to act as floating logistics vessels to store equipment before it is required to be installed offshore. The subsea construction schedule dictates that up to two LTVs will be present for a cumulative total of 13 months (Section 5.5.1). It is likely that these vessels will travel from European / USA ports (Table 10.95 above) and therefore the donor climate may be compatible with the Falklands. Further, although these vessels will be laden with cargo on arrival (therefore carrying minimal ballast water), a prolonged stay in inshore waters may give any biofouling organisms the opportunity to be transferred or to spawn. Further, the LTVs will be changed out over the duration such that vessels which are 'new' to the Islands arrive more than once. While these influencing factors may balance out to reduce the likelihood (Section 10.12.4.3), the likelihood does remain and therefore, to take a precautionary approach, the likelihood of LTVs introducing marine non-native species that go on to become invasive is considered to be '**Possible**'.

Therefore, the overall significance of the risk of introducing non-native marine species *via* LTVs, which may then go on to become invasive is considered to be '**Upper Moderate (15)**'.

10.12.6.2.4 Risk of invasive species introduction by purchaser's vessels (CTTs)

As described above, the significance of the impact of species introduction is considered to be '**High (20)**'

CTTs will arrive at the FPSO for direct offtake of the crude oil at regular intervals throughout Stages 2a, 2b and 3 of the Phase 1 & 2 Development from, as yet, unknown locations. While the CTT may travel from a tropical climate, it is still possible for non-native species in the ballast water or fouling on the hull to take hold (Section 10.12.4.3). Notably, the vessel will be carrying a large volume of ballast water and each visit by a CTT will be 'new', thus representing a new pathway for the transport of potentially invasive species (Table 10.95 above). Given the use of standard flushing procedures and treatment (Section 10.12.4.4), the resulting likelihood of introducing non-native species in ballast water will be reduced. Further, Navitas will apply a vetting system whereby the Oil Companies International Marine Forum (OCIMF) Ship Inspection Report Programme (SIRE) process is applied, which requires the inspector to verify that the vessel complies with the BWMC and that ballast water management plans, record books, certificates and biofouling management plans are in place and up to date for the incoming CTTs. However, while these influencing factors and mitigations may somewhat reduce the likelihood (Section 10.12.4.3), the likelihood does remain and therefore, to take a precautionary approach, the likelihood of the CTT introducing marine non-native species which then go on to become invasive is considered to be '**Unlikely**'.

Therefore, the overall significance of the risk of introducing non-native marine species *via* CTTs, which may then go on to become invasive is considered to be '**Moderate (10)**'.

10.12.7 Project-specific mitigation measures

The changes in legislation to regulate ballast water management practices and guidelines to manage biofouling outlined above (Section 10.12.4.4) will greatly reduce the likelihood of introduction. However, although these measures are likely to reduce the risk to ALARP, the true impact of these changes is currently unknown as the Convention only came into force in September 2019. Therefore, the initial assessment presented above remains very precautionary; largely due to the potential for long-term (irreversible) impact and the history of non-native species introductions by shipping around the world.

Given that the risks of introducing marine invasive species are considered to be **'Moderate (10)'** and **'Upper Moderate (15)'** despite the legislation and use of industry-standard mitigations, it is necessary to consider project-specific mitigation measures for all vessels and both types of species introduction. As it can be almost impossible to remove invasive marine species, the focus of mitigation should be on prevention.

10.12.7.1 Ballast water

All vessels will operate a D3 ballast water management plan with a D2 level of ballast water treatment, which will be vetted prior to hire of vessels (Section 10.12.5.1). This is considered to lower the risk to ALARP so no additional mitigation measures for impacts from ballast water discharges are proposed.

10.12.7.2 Biofouling

It is recognised that the initial risk assessments for all vessel types are considered to be significant. However, due to the physical difficulty of accessing and monitoring the niche spaces where biofouling organisms are most likely to persist, the introduction of non-native species *via* biofouling is arguably more difficult to mitigate than introduction through ballast water. The risk posed by each vessel is linked to its previous history (geographical location and activity), maintenance schedule (dry-docking and condition of antifouling coatings) and residence time. For these reasons, the risk posed by each vessel should be assessed on a case-by-case basis.

In order to specifically mitigate the **'Upper Moderate'** risk of species introduction *via* bio-fouling which is posed by the LTVs used as floating logistics barges, these vessels will be required to have a hull inspection prior to transport to Berkeley Sound and consideration will be given to hull cleaning, depending on the results of the survey. If hull cleaning is required, this would not be done in Falklands waters. Further, the standard used will be agreed in collaboration with FIG, with reference to, for example, the IMO 2023 Biofouling Guidelines (Table 1 - Rating Scale) as appropriate.

10.12.8 Residual impacts and risks

10.12.8.1 Sea Lion in-field vessels

Given that the risk posed by in-field vessels is a one-off and Navitas is likely to have stricter control of auditing and maintenance procedures prior to deployment, the initial assessment is considered to be ALARP. Project-specific measures are largely based on monitoring which may help to detect any breaches of biosecurity but do not warrant a change in the likelihood. Therefore, it is considered appropriate and precautionary, for the overall significance of the risk to remain '**Moderate (10)**'.

10.12.8.2 *Ad hoc* freighter vessels

Throughout the course of Field Life, the project-specific measures cannot eliminate the risk entirely and introduction of invasive species world-wide is a frequent occurrence. Further, given the number of 'unknowns' within the assessment, it is considered appropriate and precautionary, for the overall significance of the risk to remain '**Moderate (10)**'. Outcomes of sampling and monitoring throughout Field Life (Section 10.12.10.1) will enable this assessment to be 'ground-truthed' throughout the Development.

10.12.8.3 Large Transport Vessels

Hull inspections for potentially invasive species for LTVs prior to departure for the Falklands, together with appropriate action if required, will reduce the likelihood of introducing biofouling non-native species. However, hull inspections and treatments are still limited in the extent to which they can eliminate biofouling and therefore, the post mitigation likelihood of introducing invasive species can only be reduced from '**Possible**' to '**Unlikely**'. Therefore, with a '**High**' impact and a likelihood rating of '**Unlikely**', the residual risk for in-field vessels is only lowered to '**Moderate (10)**'.

10.12.8.4 CTTs

CTTs arriving at the Sea Lion field to load cargo and discharge ballast water will have undergone a vetting process to ensure compliance with the Biosecurity Management Plan which will include compliance with their BWMP and BFMP. These mitigations are already factored in as industry standard (section 10.12.5.1), so the post mitigation likelihood of introducing invasive species cannot be reduced and remains '**Unlikely**'. Therefore, with a '**High**' impact and a likelihood rating of '**Unlikely**', the residual risk for in-field vessels remains '**Moderate (10)**'.

10.12.9 Cumulative impact

Numerous vessels arrive in Stanley Harbour and Berkeley Sound from all over the world and there is the potential for this to lead to cumulative impacts through increased 'concentration' and increased 'extent and proportion' (Section 8.9.1). To varying degrees (according to the influencing factors described in Section 10.12.4.3 above), all of these vessels, which may not have stringent management systems in place, have the potential to introduce non-native species.

Vessels that spend prolonged periods laid-up in ports have the greatest potential as vectors for non-native species, especially biofouling. However, vessels associated with the Phase 1 & 2 Development will increase the number of introductory pathways for non-native species, which adds to the existing threat from other vessels. Between 2010 and 2022 an average of 304 vessels visited Berkeley Sound annually. In support of the Stage 1 and 2 subsea construction campaigns, up to two LTVs will be anchored in Berkeley Sound for a combined period of up to 13 months with the OCV / PSV visiting regularly to transport subsea equipment offshore. There will also be *c.* 12 *ad hoc* freighter visits to the Islands. These vessel visits all lead to cumulative impacts through increased 'concentration'.

There is also potential for vessels based in the Islands to accelerate the spread of invasive species that are already present in the region. For example, the invasive vase tunicate (*Ciona intestinalis*) was historically introduced to Stanley Harbour and Mare Harbour (SMSG, 2011). This species has a high potential for natural dispersion and is known to be established in Port William and may have reached Berkeley Sound already (P. Brickle, *pers. comm.*). Vessels based in Stanley Harbour but travelling elsewhere have the potential to accelerate the natural spread of this, and potentially other invasive species, to other parts of the archipelago. It may be too late to prevent the further spread of the invasive vase tunicate to Berkeley Sound but future monitoring should focus on the potential pathways to spread invasive species within the Islands and identify pre-existing non-native species and trends. Although this is not solely an O&G issue, Navitas has committed to monitoring of non-natives connected with their activities (Section 10.12.10.1).

At present, there is limited exploitation of inshore resources and aquaculture in the Falklands but this could develop in the future and the introduction of parasites, disease, competitors or predators could impact these industries.

10.12.10 Confidence

While the nature of the impact of invasive species on the marine environment will depend on the species involved, it is understood that the introduction, and potential invasion, of any non-native species can be detrimental and the impacts are well documented.

However, predicting the likelihood of introducing a species, the likelihood of it becoming invasive and then the extent of the impact of any particular invasive species on the local environment is very difficult. The likelihood of vessels carrying potentially invasive species is very vessel-specific and depends on a number of factors (as described in Section 10.12.4.3), many of which are currently unknown e.g., origin and history of vessels etc. Therefore, while, the mitigation practices proposed are used internationally and are regarded as best-practice, the number of unknowns is such that the confidence in the overall assessment is considered to be **'Uncertain'** such that monitoring is required.

10.12.10.1 Monitoring required

The vetting of third-party vessels will require scrutiny of ballast water exchange logs, BMPs and BRBs during pre-selection and pre-mobilisation audits (Section 10.12.4.4).

While the IMO requirements implement preventative mitigation against the introduction of non-native species, experience in other regions, such as parts of the UK, has shown that it is still prudent to undertake monitoring. This should be carried out to:

- Identify 'background' levels of non-native species so that existing problems or trends are not inappropriately attributed to the Phase 1 & 2 Development,
- Confirm that valuable sites are not being put at risk from non-native species resulting from the proposed Development, and
- Confirm that non-native species are not being introduced by the proposed operation in general.

Monitoring specifically related to this project requires:

- The deployment of settlement plates in Stanley Harbour, Berkeley Sound and other appropriate locations,
- The use of metagenomic[90] technology to detect genetic material from non-native species in the environment (water samples), and
- In the event that marine invasives are found, pathway analyses will be conducted to determine where / how invasives are being brought into the Islands.

10.12.10.1.1 Ballast water sampling

While sampling of each discharge is not required by IMO, to ensure assessment of ballast waters against IMO Regulation D2 (Section 10.12.10.1), Navitas will ensure samples are taken of discharges in Berkeley Sound when the OCVs/PSVs arrive in the Sound. As a precaution and due to the potentially significant impacts of introducing marine invasives species, even though these vessels will have conducted a ballast exchange operation at the 200 nm limit, in compliance with IMO, they will be discharging this ballast into Berkeley Sound as they take on cargo from the LTVs. These samples will be analysed in a specialist laboratory for monitoring purposes and results shared with FIG Biosecurity. While the length of time required for transporting and analysing the sample means the results are not known until after the ballasting operation, the results are used as a guide to future operations, and to confirm the ballast exchange operations are effective.

10.12.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

10.12.12 Findings summary

[90] The study of the structure and function of entire nucleotide sequences isolated and analysed from all the organisms (typically microbes) in a bulk sample.

Table 10.96: Summary of the residual risk assessment for the introduction of invasive marine species during the Phase 1 & 2 Development

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Introduction of invasive species by Navitas' Sea Lion in-field vessels	Marine Invasive species (biosecurity)	Introduction of marine invasive species through ballast water or biofouling Potential to have irreversible impact on biodiversity and designated sites	Unplanned	1	High	Major	Unlikely	**Moderate (10)**	**Moderate (10)**	**Uncertain**	**Industry-standard:** Pre-selection and pre-mobilisation audits. Compliance with BWMC requirements - Exchange of ballast water *en route* or D2 treatment process. Vessel specific BMP and audit prior to leaving shipyard for to Falkland Islands. OCIMF SIRE Programme will be applied to audit BWMP and the BFMP and all records, Implementation of a reviewed BMP. **Project-specific:** LTVs used as floating logistics vessels will have their hulls inspected prior to departure for the Falklands, Non-natives species monitoring programme and ballast sampling.
Introduction of invasive species inshore by *ad hoc* freighter vessels			Unplanned	1, 2a, 2b & 3	High	Major	Unlikely	**Moderate (10)**	**Moderate (10)**	**Uncertain**	
Introduction of invasive species inshore by the LTVs			Unplanned	1, 2a & 2b	High	Major	Possible	**Upper Moderate (15)**	**Moderate (10)**	**Uncertain**	
Introduction of invasive species offshore by CTTs			Unplanned	2a, 2b & 3	High	Major	Unlikely	**Moderate (10)**	**Moderate (10)**	**Uncertain**

10.13.1 Introduction

Numerous vessels and charter flights will be used throughout Stages 1, 2a, 2b and 3 of the Phase 1 & 2 Development to deliver supplies to the Falklands. While the delivery of cargo is a planned event, the introduction of non-native terrestrial species associated with cargo would be an unplanned event and it is therefore necessary to consider this risk. The potential for the introduction of non-native species was also raised as a concern by stakeholders during scoping consultations (Chapter 6).

Historically, many species have been introduced to the terrestrial environment of the Falklands, some intentionally and some unintentionally. Species introduced from similar climates and which have the potential to flourish in the Falkland Islands are of particular concern. For example, ecologically, the terrestrial habitat of the Falklands is comparable with that of the UK and species that may be transported from the UK are very likely to survive and potentially become established in the Falklands (*c.f.* European earwig, see Section 10.13.4.1.1).

Introduced species can impact on native species through predation, competition and habitat loss which can affect the biodiversity of the Islands. Russell *et al.* (2017) noted that impacts to biodiversity tend to be disproportionately worse for islands, as compared to continents, due to the relatively high number of endemic species. In 2015, a review of the Falklands Biodiversity Framework upgraded invasive species and biosecurity from a medium to high priority threat (FIG, 2016a). In addition, invasive species are mentioned extensively in FIG's Environment Strategy as a high priority (FIG, 2021a).

Equally, micro-organisms could introduce disease to Falklands' livestock. Since 2002, the Falklands Islands have been EU accredited for the exportation of mutton and lamb and approval to export beef has recently been achieved. Countries to which these products are exported must be assured that the goods received are free from pests and disease and therefore biosecurity plays a key role in safeguarding the export industry. In recent years, there has been a concerted effort by FIG to reduce the risk of materials arriving on the Islands unintentionally introducing more non-native species and consequently, biosecurity procedures have become more stringent.

This chapter specifically assesses the risk of introducing non-native species to the terrestrial environment *via* cargo deliveries associated with the Sea Lion Phase 1 & 2 Development.

Note: the risk of introducing non-native species to the marine environment is assessed in Section 10.12 and other impacts associated with vessel use and fixed-wing flights are described elsewhere in this document, as described in Table 2.2.

10.13.1.1 Falkland Islands legislation and guidelines

The import of goods that potentially pose a biosecurity risk is to some extent controlled by:

- The Plant Disease Regulation and Plant Import Regulation Ordinance.
- The Prohibited Goods Ordinance 1992.
- Animal Health (Emergency Measures for Outbreaks of Infectious Diseases) Order 2022.

As FIG officials, Biosecurity Officers are also invested with the powers of Customs Officers, which allows them to work under the Customs Ordinance 2003.

Additionally, preventative guidelines are provided in:

- 'Falkland Islands Biosecurity, protecting our home, environment and economy' (FIG, 2015c).

The Falklands rely on imported goods, which are categorised into groups depending on their perceived biosecurity threat. The import of higher risk items is controlled to ensure that threats to the Islands' biosecurity are minimised. Some categories of import may require an Import Permit such as live

animals, meat, dairy products, eggs and plant materials, which include fruit and vegetables. FIG (2015r) specifies the requirement for importers to notify the Biosecurity Officer of arrivals in advance so that inspections can be arranged. All cargo is inspected for 'pests, diseases and invasive species' prior to being released.

Further, in compliance with the FIG biosecurity declaration, all visitors to the Falklands, whether by air or sea, are briefed on what is / is not allowed to be imported to the Islands. Each passenger must sign a declaration to the effect that they are complying with the regulations. Additionally, visiting vessels are also briefed on the disposal of organic waste, and other waste streams, *via* the 'Falkland Islands Ports and Harbours Information' (FIG, 2024a).

10.13.2 Sources of non-native species introduction

The key potential source of non-native species introduction associated with the Phase 1 & 2 Development is the delivery of cargo to the Falkland Islands. Any cargo arriving from outside the Islands in support of the Sea Lion Development poses a risk of unintentionally introducing non-native species. Deliveries of cargo will occur via:

- Initial import / arrival of the offshore support vessels (i.e., the AHTS, ERRV, PSV, MRSV),
- *Ad hoc* freighter vessels, and
- Charter flights.

A full inventory of the vessels used during Stages 1 to 3 of the Development is provided in Section 5.11.2.

Non-native species may be found within the intended cargo, within the associated packaging or within inadvertently adhered material e.g., mud from the site of origin on the bottom of a container. With regard to cargo therefore, introduction of species can result from the:

- Importation of materials and equipment,
- Importation of food stuffs:
  - Fruit and vegetables, and
  - Food Of Animal Origin (FOAO).
- Disposal of international catering waste.

10.13.2.1 Importation of materials and equipment

All non-food materials related to the Development are likely to be extensively packaged in containers, wood and plastics, all of which can be contaminated with invertebrates, seeds and soil (containing micro-organisms) that can adhere to the outside of packaging and / or may be hidden within cargo.

10.13.2.2 Importation of foodstuff

10.13.2.2.1 Importing fruit and vegetables

It is anticipated that fresh fruit and vegetables will be imported into the Falkland Islands on the charter flights utilised during the Development. While fresh fruit and vegetables entering the local market *via* this route has been welcomed by local residents during previous exploration campaigns and was considered a positive impact during informal consultations on the Phase 1 & 2 Development (Chapter 5), it also represents one of the greatest risks of introducing non-native species within the produce, adhering soil or packaging.

Additionally, it may be necessary to air freight other cargo from the UK to Mount Pleasant *via* the charter flight. While this is not the preferred method for importing materials to the Islands, it may be used if urgent supplies are required.

10.13.2.2.2 Importing Food of Animal Origin (FOAO)

During previous exploration campaigns frozen meat for human consumption was acquired from outside the EU (albeit EU certified) and was imported to the Falklands as 'in-transit' goods. In accordance with the Falklands biosecurity policy, these in-transit goods were kept secure (under Customs seal) on land and were transferred to the drilling rig support vessel under supervision from the Biosecurity Officer or Customs.

All FOAO supplied during the Phase 1 & 2 Development will be contractually required to meet UK / EU standards and will be certified as such.

10.13.2.3 Disposal of International catering waste

If any food stuff arrives on-board vessels or is imported from outside the Falklands, passing through the Islands in-transit, there is the potential for the introduction of harmful pathogens within the food or packaging. This is an important consideration when managing waste (Section 10.10).

10.13.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify the specific receptors upon which the risks of terrestrial invasive species warranted further investigation (Chapter 9). The specific receptors that may be impacted include:

- All terrestrial flora and fauna, and therefore biodiversity in general, including designated sites (Section 7.4 and Section 7.5),
- Livestock and agriculture (Section 7.7.2.4), and
- Human population (Section 7.7.2).

The above may be affected in the event that:

- Non-native species which thrive to the point of becoming invasive tend to outcompete or depredate native species (although the precise receptor species would depend on the species introduced),
- The introduction of agricultural disease or pests impacted on livestock (Tangible Property) and associated exports with socio-economic implications, and
- Agricultural export became unviable which would indirectly affect the culture or 'way of life' on the Islands.

10.13.4 Characterising and quantifying the risk of non-native species

When characterising and quantifying the risks of non-native terrestrial species introduction, it is necessary to assess the:

- Potential consequences of species introduction,
  - Previous examples of species introduction.
- Cargo delivery routes.

10.13.4.1 Potential consequences of species introduction

All invasive species have the potential to impact dramatically on both biodiversity and tangible property with regard to livestock. With regard to the potential impact of non-native species introduction there are three main outcomes:

1. The species arrives on the Islands but is noticed immediately upon arrival and is removed *via* containment and treatment,

2. The species is unintentionally introduced to the Islands, is not noticed immediately and begins to 'take hold' but is effectively removed and disposed of once its presence is discovered, or
3. The species is unintentionally introduced, finds a niche and becomes established within the Falkland Islands and is thus considered 'invasive'.

While all species might fall under any of the categories above, it is generally understood that small mobile organisms (such as invertebrates), pathogens (micro-organisms) and plants are the most difficult to detect and are the most difficult or costly to eradicate once established. Eradication of invasive species on islands is possible in the early stages of introduction, particularly for mammals, but for other invasives, control may be the only option (Russell, *et al.,* 2017).

With regard to pathogens, it is possible that FOAO can harbour disease or pathogens that could be disastrous for the agriculture in the Islands. For example, if foot and mouth disease were to be introduced, it could result in large numbers of animals being destroyed and devastate the meat export industry.

10.13.4.1.1 Previous examples of non-native terrestrial species introduction

There are numerous examples in the Islands where invasive species have had both socio-economic impacts and impacts on the biodiversity of the Islands. For example, brown rats (*Rattus norvegicus*) arrived in the Islands with early visitors, became established and spread to many islands in the Falklands archipelago. These rats are known to be detrimental to native birds (e.g., Cobb's wrens, *Troglodytes cobbi*, and tussac birds, *Cinclodes antarcticus*) and recent studies have shown that islands with invasive rats show a reduction in species richness and a different community structure within the bird species than on islands on which rats have not become established (Tabak, *et al.,* 2016).

More recently, the invasion by the European earwig (*Forficula auricularia*) in Stanley is a timely reminder of the risks posed by non-native species. It is understood that European earwigs were first accidentally introduced to Stanley between 1990 and the early 2000s (anecdotal). Since then, they have spread throughout the town and to outlying settlements and increased hugely in number. These pests have had a number of consequences for the residents of Stanley such as:

- A direct nuisance from home invasions,
- The loss or damage of fruit and vegetable crops, eaten by earwigs, and
- The long-term indirect impact on native invertebrates from the use of chemical pesticide treatments.

The implications for the Islands should earwigs spread beyond settlements are unknown. To date FIG has expended much time and resource to combat the spread of earwigs with limited success. A trial to conduct biological control, with a parasitic fly, was undertaken. While this method had the potential to control (but not eradicate) earwigs without impacts on other environmental receptors (CABI, 2013), the project was not progressed. Recently a new PhD programme has started with the aim of examining the invasion ecology of earwigs in order to inform potential future biological control (P. Brickle, *pers. comm.*).

10.13.4.1.2 Previous biosecurity 'near misses' in the Falklands O&G industry

There have been cases of non-native species arriving on cargo associated with the previous exploration drilling campaigns. During the 2015 campaign, three biosecurity incidents were reported:

- Contaminated dunnage (packaging wood) was delivered with a certificate to state it had been treated; however, an infestation of beetle larvae was clear upon arrival. The dunnage was segregated and treated by a local company under advice from the FIG Biosecurity Officer,

- The 'Snoozebox' intended for use as temporary accommodation was delivered with mud from its previous location still compacted to the base, and
- A second-hand imported vehicle was delivered with mud and road grime (including vegetation) on the under axel. In this instance, the trailer was washed down by a pressure washer on the supply base in the designated washing area with approval and advice from the FIG Biosecurity Officer (S. Cockwell, *pers. comm.*, 2015).

These incidents were reported to the FIG Biosecurity Officer and treatment was applied to remove the possibility of non-native species spreading and becoming established.

10.13.4.2 Cargo delivery routes

Cargo associated with the Phase 1 & 2 Development will be delivered to the Falkland Islands *via* marine and air freight (Section 10.13.2), each of which may have the potential to introduce non-native species:

- LTVs will be used during offshore construction to deliver the subsea infrastructure that requires installation on the seabed. Up to two LTVs at any one time will carry down the installation equipment and anchor in Berkeley Sound acting as floating storage vessels while the installation processes take place.
- *Ad hoc* freighter vessels will arrive in Stanley, from global locations (including the UK, EU and USA) throughout the life of the Development. During Stages 1 to 3, it is anticipated that 12 *ad hoc* freighters will deliver cargo to Stanley. Each vessel will carry a range of cargo to facilitate all aspects of the Phase 1 & 2 Sea Lion Development. During Stage 3, steady production, it is anticipated that all support goods will come into the country on the existing sea and air services.
- Charter flights will arrive regularly throughout the Development to deliver personnel, each flight may carry a shipment of fresh fruit and vegetables.

Detailed cargo manifests are not yet available but will include items such as:

- Subsea equipment for installation during Stages 1, 2a & 2b:
- Drilling equipment and supplies during Stages 1, 2a & 2b,
- Bulk chemicals during all stages, and
- Food during all stages.

As described in Section 10.13.2, all the above may carry non-native species if not inspected and treated appropriately at the point of shipment, and may introduce species if the material itself and the associated packaging is not managed appropriately.

It is clear that many species have been introduced in the past. However, quantifying the risk is not straight-forward. It is likely that many cargos arriving in the Falklands may be harbouring some non-native species. However, whether these become invasive depends upon whether the species is:

- Exposed to the wider environment,
- Able to survive and breed, and
- Find a niche to exploit in the Falklands.

Therefore, the impact of any introduction should be assessed on a case-by-case basis.

10.13.5 Industry-standard mitigation

As part of the planning consent for the Temporary Dock Facility (TDF), a Biosecurity Management Plan (BMP) was developed and implemented by Noble Energy Falklands Ltd. and POEPL (BSP, NEFL, 2015b, 021-15-EHSR-BSP-PA-T4) and has continued to develop over the lifetime of the facility.

The biosecurity procedures followed by Navitas will adhere to the guidelines drawn-up by Noble Energy (NEFL, 2015b), with a review to incorporate lessons learned from the 'near misses' described above (Section 10.13.4.1.2), to cover onshore operations during the Phase 1 & 2 Development.

10.13.5.1 Biosecurity Management Plan

10.13.5.1.1 Planning and preparation

An integrated management approach will be implemented and will include:

- Prevention:
  - Prevention is the most effective way to avoid impacts to the ecosystem. Preventative measures include identifying potential pathways and implementing controls to minimise the impact of invasive species, and
  - All imported goods / cargo will be inspected and treated prior to departure from their point of loading.
- Monitoring, detection and elimination:
  - Personnel in Stanley will be made aware of the importance of biosecurity and inspect cargo as it is unloaded,
  - The onshore supply base will have a dedicated biosecurity area where non-conforming cargo can be quarantined, inspected and treated. Equipment will be available to clean any cargo that does not meet the specified standards and a biosecurity bin will be available in the supply yard waste area to ensure appropriate segregation and disposal. Any waste generated from this exercise will be dealt with in accordance with the Waste Management Procedure,
  - Adequate schedules for monitoring will be set,
  - The TDF Operator will ensure steam / pressure washing equipment is installed and available at the TDF. This will be utilised in cases where it is necessary to mechanically clean material or equipment that is being offloaded at the TDF, and
  - Vermin attraction / containment / detection devices will be used on vessels to monitor pest populations and activity. Visual inspections of the devices will identify specific areas of infestation, if any, and assess the need for further action.
- Management and controls:
  - Controls to minimise the potential for invasive species incursion, including pest infestation controls and eradication measures. Additionally, if a potential infestation is identified a risk / impact assessment will be conducted for the specific non-native species involved. This will ensure the most appropriate mitigation measures are identified, selected and implemented,
  - In the event of a biosecurity incident, FIG Biosecurity will be informed and asked to advise on required treatment and disposal, and
  - Prior to the loading of any material or equipment (intended for transport to the Falkland Islands), appropriate pre-treatment activities will be conducted. These measures include:
    - Wood / dunnage material will be heat treated or fumigated with pesticides and marked with an accredited seal, when applicable,
    - Equipment will be steam / pressure washed and cleaned thoroughly,
    - Any container destined for offloading in the Falkland Islands will be fumigated prior to being secured for transport,

- Rat guards will be used when vessels are berthed at the TDF in Stanley Harbour, and
- Pesticides may be applied if pest / insect populations exceed an acceptable level and will be applied if an infestation is observed prior to arriving at the TDF.

o Awareness campaigns and training will be used to highlight biosecurity risks.

- Regulatory inspections:
  - o If a vessel with an observed / documented infestation arrives to be offloaded at the TDF, the TDF Operator will coordinate the relevant governmental agencies / regulatory bodies to ensure appropriate measures are taken.

10.13.5.1.2 Importation of food and food waste disposal

The importation of all goods and food stuffs will follow the guidelines outlined in FIG's 'Falkland Islands biosecurity: protecting our home, environment and economy: A guide to importing goods' (FIG, 2015c).

During the 2015 exploration campaign, there were some issues regarding in-transit FOAO. As in-transit products have not been through the usual importation procedures and may be sourced from outside the EU they may pose a risk of introducing disease or pathogens to the Falklands. The long-term storage of food in-transit is not appropriate as it requires continuous supervision; FIG officials are present every time in-transit food is moved. This issue can be easily mitigated by procuring meat that is UK / EU certified as it can therefore go through the usual import process, or source meat locally, which is also EU certified. The next revision of the BMP will detail these improvements, with greater focus on pre-export improvements.

Food, galley waste and associated packaging sourced from outside the Falkland Islands EEZ are termed International Catering Waste (ICW). ICW carries a risk of introducing pests and diseases and must be disposed of accordingly. At-sea, food waste may be disposed of in accordance with MARPOL regulations and discharged to sea (Section 10.10.1.1.) but packaging and associated wastes will be returned to shore for incineration in accordance with the Waste Management Plan (Section 10.10).

10.13.6 Risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor', the 'Severity of Effect' and the 'Likelihood of Occurrence' to determine the overall 'Risk'.

A summary of the risk assessment outcomes for this Development is tabulated in Section 10.13.12 which shows the worst-case risk for each activity.

10.13.6.1 Introducing terrestrial non-native species in marine or air freight

If invasive species were introduced during the Phase 1 & 2 Development the impact on the ecology of the Islands through parasites, disease, competitors or predators may not be immediately evident but may have long-term implications. Initially the impact would be felt locally, however, once established invasive species may spread 'naturally' or with anthropogenic assistance to other parts of the Falklands archipelago. There is potential to have an impact on a national scale and therefore the sensitivity of the receptors to invasive species is considered to be '**High**'.

If found, potentially invasive species can be removed and disposed of before becoming established. However, detecting microscopic or small mobile organisms (such as invertebrates) is very difficult once onshore. If such non-native species become invasive, the long-term implications for the Islands could be severe and difficult to reverse. In the terrestrial environment the possibility of detecting invasive species, and eradicating them to reverse the effect, is feasible but may be costly, in both time and money. On this basis, the severity of effect is initially considered to be 'Serious'. However, taking into

account the measures implemented as part of the Biosecurity Management Plan (BMP), the severity of effect is considered to be '**Moderate**'.

Therefore, the worst-case significance of the impact has been assessed as '**Upper Moderate (12)**'.

Vessels and charter flights will be arriving in Stanley throughout the life of the Development and a large amount of cargo will be taken onshore. The transportation of invasive species to the Falklands has happened in recent years, and the introduction of invasive species has occurred in the Oil and Gas (O&G) industry elsewhere in the world. Indeed, non-native species (with the potential to become invasive) arrived in the Falklands in cargo associated with the 2015 exploration drilling campaign, although they were detected and recorded as 'near misses' (Section 10.13.4.1.2). Nonetheless, while the biosecurity incidents were detected and remedial action taken, no biosecurity plan is absolutely fool-proof and it is possible that other minor breaches went undetected. Therefore, despite improvements to biosecurity procedures, the likelihood of invasive species becoming established as a result of the Sea Lion Field Development is considered to be '**Possible**'.

The movement of large quantities of cargo has discernible environmental and social risks in terms of the potential to introduce non-native species. While there are means of reducing the risk (Section 10.13.5), the overall significance of the risk of introducing non-native terrestrial species has been assessed as '**Upper Moderate (12)**'.

10.13.6.2 Introducing disease or pathogens in food of animal origin

As described in Section 10.13.4.1, the consequences of introducing a pathogen from FOAO could be disastrous. The Tangible Property receptor (agriculture) has little or no capacity to absorb change on this scale and this situation would be unacceptable to all stakeholders. Therefore, the sensitivity of receptor impacted by the introduction of animal disease or pathogens is considered to be '**Very High**'.

Although an outbreak of disease may be recoverable over time, the resulting loss in confidence from consumers (i.e., foreign buyers of meat products) could be very long-lasting and potentially jeopardise the industry. Therefore, the potential for a long-term negative effect on livelihood means that the severity of effect is initially considered to be 'Serious'. However, taking into account the measures implemented as part of the Biosecurity Management Plan (BMP), the severity of effect is considered to be '**Moderate**'.

Overall, the significance of the impact of introducing disease or pathogens that could infect livestock has been assessed as '**Upper Moderate (15)**'.

Ensuring that all FOAO is acquired from UK/EU certified sources and goes through the usual import permitting process for FOAO entering the Falklands, the likelihood of introducing pathogens is reduced to '**Very Unlikely**', and the residual risk is reduced to '**Low (4)**'.

10.13.7 Project-specific mitigation

10.13.7.1 Introduction of terrestrial non-native species in marine or air freight

All industry-standard and legally required mitigation measures available to reduce the risk of introducing terrestrial non-natives to ALARP are already in place (development of the BMP and adherence to FIG biosecurity guidelines), although it is acknowledged that improvements will be made to the BMP wherever possible during its development. This, along with the Navitas OMS, are factored into the initial risk assessment. Therefore, the impacts and risks, as determined from the initial assessment, are considered to be ALARP.

10.13.8 Residual risk

10.13.8.1 Introducing terrestrial non-native species

The initial assessment of the introduction of non-native species through marine or air freight takes account of all the mitigation measures which are built-in to the basis of design and while improvements may serve to reduce risks in future, at this time, they cannot change the initial assessment. Further, given the number of 'unknowns' within the assessment, it is considered appropriate and precautionary for the significance of the risk of introduction of invasive species by marine or air freight to remain '**Upper Moderate (12)**'.

10.13.9 Cumulative effects

The Sea Lion Development will add to the existing risk of introducing invasive species to the Falkland Islands and there is the potential for this to lead to cumulative impacts through increased 'concentration' (Section 8.9.1). Any cargo coming into the Falklands has the potential to transport non-native species into the Islands. The risk posed by each vessel will be related to the type of cargo carried, the origin of that cargo and the condition of the cargo when loaded (clean or soiled / contaminated). Pre-loading preparation and checks of cargo are critical factors but very open to human error, which introduces a degree of uncertainty. It is assumed that each vessel associated with the Sea Lion Field Development will be carrying similar cargo and therefore each vessel will pose a similar risk of introducing non-native species. The risk of each vessel introducing non-native species may be low; however, with each vessel arriving, the probability of introducing non-native species increases (i.e., each load of cargo coming ashore increases the risk of introducing 'hitch hiking' non-native species).

10.13.10 Confidence

The nature of the impact of currently established invasive species on the terrestrial environment of the Falklands is understood. It is known that during the 2015 exploration drilling campaign the O&G industry brought non-native species to the Islands. However, it is difficult to predict the impact of the arrival of additional non-native species, as it will depend on the species involved and measures taken to remove them, and this is acknowledged as a data gap. Additionally, many of the mitigation measures rely on the diligence of the personnel handling the cargo, which is prone to human error. Therefore, there is a degree of uncertainty regarding the sensitivity of environment receptors. Confidence in the assessment is therefore assessed as '**Probable**'.

10.13.10.1 Monitoring required

Monitoring will be an inherent part of the project-specific BMP. Monitoring as cargo is prepared and loaded, and of incoming cargo, will help to evaluate the efficacy of the biosecurity protocols and indicate if revision is required. Detailed monitoring requirements have been established during the Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 EMMP (an outline EMMP is provided in Chapter 15).

10.13.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

10.13.12 Findings summary

Table 10.97: Summary of the risk assessment for the introduction of invasive terrestrial species during the Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Introduction of terrestrial non-native species by marine and air freight	Terrestrial biosecurity	Introduction of invasive species with potential to negatively impact biodiversity and designated sites	Unplanned	1, 2a, 2b & 3	High	Moderate	Possible	**Upper Moderate (12)**	**Upper Moderate (12)**	**Probable**	**Industry-standard:** Implementation of a reviewed Biosecurity Management Plan (BMP) **Project-specific:** None proposed
Introduction of pathogens species in FOAO	Terrestrial biosecurity	Introduction of disease or pathogens *via* food of animal origin to negatively impact tangible property e.g., agricultural livestock	Unplanned	1, 2a, 2b & 3	Very High	Moderate	Very Unlikely	**Low (4)**	**Low (4)**	**Probable**	**Industry-standard:** Implementation of a reviewed Biosecurity Management Plan (BMP) Source food of animal origin from UK / EU certified sources and from within the UK / EU. **Project-specific:** None proposed

11.1.1 Introduction

The development of The Sea Lion Field Northern Development Area will require the placement of installations offshore (both topside and subsea) and will lead to a long-term increase in vessel traffic throughout these waters.

The waters of the North Falkland Basin (NFB) are used for commercial fisheries. Therefore, the presence of Navitas installations and their supporting vessels may lead to disturbance of other users of the sea and / or an increased risk of collisions offshore. The presence of subsea infrastructure could lead to the snagging of fishing gear, which alongside damage to tangible property could lead to environmental impact such as oil spill (Section 12.1). The use of exclusion zones around offshore installations is a key mitigation against such risks as snagging and collisions but may lead to impacts in their own right in terms of fisheries and shipping lanes. Impact on other users of the sea was raised by stakeholders during scoping consultations held in 2014, 2015 and 2016 (Chapter 6).

Owing to the differences in the proposed use of the offshore and inshore locations and the variety of potential impacts and risks, the assessment on other users has been split into two sections (offshore and inshore) as shown in Table 11.1.

This chapter assesses the impacts and risks to the Human Population and Tangible Property during the offshore activities, and focusses on other users of:

- The offshore, Sea Lion Phase 1 & 2 Development location (the Sea Lion Field), and,
- The shipping routes between the Sea Lion Field and inshore operations.

Note: the other impacts associated with vessel use, competition for resource and the installation of subsea infrastructure etc. are described elsewhere in this document, as described in Table 2.2.

Table 11.1: Summary of potential impacts and risks to other users of the sea

Location	Receptor	Potential impact	Potential risk	Assessed in
Offshore	Vessels on passage	Requirement for vessels to navigate around exclusion zones	Vessel collisions with FPSO[1] and / or MODU[2]	This chapter
	Fishing vessels	Fishing prohibition within the exclusion zones may impact upon fisheries revenue	Exclusion zones are not respected resulting in snagging on subsea infrastructure and potential for loss of vessel and / or gear	This chapter
Stanley Harbour	Fishing, Reefer, Cruise, Cargo and Recreational vessels	Competition for berthing space in Stanley Harbour	Potential for collision between vessels in confined waters	Section 11.2
Port William		Competition for anchorage space		
Berkeley Sound				

[1] Floating Production, Storage and Offloading Vessel.
[2] Mobile Offshore Drilling Unit.

11.1.1.1 Relevant legislation

Legislation relevant to the potential for disturbance to other sea users includes:

International conventions:

- United Nations Convention on the Law of the Sea (UNCLOS), 1982.
- International Convention for the Safety of Life at Sea (SOLAS, 1974, as amended).
- Standards for Training, Certification, and Watch-keeping (STCW), 1978.
- International Regulations for Preventing Collisions at Sea (Collision Regulations or ColRegs). 1972.
- Maritime Pollution Regulations (MARPOL), 1973.
- International Convention on Maritime Search and Rescue (SAR), 1979.

UK legislation:

- Petroleum Act 1987.
- Petroleum Act 1998 (as amended by the Energy Act 2008).

Falkland Islands specific maritime legislation and guidelines:

- The Offshore Minerals Ordinance (1994) specifies the requirement for an exclusion (safety) zone of 500 m radius around offshore installations.

Note: while the use of exclusion zones is required by legislation, no legislation exists with regard to minimising the impacts of these on other users of the sea.

- OSPAR Decision 98/3 on the Disposal of Disused Offshore Installations.

11.1.1.1.1 Navigation compliance ('Rules of the Sea')

The International Regulations for Preventing Collisions at Sea 1972 (ColRegs) are published by the International Maritime Organisation (IMO) and set out, among other things, the 'Rules of the Sea' or navigation rules to be followed by ships and other vessels at sea to prevent collisions between two or more vessels. All vessels should conduct themselves in the following manner:

- Every vessel shall at all times maintain a proper look-out by sight and hearing as well as by all available means appropriate in the prevailing circumstances and conditions so as to make a full appraisal of the situation and of the risk of collision,
- Every vessel shall at all times proceed at a safe speed so that she can take proper and effective action to avoid collision and be stopped within a distance appropriate to the prevailing circumstances and conditions, and
- Vessels must use all available means to determine the risk of a collision, including the use of radar (if available) to get early warning of the risk of collision by radar plotting or equivalent systematic observation of detection.

11.1.1.1.2 Offshore exclusion zones (safety zones)

Exclusion zones are required under the Petroleum Act (1987) and the Falkland Islands' Offshore Minerals Ordinance (1994). An offshore exclusion (safety) zone is an area extending a minimum 500 m from any part of offshore O&G installations and is established automatically around all installations which project above the sea at any state of the tide.

Under the Ordinance, subsea installations also require exclusion zones to protect them. Offshore exclusion (safety) zones are 500 m radius from a central point and vessels of all nations are required to respect them. It is an offence (under Section 23 of the Petroleum Act 1987) to enter an exclusion zone except under the special circumstances (HSE, 2008).

Details of exclusion (safety) zones will be promulgated *via* Maritime Safety Information (MSI) under Coastal State obligations.

Further, under the Falkland Islands' Offshore Minerals Ordinance (1994), any fishing vessel that strayed into the exclusion zone would be committing a legal offence and the owner and Master of the vessel would be liable to a fine without limit.

11.1.1.1.3 Decommissioning

Under the Petroleum Act 1998 and OSPAR Decision 98/3 it is necessary to remove all subsea pipelines and installations at the end of Field Life. While comparative assessments may be used to justify the leaving of certain pipelines *in situ*, and Derogation from the OSPAR requirement to remove installations may be sought under very specific circumstances (OSPAR, 1998), all Phase 1 & 2 installations will be constructed with a view to complete removal (Section 5.12).

Therefore, at the end of Field Life all subsea equipment associated with the Phase 1 & 2 wells SPS (Subsea Production System), which includes subsea manifolds, and Subsea Umbilical, Risers and Flowlines (SURF), will be removed so that nothing is left in place which may pose a risk to other users of the sea. Where necessary, and in line with the legislation, equipment placed beneath the seabed e.g., well conductors, will be cut to a depth which will ensure that the object will remain below the level of the seabed in the face of prevailing currents.

Note: impacts and risks associated with decommissioning will be covered by a dedicated EIA, which will be written towards the end of Field Life and in support of the Decommissioning Programme (Section 5.12).

11.1.2 Sources of disturbance to other users of the sea

Sources of impact and risk to other users of the sea offshore include:

- The physical presence of offshore infrastructure including:
  - Short-term anchored installations e.g., the Mobile Offshore Drilling Unit (MODU),
  - Long-term anchored installations e.g., the Floating Production, Storage and Offloading (FPSO) vessel, and
  - Subsea infrastructure e.g., anchor arrays, manifolds, wellheads, flowlines etc.
- 500 m exclusion zones around the MODU,
- 1,275 m exclusion zone around the FPSO,
- Additional vessel traffic in:
  - The Falklands Conservation Zones, and
  - In transit between the Sea Lion Field and Stanley Harbour and also between the Sea Lion Field, Stanley Harbour and Berkeley Sound (during the offshore construction phase).

11.1.2.1 Physical presence of offshore installations

Offshore installations associated with the Sea Lion Development will present a navigational obstacle to vessels on passage through the NFB for the entire duration of their presence. During Stage 1 there will be a construction phase with a number of vessels on location in the Field. Drilling will commence in Stage 1 with a MODU and support vessels *in situ*. In Stages 2a, 2b & 3, production will be underway with the FPSO and its support vessels. During Stages 2a & 2b there will be periods of Simultaneous Operations (SIMOPS) where both the MODU and the FPSO will be in operation in the Field.

11.1.2.2 Offshore exclusion zones

In line with the requirements of the Petroleum Act 1987 (HSE, 2008) and FIG's Offshore Minerals Ordinance (1994), a 500 m exclusion (safety) zone will be established around installation extremities. For the FPSO this includes the length of hose connecting the FPSO and the export tanker, and the tanker itself such that the exclusion zone will extend to 1,275 m around the FPSO. All anchors, mooring

lines and flowlines will be surrounded by a 200 m exclusion zone as per industry accepted best practice. The overall extent of the offshore exclusion (safety) zone is illustrated in Figure 11-1, third-party vessels, such as fishing vessels, will be prohibited from entry into the exclusion area.

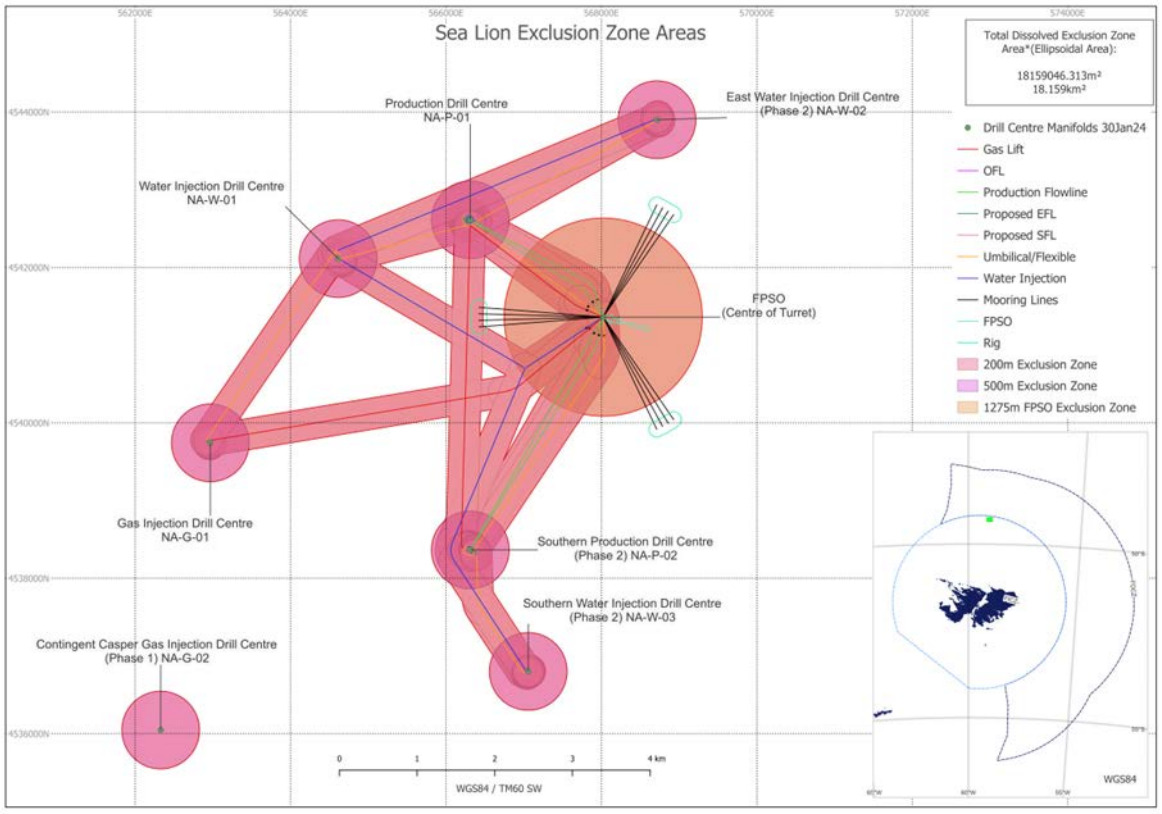

Figure 11-1: Offshore exclusion zones associated with the Sea Lion Development

11.1.2.3 Additional vessels

Numerous different vessels will be deployed offshore for specific tasks during the life of the Phase 1 & 2 Development. These range from the use of installation vessels i.e., Offshore Construction Vessels (OCVs) and supporting Platform Supply Vessels (PSV), drilling vessels (the MODU) and its supporting Emergency Rescue Response Vessel (ERRV) and Anchor Handling Tug Supply (AHTS) vessels during Stages 1, 2a & 2b, to the use of an ERRV / Multi-Role Support Vessel (MRSV) and AHTS to support the FPSO throughout Field's production life.

A detailed inventory of all vessels required is provided in Section 5.11.2 and a summary for the purposes of this chapter, with division according to the locations of the vessel activity, is provided in Section 11.1.4.1.

While at-sea, all Navitas project vessels which are not at anchor (i.e., they are on passage or waiting to attend the FPSO or MODU) will continue to maintain 24-hour watch-keeping using radar, AIS and visual sightings. If a third-party vessel is detected on a collision course, they will follow the international collision regulations and give way if appropriate, like any other sea-going vessel. Therefore, this source of risk should be similar to that posed by any vessel steaming at-sea and has not been considered further.

11.1.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify the specific receptors upon which the impacts and / or risks to other users of the sea warranted further investigation (Chapter 9). The specific receptors that may be impacted include:

- Vessels licensed to fish the waters surrounding Sea Lion Development (Section 7.7.3.1.1.1):
  - Fishing vessels targeting *Illex* squid.
- Vessels transiting through the NFB (Section 11.1.4.4.1):
  - Fishing vessels,
  - Cargo vessels,
  - Tankers, and
  - Cruise ships.

11.1.4 Characterising and quantifying the impact

When characterising and quantifying the impacts and risks to other users of the NFB, it is necessary to consider the:

- Type, location and behaviour of Phase 1 & 2 vessels used offshore,
- Impact of offshore exclusion zones on fisheries in the Sea Lion Field:
  - Potential for loss of fishing grounds.
- Potential for interference between fishing vessels and offshore subsea infrastructure:
  - Overtrawlability studies.
- Modelling of third-party vessel collisions with the FPSO which includes:
  - Identification of the shipping routes passing the Phase 1 & 2 location,
  - Estimation of the Phase 1 & 2 infield vessel activity,
  - Estimation of the offshore vessel and FPSO collision risk frequencies, and
  - Estimation of the consequences of a collision.

11.1.4.1 Type, location and behaviour of Phase 1 & 2 vessels offshore

In order to inform the assessment of impacts and risks, it is necessary to have an appreciation of the additional offshore vessel traffic incurred as a result of the proposed Phase 1 & 2 Development. A detailed inventory of the offshore vessels used is provided in Section 5.11.2 and a summary of the vessel type, purpose and specification is provided in Table 11.2.

Table 11.2: Summary of the type, purpose and behaviour of offshore Phase 1 & 2 vessels used to inform the impact and risk assessment

Vessel / installation type	Vessel purpose	Analogous Vessel	Vessel specification			Total number of operations / visits		
			Length (m)	GRT (tonnes)	Max. speed (kn)	Stage 1 (31 months)	Stage 2a & 2b (35 months)	Stage 3 (*c.* 27 years)
MODU's AHTS	MODU tow, supply and ERRV	*Pacific Champion*	86	3,330	15	99	108	4
MODU's ERRV	Supply and ERRV	*Esvagt Don*	56.4	1,863	12	90	99	n/a
OCV	Offshore construction	*Skandi Skansen*	107	4982	15	39	26	n/a
PSV	Offshore construction	*Pacific Leader*	97.3	5,260	16	52	26	n/a
MODU (anchored)	Drilling	*Stena Don* (moored)	122	42,570	0	500 m exclusion zones around main well clusters		n/a
Subsea	Production	n/a	n/a	n/a	n/a	500 m exclusion zone around installation extremities (see Figure 11-1)		
FPSO	Production	*FPSO Aoka Mizu*	284	88,059	0	n/a	Anchored on site with 1,275 m exclusion zone	
FPSO's AHTS / ERRV	Supply and ERRV	*Nor Solan*	97	5,179	14	56	151	1,398
FPSO's MRSV / ERRV	Supply and ERRV	*Nor Solan*	97	5,179	14	56	151	1,398

11.1.4.2 Impact of offshore exclusion zones on fisheries

The presence of exclusion zones around the surface and subsea infrastructure (Figure 11-1) has the potential to lessen the availability of fishing grounds.

The Falkland Islands Fisheries Department (FIFD) closely monitors all vessels licensed to fish within Falkland Islands waters. An average of 176 fishing vessels pass through the Sea Lion area annually (Anatec, 2024a). The data show that most vessels passing through the area were travelling at speed and so were not actually engaged in fishing in this region. Therefore, it is recognised that the Sea Lion Field is located in the centre of a route well used by fishing vessels on passage from the high seas to / from the main harbours of the Falklands. Vessels which were engaged in fishing were located approximately 30 nm to the south and west of the Sea Lion Field along the 200 m depth contour at the edge of the continental shelf which is known as a productive fishing ground (see Figure 11-2 below).

11.1.4.2.1 Potential for loss of fishing ground

The drill centre for the Phase 1 & 2 Sea Lion Field Development is located within FIFD grid square XFAK, approximately 20 to 37 nautical miles north-east of the 200 m depth contour line, in water approximately 450 m deep. The fisheries statistical square surrounding the Sea Lion Development

(XFAK) has only been open to vessels with Type B licences[91]. The B licence allows vessels (jiggers) to fish for Argentine shortfin squid and, rarely, for the sevenstar flying squid (*Martialia hyadesii*). Data extracted from the Fisheries department database in 2023 (Section 7.7.3.1.1.1) indicate that both jiggers and trawlers have fished the area, but there is considerable inter-annual variation in fishing effort and catch in the area. Catches and fishing effort in the grid square occupied by the Sea Lion Field (XFAK) is relatively low (FIG, 2023n). Exceptionally high catches of *Illex* squid were made in 2014, 2017 and 2022 reflecting high catches throughout the zone during these seasons. Nonetheless, the data indicate that generally the area of the Sea Lion Field is rarely fished.

Therefore, while fishing vessels may prospect in the area, the region of the Sea Lion Field is not considered to be a regular fishing ground such that no impacts upon future fish catches are anticipated.

11.1.4.2.2 Stakeholder comments

Stakeholders from the fishing industry were consulted as part of the 2016 scoping consultation, in 2020 during the last full consultation of the Sea Lion Development EIS, and most recently during the 2023 scoping consultation (Chapter 6). FIFCA (Falkland Islands Fishing Companies Association) have facilitated consultation with local fishing companies (who are in some cases vessel owners) and vessel agents throughout the evolution of the Sea Lion project. The nature of the Falklands' fishing industry is such that ship's captains are not particularly accessible (they spend limited, if any time onshore, and often do not speak English) so direct consultation with captains has not been possible. Competition between sea users and the associated risk of collision has been brought up by stakeholders during each consultation, though this was mostly in relation to the use of Berkeley Sound (which is discussed in Section 11.2).

11.1.4.3 Potential for interference between fishing gear and subsea infrastructure

Illex jiggers use powerful lights and light weight 'jigging' lures to lure squid to the surface and are not believed to be a risk to, or at risk from, subsea installations. In the past some trawlers targeted *Illex*, however the B licences for trawlers were removed in 2023 (P. Brickle, *pers comm.*).

Given that the behaviour of fishing vessels can be unpredictable, it is not uncommon for vessels to fish in areas where they are not permitted. In the unlikely event that vessels were to ignore exclusion zones with the intent to operate in the vicinity of the Phase 1 & 2 Development they would be deterred by installation guard vessels (ERRV/AHTS/MRSVs). However, if unchallenged, fishing gear has the potential to interfere with the:

- Subsea Production System (SPS), the Subsea Umbilicals, Risers and Flowlines (SURF), the wellheads, X-mas trees and the Drill Centres which will, in total, cover a total combined area of 0.024 km^2, spanning an area of approximately 18 km^2,

Snagging of fishing gear from trawlers specifically could result in:

- Damage to the subsea infrastructure,
- Loss of the fishing gear (Tangible Property), and
- The potential for damage to the fishing vessel and injury / loss of life to crew.

Note: importantly, it is out with the scope of this EIA to assess the safety implications with regard to the injury or loss of life on fishing vessels. Safety implications will be addressed by other Navitas processes, other legislation and other industry good practices, while the EIS is focused on the environmental impacts and risks.

[91] The B licence allows vessels (jiggers) to fish for Argentine shortfin squid and, rarely, for the sevenstar flying squid (*Martialia hyadesii*).

11.1.4.3.1 Overtrawlability studies

The previous operator of the Sea Lion Field (POEPL) and their JV partner commissioned three separate studies which aimed to define the level of fishing activity in the Sea Lion area and to recommend the type of mitigation required to protect subsea equipment and flowlines as well as fishing vessels and their trawling gear.

These studies comprised the:

- AGR Petroleum Services screening study - Falkland Islands fisheries and risk to subsea infrastructure (AGR, 2012),
- Pale Maiden Consulting Ltd - Fishing Activity Report that uses VMS data (Pale Maiden, 2013), and
- Jee Subsea Consultants - Sea Lion Development: Fishing and trawl risk assessment (Jee, 2013) based on published Falkland Islands fishery statistics and the results of the above studies (Jee, 2013).

The AGR (2012) report utilised pre-2006 fishing data, which due to changes in licence conditions, is now regarded to be out-of-date. The Pale Maiden report (2013) used more recent data (up to 2012) to assess the level of fishing activity in the Sea Lion area. However, during this EIA, discrepancies between the reported position of vessels (i.e., the statistical square) and the actual position of vessels (derived from VMS data) were since identified, which place doubt on the fishing effort reported for the area in the Pale Maiden document. Nonetheless, the demersal trawler activity within the Sea Lion Field, as described in the Pale Maiden report, was confirmed by VMS data in 2012. The Jee report utilised information from the AGR and Pale Maiden reports alongside additional scoping with all interest groups. Further, during the recent Collision Risk Assessment, Anatec confirmed that no fishing vessels recorded as broadcasting on AIS appeared to be actively fishing in the area during 2022 and 2023 (*J. Campbell, pers comm., 2024*).

In summary, the Jee report (2013) concluded that there is negligible risk of snagging with subsea infrastructure and that there is therefore no need to make the subsea infrastructure overtrawlable. The Jee report (2013) recommended that further monitoring is conducted to ensure that the situation does not change in the future. More recent AIS data from the Anatec (2024a) study confirms fishing activity to be very low within the area. The Jee (2013) report concluded that the most appropriate way to safeguard subsea infrastructure, and to prevent the loss of fishing vessels (and all incumbent consequences) is *via* reliance upon exclusion zones and the use of a designated guard vessel once installation commences.

11.1.4.4 Modelling of third-party vessel collisions with the FPSO

With regard to the impact on other users of the sea, Navitas commissioned Anatec Ltd. to calculate the risk of collisions between the FPSO and third-party vessels passing the Sea Lion Field (both powered vessels and drifting vessels). Note that this model is also used to assess the likelihood of collisions between Navitas vessels in the offshore oil spill assessment (Section 12.1).

The modelling uses the Health and Safety Executive (HSE) research methodology together with:

- Site-specific inputs for the Sea Lion FPSO,
- Site-specific inputs for the MODU, and
- The use of a dedicated ERRV with both AIS and radar ship tracking.

Note: during Stages 1, 2 a & 2b the MODU will be stationed in the Sea Lion Field at several different locations. Only one location for the MODU has been modelled although it will move around the field during Stages 1, 2a & 2b.

11.1.4.4.1 Identification of shipping routes passing the Phase 1 & 2 location

Details of all of the shipping routes passing close to the Sea Lion Field were identified using detailed analysis of AIS (Automatic Identification System) data (Anatec, 2024a). AIS is an automated tracking system used on ships and by vessel traffic services for identifying and locating vessels through the electronic exchange of data (e.g., unique identification, position, course and speed) with nearby ships, AIS base stations and satellites. The IMO's International Convention for the Safety of Life at Sea (SOLAS) requires AIS to be fitted onboard international voyaging vessels with a gross tonnage of > 300 t.

Although the Sea Lion Field lies on the shipping routes between Stanley and both the fishing grounds and the South American mainland, the number of vessels using these routes is consistent with areas of low shipping activity (Anatec, 2024a). The nearest area of high-density shipping activity is found approximately 30 - 50 nautical miles to the south-west of the Sea Lion Field (Figure 11-2). As shown, these vessels are primarily engaged in fishing activity (trawling) and generally move back and forth at low speeds (approximately four knots).

Looking more closely, there are eight main shipping routes that pass within 15 nm of the Sea Lion Field, with a total of 216 ships per year travelling on these routes (Figure 11-3a; Table 11.3). This is equivalent to between zero and one vessel passing the Field every day. The types of vessel using each of the eight routes shown in Figure 11-3a are quite distinct and are described in Table 11.3. The number of vessel-hours that each square nautical mile surrounding the Sea Lion Field is exposed to on an annual basis is provided in Figure 11-3b.

The majority of vessel traffic comprises fishing vessels travelling to and from fishing grounds (routes 1, 3, 4, 5, 7 & 8 Figure 11-3a), although it should be noted that there is likely to be considerable inter-annual variation in the number of these vessels. Route 2 is used by a small number (4 % of all vessel traffic) of large vessels (tankers and bulk carriers) exceeding 15,000 Dead Weight Tonnes (DWT). Vessels using Route 6 are typically cruise ships which are large fast-moving vessels but generally have a lower mass than large cargo vessels.

The impact energy of a collision is related to the squared speed and mass of the vessels involved and is measured in Mega Joules (MJ). DWT is a measure of how much mass a ship is carrying or can safely carry.

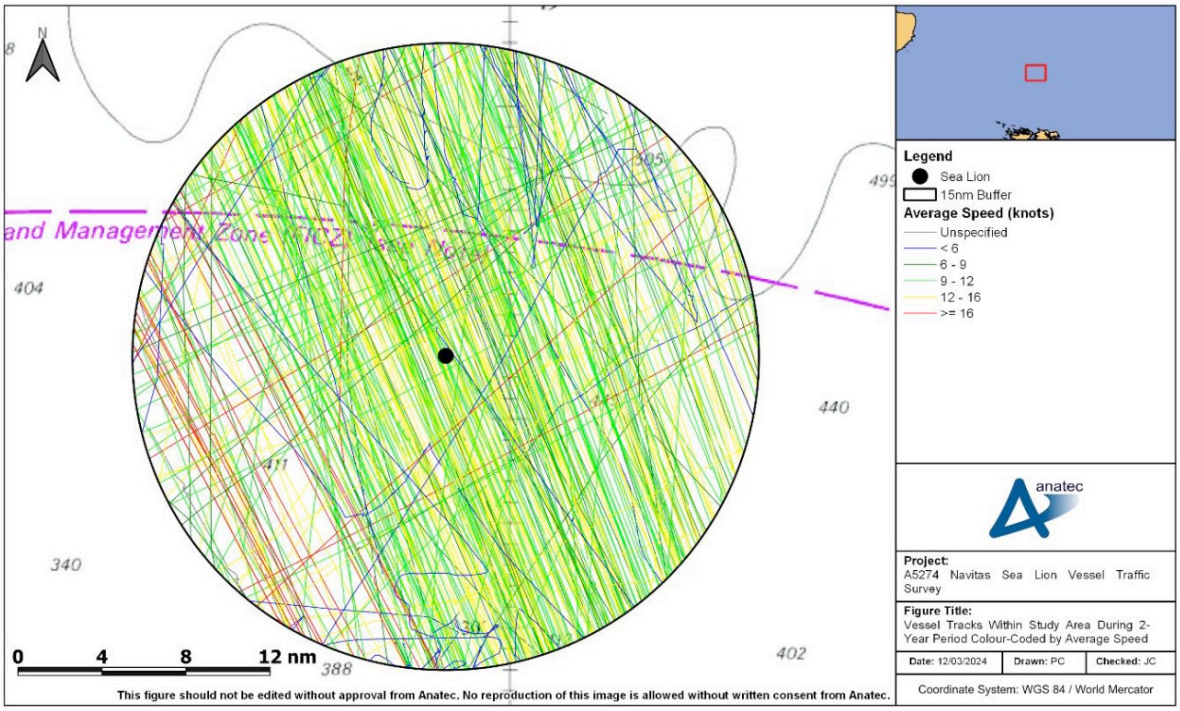

Figure 11-2: Overview of AIS shipping data for the Sea Lion Location (2022-23) ***(Source: Anatec, 2024a)***

Table 11.3: Ship Routes Passing within 15 nautical miles of the Sea Lion Field ***(Source: Anatec, 2024a)***[1]

Route No.	Description	Type of vessel	CPA (nm)a	Bearing (°)	Vessels per year	% of Total
1	Fishing grounds – Falkland Islands	Fishing vessels	1.0	249	51	24 %
2	South America – South Africa	Tankers	3.0	331	9	4 %
3	East Asia – Fishing grounds	Fishing vessels	4.1	70	40	19 %
4	Falkland Islands – Fishing grounds	Fishing vessels	5.1	249	40	19 %
5	Falkland Islands – Fishing grounds	Fishing vessels	7.7	70	31	14 %
6	Stanley – Puerto Madryn	Cruise ships	11.0	245	16	7 %
7	East Asia – Fishing grounds	Fishing vessels	11.6	252	8	4 %
8	Fishing grounds – Falkland Islands	Fishing vessels	12.5	70	21	10 %
Total					**216**	**100 %**

[1] Where two or more routes have identical Closest Point of Approach (CPA) and bearing they have been grouped together. In this case, the description lists the sub-route with the most ships per year.

b) Vessel shipping density withing 15 nm

Figure 11-3: Averaged shipping routes and vessel shipping density within 15 nautical miles of the Sea Lion FPSO (see Table 11.4 below for detail on the shipping type associated with each route number) ***(Source: Anatec, 2024a)***

11.1.4.4.2 Estimation of vessel activity in the Sea Lion Field

At the time of the Anatec assessment (2024b), detail on the specific vessels likely to be used was unknown. At the time of the modelling, the analogous vessels were based on typical vessels used in the UK North Sea and West of Shetland. Detail on the MODU and FPSO analogies assumed for the Anatec model is presented in Table 11.4.

Table 11.4: Details of the analogous vessels used in the modelling ***(Source: Anatec, 2024b)***

Vessel Type	Analogous vessel	Length (m)	Width (m)	Dead Weight Tonnage (DWT)	Estimated attendance
MODU	*Stena Don*	95.5	81	-	All year round
FPSO	*Aoka Mizu*	248.1	42	-	All year round
ERRV	*Biscay Sentinel*	62	15.5	1,500	Permanently on stand-by
Supply	*Pacific Leader*	97.3	20	5,260	Every 4 days

11.1.4.4.3 Estimation of offshore vessel collision frequencies

The COLLRISK model was used to estimate collision risks on an annual basis (Anatec, 2024b). The consequence of collisions was estimated by taking into account impact energy based on the size and speed of respective vessel types (Section 11.1.4.4.4).

The model is based on the premise that the collision frequency is proportional to the volume of traffic interacting with the FPSO / MODU. This stems from a review of historical data, which indicated that failure in watch-keeping systems tends to be the cause of collisions between passing vessels and offshore installations.

The following provides only the detail required to enable appreciation of the results in the context of third-party vessel collisions with the FPSO and MODU. Details on the specific parameters used within the COLLRISK model with regard to metocean data are provided in Section 7.3.5.

A summary of the main assumptions used in the model and the analysis, and the estimated collision frequencies between third-party vessels and the FPSO is provided in Table 11.5.

Table 11.5: Summary of the assumptions and results of the COLLRISK collision frequency model
(Source: Anatec, 2024b)

Vessel type	COLLRISK Model basis and assumptions	Estimated collision frequency between vessel and FPSO / MODU
Third-party passing powered vessels	Vessels operating on these routes have ample room available to increase their passing distance from the Sea Lion Development. With no nearby offshore installations or exclusion zones in place the vessels have space to transit the area safely; this can be observed from the AIS data, where the routes taken by vessels are relatively diverse across the area. If vessels do increase their mean passing distance, the effect on navigation is expected to be negligible.	Due to the low levels of shipping in the area of the Sea Lion Field the potential frequency of events is low. Passing powered collision frequency is 2.6×10^{-7} collisions / year (an equivalent of one collision in 3.8 million years) for the MODU and 5.8×10^{-7} (one in 1.7 million years) for the FPSO.
Third-party passing drifting vessels	The model for calculating passing drifting collision risk is based on the premise that the engine(s) on a vessel must fail before a vessel will drift. The model takes account of the likelihood of vessels having multiple engines based on fleet data for different ship types and sizes. Using this information it is possible to estimate the overall rate of breakdown in proximity to the location. The probability of a vessel drifting towards the installation and the drift speed are estimated using the wind rose for the area. Finally, the probability of a ship being repaired before reaching the location is estimated based on the time available. Ships that are not repaired within the time it takes to reach the FPSO / MODU are assumed to collide. Figure 11-3b above illustrates the number of vessel-hours that each square nautical mile surrounding the Sea Lion Field is exposed to on an annual basis. These data are used to model the risk of passing ships losing power and drifting into the Sea Lion Field and takes into account vessels within a 10 nautical mile radius.	Passing drifting collision frequency is 1.9×10^{-6} collisions / year (or once in 535,000 years) for the MODU and 6.4×10^{-7} (once in 1.5 million years) for the FPSO.
Attendant vessel	Vessel collisions involving attendant (visiting) vessels tend to be more frequent than passing vessels due to their ongoing proximity. The consequences associated with these types of impacts generally tend to be less severe due to the size and speed of the vessels. During SIMOPS the ERRV will be permanently supporting the MODU and the FPSO and will normally be located between them, approaching each installation for close standby when required for operational purposes. For supply operations, a supply vessel will visit the FPSO every 4 days. The duration of visits is estimated to be 4 hours (i.e., within the 500m exclusion zone.)	The total vessel collision frequency for the MODU is estimated to be 2.2×10^{-2} per year (once in 46 years), with the majority of collisions generating total energies below 14 MJ; The total vessel collision frequency for the FPSO is estimated to be 9.2×10^{-3} per year (once every 109 years), with the majority of collisions generating total energies below 50 MJ.

11.1.4.4.4 Consequences of a collision

The relationship between predicted damage to the FPSO and collision impact energy is presented in Table 11.6. This assessment is based on research into collision resistance of structures, professional judgment and the experience of other FPSOs and MODUs (Anatec, 2024b).

Table 11.7 summarises the estimated collision frequencies for different vessel types and different energy levels. According to the model, ship collisions involving infield vessels may be more frequent

than for passing ships due to their ongoing proximity, however, the consequences associated with these types of impacts tend to be less severe due to the speed of the vessels and the associated energy of the strike.

Table 11.6: Impact energy and predicted consequences ***(Source: Anatec, 2013)***

Energy	Description
<50 MJ	Due to the size of FPSO vessels, it is considered that events of this scale will not jeopardise the FPSO's integrity. Localised damage is likely to be experienced. Due to relatively small size, damage to the third-party colliding vessel may be more substantial.
50-200 MJ	Due to the size of FPSO vessels, it is considered that events of this scale will not jeopardise the FPSO's integrity. However, there is the potential for damage to topside equipment, which may lead to hydrocarbon release, particularly if the impact is direct. Due to their relative size, collisions of this scale are likely to result in serious damage or loss of the smaller classes of potential third-party colliding vessel.
>200 MJ	These are catastrophic events which could lead to significant levels of damage to the FPSO. These impacts are likely to threaten the integrity of the entire installation and evacuation is likely to be necessary.

Table 11.7: Vessel, MODU and FPSO collision frequencies (per year) at different impact energies ***(Source: Anatec, 2024b)***

Impact Energy (MJ)	Annual Collision Frequency			
	Passing Powered	Passing Drifting	Attendant Vessel	Total
MODU				
0-14	1.1E-07	1.8E-06	2.1E-02	**2.1E-02**
14-50	1.0E-07	4.5E-08	7.8E-04	**7.8E-04**
50 -100	1.7E-08	2.0E-08	4.3E-06	**4.3E-06**
100-200	7.3E-09	1.6E-08	Negligible[1]	**2.4E-08**
≥200	3.1E-08	4.1E-09	Negligible[1]	**3.5E-08**
Total	2.6E-07	1.9E-06	2.2E-02	**2.2E-02**
FPSO				
0-50	4.6E-07	6.3E-07	9.3E-03	**9.3E-03**

[1] where negligible = <1.0E-10.

11.1.5 Industry standard mitigations

11.1.5.1 Exclusion zones

The use of exclusion zones is a legal requirement and is therefore a mitigation in itself against the risks of collision. No other industry-standard mitigations are required to minimise the impact of these on other users of the sea.

11.1.5.2 Interference between fishing gear and subsea infrastructure

No industry-standard mitigations are required to prevent the snagging of fishing gear over and above an ALARP demonstration of the risks and as per the legislative requirements described in Section 11.1.1.1.1.

11.1.5.3 Vessel operations

In addition to the legislative requirements above, the following will be used as industry-standard to minimise the risk of collision:

- Installation of AIS in the field vessels (in combination with radar and visual lookout) to provide early detection of passing vessels, and improved information to aid in the management of this hazard. Systems will be installed on the FPSO, MODU, AHTS/ERRV and MRSV/ERRV,
- Availability of chart displays to monitor third-party vessel positions relative to the FPSO and MODU with alarm functionality:
  - It will also be considered beneficial, when possible, to relay the data to shore for use in both routine marine traffic management and emergency response.
- Use of field-specific AIS data to establish collision risk management procedures at Sea Lion giving account of the traffic pattern and the evacuation requirements on the installation:
  - Use of alarms which will be set by 'Time to the Closest Point of Approach' and 'Closest Point of Approach'.
- Installation of an AIS aid to navigation on the FPSO and MODU to ensure identification of the FPSO to passing vessels,
- Operational control:
  - Development of a full Marine Operations Manual for the Sea Lion Field including factors such as vessel selection and inspection, crewing and competency, and
  - Site-specific procedures for AHTS/ERRV and MRSV/ERRV watchkeeping and emergency response.

Note: many of the industry-standard mitigations listed above were not assumed to be in place by the Anatec model such that the model can be considered to be precautionary in its results.

11.1.6 Impact and risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. The assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes for this Development is tabulated in Section 11.1.12, which shows the worst-case impact / risk for each activity and receptor and details are provided below.

11.1.6.1 Impact assessment of offshore activities

11.1.6.1.1 Impact of offshore exclusion zones on fisheries

The Sea Lion Phase 1 & 2 Development sits within the fisheries statistical square XFAK that has historically been the subject of very low fishing effort (Section 11.1.4.3). Currently, the area is only open to vessels licensed to fish for *Illex* squid and is rarely fished (Section 11.1.4.3) such that few receptors (fishers) are likely to be exposed. In terms of impact on squid catch, the declaration of a 1,275 m exclusion zone around the Development FPSO, 500 m exclusion zones around the MODU and drill centres and 200 m either side of subsea infrastructure would therefore be insignificant to the fishing vessels concerned. The human population (fishing industry) is able to tolerate a change on this scale and it is anticipated that the exclusion zones will be acceptable to all stakeholders. Therefore, the sensitivity of the receptor Is considered to be '**Very Low**'.

The application of monetary fines could be incurred if exclusion zones are ignored or strayed into (Section 11.1.1.1). However, this would occur only in the event that all communication on the presence of exclusion zones was ignored, which is out with Navitas' control. With regard to impact upon catch, the historical level of fishing effort in the Sea Lion Field is such that the prohibition on fishing within

the exclusion zone is anticipated to have no impact on the livelihood of fishers and the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of the impact of the exclusion zone on the human population is assessed as '**Very Low (1)**'.

11.1.6.2 Risk assessment of offshore activities

11.1.6.2.1 Risk of interference between fishing gear and subsea infrastructure

Under 'normal' fishing conditions, the loss of fishing gear is not an unusual event. Therefore it is anticipated that the human population (fishers) would have a moderate capacity to absorb the loss of gear and the sensitivity of the receptor is considered to be '**Moderate**'.

If a demersal trawl net became snagged on subsea infrastructure, the fishing gear could be extensively damaged and possibly lost. Additionally, there could be damage to the seabed infrastructure, with consequential legal implications. Assuming a worst-case event involving the loss of fishing gear, the severity of effect would be expected to have a medium-term impact on livelihood and therefore the severity of effect on the human population is considered to be '**Moderate**'.

The significance of the impact of a fishing vessel snagging gear on subsea infrastructure is therefore assessed as '**Moderate (9)**'.

Since 2013, statistical square XFAK has only been open to vessels with Type B (*Illex*) licenses, and since 2023, only to jiggers. If a vessel was to approach the exclusion zone, it would almost certainly be detected and intercepted by the MRSV/ERRV or AHTS/ERRV before interfering with subsea infrastructure. Therefore the likelihood of occurrence of fishing gear becoming snagged on subsea infrastructure in considered '**Unlikely**'.

Therefore the significance of the risk is assessed as '**Low (6)**'.

11.1.6.2.2 Risk of third-party vessel collision risk with the FPSO / MODU

With any collision incident between passing powered or passing drifting vessels there is a range of possible outcomes, dependent on the size, speed and angle of approach of the vessels concerned (Section 11.1.4.4.4). While the majority of these scenarios are unlikely to generate critical energies sufficient to cause an environmental impact (Section 11.1.4.4.4) all have the potential to cause damage to the FPSO or MODU and would therefore, almost certainly, result in damage to, and possible loss, of a smaller third-party vessel. It is anticipated that such loss would be unacceptable to all stakeholders and therefore the sensitivity of the receptor to such an incident is considered to be '**Very High**'.

Following this worst-case scenario, the effect on the livelihood of the receptor could be long-term and the severity of effect on the human population is considered to be '**Serious**'.

Therefore, the overall significance of the impact of a collision between a third-party vessel and the FPSO or MODU is assessed as '**High (20)**'.

The analysis of collision frequency undertaken by Anatec (2024b) and summarised above (Section 11.1.4.4.3) indicates that the likelihood of any collision is extremely low and is lower still for an event resulting in catastrophic damage (Section 11.1.4.4.4). Incidents on this scale have occurred very rarely in the industry and the failure of numerous operational controls would be required. Further, as described above, the Anatec model does not take account of all the industry-standard mitigation practices such that it is very precautionary. Taking account of the modelling outcomes and the industry-standard mitigations described above, the likelihood of occurrence is considered to be '**Very Unlikely**'.

Therefore, the significance of the risk is considered to be '**Low (5**)'.

11.1.7 Project-specific mitigation measures

With legislation and industry-standard mitigations applied, the impacts and risks assessed above are considered to be 'Low' or 'Very Low' and therefore project-specific mitigation is not proposed.

11.1.8 Residual impacts and risks

Not applicable.

11.1.9 Cumulative impact

The activities of Navitas' vessels will add to the existing vessel traffic within Falkland Islands waters, leading to an increase in the 'concentration' of shipping activity (Section 8.9.1). The offshore Sea Lion Development is situated in an area where shipping traffic is relatively low. With no nearby offshore installations or exclusion zones in place, all vessels have space to transit the area safely. Vessels operating on these routes have ample room available to increase their passing distance around the Development site and therefore there is expected to be little cumulative impact.

11.1.10 Confidence assessment

Owing to the use of data on historical fishing effort, the assessment of the impact of exclusion zones offshore is considered to be '**Certain**'.

Much of this assessment is informed by AIS data and collision risk modelling that is widely used and accepted. Although the data used are representative, there is considerable inter-annual variation in vessel traffic, largely due to variations in *Illex* squid abundance.

Stakeholders within FIG and from the fishing industry were consulted as part of the 2016 scoping consultation, in 2020 during the last full consultation of the Sea Lion Development EIS, and most recently during the 2023 scoping consultation (Chapter 6). Their views have been taken into consideration and therefore confidence in the assessment is considered to be '**Probable**' and further monitoring of vessel movements and analysis will help to improve confidence in this assessment.

11.1.10.1 Monitoring required

An AIS based survey will be carried out at the location of the Sea Lion Development to confirm the shipping traffic pattern in the area once the exclusion zone is in place. The presence of Development infrastructure, project vessels and exclusion zones may have an influence on shipping routes, as vessels may deviate from established routes to avoid potential risks. This is a very low-cost method of improving the confidence in collision risk analysis and understanding shipping behaviour.

Navitas will also report and investigate all incidents and near misses.

Detailed monitoring requirements have been established during the Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 EMMP (an outline EMMP is provided in Chapter 15).

11.1.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

11.1.12 Findings summary

Table 11.8: Summary of the impact and risk assessment for other users of the sea at the Sea Lion Field

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Offshore exclusion zones	Disruption to activities of other users of the sea	Reduction in the area available to *Illex* vessels and resultant impact on catch	Planned	1, 2a, 2b & 3	Very Low	Slight	n/a	**Very Low (1)**	**n/a**	**Certain**	**Industry-standard:** Exclusion zones promulgated *via* MSI under Coastal State obligation **Project-specific:** None proposed.
Interference between fishing gear and subsea infrastructure	Snagging of fishing gear	Loss of fishing gear and potential subsea damage	Unplanned	2a, 2b & 3	Moderate	Moderate	Unlikely	**Low (6)**	**n/a**	**Probable**	**Industry-standard:** Exclusion zones, Permanent presence of ERRV, Amended Admiralty charts, AIS and radio broadcasts, and Collision risk management procedures. **Project-specific:** None proposed
Offshore vessel collision	Third-party vessel collision	Damage to vessels and FPSO or MODU	Unplanned	1, 2a, 2b & 3	Very High	Serious	Very Unlikely	**Low (5)**	**n/a**	**Probable**

11.2.12 Findings summary 1013

11.2.1 Introduction

The inshore waters of the Falkland Islands, and the amenities in Stanley Harbour, are used extensively for commercial operations (e.g., vessels associated with fisheries, trade and tourism), for Ministry of Defence (MoD) activities and for recreational use by visiting yachts and the general public. The development of the Oil and Gas (O&G) industry will lead to a long-term increase in vessel traffic throughout these waters in Stanley Harbour and short-term increases in Berkeley Sound.

The presence of the Sea Lion Field Northern Development Area, Phase 1 & 2 (hereafter referred to the Phase 1 & 2 Development) vessels may lead to disturbance of other users of the sea in Berkeley Sound and Stanley Harbour and / or an increased risk of collisions inshore. Further, the use of exclusion zones around the temporary Large Transport Vessel (LTV) operations, which themselves are a base-case mitigation against collision risks, may lead to impacts and risks in their own right in terms of fisheries and shipping lanes. Impacts on other users of the sea, and Berkeley Sound in particular, were raised by stakeholders during scoping consultations held in 2014, 2015 and 2016 (Chapter 6)[92].

Owing to the differences in the proposed use of the offshore and inshore locations and the variety of potential impacts and risks, the assessment of impacts and risks on other users has been split into two sections (offshore and inshore) as shown in Table 11.9.

This chapter assesses the impacts and risks to the Human Population and Tangible Property during the inshore activities, and focuses on other users of:

- Stanley Harbour (including FIPASS), and
- The LTV site in Berkeley Sound.

Note: The other impacts associated with vessel use e.g., emissions are described elsewhere in this document, as described in Table 2.2.

Table 11.9: Summary of potential impacts and risks to other users of the sea

Location		Receptor	Potential impact	Potential risk	Assessed in
Offshore		Vessels on passage	Requirement for vessels to navigate around exclusion zones.	Vessel collisions with FPSO[1] and / or MODU[2]	Section 11.1
		Fishing vessels	Fishing prohibition within the exclusion zones may impact upon fisheries revenue.	Snagging on subsea infrastructure and potential for loss of vessel and / or gear	Section 11.1
Inshore	Stanley Harbour	Fishing, Cruise, Cargo and Recreational vessels	Competition for berthing space in Stanley Harbour (including FIPASS)	Potential for collision between vessels in confined waters	This chapter
	Port William	Fishing, Reefer, Cruise, Cargo and Recreational vessels	Competition for anchorage space	Potential for collisions between vessels in confined waters	This chapter
	Berkeley Sound	Fishing, Reefer, Tanker vessels, Cruise ships and Recreational vessels	Reduction in available sea room due to exclusion zones and competition for anchorage space	Potential for collisions between vessels in confined waters	This chapter

[1] Floating Production, Storage and Offloading Vessel.
[2] Mobile Offshore Drilling Unit.

[92] The concerns about project activity in Berkeley Sound in particular were raised by stakeholders at a time when the project was considering inshore Ship-to-Ship transfer of crude oil between tankers. This aspect of the project has been superseded by direct offshore transfer (Section 2.1.1 and Section 4.3.2.2).

11.2.1.1 Relevant legislation

Legislation relevant to the potential for disturbance to other sea users inshore is the same as that for the offshore activities and is described in Section 11.1.1.1 above.

Additional Falkland Islands legislation relevant to the inshore operations alone are:

- Maritime Ordinance 2017.
- Maritime (Amendment) Ordinance 2019.
- Maritime (Port State Control) Regulations 2021.
- Harbour and Ports Ordinance 2017.
- FIPASS Ordinance (1989).
- Falkland Islands Harbour Regulations.

11.2.1.1.1 FIPASS Ordinance (1989)

The Harbour Master[ibid] and FIPASS Manager have powers under the provisions of the FIPASS Ordinance 1989 to regulate shipping within FIPASS waters, which are defined as those waters within one nautical mile from FIPASS.

11.2.1.1.2 Falkland Islands Harbour Regulations

Under the Falkland Islands Harbour Regulations it is an offence for vessels within Falklands harbours (including Berkeley Sound) to:

- Spill or discharge oil or oily mixtures into the harbour,
- Dump garbage or refuse into the harbour, and
- Supply bunkers to another vessel if they are unlicensed to do so by Stanley Services Ltd. within the Territorial Waters of the Falkland Islands.

Further, all vessels using the harbours should be correctly marked with their name on port and starboard bow and at the stern with name and port of registry.

11.2.2 Sources of disturbance to inshore users of the sea

It is the intention of Navitas to use the Temporary Dock Facility (TDF), which was used for the exploration drilling campaigns, to support Sea Lion Phase 1 & 2 activities. Further, Navitas shall propose modifications to improve the Dock's functionality. As described in Section 5.11.1.1.1, proposals to upgrade the TDF facilities will have to go through the planning process, and may require a full EIA, as advised by FIG.

For the purposes of this EIS however, it is assumed that operations at the TDF, and FIPASS, will continue on the same basis as in the 2015 exploration campaign.

Sources of impact and risk to other users of the sea inshore include:

- Additional vessel traffic in:
  - Stanley Harbour (including at FIPASS),
  - Port William, and
  - Berkeley Sound.
- The presence of LTVs anchored in Berkeley Sound (for a total combined and non-consecutive duration of 13 months), the associated exclusion zones and the intermittently attendant Offshore Construction Vessels (OCVs) and Platform Supply Vessels (PSVs).

11.2.2.1 Additional vessels

Numerous different vessels will be deployed inshore for specific tasks during the life of the Phase 1 & 2 Development. Support vessels such as *ad hoc* freighters and offshore support vessels will use Stanley Harbour and FIPASS (for bunkers in the event a fuel line is not added to the TDF) and are further quantified in Section 11.2.4.1.2 below.

11.2.2.2 LTV presence in Berkeley Sound

The LTVs will be required to transport the subsea equipment and the FPSO mooring infrastructure from various parts of the world to the Falkland Islands. The LTV specifications will range from 110 - 160 m in length and 20 - 28 m in beam with a Gross Registered Tonnage (GRT) ranging from 9,000 – 15,000 tonnes. All vessels will have two large cranes.

Upon arrival, they will be anchored in Berkeley Sound and will act as floating logistics vessels for up to a maximum (and non-consecutive) period of 13 months, spread over a 5.5 year period (approximately). At this time, the LTVs will be used to store equipment during the construction process with OCVs and PSVs visiting to collect the infrastructure for transportation to its installation location offshore (Section 5.11.2).

Each vessel will have its own individual 500 m exclusion zone (Table 11.10) and Navitas will work with the Falkland Islands Harbour Master and the Falkland Islands Maritime Authority (FIMA) to identify optimum locations within Berkeley Sound that will cause the least disruption to other users during periods of high marine traffic in the Sound. Enforcement and management of the exclusion zones will be agreed in discussion with FIMA (e.g., the use of guard vessels etc.). Although the exact location of the LTVs and associated exclusion zones are not yet agreed (Section 5.5.1), indicative locations are shown below in Figure 11-4.

Depending on transport opportunities and pick-up locations, up to four different LTVs may be required over the course of the installation period to transport all the equipment, but a maximum of only two vessels will be anchored in the Sound at any one time and other users will be advised of the location to prevent any conflict.

Table 11.10: Exclusion zones applying to Phase 1 & 2 Development LTVs in Berkeley Sound

Location	Facility	Stages	Permanent	Temporary
Inshore in Berkeley Sound	LTV movements and placements	1, 2a & 2b	n/a	500 m radius each (for up to thirteen months)

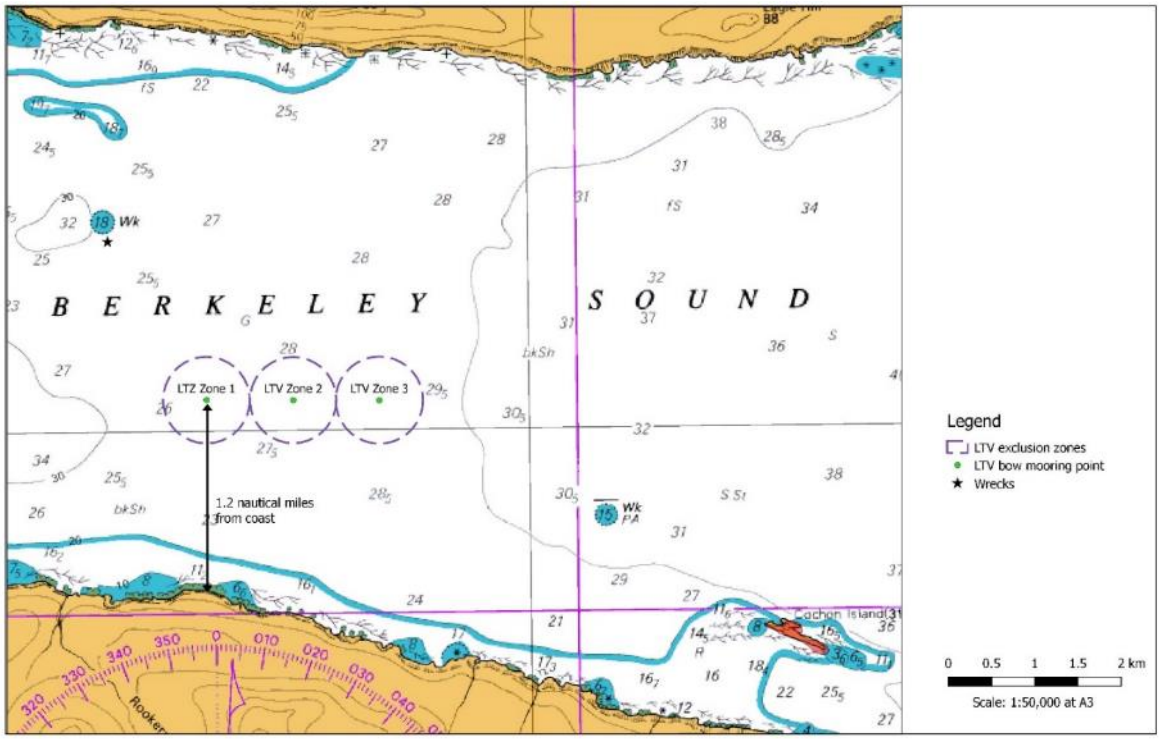

Figure 11-4: Indicative locations of LTVs and associated exclusion zones (three potential locations shown, maximum two LTVs anchored at any one time)

11.2.3 Potential receptors

The Environmental Impact IDentification (ENVIID) workshop was used to identify the specific receptors upon which the impacts and risks to other users of the sea warranted further investigation (Chapter 9). The specific inshore receptors that may be impacted include:

- Users of Stanley Harbour (Section 7.7.4.1.2):
  - Fishing vessels,
  - Cargo vessels,
  - Cruise ships,
  - MoD, and
  - Recreational craft.
- Users of Berkeley Sound (Section 7.7.3.2):
  - Primarily vessels associated with the fishing industry (fishing vessels, reefers and bunkering tankers).

11.2.4 Characterising and quantifying the impacts and risks

When characterising and quantifying the impacts and risks to other users of the sea in inshore waters, it is necessary to consider the:

- Quantification of inshore Phase 1 & 2 activities:
  - Type, location and behaviour of Phase 1 & 2 vessels / infrastructure used inshore, and
  - Phase 1 & 2 use of amenities in Stanley Harbour.
- Quantification of inshore third-party activity:

- The number, type and behaviour of third-party vessels in Stanley Harbour and Berkeley Sound, and
- History of third-party vessel incidents in Stanley Harbour and Berkeley Sound.

- Stakeholder comments and third-party vessel behaviour, and
- Nature of the impacts and risks associated with the Phase 1 & 2 exclusion zones.

11.2.4.1 Quantification of inshore Phase 1 & 2 activities

11.2.4.1.1 Phase 1 & 2 vessels / infrastructure inshore

In order to inform the assessment of the impacts and risks, it is necessary to have an appreciation of the additional inshore vessel traffic incurred as a result of the proposed Phase 1 & 2 Development.

A detailed inventory of the vessels used is provided in Section 5.11.2. A summary of the inshore vessel type, purpose and specification, segregated by location, is provided in Table 11.11.

Table 11.11: Summary of the type, purpose and behaviour of inshore Phase 1 & 2 vessels used to inform the impact and risk assessment

Vessel type	Purpose	Analogous Vessel	Vessel specification			Total number of operations / visits		
			Length (m)	GRT (tonnes)	Max. speed (kn)	Stage 1 (31 months)	Stage 2a & 2b (35 months)	Stage 3 (*c.* 27 years)
Stanley Harbour								
Ad hoc freighters	Cargo operations	HHL Congo	138	9,616	14	5	4	3
MODU's AHTS	Refuelling and resupply	Pacific Champion	86	3,330	15	99	108	4
MODU's ERRV	Refuelling and resupply	Esvagt Don	56.4	1,863	12	90	99	n/a
PSV	Refuelling, cargo operations	Pacific Leader	97.3	5,260	16	52	26	n/a
FPSO's AHTS / ERRV	Cargo operations and refuelling	Nor Solan	97	5,179	14	56	151	1,398
FPSO's MRSV / ERRV	Cargo operations and refuelling	Nor Solan	97	5,179	14	56	151	1,398
Berkeley Sound								
Large Transport Vessels (LTV)	Transport of infrastructure to Falklands and floating logistics barge	Jumbo Fairplayer (typical LTV / HLV)	144	15,000	17	Up to two vessels for up to 7 months	Up to two vessels for up to 5 months	Up to two vessels for up to 1 month
OCV[1]	Visiting LTVs to collect infrastructure for installation offshore	Seven Arctic Inst vessel	163	TBC	15	39	26	n/a
PSV		Seven Arctic Inst vessel	163	TBC	15	52	26	n/a

[1] The OCV will likely be refuelled in the field by the PSV so will not come into Stanley Harbour.

11.2.4.1.2 Phase 1 & 2 use of amenities in Stanley Harbour

As described above (Section 11.2.2), the TDF will be upgraded to improve operability. During this upgrade it is planned to install a fuel line to the TDF which would mitigate against impacts on the use of amenities in Stanley Harbour. However, as a worst-case scenario for the current EIA, it is assumed that refuelling of Sea Lion Phase 1 & 2 related vessels using the TDF will take place at FIPASS.

In order to quantify the number of times the Phase 1 & 2 vessels will refuel at FIPASS, some assumptions have been made. It is assumed that *ad hoc* freighters, AHTS, MRSVs, ERRVs and PSVs will refuel every second time they visit the TDF. All other vessels will re-fuel in the field. Based on these assumptions, the estimated number of refuelling visits during each Stage of the Phase 1 & 2 Development by vessel type is shown on a monthly basis in Table 11.12.

Table 11.12: Estimate of the monthly number of refuelling visits to FIPASS

Vessel Type	Total number of refuelling operations (visits to FIPASS) per month		
	Stage 1	Stage 2	Stage 3
Ad hoc freighter	0.08	0.06	0
AHTS/ERRV/MRSV	4.85	7.25	4.31
PSV	0.83	0.37	0
Total	**5.77**	**7.67**	**4.31**

11.2.4.2 Quantification of inshore third-party activity

11.2.4.2.1 Number, type and behaviour of third-party vessels inshore

11.2.4.2.1.1 Stanley Harbour

On entering, and exiting Stanley Harbour *via* Port William, vessels are required to report to the Harbour Master[ibid] stating their intended movements. Information collected over recent years gives a good indication of the movements of vessels into and out of the Harbour, by type and on a seasonal basis (Table 11.13). The greatest seasonal variation in vessel numbers occurs in February due to an influx of jiggers into the Harbour for licence inspections. Excluding jiggers and O&G related vessels, the number of vessel visits averaged 38 per month during 2014, 36 per month during 2018, and a much lower 6 per month in 2022, which can partly be attributed to the Covid-19 pandemic. In 2023, the average vessels per month (all vessels) was 24 per month (Table 11.13).

Section 11.2.4.1.2 shows the predicted number of Phase 1 & 2 vessel visits to Stanley Harbour during each Stage of the project. The monthly average number of visits will vary between Stages of the project. Assuming that vessel activity will be evenly distributed throughout the year, it is estimated that the following average number of Navitas vessels will visit Stanley Harbour to re-fuel per month:

- Stage 1 – 5.77 vessel visits per month,
- Stage 2 – 7.67 vessel visits per month, and
- Stage 3 – 4.31 vessel visits per month.

Although at times this will add significantly to the number of vessels, traffic within the Harbour will remain at a low level throughout the year.

Table 11.13: Number of vessels entering Stanley Harbour during 2014, 2018, 2022[1] and 2023[2]

Vessel Type	Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total

(Source: FIG fisheries department data (FIG, 2015b), Vessel Movements Database (DNR, 2019) and FIMA data 2023 and 2024)

[1] Note 2022 was a COVID year so vessel numbers are lower than would be expected in a normal year

[2] 2023 data was not available by vessel type but a total for each month is included at the bottom for comparison with previous years.

11.2.4.2.1.2 Berkeley Sound

Detail on existing vessel types and activity in Berkeley Sound are provided in the Environmental and Social Baseline (Section 7.7.3.2) and are presented here as appropriate to this particular impact and risk assessment.

Vessel traffic data for Berkeley Sound has been supplied by the FIG Department[93] of Natural Resources for the years 2010 to 2022 and is summarised in (Table 11.14). The data indicate that there was considerable inter-annual variation in the total number of ship visits between 2010 and 2022. The 2014-15 *Illex* seasons represent the peak in activity in recent years; as such 2014-15 data represents 'worst-case' anticipated vessel traffic in Berkeley Sound.

The main types of vessels visiting Berkeley Sound in 2015 were:

[93] Now the Directorate of Natural Resources (as at 2023).

- Jiggers – Far Eastern fishing vessels that use artificial light to catch *Illex* squid. These had a median size of 955 gross tonnage (GT). There were 122 individual vessels, making an average of four visits per vessel year, typically two weeks apart, mainly during the fishing season of February-May. There is considerable inter-annual variation in the number of jigger visits, depending on the quantity of squid caught,
- Reefers – refrigerated storage vessels for the catch from the jigger fleet. These had a median size of 8,500 GT. There were 59 individual vessels, making an average of 1.7 visits per vessel year, mainly during the fishing season of February-May,
- Trawlers – vessels fishing for finfish and loligo squid. These had a median size of 870 GT. There were only 23 individual vessels, making an average of two visits per vessel year,
- Tankers - of the tanker visits, 54 were by two 3,978 GT vessels, MV Sealion and MV Jason. There were also two visits by an 11,000 GT fishing fleet tanker, and three by 7,600 GT tankers,
- Cargo vessels - in total, there were nine visits by other cargo vessels, including one 34,000 GT bulk carrier, one 23,000 GT cargo ship, one 9,600 GT cargo ship, and six visits by a 2,600 GT cargo ships, and
- Other vessels - the only other vessel of note was a 6,500 GT passenger ship. There were just four other small vessel visits, with a median size of 2,000 GT.

Therefore, it can be seen that Berkeley Sound is utilised predominantly by fishing vessels and associated support vessels (reefers and tankers), which use the Sound as an anchorage for the trans-shipment of fish and squid, and to bunker fuel. The number of fishing and fisheries support vessels present varies considerably on a seasonal and annual basis. Seasonally the number of vessels peaks between March and June (Figure 11-5), while the annual variation is related to the catch recorded in the *Illex* jigging fishery which has varied hugely over the past ten years; from almost 358,000 tonnes in 2015 to around 2,000 in 2016 (FIG, 2023n) (Table 11.15).

Table 11.14: The number of vessel visits to Berkeley Sound recorded from 2010 to 2022

Ship type	No. of ship visits to Berkeley Sound by year												
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022

Table 11.15: Annual *Illex* catch

Year	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
Catch (tonnes)	142,619	306,111	357,722	2,360	67,445	54,405	43,449	62,663	172,537	73,053

11.2.4.2.2 History of incidents in inshore waters

11.2.4.2.2.1 Stanley Harbour

Space for vessel manoeuvres in Stanley Harbour and through the passage into Port William (The Narrows) is restricted and there have been a number of incidents involving vessel collisions and groundings within these areas (M. Jamieson, *pers. comm.*). No wrecks have been noted since 2019 (N. Port, *pers. comm.*). Although an official record does not exist, anecdotal reports of some of these incidents in recent years are listed in Table 11.16. It is believed that the majority of these incidents were due to human error and / or mechanical failure.

Table 11.16: Anecdotal data on incidents involving vessels in Stanley Harbour and Port William[1]

Date	Vessel type	Type of incident	Outcome	Environmental impact
Unknown	Tanker	Grounding Stanley Harbour	Refloated	None
Unknown	Tanker and research vessel	Collision at FIPASS	Damage to research vessel above the water line	None
Unknown	Jigger	Grounding Stanley Harbour	Refloated	None
Unknown	Reefer	Grounding Port William	Refloated	None
Feb 2014	Jigger	Grounding Port William	Refloated	None
Apr 2014	Trawler	Grounding Port William	Refloated	None
Feb 2017	Jigger	Grounding Stanley Harbour	Refloated	None
Feb 2017	Jigger	Grounding Stanley Harbour	Refloated	None
July 2017	Trawler	Grounding, Port William	Refloated	3 m^3 MGO released to sea.
Feb 2017	Jigger	Collision Stanley Harbour; 2 jiggers coming into contact	Slight damage	None
September 2019	Trawler	Collision with FIPASS	Damage to vessel and FIPASS	Not reported
Unknown	Numerous vessels	Heavy contact with FIPASS	Slight damage to FIPASS and vessels	None

[1] M. Jamieson, *pers. comm.* and A. Black, *pers. obs.*

11.2.4.2.2.2 Berkeley Sound

Historically, there have been a number of incidents within Berkeley Sound (Table 11.17). Several fishing and reefer vessels have either collided with rocks or experienced fires while in Berkeley Sound and following these events, fuel oil leaked from ruptured tanks or sunken vessels, which resulted in environmental impacts.

Table 11.17: Anecdotal data on incidents involving vessels in Berkeley Sound

Date	Vessel type	Type of incident	Outcome	Environmental impact
April 2005	Reefer	Grounding in Berkeley Sound (Cochon Island)	Refloated with damage to hull	Fuel oil leak
May 2008	Trawler (Ocean 8)	Fire in Berkeley Sound	Vessel eventually sank	Fuel oil leaks (*c.*137 Tonnes)
Unknown	Jigger	Struck a rock and sank	Vessel sank	Fuel oil leaks

11.2.4.3 Stakeholder comments and third-party vessel behaviour

Scoping consultations conducted in previous years by the previous operator (POEPL) are summarised in Chapter 6. Of relevance to this section, in August 2016, consultations were held with representatives of FIG's Fisheries Department and the fishing industry regarding all aspects of the project. During these sessions, a number of comments were made regarding the seamanship displayed by the jigging fleet in Berkeley Sound. There are often language problems and insufficient or out-of-date charts on board these vessels, officers on watch are often exhausted and have been known to fall asleep, and electronic

and mechanical equipment is not always in good working order (A. Black, *pers. obs.).* Furthermore, there is a history of non-compliance with regulations within this fleet.

FIFCA (Falkland Islands Fishing Companies Association) have facilitated consultation with local fishing companies (who are in some cases vessel owners) and vessel agents throughout the evolution of the Sea Lion project. The nature of the Falklands' fishing industry is such that ship's captains are not particularly accessible (they spend limited, if any time onshore, and often do not speak English) so direct consultation with captains has not been possible. Competition between sea users, particularly the management of Berkeley Sound, exclusion zones and collision risk has been noted during each consultation.

11.2.4.4 Nature of the impacts and risks associated with Phase 1 & 2 exclusion zones in Berkeley Sound

11.2.4.4.1 Exclusion zones

In order to mitigate against the risk of the collisions between third-party vessels and Phase 1 & 2 vessels, temporary exclusion zones will be implemented within Berkeley Sound according to the ongoing activity (Section 11.2.2.2). Navitas shall work closely with FIMA throughout the planning and execution stages of the development to ensure that:

- Final positions for the LTV anchorage sites are agreed and well communicated to mariners and other users of the sea,
- Activity Specific Operating Guidelines (ASOGs) are developed for the vessels operating in the area,
- FIMA is advised of all vessels planning to operate in the area, and
- FIMA is advised of the activities and equipment / product transferred between vessels.

However, exclusion zones bring impacts and risks of their own with regard to:

- Reduced anchorage availability, and
- Reduced sea room and increased risk of collisions / groundings of third-party vessels.

The following sections describe the nature of the above in terms of the restrictions that exclusion zones place on third-party vessels operating within Berkeley Sound. Restrictions and management of exclusion zones in Berkeley Sound was noted as a stakeholder concern (Section 11.1.4.2.2).

11.2.4.4.1.1 Reduced anchorage availability

Numerous vessels anchor within Berkeley Sound for the purposes of fuel bunkering, the transfer of fish catches and to shelter in adverse weather (noting that sheltering vessels will not always anchor) (Section 7.7.3.2.1). When in use, the temporary exclusion zones associated with the LTVs have the potential to restrict, or be seen to restrict, the available space in the Sound during peak seasons.

11.2.4.4.1.2 Reduced sea room and increased risk of collision / grounding of third-party vessels

Collisions are most frequently caused by a navigational failure of one or both vessels involved in the collision. The main factor that influences collision frequency is the density of vessel traffic and the probability of a collision increases with the vessel density squared (i.e., if the density doubles, the probability of a collision quadruples, DNV, 2010).

Groundings are effectively collisions with land, the likelihood of which is related to the proximity of a vessel to land or subsea hazards (such as rocks).

Other factors that influence the collision or grounding frequency include:

- Non-compliance with regulations (e.g., ColRegs) – education issues,

- Poor communication between vessels,
- Visibility (rain, snow, fog),
- Restricted maneuverability,
- Metocean conditions (wind, tide, swell),
- Lack of navigational aids (shore-based radar, marked channels),
- Mechanical failure (black-out, steering failure), and
- Vessel standard (hardware and software).

The use of exclusion zones effectively reduces the space available to other users of Berkeley Sound to the north and south of the LTVs. This may force vessels into closer proximity to each other and to the coastline and therefore increases the risk of collisions and groundings.

To date, vessels using Berkeley Sound generally do not venture within 1.5 km of land for safety reasons and the area utilised by vessels covers approximately 100 km^2 (Figure 11-6). However, it is recognised that restricting the sea-room available to vessels may increase the likelihood of third-party incidents.

Effect on vessel density

If the maximum number of LTVs (i.e., two) are in the Sound at any one time, the area required for the two 500 m exclusion zones (Figure 11-6) is 2.36 km^2, which is <3 % of the area used by other vessels. The LTV exclusion zones make little difference to the area available to third-party shipping and the increase in the risk of collision or grounding is likely to be insignificant (Table 11.18).

The density of vessels within the remainder of the Sound will increase by a factor of 1.02, which increases the risk of collision by a factor of 1.04. The area occupied by the LTV exclusion zones will force vessels to use a slightly narrower channel to the north of the anchorage.

Data from 2014 (a very busy year, Section 11.2.4.2.1.2) was used as a worst-case example to illustrate the influence of the exclusion zones on vessel density (Table 11.18). However, it should be noted that this data refers to all visits during each month and not all vessels will be present at any one time.

Table 11.18 indicates that the influence of the exclusion zones in Berkeley Sound will mostly be felt in the months where the most vessels are present i.e., from March – June, so during those months vessels will have less sea room than at other times of year.

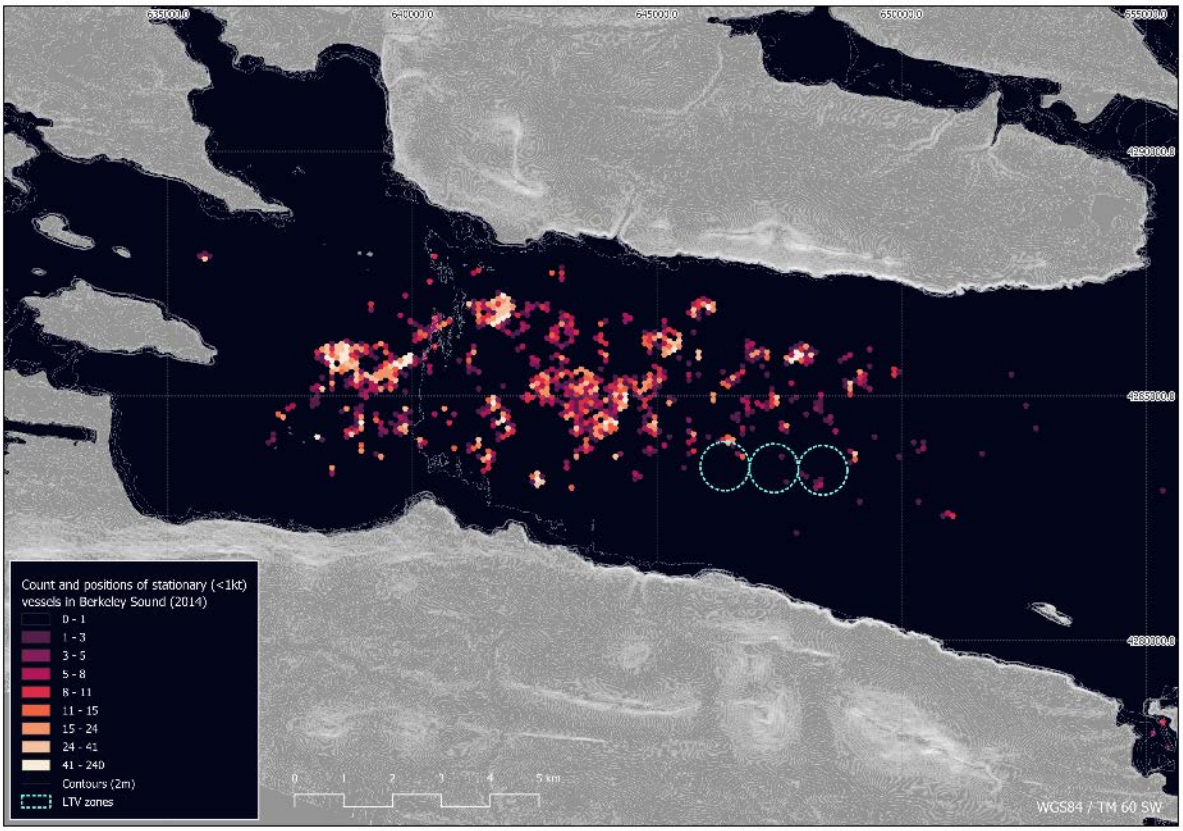

Figure 11-6: The extent of the exclusion zones associated with the anticipated LTV site in relation to the position of all vessels (from AIS) between May 2014 and May 2015 (a particularly busy year)

Table 11.18: The influence of exclusion zones on vessel 'density[1]' on a monthly basis, data from 2014

Scenario	Month											
	J	F	M	A[2]	M[2]	J	J	A	S	O	N	D
No. of vessels	6	25	137	270	225	75	18	12	11	6	3	2
Vessels / km^2 no exclusion zones	0.06	0.25	1.37	2.70	2.25	0.75	0.18	0.12	0.11	0.06	0.03	0.02
Vessels / km^2 with LTV 500 m exclusion zone	0.06	0.26	1.40	2.77	2.30	0.77	0.18	0.12	0.11	0.06	0.03	0.02

[1] Densities are rounded to two decimal places.
[2] Navitas shall use best endeavours to avoid using Berkeley Sound during peak fishing months.

11.2.4.4.1.3 Stakeholder opinion on exclusion zones

Responses from stakeholders to the proposed exclusion zones within Berkeley Sound were mixed with some positive and some negative representations made during scoping consultations (Chapter 6). However, it should be noted that these representations were made in response to the previously proposed larger, and more enduring, Inshore Transfer-related exclusion zones (which is no longer planned, Section 4.3.2.2). The LTV operations and associated exclusion zones proposed were not discussed explicitly during the 2016 scoping consultations but have been shared during subsequent consultations in 2018 and 2023.

Specifically, concern expressed in 2016 in relation to the Inshore Transfer operation was regarding the space available to other users of Berkeley Sound and the unpredictable behaviour of, and communication with, the fishing fleet was highlighted as an issue. However, the overall consensus was that the anticipated tighter regulation and management would be positive for all users of the Sound, although, while all agents of vessels operating in the Sound were consulted *via* FIFCA, it should be noted that not all the vessel Captains or vessel owners were consulted directly.

11.2.5 Industry standard mitigations

11.2.5.1 Exclusion zones

The use of temporary exclusion zones for the LTV operation is a mitigation in itself against the risks of collision. No industry-standard mitigations are required to minimise the impact of these on other users of the sea.

11.2.5.2 Vessel operations

The industry-standard mitigations used to prevent collisions between vessels inshore are the same as those described in Section 11.2.1.1 above.

Additionally, a Falkland Islands Berthing Master / Pilot will accompany the LTVs prior to entering Berkeley Sound. The Pilot will be trained in navigation of the Sound and local use of the area.

Falkland Islands ports and harbours information (FIMA, 2023) was produced to assist the Masters of all vessels using the Designated Ports around Stanley. These information sheets are available for Berkeley Sound, Port William and Stanley Harbour. In addition, a Harbour Management Plan will be developed by Navitas to facilitate vessel operations in Stanley Harbour (Section 3.2.18.1).

11.2.6 Impact and risk assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. Assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes for this Development is tabulated in Section 11.2.12, which shows the worst-case impact / risk for each activity and receptor and details are provided below.

11.2.6.1 Impact assessment of inshore activities

11.2.6.1.1 Disturbance to other users within Stanley Harbour

Disruption to the activities of other vessels in Stanley Harbour may occur but is considered to be minimal. The human population (fishing, tourism and shipping industries) are tolerant to a change on this scale and it is anticipated that occasional use of FIPASS (Section 11.2.4.1.2) will be acceptable to the majority of stakeholders. Therefore, the sensitivity of the receptor is considered to be '**Low**'.

As described above, it is assumed that refuelling of Navitas vessels will take place at FIPASS (if a dedicated fuel line is not added to the TDF). At times of high demand, berthing space at FIPASS can be oversubscribed and vessels have to wait for a berth to become available. Navitas' use of FIPASS may further exacerbate this issue. However, while the impact will be short-term with minor effects on livelihood (due to possible delayed berthing), this may be considered unacceptable to a minority of stakeholders. The severity of effect is therefore considered to be '**Minor**'.

Therefore, the overall significance of the impact on resource use in Stanley Harbour is assessed as '**Low (4)**'.

11.2.6.1.2 Loss of anchorage space due to exclusion zones in Berkeley Sound

Berkeley Sound is heavily utilised by other users of the sea (the fishing industry) on a seasonal basis, with highest activity between March and June (Section 11.2.4.2.1.2). Navitas will endeavour to avoid these winter months for offshore installation and thus avoid the periods with the most other users of Berkeley Sound. However, even with the exclusion zones in place, there is ample space available for vessels wishing to anchor and transit through the Sound in comparison with harbours elsewhere in the world. Vessels using the anchorage in Berkeley Sound are tolerant of change on this scale without detriment to its character and therefore the sensitivity of the receptor is considered to be '**Low**'.

The temporary 500 m exclusion zones surrounding the LTVs do not significantly restrict the area available to other vessels for anchoring or manoeuvering (Section 11.2.4.4.1). Any inconvenience caused is expected to be relatively short-term and minor, although this may be unacceptable to some stakeholders. The temporary exclusion zones represent a moderate use of a finite resource for limited but predictable periods and, therefore, the severity of effect is considered to be '**Minor**'.

Therefore, the overall significance of the impact of the exclusion zones on the human population is assessed as '**Low (4)**'.

11.2.6.1.3 Potential positive impact of the presence of Phase 1 & 2 Vessels

In addition to the negative impacts and risks described above, the presence of the O&G industry may also offer potential benefits to other users of the sea. In particular, the presence of large ocean-going supply vessels may be useful in the event of emergency situations that require salvage, rescue or an oil spill response. As was observed during November 2015 following a fire onboard a cruise ship, vessels with the capability to aid rescue may help to prevent environmental damage, loss of property and loss of life at-sea (A. Black, *pers. comm.*).

11.2.6.2 Risk assessment of collisions during inshore activities

11.2.6.2.1 Collisions in Stanley Harbour

The Phase 1 & 2 vessels will increase the number of vessels using Stanley Harbour but it will remain a relatively quiet port with notable busy periods during cruise ship and fishing seasons. Nonetheless, a Harbour Management Plan shall be developed prior to Sea Lion Field operations in order to manage vessel movements and other users of the Harbour are tolerant to change on the scale proposed. Therefore, the sensitivity of receptors is considered to be '**Low**'.

As a worst-case scenario, a collision between vessels has been assumed. To date, incidents of this type are rare within the Harbour and have resulted in medium term inconvenience and expense due to the necessary repairs. Here as a worst-case, we assume a similar impact and therefore severity of effect is considered to be '**Moderate**'.

Therefore, the significance of the impact on other users of Stanley Harbour is assessed as '**Moderate (6)**'.

The available information suggests that collisions or contact between third-party vessels in Stanley Harbour do occur. However, while there have been a number of single vessel incidents, most of these have been due to human error or mechanical failure. The vessels used by Navitas will be technologically advanced and manned by highly trained, competent crew, which reduces the likelihood of mechanical breakdown or human error leading to incidents. The base-case for the Phase 1 & 2 Development is for all project vessels to dock at the TDF (or anchor) whenever visiting Stanley Harbour. This will separate the activities of Phase 1 & 2 vessels and other users of the Harbour and therefore reduce the potential for incidents. Although Navitas may upgrade the TDF for operational flexibility and to include a fuel line, this proposal is yet to go through the planning process and therefore it is assumed as a worst-case

that refuelling will take place at FIPASS as it did during the 2015 exploration and appraisal campaign. On rare occasions, there have been collisions between vessels using FIPASS, therefore the likelihood of occurrence of a major incident (such as collision) between Navitas vessels and other users is considered to be '**Unlikely**'.

Therefore, the significance of the risk to other users of Stanley Harbour is assessed as '**Low (6)**'.

11.2.6.2.2 Collision due to reduced sea room from temporary exclusion zones in Berkeley Sound

The temporary exclusion zones for the LTVs may lead vessels to navigate closer to the shoreline of Berkeley Sound than they would normally choose to (i.e., sea room is restricted). This increases the risk of watch-keeper error or problems in the event of a mechanical breakdown, which as a worst-case could lead to a vessel grounding. If a vessel grounds, it could result in significant damage to, or loss of, the vessel. Due to the size of the Sound, the other users of Berkeley Sound have moderate capacity to absorb change without significantly altering their present operations, although some stakeholders may find this unacceptable. Therefore, the sensitivity of the receptor is considered to be '**Moderate**'.

If a vessel were to run aground, the salvage and repair could have a long-term effect on livelihood and therefore the severity of effect is considered to be '**Serious**'.

The significance of the impact of restricted sea room is assessed as '**Upper Moderate (12)**'.

Given the circumstances described in Section 11.2.4.3 above, it is difficult to estimate the likelihood of collisions that may result from reduced space caused by the LTV temporary exclusion zones. Although Berkeley Sound is a large open bay, watch-keeping and mechanical failures have resulted in vessels grounding in the past 20 years (Section 11.2.4.2.2.2). The temporary LTV exclusion zones will reduce the space available to vessels and therefore may increase the likelihood of accidental events in the future. However, the zones do not limit sea room extensively and will only be in place for up to 13 months in total, spread over a period of around 5.5 years. The anticipated improved regulation in the Sound may serve to lessen the likelihood of collisions, and even alter behaviours. Therefore, on balance the likelihood of restricted sea room leading to vessel groundings is considered to be '**Very Unlikely**'.

Therefore, the overall significance of the risk associated with reduced sea room is assessed as '**Low (4)**'.

11.2.7 Project-specific mitigation

With legislation and industry-standard mitigations applied, the impacts and risks assessed above are considered to be '**Low**' such that project-specific mitigation is not actually required. However, the above assessment assumes that all third-party vessels using the Sound will operate within the 'Rules of the Sea' which, ordinarily, should be sufficient for vessels to adapt to the proposed changes without any negative impact.

However, experience has shown that this cannot be taken for granted when dealing with the fishing fleet. Scoping consultations in August 2016 highlighted several issues with vessels using Berkeley Sound regarding communication and compliance as major concerns (Section 11.2.4.3). In order to help communicate the positions and restrictions associated with the exclusion zones, briefing notes will be issued in the first languages of the vessel Captains.

11.2.8 Residual impacts and risks

The impacts and risks are unchanged from the initial assessment.

11.2.9 Cumulative effects

11.2.9.1 Stanley Harbour

The Sea Lion Development will increase the amount of vessel traffic within Stanley Harbour; however, the Port will remain relatively quiet compared with ports elsewhere in the world. Nonetheless, facilities within the Harbour are under-developed and competition for space may be an issue, potentially leading to cumulative impacts through increased 'concentration' (Section 8.9.1). Any upgrade of the TDF (Section 5.11.1.1.1) will reduce the project's reliance on FIPASS but may not completely negate the requirement for Navitas project vessels to use FIPASS. Therefore, it is anticipated that there may be some cumulative impact to users of Stanley Harbour.

11.2.9.2 Berkeley Sound

Although there are no other official exclusion zones in place within Falklands waters, any vessel at anchor effectively has an exclusion zone around it (in essence, the laws of the sea mean vessels will maintain a safe distance around vessels at anchor). Cumulative impact e.g., from increased 'concentration' (Section 8.9.1), will vary on a monthly and annual basis depending on the number of other users within Berkeley Sound.

11.2.10 Confidence assessment

11.2.10.1 Disturbance to other users within Stanley Harbour

The use of amenities in Stanley Harbour is possible to predict based on the known operation and therefore the confidence in the assessment is considered to be '**Certain**'.

11.2.10.2 Impacts and risks associated with exclusion zones in Berkeley Sound

The nature of the impact is reasonably well understood but the unpredictable behaviour of the receptors (fishing vessels) introduces an element of uncertainty. This is particularly true for vessels using the area around the LTV site in Berkeley Sound where space is a limited resource. Therefore, the level of confidence in the predictions of these impacts is considered to be '**Probable**'.

11.2.10.3 Risk of collisions between vessels

Previous collision risk modelling conducted by POEPL (now Navitas) with regards to the previously proposed Inshore Transfer operations (which is now discounted) was used to inform this assessment and was based on short-term poor quality AIS data, collected between 2010 and 2014. There is considerable inter-annual variation in vessel traffic, largely due to variations in *Illex* squid abundance but 2014-15 was demonstrably a peak *Illex* fishing season, and as such represents a worst-case in respect of expected vessel traffic and associated collision risk.

Stakeholders within FIG and from the fishing industry have been consulted as part of the scoping process for this EIA (Chapter 6). Their views have been taken into consideration and therefore confidence in the assessment is considered to be '**Probable**' and further monitoring of vessel movements and analysis will help to improve confidence in this assessment.

11.2.10.4 Monitoring required

The activities within Berkeley Sound are expected to be managed more rigorously than they have been in the past, with the aid of AIS monitoring. It is likely that this initiative will be driven by FIG.

Detailed monitoring requirements have been established during the Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 EMMP (an outline EMMP is provided in Chapter 15).

11.2.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

11.2.12 Findings summary

Table 11.19: Summary of the impact and risk assessment on other users of the sea inshore

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Presence of vessels	Use of amenities in Stanley Harbour	Disturbance to other users of Stanley Harbour (e.g., competition for space at FIPASS)	Planned	1, 2a, 2b & 3	Low	Minor	n/a	**Low (4)**	**n/a**	**Certain**	**Industry-standard:** Vessels will adhere to the Stanley Harbour Management Plan. **Project-specific:** None proposed.
Inshore exclusion zones	Reduction in the area available to navigating and anchoring vessels	Loss of potential anchorage	Planned	1, 2a & 2b	Low	Minor	n/a	**Low (4)**	**n/a**	**Probable**	**Industry-standard:** Use of local pilots for Navitas managed vessels in Berkeley Sound, and Status issued in 'Notes to Mariners' and on radio. **Project-specific:** Briefing documents issued in the language of the Captain.
Increased vessel traffic due to addition of	Collision in Stanley Harbour	Damage to vessels	Unplanned	1, 2a, 2b & 3	Low	Moderate	Unlikely	**Low (6)**	**n/a**	**Probable**	**Industry-standard:** Vessels will adhere to the Stanley

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Phase 1 & 2 vessels											Harbour Management Plan. **Project-specific:** None proposed.

11.3.12 Findings summary 1026

11.3.1 Introduction

The onshore and offshore personnel associated with the Phase 1 & 2 Development will require temporary and longer-term accommodation in the Falkland Islands. This chapter investigates the requirement for personnel accommodation in comparison to the current level of housing stock, overnight bed accommodations and proposed levels of new housing provision in Stanley. The forecast difference between development need and the current excess capacity determines the level of competition and the sensitivity of the receptor.

As described in Section 6.2.2.1.1, socio-*economic* impacts are out of scope for this EIS and Navitas are conducting a separate Socio-economic Impact Assessment (SIA), building on and updating the previous work undertaken for FIG and Rockhopper by Regeneris (2013; 2015), Plexus Energy (2012), and POEPL (Maplecroft, 2019) for pre-sanction consideration alongside this EIS. Therefore, this assessment focuses on the social impact of resource competition and not the secondary implications of such competition which may be socio-economic in nature e.g., competition on accommodation rental values.

Both the carrying capacity of existing infrastructure and competition for resources were raised as a concern during the scoping consultations (Chapter 6).

Note: impacts related to competition for other resources e.g., freshwater, electricity etc. are described elsewhere in this document, as described in Table 2.2.

11.3.1.1 Relevant legislation

Resource competition is not legislated for within any specific Ordinance or Regulation. No statutory limits are defined through legislation.

Nonetheless, Falkland Islands legislation that is relevant to environmental and social impact assessments are as follows:

- Offshore Minerals Ordinance 1994 (1997 and 2011 Amendments).
- Planning Ordinance 1991.

11.3.1.1.1 Competition for resources assessment

As was agreed during the consultee scoping workshop with FIG in 2015 (Chapter 6), the social impacts of competition for resources such as accommodation was considered to be within the scope of the EIS as defined by the EIA Guidance Note (FIG, 2016e).

11.3.1.1.1.1 Stanley Town planning

Aspects of resource competition are implicit within hierarchical planning legislation and planning policy that guides development and assessment of planning applications, setting them within an overall framework to achieve strategic development aims.

Planning policy is one of the key tools available to achieve the stated FIG aim of sustainable development. The Development Plan is a statutory document and provides a framework for the future spatial development of the Islands. It is made up of the Islands-wide Structure Plan, which provides the overall strategic approach, and Local Plans, such as the Stanley Town Plan, which provide more detail and land-use zoning for specific areas within the Islands (FIG, 2015d).

The Stanley Town Plan recognises and makes provision for the consideration of service utility capacity and housing needs. Prioritised and addressed within the Stanley Town Plan are:

- Expansion of housing stock,
- Diversification of accommodation types with specific reference to O&G requirements for transit-type accommodation, and

- Land-use zoning to encourage and facilitate appropriate development.

11.3.2 Sources of impact and risk

Any activity or asset that requires personnel is a potential source of competition for accommodation resources. The personnel requirements of the project, whether based offshore and transiting through the Falkland Islands, or whether based onshore in a support and logistical capacity, will determine the level of accommodation needed and thus the level of competition.

Sources of demand for accommodation, and thus competition for resource, during the Phase 1 & 2 Development include:

- Onshore / at-shore personnel:
  - Onshore baseline accommodation:
    - Port facility personnel (TDF),
    - Onshore laydown yard personnel,
    - Logistical support and office staff,
    - Accommodation / hospitality / domestic support staff, and
    - Helicopter pilots and aviation support staff / ground crew.
  - Transit accommodation outwith normal rotations:
    - Fixed-wing flight crew lay-over, and
    - Technicians for specialist onshore work or awaiting transfer offshore for specific technical tasks outside standard crew exchanges.
  - Onshore visitor accommodation:
    - Management utilising hotel accommodation.
- Offshore / near-shore personnel:
  - In-transit accommodation for crew exchange between the:
    - Mobile Offshore Drilling Unit (MODU) (Stage 1, 2a & 2b),
    - Floating Production, Storage and Offloading (FPSO) unit (Stage 2a, 2b and 3),
    - Supply Vessels (Stages 1, 2a, 2b and 3),
    - Offshore Construction Vessels (OCVs) (Stages 2a & 2b), and
    - Large Transport Vessels (LTVs) (Stage 1, 2a & 2b).
- Contingency accommodation requirements:
  - Offshore down manning of MODU or FPSO, and
  - Major incident response.

11.3.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts of resource competition warranted further investigation (Chapter 9).

Receptors that may be impacted by accommodation resource usage associated with the Phase 1 & 2 Development include:

- Human Population (in Stanley) (Section 7.7.2), and
- Tangible Property (including utility services and infrastructure (Section 7.7.4).

Any impact on utility infrastructure (e.g., provision of water utility services to residential accommodation), which may be classed as tangible property, will additionally impact upon the human population that is reliant upon it.

Further, inshore logistical support and associated accommodation requirements will be based within close proximity to Stanley, which is home to around 80 % of the Falkland Islands' population and the only location serviced by public utilities. Therefore, the assessment is based upon the human population of Stanley within the area covered by the Stanley Town Plan.

The assessment assumes a worst-case accommodation requirement being resourced from within Stanley where the greatest levels of domestic competition are likely located. Personnel figures and the need for accommodation will continually be reassessed through the project's phases and accommodation requirements may decline as operational logistics are finalised, also the potential for locally recruited staff would also reduce additional accommodation requirements. Current figures are assumed as a worst-case scenario.

11.3.4 Characterising and quantifying the impact

11.3.4.1 Nature of potential impact

Adequate accommodation is a basic human need and a necessity for all residents.

Within the scope of the current assessment, only the level of competition for housing resources will be considered. Whilst increased competition for housing undoubtedly has additional knock-on effects these are primarily socio-economic in nature, and further detail is not provided here. A fuller assessment of these associated impacts are covered by the Navitas SIA, as described in Section 7.6.4.

11.3.4.2 Quantifying the impact

In order to quantify the impacts of the Phase 1 & 2 accommodation needs on the Human Population and Tangible Property, it is necessary to have an understanding of the accommodation currently available in Stanley and to compare this to the Navitas requirements, taking account of the accommodation that Navitas intend to provide.

Full detail on the baseline Stanley accommodation is provided in the Environmental and Social baseline (Section 7.7.4.5.1) and details on the Phase 1 & 2 Development needs and provisions are given in the Development Description (Section 5.11.4.1). The key data are summarised below:

- Available accommodation in Stanley,
- Phase 1 & 2 accommodation requirements,
- Navitas provision of accommodation:
  - In-transit, routine and surge accommodation provision,
  - Use of locally based personnel,
  - Proposals for accommodating long-term onshore personnel, and
  - Development of new housing.
- Stakeholder opinion.

11.3.4.2.1 Available accommodation in Stanley

Following the 2021 Census (FIG, 2023l), the rental market in Stanley accounts for 40.2 % (481 households) of the housing stock whilst owner occupancy, including mortgaged premises, accounts for 54 % of the housing stock. The occupancy of these existing houses is relatively low at only 2.3 people / unit; and 72 % of the housing stock is detached housing units (FIG, 2021c).

It is recognised that existing Stanley housing stock cannot meet either the volume or type of personnel accommodation needs of the Sea Lion Phase 1 & 2 Development due to:

- Low number of rental properties,

- Low density of existing housing type with predominance of detached properties, and
- Lack of flats and catered hostel type accommodation to suit and the needs of the Oil and Gas (O&G) sector.

Within the exploration and appraisal drilling campaigns, which were of a temporary nature, the accommodation of 'long-term' onshore personnel was fulfilled through private rentals within existing rental stock, which did serve to increase rental competition. At present, FIG housing lists are at capacity and residential building plots that have been released at Sappers Hill and Bennet's Paddock to date are fully subscribed (Section 7.7.4.5). It is considered that there is an on-going shortage of affordable housing for purchase and rental, and that lack of housing provision already limits economic growth (Regeneris, 2013; Maplecroft, 2019).

Current hotel bed-space is approximately 142 beds (Section 7.7.4.5.1.3) and while hotels could be utilised to partially meet Navitas needs, this would seriously impact tourism and other business sectors.

Further, in addition to the needs of the long-term resident population there is a significant existing demand from Work Permit Holders (WPH) who require rental accommodation for the duration of their contract. WPH are essential to the economy of the Falklands and fill many specialist management, technical, education and service sector posts across both the public and private sectors.

It is recognised by Navitas that the existing accommodation is not sufficient to meet the needs for the Phase 1 & 2 Development, and thus has the potential to be a limiting factor with associated social impacts.

11.3.4.2.2 Phase 1 & 2 accommodation requirements

The peak demands for accommodation throughout Phase 1 & 2 are detailed in Table 11.20 below, alongside a description of the proposal for how these needs will be met. For the purposes of assessment, the maximum in-flux personnel from overseas is assumed in order to represent the worst-case scenario as the level of local recruitment for posts cannot be accurately quantified at this stage.

It is likely that a proportion of onshore personnel will be recruited locally in both permanent and temporary positions. The effect of local employment on accommodation provision is detailed in Section 11.3.4.2.2.

There is likely to be a central core requirement for accommodation throughout the field's life for onshore personnel, crew change delay and down-manning. Additional requirements to meet peak demands in Stage 1, Stage 2a and Stage 2b may be removable. However, the exact configuration of accommodation is subject to solutions put forward through the contracting strategy and tender process. The fate and/or decommissioning of this additional surge accommodation once needs reduce is not yet confirmed and will be determined at that time.

Table 11.20: Estimated maximum accommodation requirement for personnel required to support the Sea Lion Phase 1 & 2 Development

Personnel type	Accommodation Requirement[1]	Stage 1		Stage 2a &2b:		Stage 3:		Base-case provision of accommodation by Navitas[2]
		31 months		35 months		27 years		
		Max no. people[2]	% Stanley pop[3]	Max no. people[2]	% Stanley pop[3]	Max no. people[2]	% Stanley pop[3]	
Permanent onshore personnel who live in Stanley (office, supply base, heliport)	The ability to accommodate all onshore personnel will be required four - six months prior to the start of drilling activity and will endure for the duration of the Sea Lion Field life	26	1.02	24	0.95	24	0.95	Housing strategy to encourage private sector provision
Temporary rotational onshore personnel required during high intensity periods or stand-by personnel who live in Stanley for a few weeks to a few months	Routine and surge hostel-type accommodation for personnel employed onshore within support yards and logistics (on a 28 x 28 day rotation), who are on stand-by, and overnighting fixed wing air crew.	74	2.92	70	2.76	13	0.51	Temporary modular accommodation units initially provided by Navitas, supplemented by local hotels. Transferring to in-transit accommodation as soon as available.
Offshore personnel (in transit) requiring accommodation prior to going offshore	Overnight hostel-type accommodation for personnel at the beginning and end of offshore rotations	62	2.44	62	2.44	60	2.36	In-transit accommodation unit provided by Navitas.
Personnel down-manned to shore in the event of an emergency	Short term contingency accommodation in the event of an emergency down manning of the drilling rig or the FPSO. Required for Field Life[4]	140	5.52	140	5.52	100	3.94	Above accommodation facilities can be double occupancy for up to three days
Visiting senior personnel	*Ad hoc* hotel accommodation	Not estimated as yet but anticipated to be similar to the exploration campaign						None
Total requiring accommodation at any time		**302**	**11.9**	**296**	**11.66**	**197**	**7.76**	

[1] Based on Navitas' Sea Lion Phase 1 & 2 Development projections.
[2] See Development Description (Section 5.11.4.1) for detail.
[3] Stanley population from the last census, 2,538 usually resident and present (FIG, 2023l).
[4] Figures provided by Navitas Logistics and Infrastructure Overview.

11.3.4.2.3 Navitas provision of accommodation

11.3.4.2.3.1 In-transit, routine and surge accommodation provision

Recognising the current pressure on housing stock and hotel accommodation, Navitas is committed to provide accommodation that will meet the needs of:

- Rotational onshore personnel,
- Offshore personnel in transit, and
- Contingency accommodation in the event of a crew change delay or an emergency.

The contracting strategy will align with the Falkland Islands Local Content Code of Practice and accommodation provision will be tendered.

It is hoped that innovative solutions will be driven by the private sector and it is likely that all of the above accommodation needs may be serviced by 'hostel-type' accommodation. The location of new accommodation will take into account access and servicing requirements. Ideally the facility will have easy access to the By-pass / Airport Road to remove the need for transit through town and to provide easy access to the Temporary Dock Facility (TDF) and logistical bases, however this will be determined through tender and the Planning Permission process.

The hostel-type accommodation will be sufficient to provide contingency accommodation in the event of a crew change delay or an emergency because:

- Down-manning of the MODU or FPSO would be unlikely to occur coincidentally to crew change (2 days every fortnight) and hence transit accommodation would be available for down-manned personnel,
- All accommodation will be based on single room occupancy in normal conditions but will be equipped with a second fold-down bed to double accommodation capacity thus meeting full down-manning requirements,
- Durations of contingency accommodation requirement would be short as if an extended duration of down-manning occurs, it is likely that crew would be flown out of the islands and repatriated on a specially chartered flight, and
- Use of additional vessel assets and third manning in rooms is feasible, though would not normally be required.

Planning policy is supportive of the provision of dedicated accommodation specifically designed for the requirements of the oil sector (FIG, 2015d). The Stanley Town Plan recognises the need to diversify the range of accommodation and supports, in principle, proposals for permanent structures to provide 'in-transit' and short-term surge accommodation on land identified and zoned for light industrial uses (FIG, 2015d).

Further, existing Stanley hotel accommodation will only be utilised for a small number of short visits e.g., by management, where hostel-type accommodation may not be suitable. This is foreseen to be at similar rates to those already experienced during previous exploration and appraisal campaigns.

Therefore, at present, and as shown in Table 11.20, only longer-term onshore personnel, numbering approximately 26 at peak, are not covered by the bespoke accommodation provision. A specific housing strategy focused at promoting private sector provision will be adopted during sourcing processes and will be influenced by the degree of local versus expatriate personnel fulfilling these roles. In a worst-case scenario this amounts to a 6 % rise in the number of WPH's requiring accommodation needs within Stanley.

11.3.4.2.3.2 Use of locally based personnel

Long-term residents holding either 'Permanent Resident Permit' or who have 'Falkland Islands Status' will already have access to accommodation. Therefore, the use of local personnel and transfer of employment might be considered as having no net effect on competition for accommodation. However, transferal of employment from a local position to the Sea Lion Phase 1 & 2 project may require the local employer to source a WPH to fill the resultant vacancy. With less than 1 % unemployment, and around 17 % of the working population having double employment, there is a limited capacity for employers to recruit locally (FIG, 2023l). Further, it is likely that those moving to the Seal Lion project will be skilled and internationally certified; and therefore the capacity to replace them from the local workforce may be limited. Therefore, it may be necessary for local employers to recruit externally if there is a significant movement of local personnel to the oil sector.

Ultimately, this would still result in a need for additional accommodation in Stanley, albeit now one-stage removed in impact from the O&G sector.

If, due to local recruitment into the O&G sector (rather than an influx of expatriate personnel), there is an increase in WPH accommodation requirements from third-party employers, the increase in competition may be greater in this case as occupancy rates would be lower resulting in a greater number of housing units being required.

In the worst-case scenario all 26 permanent onshore posts will result in the need for more rental accommodation.

11.3.4.2.3.3 Proposals for accommodating long-term onshore personnel

With regard to the 26 onshore posts it is likely that some of these will be suited to more permanent housing rather than the purpose-built communal hostel units. Navitas recognise that hostel-type accommodation may be less suitable for the low number of senior managers and longer-term technicians for whom self-contained flat accommodation, or housing accommodation shared by two personnel may be more appropriate. This would include:

- Navitas Stanley office staff,
- Management staff of port facilities and yards,
- Contractor management staff,
- Helicopter personnel, and
- Component of onshore personnel remaining during Stage 3 Field Life.

In addition, hotel or upgraded hostel accommodation may be appropriate for some staff that may be on a working rotation with only temporary periods of residence.

Development of new housing

Navitas is committed to increase local housing supply to meet Sea Lion needs and will enter into a contract or contracts for the construction of *c.* 20 management housing units. Since the Phase 1 & 2 Field Development is long-term in nature, and thus more attractive to capital investment, it is expected that the private sector will support new build investment to fulfil these needs, encouraged and facilitated by the Navitas contracting strategy in accordance with the Falkland Islands Local Content Code of Practice.

The Stanley Town Plan (FIG, 2015d) includes zoning for housing and residential areas with a potential capacity for up to 768 building plots identified (FIG, 2015d). Thus, the availability of land for residential building plots is not considered limiting for a demand of a maximum of 30 single units or 15 shared units (occupancy by two personnel) that may be of higher density incorporating flat or semi-detached properties.

Navitas will encourage private sector market response through new development, rather than the use of existing housing stock, through pre-notification of housing needs to the private sector. An Expression of Interest exercise conducted in Q1 2024 demonstrated market appetite for the provision of housing. The long-term contracting strategy will allow internal appraisal of whether tenderers / service contract providers can meet needs without potential impacts on the local market. The willingness of the private sector to meet such demands is already indicated by a number of outline planning applications for flats and mixed-use development that have already been progressed to Outline Planning Permission (including Dairy Paddock, Old Butchery / Mink Park, Moody Brook, Butchery Paddocks / ESRO Station and Old Filtration Plant / Moody Brook).

In summary, Navitas will contract the construction / provision of transit accommodation (Section 11.3.4.2.3.1) and will also issue Invitations to Tender for the construction and provision of additional housing units suitable for oil and gas needs.

11.3.4.2.4 Opinions of stakeholders

A review of stakeholder consultations with respect to scoping concerns is provided in Chapter 6. In general, queries relating to competition for resources and specifically accommodation related to information requests to provide further clarifications on personnel numbers whilst highlighting the current limited housing capacity available.

Further concerns were raised regarding timelines of construction and the need for aggregate, building supplies and construction labour if multiple infrastructure projects were to be progressed simultaneously. This fine scale planning detail is not available at present and lies outwith the scope of the current EIA (Section 6.2.2.1.1), which is concerned only with development operations. Accommodation facilities will be subject to planning approval.

11.3.5 Industry standard mitigations

Within larger economies, competition for resources is not generally considered to be significant as there is a country-wide network with the capacity to absorb and respond to increased demand. Therefore, no acceptable or permissible limits are set through industry codes of practice.

11.3.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities. The assessment of unplanned events includes an assessment of the 'Likelihood of Occurrence' to determine the 'Risk'.

A summary of the impact and risk assessment outcomes is tabulated in Section 11.3.12, which shows the worst-case impact / risk for each activity and receptor.

11.3.6.1 Impact assessment

11.3.6.1.1 In-transit, routine and surge accommodation

Navitas appreciates that accommodation may be a limiting factor with regard to community resources.

As described above, the project basis of design includes the provision of high-density hostel-type accommodation units to house 'in-transit' and rotating onshore personnel within the planning and contracting scope of the Development. These units are factored in to the impact assessment such that the arrival of 'in-transit' and rotating onshore personnel are expected to have no impacts with regards to competition for accommodation, as need will be met by a dedicated accommodation solution. As the accommodation provision will be separate from domestic housing the sensitivity of the receptor (of both Tangible Property and the Human Population) is considered to be '**Low**'.

As capacity will be designed to meet full onshore and transiting offshore personnel needs the severity of effect (on both Tangible Property and the Human Population) is considered to be '**Slight**'.

Therefore, the overall impact is considered to be '**Very Low (2)**'.

11.3.6.1.2 Impact of onshore (expatriate or local) personnel on Stanley's housing stock

Given current housing in Stanley, there is limited capacity to absorb additional accommodation needs (Section 7.7.4.5.1). Only a small number of personnel (*c.* 26) will be required to permanently live in Stanley and these needs will be met by a contracting strategy that will promote and encourage housing built by the private sector. Dual occupancy or flat accommodation will reduce unit needs for expatriate personnel. FIG also noted that by the end of 2022 they would be introducing 'incentives to encourage the private sector to develop new affordable rental housing' (FIG, 2021c). It is understood this work is ongoing (R. Cordeiro, *pers. comm.*). Therefore, reliance on the existing housing stock is expected to be minimal and short-term in nature until the private sector responds to increase supply and is not considered to be unmanageable or unsustainable. Further, the population is likely to be tolerant of the change without detriment to its character. Therefore, the sensitivity of the receptor (of both Tangible Property and the Human Population) is considered to be '**Low**'.

The provision of accommodation by the private sector will be actively promoted and managed within the Development programme to ensure that the solutions are largely based upon bespoke accommodation rather than existing housing stock. However, there will be some short-term competition for rental accommodation in the early stages of Development (early onshore construction), until the market responds and supply increases to meet demand. Therefore, the severity of effect (on both Tangible Property and the Human Population) is considered to be '**Minor**'.

Therefore, the overall significance of the impact of competition for accommodation on the resource of housing stock within Stanley is considered to be '**Low (4)**'.

11.3.6.2 Risk assessment

11.3.6.2.1 Contingency accommodation needs

The design of the purpose-built accommodation is such that it incorporates full capacity requirements for contingency accommodation in the event of a down-manning or environmental incident (Section 11.3.4.2.3).

Therefore, existing transit, routine and surge accommodation could be used to accommodate sufficient numbers of personnel in the short-term and there is anticipated to be no risk of impact from Phase 1 & 2 emergency events should they occur.

11.3.7 Project-specific mitigation

As the impact of Sea Lion Phase 1 & 2 Development accommodation needs on Stanley's housing stock (Tangible Property) and the Human Population is considered to be '**Low**', project-specific mitigation measures are not proposed at this stage. Rather, monitoring of accommodation use and socio-economic impact on the rental market will be incorporated within both the FIG Social Effects Monitoring Programme and Navitas Socio-Economic Monitoring and Management Plan.

At present, Navitas is reliant upon the private sector responding to the Invitation to Tender for the construction of a small number of single flat-type units. Given the duration of the Sea Lion Development it is highly likely that this will occur; if it doesn't, private investment and development can be further stimulated by the contracting strategy and accommodation tender specification to encourage new provision over existing housing stock.

11.3.8 Residual impact assessment

Not applicable.

11.3.9 Cumulative effects

The assessment considers all direct project personnel and their accommodation needs. Included within the assessment is the potential effect of personnel drift from the local labour market to the O&G sector. This is considered an indirect impact as, were an external person on a work permit basis required to back-fill the post (vacated by the local individual) they will then have a requirement for local accommodation. It is assumed that market forces of supply and demand should respond to such needs. However, as demand levels (e.g., 'concentration', see Section 8.9.1) are harder to forecast given the uncertainty in the likely level of local recruitment, it is expected that, at least in the short-term, some level of negative socio-economic impact may occur with respect to rental availability and values until markets respond.

With increased personnel active and passing through the Falkland Islands, there will be associated expansion in economic activity and other service sectors, this will undoubtedly require a commensurate increase in population and the amount of accommodation required. However, any impact of wider increased economic activity is outwith the scope of the current assessment. Such an assessment has previously been undertaken by FIG (Regeneris, 2013), is included as a component within the Regeneris SEMMP (Regeneris, 2015) and will be considered further in the forthcoming update to the SIA.

11.3.10 Confidence

Personnel accommodation needs have been conservatively defined. Planning policy is specifically supportive of hostel-style accommodation on land zoned for light industrial use and similar, temporary accommodation during exploration rounds has been approved and proven to be acceptable. Higher density flat accommodation has been identified as appropriate for residential areas and a number of speculative planning applications have been approved for outline planning permission. This shows the proactive willingness of the private sector to respond to accommodation demands.

However, at the time of writing the accommodation contracting process has not yet been initiated and thus the final designs have not yet been confirmed nor progressed through planning controls by the contracted service provider. While assumptions can be made regarding private sector uptake of opportunities for rental development, these discussions have still to be conducted.

The level of confidence in the impact / risk predictions and mitigation is therefore '**Probable**'.

11.3.10.1 Monitoring required

For a small proportion of the accommodation needs of onshore personnel, Navitas is reliant upon the private sector rental market to respond to contracting strategy calls for development of rental accommodation units. Monitoring of private rental use and indicators of rental competition are ways in which this can be monitored. If monitoring shows that competition may become an issue, private investment and development can be further stimulated by the contracting strategy and accommodation tender specification to encourage further new provision over existing housing stock. All monitoring requirements agreed by Navitas will be recorded and managed *via* the project-specific Phase 1 & 2 Socio-Economic Monitoring and Management Plan (SEMMP).

11.3.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

11.3.12 Findings summary

Table 11.21: Summary of the impact assessment for accommodation resource competition

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Accommodation for onshore surge personnel, in transit personnel and down-manning contingency provision	Need to accommodate transitory personnel	Competition with domestic housing needs	Planned	1, 2a, 2b & 3	Low	Slight	n/a	**Very Low (2)**	**n/a**	**Probable**	**Industry-standard:** None. **Project-specific:** None proposed.
Accommodation for semi-permanent, management and technical onshore personnel	Need to accommodate permanent personnel	Competition with domestic housing needs	Planned	1, 2a, 2b & 3	Low	Minor	n/a	**Low (4)**	**n/a**	**Probable**	**Industry-standard:** None. **Project-specific:** Contracting strategy encouraging construction of additional housing.

11.4.11 Offsetting 1045
11.4.12 Findings summary 1045

11.4.1 Introduction

Onshore infrastructure associated with the Sea Lion Field Northern Development Area, Phase 1 and 2 will require connection to the existing Stanley water utilities. In addition, the onshore water supply will provide a proportion of the water required by offshore assets including offshore support vessels and the Mobile Offshore Drilling Unit's (MODU) drilling requirements for muds, cements, brines and domestic use.

The Falkland Islands Government (FIG) is the single water utility supplier and the Stanley water filtration plant has a fixed capacity, limited by the existing infrastructure. Fresh potable water is therefore considered a limited resource and any use of fresh water above the current baseline usage has the potential to lead to competition with the local users in Stanley. Both the carrying capacity of existing infrastructure and competition for resources were raised as a concern during the scoping consultations (Chapter 6).

This chapter assesses the impact of the Phase 1 & 2 Development by comparing the forecast water use with the level of water available. The forecast difference between development demand and the current excess capacity determines the level of competition. The assessment relates to fresh potable water processed and supplied through the Stanley filtration plant. Some process usage and drilling does not require potable water, however as all freshwater supplied from shore in Stanley is from a potable main and no alternative unprocessed freshwater main system is available; all reference to water is assumed to be potable fresh water unless stated otherwise.

Note: as described in Section 6.2.2.1.1, socio-*economic* impacts are out of scope for this EIS. The previous operator of the Sea Lion Field (POEPL) conducted a separate Socio-economic Impact Assessment (SIA), building on and updating the previous work undertaken for FIG and Rockhopper by Regeneris (2013; 2015) and Plexus Energy (2012). This is now being updated again by Navitas, with the support of HATCH. Therefore, this assessment focuses on the social impact of competition for water on the human population and tangible property as receptors, and not any secondary, economic, implications of such competition or use of property.

Note: impacts related to competition for other resources e.g., accommodation, electricity etc. are described elsewhere in this document, as described in Table 2.2.

11.4.1.1 Relevant legislation

Resource competition specifically is not legislated for within any Ordinance or Regulation. However, as was agreed during the consultee scoping workshop with FIG in 2015 (Chapter 6), the impacts of competition for resources such as water was considered to be within the scope of the EIS as defined by the FIG EIA Guidance Note (FIG, 2016e)).

11.4.2 Sources of freshwater use and competition for resource

Water may be used onshore by support services activity and infrastructure, or provided through the Temporary Dock Facility (TDF) to the offshore support vessels for offshore use. Specific sources of freshwater use during the Phase 1 & 2 Development include:

- Drilling offshore by the MODU (Section 5.4),
- Use of vessels (Section 5.11.2):
  - Anchor Handling Tug Supply (AHTS) vessels, Emergency Response and Rescue Vessel (ERRV), Platform Supply Vessels (PSV), used as Mobile Offshore Drilling Unit (MODU) and Floating Production, Storage and Offloading (FPSO) unit supply vessels for the movement of materials and equipment,
  - Construction and installation vessels,

- *Ad hoc* freighter vessels, and,
- Large Transport Vessels (LTVs).

- Onshore / At-shore usage:
  - TDF, which is the point of delivery for offshore usage, although there will be minimal water usage by the TDF directly (Section 5.11.1.1.1),
  - Onshore supply base(s) and warehouses, Liquid Mud and Bulk Facility and associated offices (Section 5.11.1.2), and
  - Personnel accommodation (Section 5.11.4.1.1).

Note: during production, the FPSO will require water for domestic use and marine and topsides systems. It is estimated that the FPSO will require 30 m^3/day and to meet this need it will carry a water-maker. It is anticipated that the FPSO will be able to produce enough water to meet its own demand and thus be self-sufficient in water. Since water availability is critical for the process, water-maker volume requirements and redundancy will be incorporated within the FPSO design. In the event of complete failure of the water-makers, it is likely that water could be sourced, in the short-term, from other vessel water makers and / or a large standby of bottled water from the supply base. Failing this, the FPSO would shut down until the water-makers could be reinstated. Therefore, process water use on the FPSO is not factored into the following impact assessment with regard to competition for Stanley water resources.

11.4.2.1 Drilling

The MODU will require water for domestic use as well as for the drilling and cementing process, the mixing of drilling muds, brines and cement, well suspension, sweeps and completion. Freshwater used for drilling activity does not require to be potable and buffer storage in the TDF tanks that may not be certified for potable water storage is permissible.

It is anticipated that the MODU will be equipped with a desalination plant (water-maker), as was the *Eirik Raude* used during the 2015 drilling campaign. However, the water-maker is intended mainly for rig utilities and accommodation and is not sufficient to meet water needs required for drilling fluids. Indeed, the experience of exploration drilling campaigns suggests that allowance for drilling requirements should be made from onshore freshwater sources.

Note: while some drilling muds may be mixed onshore for shipment to the MODU by a supply vessel, this does not modify total usage.

11.4.2.2 Use of vessels

The vessels required throughout the different stages of the Phase 1 & 2 Development will all require water for onboard domestic and vessel use. It is anticipated that the majority of vessels will have water-makers on board, though at times some net deficit and opportunistic tank top-up would be expected. Therefore, it is likely that these vessels will take on water at the TDF for delivery to the FPSO for domestic use in the event of water-maker failure and / or to supply the MODU in the event of water-maker failure. A nominal amount based upon the exploration experience has been assumed for vessel usage and included within the assessment.

11.4.2.3 Onshore / at-shore usage

The resources onshore will require water for domestic and general usage such as cleaning. However, with the exception of the muds and brine plant that is included within offshore drilling estimates (Stages 1, 2a & 2b), no major onshore process use is expected. As described above, the TDF will act as a conduit supplying shore-side water to offshore assets *via* the supply vessels when necessary.

11.4.3 Potential receptors

The ENVironmental Impact Identification (ENVIID) workshop was used to identify those receptors upon which the impacts of resource competition warranted further investigation (Chapter 9).

Receptors that may be impacted by the use of the Stanley freshwater supply during the Phase 1 & 2 Development include:

- Human Population in Stanley (Section 7.7.2), and
- Tangible Property (e.g., fresh (potable) mains water supply (Section 7.7.4.5.2)

Interdependence exists between the two receptors. Any impact on the water supply will additionally impact upon the human population that is reliant upon it.

The onshore logistical support services (e.g., the TDF, supply base, Liquid Mud Plant, offices etc.) and associated accommodation will be based within close proximity to Stanley which is the only location serviced by public utilities and where the majority of the population resides. Therefore, the following assessment is based upon the human population of Stanley and confined to the area within the coverage of the Stanley Town Plan and the public mains supply system.

11.4.4 Characterising and quantifying the impact of competition for water

11.4.4.1 Nature of potential impact

Water is an essential human requirement and access to clean fresh water can be considered as a basic human need and right.

As is detailed in the Environmental and Social Baseline Description (Section 7.7.4.5.2), potable water supply is provided to Stanley through a single source water filtration plant. To safeguard against single point system failure, the Public Works Department (PWD) are remitted to hold 2 - 3 days water supply in storage tanks. However, no alternative supply is available and water usage has been increasing in Stanley since 1980 (Section 7.7.4.5.2.1).

The untreated water (i.e., rain) supply line from Moody Brook, where the dual catchments join, to the central Stanley filtration plant, was installed in *c.* 1989. But between 1986 and 2021, the number of Stanley households has increased to 1,148 (FIG, 2023l). The overarching trend indicates that Stanley water consumption is increasing with population growth.

Therefore, in practical terms, water must be treated as a limited finite resource.

11.4.4.1.1 Potential for water shortages

With a single point supply which is limited by a finite supply rate and thus a finite supply volume, the provision of potable water to Stanley residents and other commercial users is vulnerable to any increase in demand. Specifically, impacts to the local users may arise from:

- Increases in the volume of demand,
- Increases in the rate of demand, and
- Significant reduction in rainfall patterns.

Increased volume of demand (m^3) may cause:

- Deficits leading to temporary water restrictions to residents and commercial users,
- Draw down of storage tanks and loss of contingency reserves making users vulnerable to any short-term interruption to the water supply (PWD are remitted to hold 2 - 3 days of water supply to safeguard against single point system failure). Of note:

  - Without excess processing capacity, subsequent recharge of reserve tank storage may take an extended time, and
  - There may be a loss of water quality if tanks are fully drawn down and tank and system sediment enters the system.
- Increased wear and tear of filtration plant infrastructure if it operates at capacity for extended periods in a system vulnerable to single point failure,
- Increased demand rates (m^3/hr) may cause:
  - Draw down of storage tanks if demand extraction rate exceeds processing refill rates, leading to possible water quality contamination through re-suspension of tank sediments and staining, and
  - Loss of water mains pressure to other users on a series spur main in extreme cases as water takes the path of least resistance to the greatest outlet.

11.4.4.1.2 Nuisance to other users

In addition to domestic users, commercial and high-volume users which may be affected by the above include:

- Falklands Interim Port and Storage System (FIPASS),
- Abattoir,
- Fish processing plants,
- Stanley Growers market garden (horticulture),
- Hotels,
- Public houses, and
- Car washes.

Nuisance to domestic users, and logistical and financial implications for commercial users, may be caused by:

- Restriction in volume of water available,
- Reduction in mains pressure,
- Reduction in supply rate, and
- Reduction in water quality and clarity.

11.4.4.2 Quantifying the impact

When quantifying the potential for water shortage, and therefore impacts to other users, it is necessary to consider the:

- Current freshwater supply *versus* current Stanley demand:
  - Stanley freshwater operating system,
  - Stanley freshwater use, and
  - Impact of past exploration drilling campaigns.
- Phase 1 & 2 freshwater provision and mitigations, and
- Estimated Phase 1 & 2 net water demand:
  - Estimated volume demands, and
  - Estimated rate demands.

11.4.4.2.1 Current freshwater supply versus current recent demand trends

11.4.4.2.1.1 Current Stanley water operating system

Within the current Stanley water system, rainfall catchment is not considered to be a limiting factor and the source of supply is considered secure and continuous year-round. The Stanley water system can 'produce' about 73 m^3 of water per hour or around 1,100 m^3 per day, assuming a 15 hour day is worked. However, due to backwashes and dumps a more realistic figure is a production rate of *c.* 1,000 m^3 per day (Z. Stephenson, *pers. comm.*).

Note: FIG note that with capital funding commitments there will be significant changes to the water provision by 2025/26 (C. Summers, *pers. comm.*).

11.4.4.2.1.2 Stanley water use

Over the 22-year period between 1995 and 2017, annual average Stanley water consumption rose by 74 %; from 492 m^3/day to 865 m^3/day. Stanley thus exhibits a long-term increase in water usage of approximately 3.5 % per annum (FIG Environment Department, *pers. comm*.). Water use peaked in 2015 during oil exploration activities at 946 m^3/day and subsequently dropped back in 2016 and 2017 to 860 m^3/day, lower than the 2015 peak but in-line with the underlying average increasing trend in Stanley water usage.

More recent water forecasts have been difficult to determine (Z. Stephenson, *pers. comm.*). However, the year-on-year increase in Stanley consumption has continued into the present with increases of *c.* 3.5 % p.a. resulting in a baseline maximum annual water use of 335,070 m^3 (i.e., 918 m^3/day) in 2023 (Figure 11-7).

With a daily supply currently limited to 1,000 m^3/day under standard working conditions the 2023 usage figure of 918 m^3/day shows that there is only 82 m^3/day of excess production capacity. With continued increases in water demand of 2-3 % p.a., the baseline water usage can be expected to exceed current working practice limits by 2027 (Section 7.7.4.5.2.2).

11.4.4.2.1.3 Impact of past exploration drilling campaigns

During previous drilling campaigns the baseline water capacity of the Stanley system was around 870 m^3/day[94]. Relating to past exploration rounds, annual average daily consumption figures for Stanley show peaks in 1998-99, 2010-12 and 2015 (Figure 11-7). Previous estimates by FIG suggest that the *Ocean Guardian* (2010-12) and *Leiv Eiriksson* (2012) drilling campaigns resulted in increases over the baseline water demand of *c.* 10-16 %. The spike in demand between 2014 and 2015 when the *Eirik Raude* was active was 24 % (183 m^3/day) over the baseline supply. While these overall figures represent all economic activity and may not be wholly attributable to oil development, they do serve to provide an indication of the likely overall trend associated with increasing Oil and Gas (O&G) activities. However, even if not attributed to, and not associated with O&G activity, the additional increase in demand would still represent an increase in Stanley domestic usage that would limit available excess capacity for O&G development usage.

During the last oil exploration campaign in 2015-16 the current standard filtration capacity (870 m^3/day at the time) was surpassed for the first time, leading to an average daily consumption of 946 m^3/day in 2015 (Figure 11-7).

This signifies that for periods of time, despite the base-case mitigations used within the exploration rounds, it was necessary to extend the working day and pumping durations of the filtration plant and to operate the Dairy Paddock Reservoir (DPR) with a temporary daily deficit.

[94] Since the improvements to the water system in Stanley and improved working practices have increased the available capacity of the system; baseline water capacity of the system is now (as at 2024) around 1,000m^3/day.

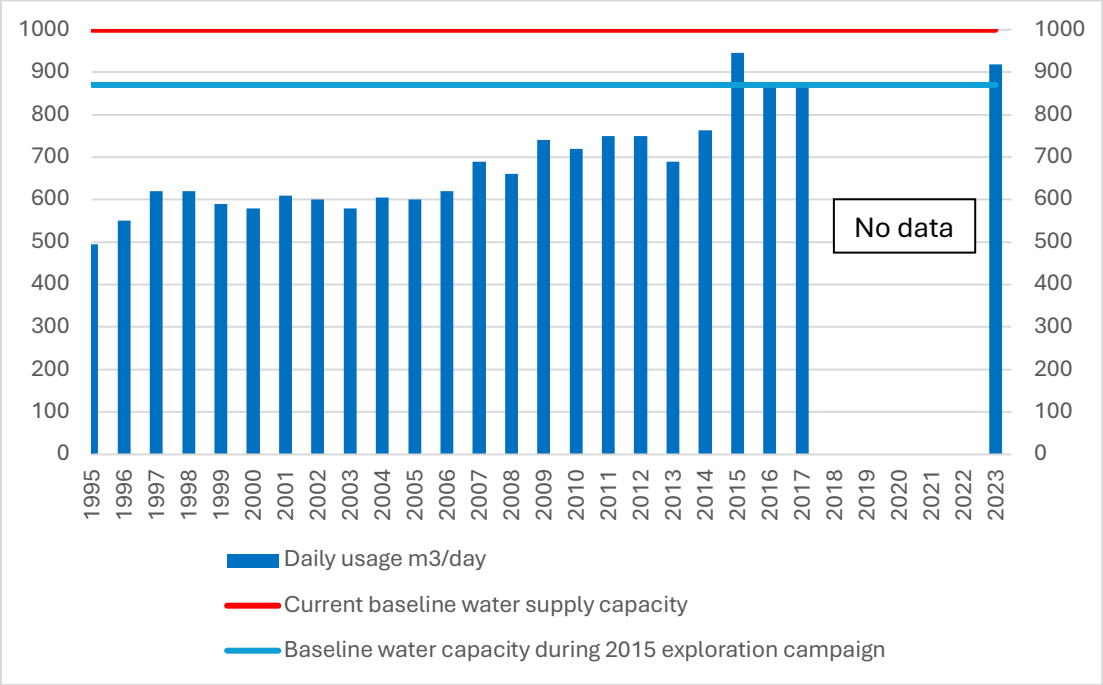

Figure 11-7: Average daily water consumption (m^3/day) in Stanley by year from 1995 to 2023. Note: water usage figures between 2018 and 2022 were unavailable

11.4.4.2.2 Phase 1 & 2 base-case mitigations

A number of measures have been built-in to the basis of design for the Phase 1 & 2 Development with regard to minimising the reliance on water from local resources. These are similar to those that were used for the 2015 exploration drilling campaign. However, it should be noted that while these mitigations can serve to reduce the water demands of any O&G campaign, they do not serve to eliminate the need for 'top-up' from the local water supply, as is evidenced by the above. A description of the base-case mitigations, and the potential limitations of these measures is described in Table 11.22. These mitigations are factored into the initial impact assessment (Section 11.4.6.1).

Table 11.22: Mitigations built-in to the Phase 1 & 2 Development basis of design

Built-in mitigation	Location	Background and description	Benefits and limitations in practice
MODU water-makers	MODU	All offshore assets will be equipped with desalination plants. Capacities and redundancy will be incorporated within design and contracting requirements, such that all should be largely self-sufficient in water provision. As described in Section 11.4.2, the FPSO is the greatest long-term user of fresh water which is critical for both onboard processing and safety systems. Complete failure of water systems would result in shut-down of processing rather than drawing upon onshore resources.	While full offshore requirements need not be met by the Stanley supply, exploration usage would suggest a precautionary approach is required. Therefore, a contingency to take on water for vessel tank top up and the drilling needs of the MODU is included, as was required during the exploration drilling campaign (Section 11.4.4.2.3.1). These estimated figures for drilling requirements are however lower than were observed during the exploration campaigns mainly due to use of Non-Aqueous Drilling Fluids. Shut-down of the FPSO in the event of complete failure of water-makers and all other water sources would impact upon the operation but not upon onshore supplies.
FPSO water-makers	FPSO		
Vessel water-makers	All vessels		
Construction of a freshwater holding and header tank	Bulk water storage incorporated within, TDF hull tanks, mud/bulk plant header, and/or dedicated buffer tank in at-shore tank farm adjacent to the TDF causeway	The design assumption is that the header tank will have sufficient capacity to balance demand such that needs can be levelled off to a steady daily requirement. The project will likely incorporate a minimum of 3.5 days storage plus a contingency, based upon two vessel visits a week. The exact combination and volumes of the tanks will be determined within FEED.	Storage tanks do not reduce the overall quantity of water required. Storage only levels daily demand to the averaged constant demand such that daily spikes in demand, e.g., a vessel taking on 400 m^3, can be excluded from the consideration and only average demand assessed. The volumes of the tanks have yet to be confirmed and this will determine which of the three bulk storage options are used. The potential use of three storage options will provide flexibility to balance demand. Storage within the TDF is limited to non-potable process water for drilling. Further analysis of needs will determine whether this measure should be extended to give sufficient supply for the contingency of two vessels berthing in close proximity to take on water.

Built-in mitigation	Location	Background and description	Benefits and limitations in practice
Voluntary restrictions i.e., daily limits to store and buffer against water draw-down.	TDF	During the previous exploration and appraisal drilling campaigns, a voluntary limit of 100 m^3/day at a supply rate of 10 m^3/hr was applied. TDF usage during exploration was sporadic and determined by the number of vessel visits. A volume of >100 m^3 of water was drawn on 24 % of days, whilst zero water was drawn on 42 % of days. Therefore, it can be seen that there is the potential to store a proportion of the 100 m^3 daily limit on days when full volume is not required, and thus buffer the drawdown against demand spikes. This has additional benefits as tanks can be refilled at the lower rate of 10 m^3/hr as a 'trickle' feed (which safeguards against a mains pressure drop to other users and against Stanley header tank level drawdown), but pumped to vessels above mains rates to reduce berthing durations. Water volumes are thus accumulated in advance at sustainable rates.	A close working relationship with the water department is required and a daily update of forecast water needs must be provided to assist with demand planning and Stanley header tank volume balancing. Through this liaison the voluntary limit may be exceeded on occasion if supply conditions permit. In consultation with FIG, appropriate limits and a liaison procedure can be established.
Sustainable design	Supply base, accommodation units	Potential to incorporate sustainable design features including: Water conservation design (low volume showers and toilet flush, shut-off timers, visible overflows so leaks are detected, etc.) and grey water recovery.	A *Per capita* consumption of 300 litres / person / day is assumed. This is a conservative estimate and with water efficient design it is hoped to reduce domestic water use to the lower UK equivalent of 150 litres / person / day.
Salt-water substitution	Offshore drilling	Offshore drilling estimates assume use of process freshwater for drilling, cementing, well suspension and completion. However there is the potential to use salt-water in some components such as sweeps.	The investigation of where salt-water is appropriate for use will be continued through FEED and this will reduce offshore water demand for drilling activities from shore sources.
Alternative water sources	TDF and offshore	Whilst drilling usage requires freshwater it does not necessarily require fully treated potable water. In extenuating circumstances it may be possible to source raw untreated freshwater from alternative sources (for example the dual catchments sustain greater volumes than is supplied to Stanley) and to transfer raw water to the TDF by tanker. Any vessels coming into Falkland Island waters can do so with full water tanks	Stanley water filtration plant is the only source of treated potable water available on-island however pumping from raw water reservoir catchment source to a tanker may substitute for process water needs in extenuating circumstances.

11.4.4.2.3 Forecast Phase 1 & 2 freshwater usage

The Phase 1 & 2 Development freshwater usage has been estimated with consideration of water usage data from the 2015 exploration campaign. A breakdown of the net water usage data from the 2015 exploration drilling campaign has been undertaken.

In forecasting the Phase 1 & 2 Stanley water usage, the use of construction batch plant buffering, the mud plant header-tank, TDF barge storage and possible dedicated buffer tank storage (if calculated volumes demand) (Section 11.4.4.2.2) will allow daily water use to be buffered and levelled to the average daily water use. It is therefore possible to ignore peak single day usage that occurred during exploration (e.g., a vessel taking on water) and consider only average figures.

In addition to average use figures over the entire period or during each Development Stage, peak period data are also considered. Peak period figures are distinct from single day usage spikes as they consider the average daily use over a period of a month and take the highest expected monthly daily usage within each Development Stage. Due to the extended period of a month it is not possible to fully buffer against extended supply deficit and thus water supply must be able to cope with the demands of the highest demand period within each Stage.

Estimates were made for:

- Water volumes required by the Phase 1 & 2 Development, and
- Water usage rates during the Phase 1 & 2 Development.

11.4.4.2.3.1 Estimated volume demand

Both the highest average water demand and peak periods of direct water demand occur during Stages 1 (pre-First-Oil drilling) and 2a & 2b (simultaneous drilling and production operations), as would be expected during times of active drilling and higher personnel numbers. During Stages 1 and 2, average water demand from the main onshore centres and offshore assets ranges from 99.5 – 112.5 m^3/day, which is just over the excess Stanley capacity of 82 m^3/day that would be available for O&G development. Peak period usage ranges between 162.5 – 236.58 m^3/day, which would exceed current capacity (Table 11.23).

During Stage 3 (steady state production), direct water use drops to 44 – 77 m^3/day and is within sustainable limits for supply.

In addition to the water use by the main onshore centres, a range of indirect uses could further increase demand such as:

- Increased water use by supply and services (e.g., laundry, heli-ops, etc.) as a result of increased personnel in Stanley, and / or
- Coincidental increases in water use due to other economic sectors or diversification.

During exploration, these associated services accounted for an average of 81 m^3/day over and above the directly attributable and metered centres. During the *Eirik Raude* campaign in 2015, the allocated O&G usage increased the overall Stanley water usage by 13-18 %. However, the overall Stanley usage spike during the same period was 24 % such that an additional 11 % increase in water usage may be attributable to activities associated with O&G. However, there is a degree of uncertainty in the data regarding unattributed sources of water use.

Nonetheless, whilst the exact contribution of O&G activities to wider water use is unknown, all unrelated and domestic sources of increase to baseline water usage would still reduce the excess water capacity available in Stanley.

In summary, while it is not possible to fully attribute associated water use, if levels during the Phase 1 & 2 Development, are similar to those observed during exploration, then average water use will exceed current capacities in Stage 1, 2a & 2b, and will likely exceed that in Stage 3 also. Additionally, within the current system spare capacity will decrease each year as Stanley exhibits an increasing water use trend (Section 11.4.4.2.1.2) so extrapolation to Stage 3 may not be fully accurate.

Table 11.23: Estimated shore water used by the Sea Lion Development by activity centre

Activity	Exploration 2015		Assessment	Stage 1		Stage 2 (a & b)		Stage 3	
	Average (m^3/day)	Peak[1] (m^3/day)		Average (m^3/day)	Peak[1] (m^3/day)	Average (m^3/day)	Peak[1] (m^3/day)	Average (m^3/day)	Peak[1] (m^3/day)
Offshore Demand (supplied from TDF)

Bulk, mud & brine storage	0	0	Included in offshore drill estimates	0	0	0	0	n/a	n/a
Personnel and accommodation	31	48	*Per capita* rate of 300 l/pp/day[3]	70	140	64	126	32	65
Total inshore demand				**83.5**	**189.5**	**69.5**	**131.5**	**34**	**67**
Total demand *vs.* supply capacity									
Total O&G Demand	102	140	-	112.5	236.5	99.5	162.5	44	77
Percentage increase in Stanley usage (%)	13	18	-	12	-	11	-	5	-
Unallocated associated activity demand (**Note:** Only a proportion of this may be directly attributable to O&G activity)	81	-	Based on observed 2014 - 15 exploration total usage increase of 183 m^3/day (24 %)	81	-	81	-	81	-
Total forecast demand	183	-	-	193.5	-	180.5	-	125	-

Activity	Exploration 2015		Assessment	Stage 1		Stage 2 (a & b)		Stage 3	
	Average (m^3/day)	Peak[1] (m^3/day)		Average (m^3/day)	Peak[1] (m^3/day)	Average (m^3/day)	Peak[1] (m^3/day)	Average (m^3/day)	Peak[1] (m^3/day)
Maximum Available Spare Capacity (for comparative purposes)	107[4]	-	-	82	-	82	-	82[5]	-

[1] Peak usage relates to the month with the highest daily average usage during drilling and includes accommodation during peak in-transit crew exchanges.

[2] Note that water usage estimates for the development wells are lower than the exploration wells as the development wells will be drilled with NADF, whereas the exploration wells were drilled with WBM. NADF uses less water per well, see Table 11.22.

[3] This is a high estimate and is used to account for the observed direct and indirect increase in demand during the last exploration well campaign. This may be reduced to 150 litres per day using sustainable design (Section 11.4.4.2.2) but is kept at 300 litres per day to assume a worst-case.

[4] 107 m^3/day was the available spare capacity during the 2015 exploration drilling campaign; this has now reduced to 82 m^3/day available spare capacity in the Stanley water system.

[5] Note the available spare capacity will decrease each year as Stanley exhibits an increasing water use trend (Section 11.4.4.2.1.2) so extrapolation to Stage 3 may not be fully accurate.

11.4.4.2.3.2 Estimated rate demands

In addition to total average consumption, consideration of daily spikes in water use (m^3/day) and usage rate (m^3/hr) can also be important.

During the 2015 exploration campaign, whilst the TDF showed an overall average utilisation of 55 m^3/day, periods of higher daily usage were recorded. Daily usage ranged from 433 m^3/day (a single incident of accidental leakage caused by human error) or 306 m^3/day (actual operational peak demand), to zero when vessels were absent. During a number of periods extending for up to 21 days the average water use increased to 137 m^3/day, and monthly daily averages reached 90 m^3/day.

A voluntary limit of 100 m^3/day was applied during exploration with greater volumes requiring specific authorisation from the water section. Greater than 100 m^3 of water was drawn on 24 % of days and zero water was drawn on 42 % of days.

To reduce pressure from daily spikes in water usage, Navitas has committed to the use of buffer storage tanks (Section 11.4.4.2.2). Buffer storage can be provided within the TDF hull tanks, and as a header tank to the mud plant with the potential for additional dedicated buffer tanks in the at-shore bulk supply base. The necessary capacity of the tanks will be calculated based on the average daily demand which should ensure that daily spikes can be accommodated. Therefore, spikes in usage and the associated risks to supply can be excluded from the assessment.

11.4.5 Industry-standard mitigation

Within larger economies there is generally a country-wide water supply network with the capacity to absorb and respond to increased demand. This is especially true of water distribution that works within a national supply grid. As competition for resources is not generally significant, no industry-standard mitigations or Codes of Practice exist. Nonetheless, within the Falkland Islands, FIG operate systems to safeguard the water supply for domestic and commercial users in Stanley.

11.4.5.1 FIG water prioritisation

Regardless of trends in supply *versus* demand, the FIG Water Section is tasked with maintaining a two-day supply of stored potable water. To safeguard emergency services and domestic users in the event of a production failure, a system of user prioritisation would be applied.

Light-industrial use is prioritised at the lowest level and would be the first to have supply restricted. The likely order of restriction would be TDF, FIPASS, Public Works Department's site, Megabid.

As such, security of water supply is a greater risk to Phase 1 & 2 Development activity than it will be to domestic users. If water usage was excessive at any time, the supply to the Development infrastructure would be cut before there was any impact to the domestic sector.

However, it should be noted that while this mitigation safeguards the human population, it may not be sustainable as a valid or reliable long-term 'mitigation' with regards to the Phase 1 & 2 Development if water demands cannot reliably be met.

11.4.6 Impact assessment

Assessment of the impact of water use at this time may not be representative as it is understood that improvements to the water system are planned by FIG by 2025/26 (C. Summers, *pers comm.*), which could effectively alter the baseline against which this assessment is made. However, this is outwith Navitas' control and the below assesses water use against the existing baseline.

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

A summary of the impact assessment outcomes for this Development is tabulated in Section 11.4.12 which shows the worst-case impact for each activity and receptor and details are provided below.

11.4.6.1 Impact assessment assuming current Stanley operating system

11.4.6.1.1 Water use during Stage 1 and Stages 2a & 2b

Stages 1 and 2 (a & b) are assessed together as both incorporate active drilling and increased personnel, and the forecasted average water demands are similar (Section 11.4.4.2.3).

Without improvements to the system, the Stanley water supply is already at near capacity. The forecasted average water use by the Development during Stages 1 and 2 (a & b) is 106 m^3/day and the peak daily use is 236.5 m^3/day (Section 11.4.4.2.3.1). The excess capacity in the Stanley water supply is estimated at only 82 m^3/day (Section 11.4.4.2.1.2), and while the Phase 1 & 2 usage estimates are conservative, the Development demand is expected to exceed supply. This is supported by the fact that usage did indeed exceed supply in the 2015 exploration campaign (Section 11.4.4.2.1.3) and required a responsive change in FIG working practices to meet the short-term increased demands. Adding to this, the indirect and unallocated water use was *c.* 81 m^3/day during the 2015 exploration (Section 11.4.4.2.3.1), it is likely that the capacity of the system will be exceeded.

Furthermore, with the number of households in Stanley increasing (Section 11.4.4.2.1.2) along with general diversification of the economy, there is a long-term trend of increasing annual water usage of 3.5 % per annum. Recent usage figures from 2023 show that current baseline water demand is 918 m^3/day so that the system is already close to capacity (*c.* 1,000 m^3/day) under current working practices.

While the Stanley population and other water consumers will be prioritised by FIG in the event of water shortage or system malfunction (Section 11.4.5.1) and the use of buffer tanks will reduce the risk of any daily demand spikes and associated drawdown in mains header tanks, there is still the potential for nuisance to other users (Section 11.4.4.1.2). Further, the above shows that with the ever-increasing Stanley usage, the existing water supply may not sustain the Development in the long-term. Therefore, the sensitivity of the receptors (Human Population and Tangible property) is considered to be **'Very High'**.

Restriction in supply or reduction in water quality through tainting caused by tank drawdown (Section 11.4.4.1.1) would be considered negatively. The consumers most likely to be impacted would currently be those on the low-level mains system predominantly in central Stanley, along the harbour front and FIPASS that share the same low-level supply tanks at Murray Heights as the TDF. However, since the whole of Stanley is reliant on a single filtration plant with potential single point failure, any significant issue could have wider 'knock-on' effects. These effects would generally be short-term and reversible, however with supply / demand in equilibrium, any unplanned usage or human error could cause impacts and following tank-draw down, the system may take several days or weeks to be fully recharged to capacity. Anecdotally, during exploration the accidental drawdown of one header tank took over a month to refill due to the equilibrium between demand and supply and insufficient excess to refill the tank (S.Cockwell, *pers. comm.*).

While development usage through Stages 1, 2a & 2b is not significantly different from exploration usage (offshore demands decrease but onshore demands increase relative to exploration), the system is currently operating at near capacity and average daily demand exceeded supply during the previous exploration campaign (Section 11.4.4.2.1.3). The ability to respond to increased demand or recover from tank drawdown is limited and the ability to maintain 2 - 3 full days' supply at all times may be restricted. Options to regulate demand (buffer storage) and reduce use have been identified, and the use of buffer storage has been committed to by Navitas (Section 11.4.4.2.2). However, as full analysis

of required tank volumes has not been confirmed, and since tank storage does not change the overall used volume but only buffers against demand spikes, the inherent capacities of the production system remain valid. Since it is currently FIG operating policy to restrict water supply to light industrial uses before any effect is transferred to domestic users, there is a degree of insulation from impact. However, if sustained deficit occurs, this restriction may not be sustainable for either the human population or the Development needs beyond a short-term response to temporary shortage. Therefore, the severity of effect of water usage on the Human population and the effect on Tangible property is considered to be '**Serious**'.

The overall significance of the impact of water use on the Human population and the impact on Tangible property during Stages 1, 2a & 2b is therefore considered to be '**High (20)**', and consequently project-specific mitigation measures to reduce the significance will be developed and implemented.

11.4.6.1.2 Water use during Stage 3

The impact assessment of Stage 3 must look forward *c.* 30 years and with uncertain predictions for the future growth of Stanley and associated increased water usage, all predictions become less certain (Section 11.4.4.2.1.2).

The sensitivity of the receptor is the same as described above. Water use by the Development will have decreased but Stanley usage may well have increased in line with ongoing trends (Section 11.4.4.2.1.2) and therefore there is uncertainty in the level of buffering capacity. Therefore, the sensitivity of the receptors (Human population and Tangible property) is considered to be '**Very High**'.

At commencement of Stage 3, upon cessation of drilling operations and simultaneous operations, the offshore water requirements drop to only vessel top-up and the onshore personnel numbers also reduce. However, whilst forecasted water demand drops, it is likely that Stanley usage will continue to increase over the intervening years. Since supply and demand are predicted to become matched in 2027, the forecast direct and indirect total for Stage 3 usage of 125 m^3/day will still exceed supply (Section 11.4.4.2.1.3). However it should be noted that with the historical trend of 3.5 % per annum increase in Stanley usage, the current capacity of 1,000 m^3/day will be surpassed with or without the addition of the Development demand. As such, FIG have already committed capital funding to improve the water supply system by 2025/26 (C. Summers, *pers.comm.*). The supply will therefore have changed relative to the demand making all predictions uncertain. This is addressed within the Cumulative Impacts section below (Section 11.4.9)

Given the closer equilibrium between forecasted supply and the forecasted demand during steady state production, any deficit is likely to be of short duration, most likely associated to crew changes within a two day period thus allowing time to accumulate water in the storage tanks. This ensures there will be some buffer against nuisance to the human population (Section 11.4.4.1.2). Therefore, the severity of effect of water usage on the Human population and the effect on Tangible property is considered to be '**Moderate**'.

The overall significance of the impact of water use on the Human Population and the impact upon Tangible Property during Stage 3 is therefore considered to be '**Upper Moderate (15)**' and consequently project-specific mitigation measures to reduce the significance will be developed and implemented.

11.4.7 Project-specific mitigation measures

Navitas will work closely with FIG to ensure that water utilities are developed and water use is suitably controlled. This will require liaison and cooperation between the public utility sections of FIG and Navitas in order to best meet increased demands without impacting domestic residential supplies or commercial sector usage.

Project-specific mitigation that is within Navitas' control is primarily based around planning and logistics.

11.4.7.1 Offshore planning & supply logistics

All planning will remain cognisant of the need to minimise water requirements and will continue to identify where water efficiency can be improved and usage minimised. There are many actual and potential measures within Navitas' control that can be instigated to balance or offset demand at peak times, including:

- Ensure reliability of water supplies is built into project design premise and operational processes/contingencies, to avoid environmental impacts from unnecessary shutdowns or slowdowns.
- Put in place, and monitor, offtake limits to the Supply Base and TDF (daily average volume and instantaneous rate, precise figures to be agreed with FIG),
- Communicate to FIG water department significant demand points within the overall schedule,
- Replacement of potable water with seawater where possible (e.g., tophole sweeps), this will significantly reduce drilling fresh water demands (Section 5.11.4.2.7),
- Potential to have the MODU pre-supplied with full water on delivery and use of storage capacity onboard the MODU,
- Importation of water to the MODU using additional incoming vessels that arrive with full freshwater tankage onboard, and
- Specify that some items will come pre-filled with inhibited water during subsea installation to reduce additional flushing needs. In some applications, seawater can be used in replacement for fresh water.

11.4.8 Residual impacts and risks

11.4.8.1 Stage 1, Stage 2a & 2b residual impacts

While the added project-specific mitigations may lessen reliance on the Stanley water system, additional mitigation focused on reduced use does not actually change the inherent sensitivity of the receptors (Human population and Tangible property) which remains **'Very High'**.

However, as regards the severity of effect, the further reductions that will be identified through the FEED process in offshore logistics will reduce reliance on shore supplies further. This will insulate current domestic usage from impact. Although not specifically a mitigation measure, monitoring of water use will highlight any issues early and allow water use to be restricted early prior to any widespread effect occurring. Furthermore, by reducing usage further, the duration of any effect will be less as the supply will be able to recover faster. Therefore, the severity of effect of competition for water usage will reduce to **'Moderate'**.

The overall significance of the impact of water competition on the human population is therefore reduced to **'Upper Moderate (15)'**.

11.4.8.2 Stage 3 residual impacts

All additional project-specific mitigation measures address planning and logistics to reduce water use during the drilling and construction phases such that there is no change to the assessment within Stage 3 and the significance of the impact remains **'Upper Moderate' (15)**.

11.4.9 Cumulative impact

Competition for water as a resource is not only incurred by O&G activities and there is the potential for cumulative impacts *via* increased 'concentration' (Section 8.9.1). Indeed, even if oil development usage remains constant, competition may still increase if domestic or other economic sector usage increases. Between 1995 to 2017, Stanley usage has increased by 74 % from 492 m^3/day to 860 m^3/day and continues to rise with a daily usage of 918 m^3/day in 2023. Forecast growth in water usage is difficult to predict and will depend upon socio-economic factors, but long-term historic trends would suggest an annual increase in water demand of between 3.5 % per annum. Further, past exploration rounds have shown an approximate 6 – 8 % increase in water use above base levels that cannot be directly attributed to O&G infrastructure use but may relate to associated services and increased economic activity.

It can be assumed that O&G development will bring associated wider economic growth that will in turn result in greater water demands. With a finite cap on water volumes available, competition is likely to increase over the duration of the project even if direct water use within the project remains constant. However, this will be buffered against once steady state production is reached (Stage 3) and water demands decrease. In the absence water usage during drilling, the offshore demand will almost cease with only contingency for support vessel top-up. The peak demand of the Phase 1 & 2 development is relatively short-term, during a period of approximately 5.5 years in Stages 1, 2a & 2b.

11.4.10 Confidence

There are a number of uncertainties within the above assessment. These are as follows:

- While the requirement for a buffer storage capacity has been included within the base-case mitigations, the tank volumes have not yet been defined and although they will be based upon the forecast (and conservative) daily averages, their efficacy will depend upon the accuracy of the forecast,
- While the yard area and accommodation bed capacities have been determined, the final design and incorporation of sustainable technologies, which may lessen water demands, have not been finalised,
- The cause of unallocated water use increase and the proportional contribution that may be associated to the wider O&G stimulated activity is difficult to quantify with certainty, and
- The Stage 3 assessment is based on the assumption of continued growth in water usage of *c.* 3.5 % p.a. which may change.

Therefore, the level of confidence in the impact assessment and the efficacy of mitigation is therefore considered to be '**Uncertain**'.

11.4.10.1 Monitoring required

Use of onshore water supply will be monitored at all infrastructure locations and will be included within the Environmental Monitoring and Management Plan (EMMP) for on-going assessment to identify any emerging issues at an early stage. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 EMMP (an outline EMMP is provided in Chapter 15).

11.4.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

11.4.12 Findings summary

Table 11.24: Summary of the impact assessment for water use resource competition during the Sea Lion Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Water use for MODU drilling, vessel top-up, onshore yards and accommodation	Competition for water resources	Restriction of water supply and/or quality	Planned	1, 2a & 2b	Very High	Serious	n/a	**High (20)**	**Upper Moderate (15)**	**Uncertain**	**Industry-standard:** End user prioritisation, Buffer tank capacity and voluntary restrictions, and Offshore desalination, **Project-specific:** Sustainable design, and Offshore planning.
Water use for offshore vessel top-up, onshore yards and accommodation			Planned	3	Very High	Moderate	n/a	**Upper Moderate (15)**	**Upper Moderate (15)**	**Uncertain**

11.5.1 Introduction

Onshore and at-shore infrastructure in support of the Phase 1 & 2 Development will require connection to the existing electrical power grid of Stanley for energy requirements. Stanley power station (owned and managed by FIG) is the single energy utility supplier and has a fixed power capacity from a finite number of generators and a series of wind turbines. Energy can thus be considered a limited resource and both the carrying capacity of existing infrastructure and competition for resources were raised as a concern during the scoping consultations (Chapter 6).

This chapter investigates the forecasted energy use and compares it to the power capacity and current level of Stanley energy demand. The forecast difference between Phase 1 & 2 Development demand and the current excess power capacity is used to inform the assessment.

Note: impacts related to competition for other resources e.g., accommodation, water etc. are described elsewhere in this document as described in Table 2.2.

11.5.1.1 Relevant legislation

Resource competition is not legislated for specifically within any Ordinance or Regulation and therefore no statutory limits are defined through legislation.

However, as was agreed during the consultee scoping workshop with FIG in 2015 (Chapter 6), the social impacts of competition for resources such as electricity was considered to be within the scope of the EIS as defined by the EIS Guidance Note (FIG, 2016e).

11.5.2 Sources of onshore energy use

Sources of energy use and thus sources of resource competition during the Phase 1 & 2 Development include:

- Use of the Temporary Dock Facility (TDF) (Section 5.11.1.1.1),
- Use of the onshore laydown yards, storage bases and associated offices (Section 5.11.1.2),
- Use of accommodation (Section 5.11.4.1):
  - Transit accommodation, and
  - Rental accommodation.
- Heliport aviation (Section 5.11.3.1.2).

11.5.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts of resource competition warranted further investigation (Chapter 9).

Receptors that may be directly and indirectly impacted by power usage associated with the Phase 1 & 2 Development include:

- Tangible Property (finite power supply) (Section 7.7.4.5.5), and
- Human Population (in Stanley) (Section 7.7.2).

A degree of interdependence exists between the receptors as any impact upon power utilities (Tangible Property) will also impact upon the Human Population that is reliant upon it.

This assessment is based upon the human population of Stanley and is confined to the area within the coverage of the Stanley Town Plan and Stanley power station supply. Onshore and at-shore logistical support services, and associated accommodation, are or are most likely to be, based within close proximity to Stanley.

11.5.4 Characterising and quantifying the impact of onshore energy use

11.5.4.1 Nature of potential Impact

Electrical energy is provided to Stanley through a single power and distribution network. No alternative supply is available. Power and energy usage is therefore capped by the existing generator capacity and thus, in a practical sense, electricity can be considered as a finite resource (Section 7.7.4.5.5).

To ensure a worst-case is assessed, the contribution of wind-power is discounted from this assessment as it is dependent upon meteorological conditions and cannot be fully relied upon. If there is no wind there is no power so it is necessary for the diesel generator capacity to be sufficient to meet needs.

With a single point supply and finite capacity, energy provision to Stanley residents and other commercial users is vulnerable to increased or excessive demand. Unlike water where buffer storage capacity may insulate users from temporary supply issues, any interruption or over-load to the electrical system will cause immediate impact.

Increased demand may cause:

- Increased wear and tear of generator infrastructure if it is operating at capacity for extended periods (it is an aging system which is vulnerable to single point failure),
- Operating at, or near, capacity removes spare stand-by generator capacity to buffer against generator drop-out or demand spikes, potentially causing temporary black-out or power surges,
- Spikes in power use within the distribution grid may cause over-load of distribution transformer boxes and / or generator surge causing black-out to users on a shared electrical main, and
- Power surge and drop out may damage modern electronics; computers, communications and even domestic appliances (such as kerosene heating and gas cooking) now largely rely upon an electric power source for operation.

All of the above may impact upon the availably of the finite resource (electricity) to the end user, thus impacting upon Tangible Property and the Human Population.

11.5.4.2 Quantification of energy use

In order to assess the sensitivity of the power grid to increased demands it is necessary to understand the baseline electrical capacity. To quantify the baseline, it is necessary to consider both the overall amount of energy available (kWh), as well as the peak power (kW) available at any given time. Therefore, electrical capacity needs to be considered in terms of the:

- ‘Overall energy use’ - this is the total energy (power use over time) used over the course of the day and is measured in KiloWatt hours (kWh) or units (1 kWh = 1 unit), and
- ‘Peak power demand’ - this is the maximum amount of power required at any given moment in a day and is measured in KiloWatts (kW).

Overall energy use is the metric used to understand the difference between normal electrical usage and the increased overall use when Oil and Gas (O&G) operations are occurring. However, as a metric, ‘overall energy use’ cannot tell us the whole story as it is also necessary to understand how much electrical power may be available at any one moment in time. As electricity must be supplied instantaneously with no storage potential, and since energy use is not uniform through the day, it is the increase in peak power demand that is critical to assessing the ability of a system, and the available generators, to supply enough electricity.

The question is: if all users 'switched the lights on at the same time', could the capacity of the existing Stanley power supply cope with the total demand?

Therefore, in order to inform the impact assessment, the following section describes:

- Current overall energy use in Stanley (i.e., the baseline usage, here including the exploration drilling campaigns),
- Forecast Phase 1 & 2 energy use relative to existing supply use, and
- Peak Phase 1 & 2 power demands and output.

11.5.4.2.1 Current energy use (including exploration drilling campaigns)

The average daily energy use over the last ten years (2013-2023) was 48,889 kWh/day.

Within the ten-year data set, the lowest average daily energy use (averaged over the year) was 44,308 kWh/day in 2013-14, during which there was no oil exploration activity. The highest, over a time which did have exploration drilling, was 51,162 kWh/day in 2015-16 which saw eight months of exploration activity. This shows that past exploration campaigns have resulted in an increase of *c.* 16 % (rounded up) of the overall daily average Stanley energy usage from the immediately preceeding year without exploration (Table 11.25). More recent figures show a continued increasing trend with a 2022/23 daily use of 53,481 kWh/day, a 21 % increase over 2013/14 Stanley usage and a 5 % increase over total energy use during the last exploration campaign in 2015. 2022/23 is the first year that Stanley energy use alone (53,481 kWh/day) has exceeded energy use of both Stanley and the O&G industry during the last drilling campaign in 2015 (51,162 kWh/day).

As such, some caution must be exercised when attributing increased energy use and power demand to oil exploration activities only. Whilst there was a 16 % increase in overall energy usage between 2013-14 (without exploration) and 2015-16 (with exploration), in subsequent years usage did not return to former levels. Indeed they continued to increase, surpassing energy used in 2015, suggesting that a component of the increases is also due to increasing residential and economic diversification activities. However, to provide a conservative and 'worst-case' scenario the current assessment assumes that the full increase (16 %) was attributable to the direct and indirect effects of oil exploration activities.

11.5.4.2.2 Forecast Phase 1 & 2 energy use relative to existing supply

11.5.4.2.2.1 Data sources

The data used to forecast energy use during the Phase 1 & 2 Development are largely based upon recorded energy use during the 2015 *Eirik Raude* exploration drilling campaign. These data were extrapolated according to the expected changes in land area used and personnel numbers during the Development. Full detail on the forecast figures for energy use are presented in Section 5.11.4.3 and summarised below (Table 11.25).

11.5.4.2.2.2 Energy use during exploration rounds

During exploration, direct usage by the four main exploration infrastructure centres (TDF, laydown yards, accommodation unit, and heliops hanger) had an average total daily usage of 3,025 kWh, representing a 7 % increase in pre-exploration Stanley usage (Table 11.25 below). However, as described above, overall Stanley usage increased by 16 % during the 2015 drilling campaign.

For the purposes of this assessment it is presumed that the remaining 9 % (rounded up to 10 % for this assessment) increase in usage can be attributed to contracted services (such as laundry, rental accommodation, offices) and associated increases in wider economic activity (hotels, restaurants, general services, water pumping, etc.), which may or may not have been fully associated with the exploration campaign. A proportion of the increase may have been down to an unrelated residential

and economic activity such as fishing industry cold-storage. Despite this unknown, it is prudent to consider a contingency for such usage within the impact assessment. An overall increase in utility use of *c.* 16 % would appear consistent with other services such as water usage that increased by comparable amounts (Section 11.4.4.2.1.3).

11.5.4.2.2.3 Forecasted Phase 1 & 2 Development energy usage

While the Development infrastructure centres will essentially be the same as those used during exploration, there are three main differences:

- During Stages 1, 2a & b, the onshore supply base will be approximately 2.5 times larger than that used during the exploration campaign and will be in place for approximately five and a half years, and
- During Stage 3, steady state production, the onshore supply base will decrease in size to approximately 40 % of the area used during the exploration campaign.

Based upon the overall increases to the supply base, accommodation requirements and heliops base, Phase 1 & 2 energy usage may total 19 % (9 % of which is directly attributable) of current Stanley usage in Stages 1 and 2, and 16 % (6 % of which is directly attributable) in Stage 3 (Table 11.25). It should be noted that as the population of Stanley grows, so will electricity demand, meaning the percentage overall spare capacity may be lower (assuming there is no increase to available electricity supplies, such as the new power station, for the duration of the Sea Lion project).

As described above, and to take a precautionary approach, an additional 10 % has been added to the attributable total to account for the additional, but unattributed, power use in contracted services and wider economic activity that may result from O&G activity. It could be argued that these unassociated increases should be proportional to the Phase 1 & 2 Development increase, however, as the exact cause of the extra 9 % usage increase observed during exploration is not known, a nominal addition is made.

Table 11.25: Summary of exploration use and forecast Phase 1 & 2 energy use

Facility	Exploration usage (kWh / day)		Proportionate increase in development usage expected	Forecast Phase 1 & 2 usage	
	kWh / day	% Increase to Stanley usage[1]		kWh / day	% Increase to Stanley usage[2]
Stages 1, 2a & 2b					
TDF base load	125	0.3	None	125	0.2
Laydown yards	358	0.8	Increase in area x 2.5	895	1.7
Accommodation facility	1,653	3.7	Increase in maximum personnel numbers x 2	3,150	5.9
Heliops base	889	2	None	889	1.7
Attributable total	**3,025**	**7 %**	**Attributable total**	**5,059**	**9 %**
Unattributable contribution[3]	-	9 %	Unattributable contribution	-	10 %
Total	**-**	**16 %**	**Precautionary total**	**-**	**19 %**
Stage 3					
TDF base load	125	0.3	None	125	0.2
Laydown yards	358	0.8	40 % of exploration yard area	142	0.3
Accommodation facility	1,653	3.7	Small increase in personnel numbers x 1.14	1,886	3.5
Heliops base	889	2	None	889	1.7
Attributable total	**3,025**	**7 %**	**Attributable total**	**3,044**	**6 %**
Unattributable contribution[3]	-	9 %	Unattributable contribution	-	10 %

Facility	Exploration usage (kWh / day)		Proportionate increase in development usage expected	Forecast Phase 1 & 2 usage	
	kWh / day	% Increase to Stanley usage[1]		kWh / day	% Increase to Stanley usage[2]
Total	-	**16 %**	**Precautionary total**	-	**16 %**

[1] Compared to Stanley usage in year immediately preceding O&G operations: 44,308 kWh/day in 2013/14

[2] Compared to Stanley usage in most recent year without O&G exploration: 53,481 kWh/day in 2022/23.

[3] Unattributable usage may not be directly related to O&G activity, however any wider increase in Stanley usage, even if unrelated, will also reduce any excess capacity so a nominal additional increase is included to cover associated and unassociated increases.

11.5.4.2.3 Peak Phase 1 & 2 power demand vs. output

As described above, it is necessary to understand the peak power demands to determine whether or not the Stanley power station will be impacted by the O&G operation making power demands at the same time as other local users.

11.5.4.2.3.1 Stanley power generation capacity

Details on the current Stanley power generation are provided in the Baseline Description (Section 7.7.4.5.5). In summary, the FIG Power Station is the electrical distribution hub and balances supply from the generators and the Sand Bay wind farm. The power station currently uses eleven generators of differing capacity. However, very importantly, the amount of power available at any given time depends upon the combination of generators that are in use, on standby or under deep maintenance.

While varying combinations of generator status exist, the maximum power capacity is around 3,200 kW (J. Greenland, *pers comm.*).

It is recognised within capital project planning and the Stanley Town Plan (FIG, 2015d) that eight of the current 11 diesel generators are reaching the end of their design life with resultant issues for capacity, reliability and maintenance costs. Three additional high-speed sets have provided an interim solution and contingency planning is progressing towards a new power station in a new location for the long term. FIG note that with capital funding commitments there will be significant change to energy provision in Stanley by 2025/6 (C. Summers, *pers. comm.*).

As these improvements are outwith Navitas' control, the following assesses the impact of Phase 1 & 2 energy use against the current Stanley baseline.

11.5.4.2.3.2 Stanley peak power demand (including exploration campaigns)

Stanley power demand varies depending upon:

- The time of year (generally higher in winter),
- The time of day (peaks late-morning / midday with lesser peak in early evening and off-peak overnight),
- Whether it is a weekend or a week-day, and
- Whether O&G activity is on-going.

Typically, energy demand is higher in the winter and higher during the day with lowest use (or off-peak use) falling between 2300 - 0600 hrs.

Peak power demand during exploration was 3,320 kW while the average peak demand without exploration was 2,756 kW (in 2013-14, the year preceding exploration). This amounts to an estimated increase of 564 kW power demand during the 2015 exploration campaign. The FIG Public Works Department (PWD) power section estimated that, on average, the total impact on Stanley power load from oil exploration was *c.* 500 kW (i.e., *c.* 18 % above non-exploration) (G. Ross, *pers. comm.*).

11.5.4.2.3.3 Phase 1 & 2 forecast peak power demand

The individual demands of exploration infrastructure centres, alongside the extrapolated Phase 1 & 2 demands, are given in Table 11.26 and approximately match expected estimates if the unattributable services (such as those described above) are also considered. However, it should be noted that it is extremely unlikely that each infrastructure facility would peak at the same time. For example, accommodation demand may be higher when yard or heliport demand was lower, and thus the likely contribution of unattributed sources is more significant than the data would initially suggest. Indeed, the unattributed sources increase the power demand to the equivalence of all facilities operating at peak. Table 11.27 shows the peak power demand as it compares to the average Stanley power demand and shows that at peak, overall demand from Stanley plus the Phase 1 & 2 Development has the potential to exceed the available capacity in the system.

Note: as stated before, the current assessment assumes a conservative worst-case scenario with all facilities peaking at once and applies it to the current *status quo* of power generation. That this approach suggests a deficit of *c.* 179 kW may occur at critical times without mitigation should be considered alongside the proposed FIG improvements to the energy supply in Stanley, which is expected to be online in 2025/26 (C. Summers, *pers. comm.*).

Table 11.26: Contribution of exploration infrastructures to power demand

Facility	Peak Power (kW) use during exploration	Smoothed 24 hour average power equivalence (kW)	Estimated Phase 1 & 2 peak power (kW)
Heliops hanger	250[1]	37[2]	250
Accommodation facility	120 – 140[1]	69[2]	137 - 160
TDF (estimate)	25	5[2]	25
Laydown yards (estimate)	75	15[2]	188
Total attributable load	470 - 490	126	600-623

[1] PWD figures (G Ross, *pers. comm.*).
[2] Figures derived from average kWh/day meter readings.

Table 11.27: Current Stanley power demand with forecast O&G development demands versus current baseline capacity

Average Stanley power demand (non-exploration) (kW)		Peak potential Phase 1 & 2 demand (kW)	Potential overall demand (kW)	Current baseline capacity (kW)[1]	Excess Capacity (kW)
Total demand of all activities if operating at the same time					
Stanley typical maximum power demand	2,756	623	3,379	3,200	(-179)

[1] Baseline Stanley power station generator capacity (J. Greenland, *pers comm.*).

11.5.5 Industry-standard mitigation

Within larger economies there is generally a national network with the capacity to absorb and respond to increased demand and therefore, no industry-standard mitigation or Codes of Practice exist.

11.5.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

Assessment of the impact of energy use is challenging as it is understood that the Stanley baseline in terms of energy availability may change within the next few years. However, this is outwith Navitas' control and, therefore, the following assessment is based on the current baseline.

A summary of the impact assessment outcomes for this Development is tabulated in Section 11.5.12 which shows the worst-case impact for each activity and receptor, and details are provided below.

11.5.6.1 Impact of power use of the Phase 1 & 2 Development

Electricity is an essential utility upon which almost all daily activity depends in an increasingly electronic age, from heating controllers, lighting, refrigeration, to computers and communications. Whilst emergency services are protected with auxiliary generators, any interruption in supply would be immediately noticed and cause high levels of inconvenience and nuisance within the Human Population. Unlike water, where a buffer storage capacity may insulate the population from immediate impacts, the effect of electrical supply issues would be immediate. Further, with regard to electricity as a Tangible Property, Stanley's current baseline capacity is such that it may be unable to sustain peak demand spikes in the short-term and therefore must be considered a finite resource which has the potential to be unsustainable in the immediate term (Section 11.5.4.2.3.1). Notwithstanding the fact that any interruption would be restored, the sensitivity of the receptor (Tangible Property) is considered to be '**High**'.

Overall energy demand from the Sea Lion development is limited to onshore assets and infrastructure. It is expected that the Phase 1 & 2 usage will be similar in nature to the exploration campaigns, with increases in power usage being proportional to the size of infrastructure and increases in personnel numbers. These increases may result in a worst-case 19 % increase in Stanley electrical energy usage during Stages 1 and 2 (Section 11.5.4.2.3.3). Further, at peak, overall demand from Stanley plus the Phase 1 & 2 Development has the potential to exceed the available capacity in the system (Table 11.27). As the use of the finite resource has the potential to be extensive but infrequent as it is only peak power usage that will exceed capacity, the worst-case severity of effect (to Tangible Property) of daytime power use is considered to be '**Serious'**.

The overall significance of the impact of competition for electrical energy during daytime hours is therefore assessed as '**High (16)**'. Consequently project-specific mitigation measures to monitor and, where possible, reduce the significance will be considered.

11.5.7 Project-specific mitigation measures

Navitas will liaise closely with FIG in preparation for 'oil readiness' to ensure that energy supply and demand are in balance. These discussions will include those based on future FIG development of power capacity (Section 7.7.4.5.5.3), not least because minimising risks of loss in energy continuity is important to the Phase 1 & 2 Development as well as to the human population.

However, while future improvements to the FIG power station may alter the impact assessment by altering the baseline (e.g., by lessening the sensitivity of the receptor as a finite resource and the severity of effect by lowering the Phase 1 & 2 demand as a percentage of the available power), these changes are outwith Navitas' control and cannot be used as a mitigation within this assessment.

Nonetheless, a number of mitigating and ameliorating strategies that *are* within Navitas' control will be incorporated into the Phase 1 & 2 Development during the FEED process. These include:

- Sustainable and energy efficient design,
- Off-peak power utilisation, and
- Presence of a small diesel fueled electricity generators at the onshore base:
    - Noise monitoring alongside the generator use.

11.5.7.1 Sustainable design

Where feasible, sustainable design and energy efficiency will be included in infrastructure and asset design, this may include where appropriate:

- Lighting set at minimum levels (which are still appropriate for safety),
- Low energy types and photosensitive light switching utilised where appropriate,
- Energy efficiency incorporated within buildings through insulation, heating systems, thermostats, timer switches, etc., and
- Back-up emergency generators and switchgear will be provided for essential systems (allowing disconnection from grid in the event of an emergency).

Optimal energy use will be incorporated within all design considerations through the FEED process, as will lessons learned during the exploration campaigns. For example, the shorter-term exploration activities relied upon modular and / or temporary built assets. The modular buildings tended to rely to a greater extent on electrical heating and usage. It is assumed that permanent buildings will be more efficient in energy design and that kerosene, water and forced air heating may be feasible options to reduce *per capita* electrical energy use. Space heating through electrical forced air heaters was the greatest power demand at the exploration heliops hangar accounting for 96 % of the peak 250 kW load.

11.5.7.2 Off-peak power utilisation

Highest power demands occur between 08:00 – 18:00 hours with an approximate mid-day peak and lower energy use at night. Therefore, there is the potential to minimise impacts by taking advantage of off-peak periods for high power use activities and processes, where possible. Such use would average overall demand through the 24-hour period and reduce the likelihood of any capacity issues or impacts through the day when domestic demand is highest. Overall energy usage (Section 11.5.4.2.1) may not drop but, as it would be utilised during a period when other demands are lower, the impacts on peak demand could be minimised.

11.5.7.3 Use of a diesel generators for electricity generation

While electrical power for the laydown yard will be sourced from the municipal supply, some small diesel fueled generators within the laydown yard may be required. In the event of power failure, contingency power will be provided by these standby generators. This is proposed as a back-up to the local supply and to prevent any domestic grid overload on Stanley supply; development of this facility will be made in consultation with PWD.

11.5.7.3.1 Noise and electricity monitoring

As is described in Chapter 15, monitoring will be carried out to assess any impacts of noise associated with the generator use and Navitas will have a formal complaints process in place, with a member of staff assigned to respond. In the event that monitoring indicates noise is an issue for local residents and that monitoring of power use through the night indicates any problem with capacity, other solutions may be sought to mitigate against both power use and noise.

11.5.8 Residual impacts

11.5.8.1 Impact of power use from the Phase 1 & 2 Development

The above project-specific mitigations (e.g., low energy buildings and the optimal use of off-peak periods) may lessen the sensitivity of the Stanley power supply (Tangible Property) as a finite resource and therefore would lessen the likelihood of the Human Population being subjected to downtime in power availability. Therefore, the sensitivity of the receptor (Tangible Property) can be reduced to '**Moderate**'.

The mitigations described above incorporate use of off-peak periods, energy optimisation and the monitoring of energy use to identify any emerging issues early. This provides for the ability to respond by modifying work practices or upgrading capacity. Energy efficiency in design will be promoted

throughout the FEED stage of the project and it is expected that savings can be made relative to exploration usage upon which the Phase 1 & 2 estimates were based. It is believed that through close attention to energy use, power needs could be further reduced below the threshold level of 3,200 kW. However, because the energy savings cannot be quantified at this stage, and to take a precautionary approach given that there is no excess capacity within the system once peak Phase 1 & 2 activities are added, the severity of effect cannot be reduced and remains 'Serious'.

The overall significance of the impact of competition for electrical energy on the human population of the Falkland Islands is therefore assessed as '**Upper Moderate (12)**'.

11.5.9 Cumulative impact

The current assessment deals specifically with the electricity usage of the Development assets and infrastructure centres. Cumulative socioeconomic impacts from wider economic activity will be further assessed within the separate Socio-economic Impact Assessment (Section 6.2.2.1.1).

However, to be conservative a component of cumulative impact is already incorporated within the assessment. The disparity between direct O&G sector usage by infrastructure centres and the overall increase in Stanley usage exhibited during exploration illustrates the cumulative effect in energy use of the overall increase in economic activity. Unattributed cumulative usage contributed an additional 9 % in usage (Section 11.5.4.2.2.2) that was considered and included in calculations. It should however be noted that as the population of Stanley grows, so will electricity demand. Consequently, the excess capacity available for O&G activity will decrease unless additional infrastructure is developed to cover the additional usage.

Note: FIG note that with capital funding commitments there will be significant changes to energy provision in Stanley by 2025/26 (C. Summers, *pers. comm.*).

11.5.10 Confidence

The scale of Development activity is defined by area and personnel, both of which are known. A degree of uncertainty exists within some of the baseline figures and exploration figures have been used to provide the basis of the assessment. These actual-use figures have been scaled by any expected changes between the level of exploration activity and development activity. Energy use (kWh) is metered and recorded however instantaneous power use which is the most critical parameter in matching development peak demands to generator capacity is not recorded at infrastructure centres and is based upon estimates. There is therefore a degree of uncertainty in figures and within the extrapolated estimates.

Overall, Stanley demand was estimated including uses directly attributable to the O&G operations, as well as noting that there were additional uses that could not be directly attributable. However exact quantification of how this is split between service sectors and how much is directly associated to O&G activity as opposed to a general increasing trend in Stanley usage remains unclear.

Liaison between Navitas and FIG, as the service utility provider, is on-going. A number of utility infrastructure upgrades are already incorporated within FIG planning and are progressing, and significant improvements to energy provision in Stanley are anticipated by 2025/26 (C. Summers, *pers comm.*). However, although this is progressing it is not within the control of Navitas and thus no assumption based on these plans were included within the assessment.

Based on the above, on balance, the level of confidence in the impact assessment is considered to be '**Uncertain**'.

11.5.10.1 Monitoring required

Energy use will be monitored and reported to measure environmental and social impacts and to identify any emerging issues early. Detailed monitoring requirements have been established during the Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 Socio-Economic Monitoring and Management Plan (SEMMP).

11.5.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

11.5.12 Findings summary

Table 11.28: Summary of the impact assessment of energy use on the competition for resources

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Electrical energy use onshore by the TDF, laydown yards, accommodation facilities & heliops	Competition with domestic energy needs	Overloading of current capacity	Planned	1, 2a, 2b & 3	High	Serious	n/a	**High (16)**	**Upper moderate (12)**	**Uncertain**	**Industry-standard:** None. **Project-specific:** Sustainable design, Off-peak power utilization, and Back-up generators

11.6.1 Introduction

In addition to the use of accommodation, freshwater and electricity, the Phase 1 & 2 Development will require the use of air-links to the Islands in order to transport personnel and cargo throughout Field Life. The Falkland Islands have limited international air-links / flights and therefore, additional and regular requirements have the potential to impact upon the availability of seats for local residents and other visitors. The level of resource competition is determined by the forecast difference between the Sea Lion Development demand, and the current excess capacity in available seats.

Both the carrying capacity of existing infrastructure and competition for resources were raised as a concern during the scoping consultations (Chapter 6).

This chapter investigates air-link provision and specifically, the competition for seat availability on international flights.

Note: other impacts related to the competition for resource e.g., accommodation, water, electricity and roads, and those associated with the use of transportation e.g., emissions etc. are described elsewhere in this document, see Table 2.2.

11.6.1.1 Relevant legislation

Resource competition is not legislated for within any specific Ordinance or Regulation and therefore, no statutory limits are defined through legislation. However, as was agreed during the consultee scoping workshop with FIG in 2015 (Chapter 6), the social impacts of competition for resources, such as the use of air-links, was considered to be within the scope of the EIS as defined by the FIG EIA Guidance Note (FIG, 2016e).

11.6.2 Sources of air transportation competition

All expatriate (expat) personnel involved during the Phase 1 & 2 Development, both onshore or offshore, will require air transportation to the Falkland Islands at the beginning and end of their contract periods. A small number of technicians, managerial and administrative personnel may also be required to visit independently of offshore work programmes and crew exchanges. The sources of competition for seats on air-links are therefore the same as those for accommodation listed in Section 11.3 above.

11.6.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts of resource competition warranted further investigation.

Receptors that may be impacted by air-link usage associated with the Phase 1 & 2 Development include:

- Human Population (Section 7.7.2), and
- Tangible Property (Section 7.7.4).

In particular, the use of existing air-links by the Sea Lion Phase 1 & 2 Development for personnel movements could significantly impact upon seat availability, thus limiting seat availability for:

- Resident travel and flexibility (including children in education),
- Commercial interests of other sectors such as:
  - Land-based tourism (land based and rural development),
  - Cruise ship tourism (passenger exchange), and
  - Fishing (crew exchange and business travel).
- Medical flight planning and capacity, and

- Veteran visits.

11.6.4 Characterising and quantifying the impact of service competition

When characterising and quantifying the impact of competition with regard to air-links to the Falkland Islands, it is necessary to consider the following:

- Availability of seats on standard air-links, and
- Navitas personnel transportation requirements.

11.6.4.1 Seat availability on standard air-links

As is detailed in the Environmental and Social Baseline (Section 7.7.4.3), the standard air-links to the Falkland Islands are currently limited to a twice weekly Ministry of Defence (MoD) flight from the UK (i.e., the air-bridge), and once weekly LATAM flights scheduled between the Islands and Chile.

On average, unallocated seat capacity is 103 seats / week (nine seats / week on the air-bridge and 94 seats / flight on the LATAM flights) (Section 7.7.4.3).

However, seat availability is highly seasonal and the unallocated seats may be used by:

- Students during school and college recesses,
- Summer tourism demand,
- Cruise vessel passenger exchanges,
- Medical flight requirements, and
- Occasional MoD operational and mobilisation requirements.

Taking the above into account, almost all air-bridge flights and around five LATAM flights per annum may be full to capacity such that the availability of excess seats for additional needs, e.g., those of Navitas, is expected to be limited and unreliable.

Furthermore, due to scheduling efficiency, Navitas has a preference for increased standards of seating-class options in certain situations. This efficiency would be reduced in the case of the MoD air-bridge which is provided with only economy class seating provision.

11.6.4.2 Navitas transportation requirements and provision

The Phase 1 & 2 Development will require available and reliable fixed-wing flights to transport all expat personnel to and from the Falkland Islands for the entire duration of the Sea Lion Field life. The forecast requirement for exchange of personnel peaks at approximately 110 people per week during Stage 1, Stage 2a and Stage 2b when simultaneous activities of the Floating Production, Storage and Offloading (FPSO) unit commissioning and continued drilling run in parallel (Table 11.29).

Recognising the limited capacity, variable seat availability and limited seating-class options within existing air-links, Navitas has committed to a dedicated charter flight to meet personnel flight requirements when drilling commences. Dedicated charter flights assume that there will not be increased commercial air-links to the Falkland Islands with sufficient capacity within the initial timeframe of the Sea Lion Development peak loading. If this changes, Navitas will assess any newly available airlinks, taking into consideration competition for seats and seat availability.

During drilling (Stages 1, 2a & 2b) of the Development, dedicated charter flights will fly fortnightly.

Following the completion of Sea Lion drilling activity and the entry of the project into steady state production operations (Stage 3), the number of personnel that need to be routinely moved to and from the Falklands reduces to a maximum of 20 per week (Table 11.29). The need for the dedicated charter flight will be reviewed at this time to determine whether or not existing commercial flights could be used without detriment to the receptors listed above (Section 11.6.3).

A dedicated charter flight is the current base-case given current available air links and seat capacity. Additional air-link initiatives and potential transfer through South America will be continually monitored at all stages to determine whether this may supplement or provide an alternative to dedicated charter flights. If other routes open up in the future these will only reduce pressure on existing routes.

In addition to charter flights for routine personnel exchange, insurances will be in place for use of an air ambulance link to hospitals in South America or outside of the Falkland Islands to facilitate the evacuation of personnel with injuries which require treatment that is not available at the King Edwards Memorial Hospital.

Table 11.29: Air-link seat capacity requirements during the three stages of the Sea Lion Phase 1 & 2 Development

Development Stage	Offshore personnel (transiting through the Falklands at beginning or end of their rotations) per month	Onshore personnel rotation per month[1]	Total per month
Stage 1: Onshore Infrastructure Construction Pre-First-Oil Drilling, FPSO Moorings (Duration = *c.* 2.5 years)	495	24	519
Stage 2a & 2b: Post First-Oil Drilling, Offshore Construction and Production (Duration = *c.* 3 years)	495	22	517
Stage 3: Steady State Production (per annum) (Duration = *c.* 27 years)	85	13	98

[1] The management staff recruited from overseas will be employed on an unaccompanied basis and so will not require regular flights for dependents. Any Sea Lion management personnel recruited locally, and their dependents are assumed to be already resident and therefore their demand for flights is included within the current baseline flight demand.

11.6.5 Industry-standard mitigation

No industry-standard mitigation, threshold levels, or codes of practice are applicable to air-link resource competition. No acceptable or permissible limits are set through industry codes of practice.

11.6.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

A summary of the impact assessment outcomes for this Development is tabulated in Section 11.6.12 which shows the worst-case impact for each activity and receptor and details are provided below.

11.6.6.1 Use of air-links

As described above, the Falkland Islands currently have limited air-link capacity and rely upon these links as the sole means of international travel into and out of the Islands. Whilst there is some excess capacity in the number of seats available (Section 11.6.4.1), this is variable through the year and insufficient for the requirements of the project without restrictive block-booking agreements which could be to the detriment of the Human Population. Therefore, the sensitivity of receptor is considered to be '**High**'.

With the Phase 1 & 2 base-case commitment to provide a dedicated charter flight to meet its transportation needs, the existing air-link capacities would only be used for a small number of *ad hoc* business unit, administrative or technician visits that may be necessary from time to time between fortnightly scheduled flights. Therefore, the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of impact upon air-link provision is '**Low (4)**'.

11.6.6.2 Provision of air-links

No commitment as to whether any Sea Lion charter flights will be available for resident or third-party use has yet been made. During exploration dedicated charter flights provided an additional option for residents' travel and freight. Should such a provision be agreed, there is the potential for a '**Beneficial**' impact.

11.6.7 Project-specific mitigation measures

With the provision of a dedicated charter flight as the base-case to meet Navitas transportation needs during peak periods, the impacts is considered to be '**Low**' such that no additional project-specific mitigation measures are proposed at this time. As described above, the need for a charter flight during steady state production will be reviewed during Stage 3.

11.6.8 Residual impacts and risks

Not applicable.

11.6.9 Cumulative impact

No cumulative impacts within the scope of the assessment are identified as, for example, any increase in cruise vessel passenger exchange would utilise existing scheduled air-link capacity and remain separate from the provided charter flights.

It is assumed that additional and potentially concurrent future exploration or development is not included within the scope of the current assessment. Assessment and any mitigation of impact would lie within that future activity's environmental assessment, should sufficient spare capacity on existing links not be available. Any options would have to be assessed at such a time and no commitments can currently be made as to the most efficient solution. Navitas will continue to review all available air-links, air-frame capacities and air-link charter partnerships if appropriate.

11.6.10 Confidence

Whilst exact air-frame capacities and fly-route have yet to be confirmed, a similar service was operated during the various oil exploration phases without problem. Confidence in the assessment is therefore '**Certain**'. Confidence in the assessment of the beneficial impact is '**Uncertain**'.

11.6.10.1 Monitoring required

Any incidental usage of existing air-links will be recorded. All monitoring required will be recorded within the project-specific Phase 1 & 2 Socio-Economic Monitoring and Management Plan (SEMMP).

Whilst not specifically required for environmental monitoring, data on anticipated personnel movements and seat occupancy on all flights may prove beneficial to FIG and FIDC in demonstrating the business case for additional commercial airlinks scheduled flights and will be shared as necessary.

11.6.11 Offsetting

As no residual impacts or risks identified in this section are considered significant, i.e., Moderate or above, offsetting is not considered necessary for this impact (see Section 8.11).

11.6.12 Findings summary

Table 11.30: Summary of the impact assessment on the competition for air-link resources

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
International movement of personnel to and from the Falkland Islands	Air-link resource competition for seat availability	Lack of seat availability for residents and third-party economic sectors	Planned	1, 2a, 2b & 3[2]	High	Slight	n/a	**Low (4)**	**n/a**	**Certain**	**Industry-standard:** A dedicated charter flight provisionally up to a fortnightly frequency, or as required depending upon personnel needs and on availability of other air links, will be provided to meet all personnel travel requirements. **Project-specific:** None proposed, although Navitas will continue to monitor and assess for use potential new air-link options and potential additional air-links as they may arise.
	Provision of additional air-link to the Falkland Islands	Potential for extra seat availability for third-party use	Planned[3]	1, 2a, 2b & 3	n/a			**Beneficial**	**n/a**	**Uncertain**	

[1] See Chapter 8 for definitions of sensitivity, severity, likelihood and significance.
[2] The ongoing need for a dedicated charter flight will be reviewed once into steady state production (Stage 3) to determine whether or not it is still required.
[3] Note that the availability of excess seating for use by third-parties will be reviewed and confirmed during the FEED process.

11.7.12 Findings summary 1083

11.7.1 Introduction

All stages of the Sea Lion Phase 1 & 2 Development will require the use of the existing road network for the movement of personnel to and within Stanley, haulage of equipment, and transport of supplies and waste between a range of different locations.

The Falkland Islands Government (FIG) Public Works Department (PWD) Highways Section is responsible for the construction and maintenance of the road network and surfaces. Whilst road capacity cannot be accurately quantified, increased utilisation may be detrimental to the road surface and may result in increased necessity for remedial repairs. Therefore, increased road usage may impinge upon both the capacity of FIG to conduct repairs, and on other road users. Indeed, both the carrying capacity of existing infrastructure and competition for resources were raised as a concern during the historical scoping consultations (Chapter 6).

As described in Section 6.2.2.1.1, socio-*economic* impacts are out of scope for this EIS. A separate Socio-economic Impact Assessment (SIA), building and updating the previous work undertaken for FIG and Rockhopper by Regeneris (2013; 2015) and Plexus Energy (2012), is being conducted by Navitas. This chapter focuses on the increase in road usage above the existing baseline to inform the assessment of impacts upon the road infrastructure and other road users. As wear and tear on the road network is proportional to vehicle passes and axle weight, it is considered that any impact will be proportional to the increase in traffic and haulage weights.

11.7.1.1 Relevant legislation

Relevant Falkland Islands legislation includes:

- The Offshore Minerals Ordinance 1994 Part VI,
- The Road Traffic Ordinance, and
- Highways (Weight Limits) Ordinance 2004.

Under the EIA Ordinance, the Hydrocarbons Environmental Impact Assessment Guidance Note 187/15 (FIG, 2016e) provides guidance on the content of an EIS. This includes Section 3.7 which suggests that impacts on infrastructure, such as wear and tear on the road network, may be a relevant part of an EIA, guided by how they are described in the National Infrastructure Plan. This was agreed during the consultee scoping workshop with FIG in 2015 (Chapter 6).

All roads have designated speed limits and maximum axle and gross load capacities, with exemptions required for any heavier loads. An annual vehicle tax is levied on all road-going vehicles.

Navitas operates a Health and Safety Transportation Policy; travel on company business is mostly limited to capped (sealed) roads within Stanley and requires a driving safety induction to have been completed.

- Key UK Legislation:
    - The Road Vehicles (Construction and Use) Regulations 1986 (as amended), and
    - Code of Practice Lighting and Marking for Abnormal Load Self escorting vehicles incorporating Operating guidance.

11.7.2 Sources of road and transport use

The activities that will result in the use of vehicles are:

- Crew rotations - transportation to and from Mount Pleasant Complex (MPC) for the charter flight,
- Daily commute from accommodation to the supply base, TDF and Stanley Airport heli-ops by minibus / coach,

- Haulage of freight:
  - Between TDF and laydown yards,
  - Air-freight from fortnightly charter aircraft, and
  - Occasional sea-freight if ports or shipping services other than TDF are used.
- Waste haulage to waste disposal site,
- On-call technician and management vehicles, and
- Domestic supply deliveries.

It is likely that the majority of the project accommodation will be centralised, and transportation from this accommodation to the place of work will be by shared communal transport such as a minibus.

Vehicle use outside of Stanley on uncapped (unsealed) roads will comprise the short section of uncapped Coastel Road between the Airport Road, Lay-down yards and the TDF. Other travel on unsealed roads will require strong justification, will be subject to journey management plans and will therefore be limited.

11.7.2.1 Crew rotations, freight haulage and use of the MPC road

The MPC road will be utilised for transfer of rotational personnel to the fortnightly air-link charter for crew exchanges. It is anticipated that transportation will be *via* minibus or coach.

11.7.2.2 Daily commute from accommodation to workplace / heliport

The Airport Road and Bypass in Stanley is the primary route that will be used to transport onshore personnel from accommodation to the supply base and TDF for shift pattern work and is the primary road giving access to Stanley Airport. It is anticipated that the selected location for the accommodation facility will have easy access to the Airport and Bypass Roads. This will eliminate transit and through traffic within Stanley.

11.7.2.3 Haulage of freight

11.7.2.3.1 Between TDF and laydown yards

The majority of all consumables and equipment will arrive at the TDF by *ad hoc* freighter vessels and will require initial movement to the lay-down yards for storage, and then redelivery to the TDF for loading to the support vessels. The majority of all port transfer and HGV usage will be limited to the short interconnecting road between the TDF and lay-down yards, locally known as Boxer Bridge Road and Coastel Road. Dependent upon the final location and layout of yards and yard access points, this will vary up to approximately 1 km transit along public roads.

During Stages 1, 2a & 2b of the Development, transfer of drilling materials will entail HGV use with high axle loads throughout the year for around five years. In Stage 3 during steady state production, bulk process chemicals e.g., methanol and pour point depressants (Section 5.9.1) may increase in volume but drilling consumables and bulks will no longer be required and overall materials will decrease. Although it may be possible to store some bulk drilling materials (dry or liquid) adjacent to the TDF access causeway, the majority are expected to be stored in the yard and will require road transportation for the short distance to and from the TDF. Logistics vessels located in Berkeley Sound will handle a large amount of heavy equipment for subsea installation and heavy lift objects such as X-mas trees. Any movement of abnormal loads, where the laden vehicle is above 38.5 tonnes, is expected to require special authorisation from the FIG Highways Section. This will be subject to restrictions on overall dimensions and individual axle weights, which would be discussed in detail relevant to each circumstance with a view to ensuring that stresses on roads and road structures are within acceptable limits.

Operation of the supply base is continuous. Staffing is expected to reduce at night during steady state production but during Stages 1, 2a & 2b activity levels will require day and night operations and vessel availability may also dictate night-time operations with some consequent vehicle movements. The main scenarios for night-time activities are drilling and installation support whereby vehicle movements would be between the supply base and TDF i.e., relatively short distances and avoiding residential areas. All non-critical activities will be efficiently coordinated with the aim that associated traffic movement will most likely occur between 7am to 7pm Monday to Friday and 7am to 4pm on Saturdays.

11.7.2.3.2 Air-freight haulage from MPC

It is likely that the fortnightly charter flights will carry a small quantity of air-freight (Section 5.11.3.1.1) that would likely be transported at the same time as exchanging crew within a Light Goods Vehicle (LGV) and would not add significantly to vehicle transits.

11.7.2.3.3 Freight haulage from other sea ports

Whilst the base-case assumes that sea-freight will be supplied through *ad hoc* freighter vessels to the TDF, it is possible that small levels of freight may be received, on an occasional basis, at Mare Harbour on the MoD charter service or *via* the regular SAAS vessel. If this were to occur this would also require transfer to Stanley supply bases. At present this is not considered to be in significant quantity or frequency and is not considered further as the current base-case or within the assessment. If at some point greater cargos were to be transported by this route and / or reception facilities at Mare Harbour are required, the implications with respect to planning consents and environmental assessment including transport impacts would be discussed with FIG.

11.7.2.4 Waste haulage

As described in Section 10.10, it is anticipated that the Falkland Island municipal waste facilities will become available in time for the project (currently anticipated to be commissioned by the end of 2026 (C. Summers, *pers. comm.*). The current proposed site for the FIG Waste Reception facility is at Megabid on the Airport / Bypass Road. It is anticipated that these new facilities will be used during the Sea Lion Development and haulage of waste would be required from the TDF / laydown yards to the location of the new waste facilities and is likely to require transit along the Airport / Bypass Road.

Where use of the municipal facility is not possible, or if the FIG facility is not available in time for operations, waste may be incinerated at the supply base (Section 5.11.4.4) or may be shipped out from the TDF to another country (Section 10.10). The latter events would not significantly contribute to on-island road use except for the short distance from the yard to the TDF.

An assessment of waste arisings (Section 10.10) undertaken for the Development predicts that onshore wastes being handled will peak at 241 tonnes per month during Stage 2a of the project, dropping to 59 tonnes per month in Stage 3 during steady state production. Assuming that the largest allowable HGV (38.5 tonnes gross vehicle weight) would be used, and that each could carry a payload of 28 tonnes *and* that waste will be stored and manipulated to minimise the number of trips, this would give potentially nine vehicle movements per month at peak falling to around two movements per month during production. However, since their destination is uncertain and there may be multiple endpoints if waste outlets are located in different sites (e.g., landfill, incineration, waste to energy and water treatment), an overall estimate would be of 3-4 movements every working week at peak falling to one movement every week during steady production.

11.7.2.5 On-call personnel and domestic supplies

On-call technicians and operatives; senior management; and permanent personnel based in rental accommodation, will require access to self-drive vehicles for flexibility for out-of-hour call outs and

requirements outside the shuttle-bus transit routes or scheduled times. An allowance for 30 vehicles making four daily return journeys along the Airport Road is included within the assessment. It is expected that some level of car-pooling between staff, and rotation of vehicles between on-call staff, will be possible, which may reduce overall vehicle number requirements. This component of transport will also have impacts within Stanley for meetings, office logistics, shopping and access to rental accommodation (depending upon where this is located).

The degree of local supply of goods and services will depend upon the level of success of the local businesses in the competitive procurement process, balanced against security of supplies for the local resident community. It is not possible to determine at this stage the degree of supply that will be sourced locally and the level which will be out-sourced and arrive in conjunction with Navitas freight supply to the TDF. Undoubtedly there will be a level of increase in local supply and economic activity serving the O&G sector including, but not limited to, supply to:

- General retail sales serving personnel in rental accommodation,
- Food and consumables to transit accommodation, and
- Fuel and consumable deliveries to heliops, yards, etc.

This will cause a resultant increase in deliveries, retail stocking and thus vehicle movements in general retail, supply and service sectors. This would predominantly be within the vicinity of Stanley but may also impact the MPC road if importation of third-party private sector goods were imported through Mare Harbour shipping links.

11.7.3 Potential receptors

The ENvironmental Impact IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts of road use warranted further investigation (Chapter 9).

Receptors that may be impacted by increased road use during the Phase 1 & 2 Development include:

- Human Population (Section 7.7.2),
- Tangible Property - road networks (Section 7.7.4), and
- Air quality if emissions and increased dust are close to residential areas.

Note: impacts on regional and local air quality from particulate matter suspended by the use of uncapped roads was scoped out during the ENVIID and was not considered further see Chapter 9.

11.7.4 Characterising and quantifying resource competition in road transits

When characterising and quantifying the impact of road use on road infrastructure and other users, it is necessary to identify the key roads likely to be used and to consider the expected usage rates in comparison to the existing baseline usage.

Therefore, the following section describes:

- Location and types of road,
- Existing road usage,
- Nature of the impact in relation to the human population and tangible property,
- Base-case mitigations, and
- Estimation of road usage during the Phase 1 & 2 Development.

11.7.4.1 Location and types of road

Detail on the existing road infrastructure is provided in Section 7.7.4.2 which details the system of road classification on the basis of its strategic importance. The main roads which will be used during the proposed Phase 1 & 2 development will be:

- The capped MPC Road between MPC and Stanley,
- The capped Airport / Bypass Road in Stanley which runs between the MPC road and FIGAS,
- The uncapped Boxer Bridge Road and Coastel Road which runs between Boxer Bridge, the Airport Road and the FIPASS turn off, and
- The capped Stanley roads.

The main arterial road network of the Falkland Islands extends to approximately 862 km in total, with 489 km on East Falkland and 373 km on West Falkland. Roads outside of Stanley, and those around the MPC, are predominantly uncapped and of variable surface quality.

In 2012 FIG introduced a Highways Asset Management Plan which categorises the Islands road network on the basis of each roads' strategic importance, and prioritises maintenance in respect of this (Table 11.31).

At present the expectation is that all activity related to the Phase 1 & 2 Development will occur within the vicinity of Stanley and between the infrastructure centres of Stanley and MPC. As such, almost all transit and transportation will occur on Class A roads (Table 11.31) which are prioritised for maintenance as a primary national asset. Use of the road network is therefore limited to roads that are already subject to on-going routine maintenance and prioritised work schedules such that duration of any degradation that may cause nuisance is minimised through remedial works as soon as weather and plant permit.

The main road usage requirements are shown diagrammatically in Figure 11-8.

Note: during the initial construction period (pre-drilling), there will be construction work at the Heliport while the Heliport is built meaning potentially some HGVs between Stanley and the Heliport, but this will be short-term in nature.

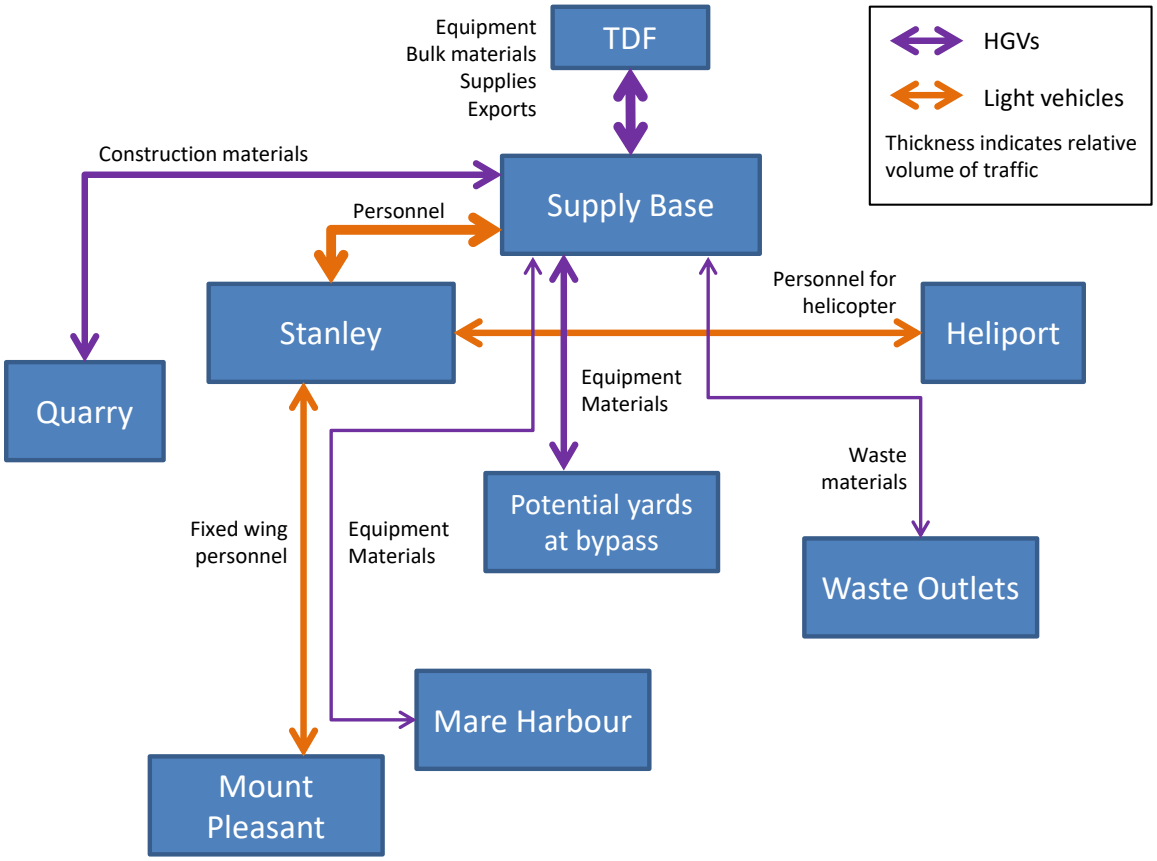

Figure 11-8: Key elements of road transport required

Table 11.31: Highways Asset Management Plan Road Classification ***(Source: FIG, 2012a; Executive Council Paper 39/12)***

Road Classification	Description	Example
Class A Road	Primary link road between major national assets. Greatest traffic use by volume and weight.	Stanley to MPC MPC to New Haven ferry terminal Port Howard ferry terminal to Fox Bay
Class B Road	Link road between all Class A and Class C roads Major tourist destinations Major supply route to abattoir	North Camp road Goose green to North Arm
Class C Road	All other roads	Link roads to individual farms or a series of 2 – 3 farms on a single branch road

11.7.4.2 Existing road usage

The FIG PWD Highways Section has previously deployed pressure activated vehicle loggers at a number of sites to determine the number of vehicle passes as well as the class, weight and speed of the vehicles.

Average daily usage on the MPC road over the three sampled periods (two locations) averaged 483 vehicle passes / day (Table 11.32). As shown in Table 11.32, the majority of these vehicles were cars, 4x4, minibuses or Light Goods Vehicles (LGV) with these groups accounting for 87.2 % of transit in 2015.

Daily usage on the Airport Road (measured between the Chandlery and Stanley Growers Market Garden), over a single sampled period, averaged at 1,755 vehicle passes / day (Table 11.32). Again, the majority of vehicles were cars, 4x4s, minibuses or LGVs with these groups accounting for 92.2 % of transit in 2015 (Table 11.33).

MPC Road usage has generally increased significantly year on year, however exact recent trends are not certain and road usage may have stabilised (Table 11.34). There has not been a full usage survey since 2015 (C. Summers, *pers. comm.*, 2023) although the population in Stanley rose by 3 % from 2016 – 2021 suggesting there has likely been an increase in traffic around the town to correlate with the increase in population (FIG, 2023l).

Table 11.32: Vehicle passes recorded by vehicle loggers

Sample Location	Providing access to	Sampling Start Date	Sampling End Date	Sampling Period (Days)	Total Vehicle Passes	Daily Average
MPC Road Sapper Hill[1]	Quarry, abattoir, wind farm, Camp Road network (north and south) and onwards to MPC and New Haven ferry terminal	19/12/2011	05/02/2012	48	30,799	642

11.7.4.3 Nature of the impacts to human population and tangible property

The nature of the potential impacts is as follows:

- Degradation in air quality due to diesel particulates,
- Potential nuisance impacts to the human population:
  - Nuisance to other road users from, for example, increased 'congestion', reduced ease of use if surface degraded or more time is spent on maintaining the roads, and
  - Disturbance caused by noise if there is increased use of HGVs close to residential areas.
- Potential impacts to the Tangible property:
  - Degradation of cappings / road surface of road networks, and
  - Wear and tear on other users' vehicles if road surfaces are degraded.

The extent of the above impacts will vary according to the location and type of road.

In general, axle weight and frequency of loading are the most important considerations in determining the stress and degradation placed on roads from vehicle traffic. Axle weights can be expressed as a load equivalency factor to determine pavement wear which typically increases exponentially with axle weight. Other factors such as the quality of suspension are also important, and many such parameters are governed by controls on permissible vehicle types (e.g., following Highways (Weight Limits) Ordinance 2004 and the UK 'Construction and Use' Regulations) and mandatory inspections and testing. Research typically finds a 'fourth power law' relationship between axle load and pavement wear (e.g., NVF committee Vehicles and Transports, 2008), which translates, for example into pavement wear being around three times worse for a 38 tonne HGV compared with an 18 tonne two-axle truck or an 18 tonne large bus, with cars being negligible. Pavement wear is therefore significantly driven by movements of HGVs with axle loads up to around 10 tonnes; to a lesser extent by medium sized vehicles such as buses or smaller lorries; and virtually no impact from cars or minibuses.

11.7.4.3.1 MPC and camp roads

With regard to impacts on the human population, dust, noise, air quality and nuisance are not considered significant due to the remoteness of the road from any significant concentration of human habitation / residential area. The length of the road in comparison to the number of daily vehicle transits also signifies that vehicle density is low and that congestion, such as to increase journey time, should not be an issue.

With regard to impacts on the road as tangible property, the MPC and wider camp road network was initially designed as 'all-weather track' for predominantly low axle weight 4x4 light passenger vehicles. Degradation of the road surface (both capped and uncapped sections) may occur, especially in winter when weather conditions and the inability to conduct routine maintenance programmes combine to reduce surface quality. The existing use of HGV's, for example to transport civilian freight from Mare Harbour to Stanley, livestock to the abattoir and camp fuel supplies, has been noted as contributing to deterioration of road condition. This is recognised as an on-going issue (FIG, 2012a) even in the absence of O&G development. The MPC road is ranked as a Category A road with the highest priority for on-going maintenance and has recently (March 2024) been fully capped from MPC to Stanley (FIG, 2012a).

11.7.4.3.2 Airport Road and Bypass

With regard to impacts, the proximity to residential areas is such that there may be some concern over air quality and noise, especially from HGVs, affecting neighbouring residents, although the road is to a large extent bunded where residential properties are adjacent. Bunding assists in reducing visual and noise intrusion. The impact of noise from the Phase 1 & 2 Development on residents is more specifically assessed in Section 11.9. The Airport Road and Bypass Roads are generally free-flowing in traffic and would accommodate increased traffic levels without detrimental levels of congestion being noticeable.

With regard to impacts on tangible property, the Airport Road and Bypass is fully capped and is thus more resistant to degradation. As detailed previously the significance of wear and tear to the surface will be proportional to the forecast increased usage in relation to current baseline usage. Capping also removes any consideration of dust impacts from passing vehicles to air-quality.

11.7.4.3.3 Coastel Road and Boxer Bridge Road

With regard to impacts to the human population, these roads are located in a light industrial area, without residential development and prevailing westerly winds are such that dust, suspension of particulate matter and noise from transportation are not likely to be significant.

In general, the Coastel Road and Boxer Bridge Road in the vicinity of the Gordon Lines area are not used as primary through-transit routes to other areas. Vehicles would generally bypass the area along

the Airport Road. Alternative diversion is possible *via* the Airport Road on capped surfaces around the whole site and the Coastel Road and Boxer Bridge Road need only be used if accessing the TDF. As such it is not a transit route that by necessity need impinge on other domestic users if congestion or degradation were to occur.

The TDF is located at the approximate mid-point of the Coastel Road. Light industrial and warehouse sites to the west of the TDF (including RSK's Construction supply base, various fishing companies and agencies linked to FIPASS and general light industry / storage) would generally access third-party sites from the west (FIPASS Road) and depart to the west, thus transport servicing these areas would not reach or transit past the TDF shore frontage. There are third-party sites towards the east corner of Boxer Bridge Road and Coastel Road, including RBC, Polar Seafish and Fortuna.

Sites to the east of the TDF or for access to the Canache, Boxer Bridge and Cape Pembroke would generally enter from the Airport Road to the east. Therefore, the middle section of the Coastel Road at the TDF access point is only relatively lightly used.

With regard to impacts on tangible property, these roads are uncapped and there are currently no plans for the surfaces to be capped. Currently no special authorisation is needed for vehicles of up to 38.5 mt gross load to use these roads. Individual axle weight is also an important consideration, and in the UK for example special authorisation is needed for axle loads greater than 10 tonnes for a non-driving axle, and 11.5 tonnes for a driving axle. Some upgrade of the road was conducted prior to the 2015 exploration drilling campaign to ensure the load capacity of the central section and to minimise spreading of road material which can create 'soft' edges. Degradation of the road surface did occur during the exploration activity and it is likely that Oil and Gas (O&G) movements comprised the majority of heavy transits and increased the rate of degradation. Salting of the clay road surfaces to maintain safety of work in winter may also have contributed to some breakdown of surface.

During Stages 1, 2a & 2b of the proposed Phase 1 & 2 Development, when transfer of drilling materials in particular will entail HGV use, it is anticipated that movements may have a detrimental impact upon the road surface above the wear and tear of existing users. However, the overall impact is likely to be low due to the:

- Relatively low existing use of this section by other road users and public,
- Location of the road within a generally light industrial area,
- Lack of necessity for other adjacent users to transit the area to the east of the warehousing sites which supply FIPASS,
- Presence of alternative routes to by-pass the area *via* Airport Road for other users, and
- Relatively short road length and its proximity to PWD plant storage and quarry aggregates making it easily accessible which minimises logistics if routine repair is required.

11.7.4.3.4 Stanley roads

As described in Section 11.7.2, general personnel working on a rotation basis will not normally have access to individual vehicles for personal use. The use of Stanley roads will therefore be limited to on-call technicians, managers and permanent onshore personnel. Transport from personnel accommodation and to central sites in Stanley will be conducted by shuttle bus or taxi services and are not expected to significantly increase congestion.

Whilst no site has yet been determined for the accommodation unit, it is expected that it will be built in a location with easy access to the Airport / Bypass Road. Therefore, daily traffic can be diverted around Stanley and should not cause additional through-traffic along the east-west routes within Stanley that may be congested at peak times relating to the start and end of the working day and at lunchtime. However, it is believed that parking, with the resultant impact on traffic flow, is perhaps a

greater issue in Stanley than the actual increase in vehicular traffic. As is detailed within the accommodation chapter (Section 11.3) some or all accommodation for the additional *c.* 26 permanent staff who will live in Stanley may be achieved by new build, and any new build will come with the provision of off-street parking in line with planning regulations. The aim of this section is to consider tangible property i.e., wear and tear on roads, and parking is considered a socio-economic impact and so is not considered further here.

11.7.4.4 Estimated Phase 1 & 2 Development road usage

11.7.4.4.1 MPC Road and air-link personnel movements

The capped MPC Road will be used for:

- Fortnightly crew exchange,
- Miscellaneous passenger exchange outside of crew rotations,
- Air-freight fortnightly, and
- Occasional sea-freight if alternative freight or coaster is utilised (not current base-case).

Crew transfer logistics will be finalised through tender processes accompanied by a risk assessment of options and therefore, the exact specification of vehicles and seat capacities cannot be confirmed at this time. The assessment is based on minibuses of 15 seat capacity that were used during the 2015 exploration campaign. However, with differing personnel numbers it may be that larger capacity options may be utilised and be more efficient in both fuel and vehicle passes for people moved. This would likely reduce impact.

While the larger buses would be heavier and have a greater impact on road surfaces they would require fewer trips and perhaps be most appropriate to passenger exchange when larger numbers must be moved to meet a single fixed check-in time. In contrast, a minibus would require a greater number of repeat trips contributing to congestion. Therefore, to assess the worst-case, use of a 15 seat minibus has been assumed in this EIA. Further, rotation crew moving offshore are restricted to 15 kg baggage allowance and therefore additional luggage capacity is not a significant concern, however an additional allowance of one luggage van per 45 personnel has been allowed for.

As is shown in Table 11.35, a maximum 0.65 % increase in daily MPC road usage would occur during the Phase 1 & 2 Development. In Stage 3, once personnel requirements decline, passenger movements would account for only 0.35 % of MPC road usage.

Even taking into account the inevitable uncertainties in estimates and timings of trips, these levels are not considered significant to road maintenance schedules or wear and tear of road surfaces and are significantly below past historical year on year increases in road usage observed in the Falkland Islands (Section 11.7.2.3.2, Table 11.34 above). Even recognising that use is a fortnightly pulse of vehicles to meet the air-charter, it is unlikely that congestion would occur given that the legal speed limit is set at 40 mph and that minibuses would not be impeding other road users who should also be travelling at below that speed.

Even with nominal additional allowance for air-freight or sea-freight transfer, the usage of the MPC road is not considered significant.

Table 11.35: Vehicle transit requirements based upon air-link capacity requirements during the three stages of the Phase 1 & 2 Development

Statistic	Stage 1	Stage 2a & 2b	Stage 3
Maximum air-link capacity requirement for crew exchange	110	110	60 / fortnight
Minibus requirement based on 15 seat capacity	8	8	4
Luggage van requirement based on 45 personnel	3	3	2
Total number of vehicles	11	11	6
Number of bus trips (based on two return trips (four passes) required per exchange for arrival and departure)	44	44	24
Number of days between air-links (fortnightly)	14	14	14
Equivalent average daily usage transits	3	3	2
Increase in MPC road usage based on current average usage of *c.* 483 vehicles/day	0.65 %	0.65 %	0.35 %

11.7.4.4.2 Airport Road usage for transport from accommodation to workplace

The capped Airport Road & Bypass Road in Stanley for:

- Crew exchange fortnightly,
- Shuttle-bus for rotational onshore personnel and heliport,
- Miscellaneous local supply deliveries, and
- Waste disposal to municipal waste processing facility.

Transportation needs are assumed based on a 12-hour shift pattern and 12-hour working day. This would necessitate all personnel being transported to work at the commencement of the day and returning at the end. At start and termination all movement would be in one direction with minibuses at capacity delivering personnel and returning empty for the next load.

A 24/7 working programme is planned. On the basis of a 12-hour dual-shift pattern, within a given maximum personnel, this would actually decrease (by approximately half) the transportation needs at commencement and end of shifts. In this scenario, half the personnel would be commencing as half the personnel were finishing and minibuses would be full in both directions.

Transport provision will be tendered and exact vehicle capacities and schedules are currently unknown. Based on the transportation used during the 2015 exploration drilling campaign, a worst and extremely precautionary case can be assumed:

- Move all personnel at 06:00 to start shift,
- Schedule of circular shuttle-bus at 30 minute departures 06:30 – 11:30 for any personnel needing to return to accommodation / Stanley,
- Move all personnel to messing facility at 12:00 (start lunch),
- Move all personnel to site at 13:00 (end lunch),
- Schedule of circular shuttle-bus at 30 minute departures 13:30 – 17:30 for any personnel needing to return to accommodation / Stanley,
- Move all personnel at 18:00 (end shift), and
- All long-term onshore personnel have individual vehicles undertaking 4 return trips / day.

Second 12 hour shift vehicle movements on the same basis.

Using these assumptions transportation needs are detailed in Table 11.36.

Requirements would be highest during Stage 1, 2a & 2b with a potential for a 17 % increase in vehicle transit by car and LGV minibus. The main increase results from car transit by permanent personnel positions rather than the shuttlebus service. In Stage 3, use would decline as the shuttle service would cease and the increased usage of 11 % would be wholly due to permanent staff vehicles.

Although the vehicle use would incorporate only car and LGV usage of low axle weight, such increases may have long-term un-quantifiable significance to road capping wear and tear. However, this wear and tear is not considered to be significant to maintenance schedules. Impact upon other road users is thought to be low.

In reality transportation needs would likely be less and not all permanent personnel are likely to have permanent access to a vehicle of single person use.

Table 11.36: Transportation requirements during the Phase 1 & 2 Development

Description		Stage 1	Stage 2a & 2b	Stage 3
Permanent / management personnel with access to self-drive vehicles				
Number of personnel	It is unlikely that all would have access to vehicles and car-pooling and vehicle rotation to the on-call person would occur. The estimate of 30 associated vehicles is conservative	26	24	24
Daily return trips	One return trip is equivalent to two vehicle passes per trip	4	4	4
Number of vehicle passes per day		**208**	**208**	**192**
Rotational onshore personnel shuttle bus requirements				
Maximum number of personnel	The maximum number of personnel would be split between 2 shifts for 24 hour working	63	63	0
06:00 return trips	Shift change over. One shift arriving and one shift returning on same return trip. Based on 15 seat minibus to move all personnel.	4	4	Not required as capacity within self-drive vehicles
06:30 – 11:30 shuttle bus departures at 30-minute intervals	30-minute one-way departures 06:30: Accom. – Yards 07:00: Yards – Accom. 07:30: Accom. – Yards 08:00: Yards – Accom., etc.	5.5	5.5	-
12:00 return trips	Based on 15 seat minibus to move all on shift day personnel for mid-shift meal.	4	4	-
13:00 return trips	Based on 15 seat minibus to move all on shift day personnel for mid-shift meal.	4	4	-
13:30 – 17:30 shuttle bus departures at 30-minute intervals	30-minute one-way departures 13:30: Yards – Accom. 14:00: Accom. – Yards 14:30: Yards – Accom. 15:00: Accom. – Yards, etc.	4.5	4.5	Not required as capacity within self-drive vehicles
18:00 return trips	Shift change over. One shift arriving and one shift returning on same return trip. Based on 15 seat minibus to move all personnel.	4	4	-
18:30 – 23:30 shuttle bus	One-way shuttle bus departures at 30-minute intervals as before	5.5	5.5	-
00:00 return trips	Based on 15 seat minibus to move all on shift night personnel for mid-shift meal.	4	4	-

Description		Stage 1	Stage 2a & 2b	Stage 3
01:00 return trips	Based on 15 seat minibus to move all on shift night personnel for mid-shift meal	4	4	-
01:30 – 05:30	One-way shuttle bus departures at 30-minute intervals as before	4.5	4.5	-
Total return trips per day		**47**	**74**	**0**
Number vehicle passes per day		**93.5**	**93.5**	**0**
Total figures				
Total daily vehicle passes	**Individual vehicles and shuttle buses**	**296**	**296**	**192**
Increase to current baseline vehicle passes	**Based upon current baseline level of 1,755 vehicle passes**	**17 %**	**17 %**	**11 %**

11.7.4.4.3 Coastel Road and Boxer Bridge Road

The uncapped Boxer Bridge Road and Coastel Road will be used for:

- Access to laydown yards and TDF,
- Transit loads between laydown yards and TDF, and
- Internal movements within yards (excluded as they do not utilise public roads).

The main bulk of all materials movement and HGV usage will be confined to the short 160 – 870 m transit between TDF access and the potential location of entrances to the lay-down yards.

The main movements of bulk materials and equipment occurs during drilling, i.e., Stages 1, 2a & 2b and is a relatively steady level of activity. The majority of HGV traffic is between the TDF and the supply base, and peak levels are related to the capacity of incoming vessels and rate of offloading. It is anticipated that these parameters will be similar to those experienced in the drilling campaign for exploration wells. Basing traffic numbers on those levels, it is anticipated that 20 two-way HGV movements could be expected over a four to six hour period related to a single vessel, before the next spell of activity. This equates to a maximum rate of 5 two-way movements per hour.

11.7.4.4.4 Central Stanley

The capped Stanley roads for:

- Potential shuttle bus from accommodation to central Stanley, and
- Limited number of self-drive vehicles for technicians, managers and office support.

As stated above, it is expected that the location of the accommodation for rotational onshore personnel during Stages 1, 2a & 2b of the Development will be located with easy access to the Bypass / Airport Road. This will remove transit and through traffic from central Stanley and prevent any increase in congestion at peak times of 08:00, lunchtime and 16:30 relating to the domestic working day.

During the 2015 exploration campaign, four return shuttle buses took personnel to Stanley during the lunchtime period. In addition, there was an additional allowance for minibus runs to central Stanley and the leisure centre in the early evening (*c.* 18:00 hrs) after the end of the working day, although the utilisation of this on-call service in comparisons to taxi use is not available.

The greatest influence on traffic within central Stanley will be the location of the rental accommodation used for the 26 permanent staff, which may increase through-traffic within central Stanley or further limit parking provision. However, any newer accommodation, or new-build accommodation is likely to have two off-street parking spaces (as required by planning guidelines), so that Sea Lion project use of such properties would not additionally limit available parking provision. At

the time of writing, the location of such accommodation is unknown, such that it is not possible to quantify the impacts of associated vehicle use.

11.7.4.5 Base-case mitigations

In addition to adherence to legal speed and vehicle weight limits (Section 11.7.1.1), a number of mitigations will be put in place to minimise impacts to the road surface from the Phase 1 & 2 Development. These are listed in Table 11.37.

Table 11.37: Base-case mitigations which will serve to minimise impacts from road use

Item / Vehicle	Location	Background and description
Crew and personnel transfers		
Minibus / coach	MPC Road and Airport Road	The most efficient transport system will be assessed through tender and subject to a risk assessment, and The transport system that achieves the best compromise between number of transit (seating capacity), axle weight (wear and tear) and safety will be selected. This is currently thought to be a mid-sized minibus or coach that would maintain axle weight within an LGV category.
Onshore rotation personnel		
Shuttlebus	Bypass & Airport Roads	No sole-use vehicles provided except in case of on-call workers or senior employees, Transfers made by scheduled shuttle-bus service to increase efficiency and minimise transits, and Accommodation is expected to be located with easy access to Bypass and Airport Roads to remove any through traffic and transit from central Stanley.
Permanent onshore personnel		
Individual Vehicles	Bypass and Airport Roads Central Stanley	HSE driving policy and risk assessment that limits vehicle trips, especially out of town and on gravel surfaces, to absolute minimum, All drivers will undergo local training on driving techniques and driving etiquette to minimise impacts, Vehicles proportional to need, car-pooling will be applied where appropriate, and Location of private rental accommodation is not yet confirmed but off-street parking will be a preference.
TDF and lay-down yards haulage		
HGV, Haulage and transfer of materials	Boxer Bridge Road & Coastel Road	The use of logistics vessels in Berkeley Sound will minimise heavy load items being brought ashore, Appropriate de-icing chemicals or grit administered by FIG – Navitas will work in liaison with FIG in respect of routes and timing of vehicle movements, Driver training and vehicle maintenance (minimise breaking, wash-boarding, etc.), and Escort vehicle or road side safety flashing lights when appropriate to warn of abnormal load movements.

11.7.5 Industry-standard mitigation

Vehicles used will conform to vehicle design regulations including the UK Road Vehicles (Construction and Use) Regulations 1986, with the exception of abnormal load trailers, which will be specifically designed for the load and road structures.

The movement of abnormal loads will comply with the Code of Practice Lighting and Marking for Abnormal Load Self escorting vehicles incorporating Operating guidance (Highways England, 2016) or similar requirements agreed with the FIG PWD Highways Section.

As per during the exploration campaign, Navitas will implement the following industry-standard mitigation measures:

- Specific applications for abnormal road movements, and
- HSE driving policy, risk assessment and local training.

11.7.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

A summary of the impact and risk assessment outcomes for this Development is tabulated in Section 11.7.12, which shows the worst-case impact / risk for each activity and receptor and details are provided below.

11.7.6.1 Degradation in air quality

As stated above, the impacts of noise on the human population are assessed in Section 11.9 and therefore this section assesses the impact of a degradation in air quality from diesel particulates due to increased traffic.

Most traffic associated with the project will be concentrated between the TDF and supply base and the accommodation, with the most likely route being the Airport / Bypass Road. This is noted as currently the most frequently used road in and around Stanley by FIG PWD Highways Section and is in close proximity to residential areas (Section 7.7.2). However, air quality from road use has not been raised as a concern by local stakeholders (Chapter 6). While roads and air quality were not raised specifically, it can be assumed that degradation in air quality for residents may be unacceptable to the majority of stakeholders such that, to take a precautionary approach, the sensitivity of the receptors (Human Population) is considered to be '**Moderate**'.

During the Phase 1 & 2 Development, the Airport Road will be used for the transportation of onshore personnel from accommodation to the supply base, TDF and the heli-ops at Stanley airport. As shown in Section 11.7.4.4.2, this use could result in an increase in traffic of up to 17 % in Stage 1, 2a & 2b, and 11 % in Stage 3. This could result in slight degradation of air quality. Therefore, the severity of effect of congestion to the Human Population is considered to be '**Slight**'.

The overall significance of the impact of degradation of air quality on the human population is therefore considered to be '**Low (3)**'.

11.7.6.2 Congestion from road use

As stated above, the impacts of noise on the human population are assessed in Section 11.9 and therefore this section assesses the impacts of congestion and associated nuisance.

Most Project HGV traffic will be concentrated between the TDF and onshore supply base and while this will be frequent at times, it has relatively low public use and such use is consistent with the designation of the area and the design of road junctions.

According to the data gathered by the FIG PWD Highways Section, the most frequently used road in and around Stanley is the Airport / Bypass Road. This road is used by residents for access to the airport and areas to the east of Stanley (Section 7.7.4.2) and is in close proximity to residential areas (Section 7.7.2). Further, the carrying capacity of existing infrastructure was raised as a concern by stakeholders on numerous occasions (Chapter 6). While roads were not raised specifically, it can be assumed that

congestion on the Airport Road and / or vehicles parked in Stanley may be unacceptable to the majority of stakeholders such that, to take a precautionary approach, the sensitivity of the receptors (Human Population) is considered to be '**Moderate**'.

During the Phase 1 & 2 Development, the Airport Road will be used for the transportation of onshore personnel from accommodation to the supply base, TDF and the heli-ops at Stanley airport. As shown in Section 11.7.4.4.2, this use could result in an increase in traffic of up to 17 % in Stage 1, 2a & 2b, and 11 % in Stage 3. This could result in some degree of congestion at peak times which may cause some inconvenience. Therefore, the severity of effect of congestion to the Human Population is considered to be '**Minor**'.

The overall significance of the impact of road use on the human population is therefore assessed as '**Moderate (6)**'.

11.7.6.3 Road degradation from increased vehicle use

As stated above, the impacts of particulate matter from uncapped road use on air quality were scoped out at the ENVIID (Chapter 9) and therefore this section assesses the impacts of degradation of road surfaces i.e., on the tangible property itself.

With regard to surface degradation, the most sensitive roads are those which are uncapped (Section 7.7.4.2). The Coastel and Boxer Bridge Roads are uncapped and will be used during the Phase 1 & 2 Development. The greatest impact on road usage and road surfaces is considered to be in the vicinity of the TDF and laydown yards located in the Boxer Bridge and Coastel Road area. The largest proportion of all supply materials, chemicals and bulks will be handled and / or transferred between these two sites. Nonetheless, given that use of the roads is sustainable and the stretch of road is short and not used by many others, the sensitivity of the receptor (Tangible Property) is considered to be '**Low**'.

Whilst impacts will occur to the road surface in this area, the length of roadway that will be impacted is short at less than a kilometre in total length from Airport Road to the TDF. Given expected use during the Phase 1 & 2 Development, this length of road may require more frequent maintenance than at present. However due to the short length and accessible location it is not considered that this would place critical restrictions on road maintenance schedules. The area is not a major transit road required for access to onward sites and thus knock-on impacts and inconvenience to other users should not be restrictive. Therefore, the severity of effect of road use to the Tangible Property is considered to be '**Minor**'.

The overall significance of the impact of road use on Tangible Property is therefore considered to be '**Low (4)**', and consequently further additional mitigations are not considered necessary.

11.7.7 Project-specific mitigation measures

A TDF / supply base traffic management plan will be put in place for operations, as has been done for exploration well activities, to minimise the impacts and risks from operational road use in this area. This will highlight operating hours, signage, allowable routes, warning devices, clothing and pedestrian precautions.

Accommodation for permanent onshore personnel within Stanley with off-street parking will be a preference.

These mitigation measures are considered sufficient to reduce impacts to ALARP and additional mitigation measures are not considered further at this point.

11.7.8 Residual impacts and risks

Residual impacts remain the same as considered for the initial assessment such the significance of the residual impacts of road use is considered to be **Low (3)** for degradation in air quality, **Moderate (6)** for nuisance and **Low (4)** for degradation of the road surface.

11.7.9 Cumulative impact

Cumulative impacts of increased traffic, or 'increased concentration' (Section 8.9.1) is most likely to occur within Stanley. Central Stanley is limited in available parking and this can, at times, cause limitations on cars travelling through Stanley. However, as described above, any new developments built for rental to permanent personnel must follow planning regulations and provide off-street parking which will mitigate against cumulative impacts.

11.7.10 Confidence

The transport and laydown yard tenders have yet to be defined and released. Alternative transport and haulage tenders will be assessed against the Supply Base Tender's Scope of Work and will require demonstration of safety risk assessment. The exact specification and capacities of vehicles is therefore not defined at this stage. However similar systems were in place during exploration activity without major incident and can be used as a template on which to base the assessment.

The level of confidence in the impact and risk predictions and efficacy of mitigation is therefore '**Probable**'.

11.7.10.1 Monitoring required

Use of roads will be monitored and will be included within the EMMP for on-going assessment to identify any emerging issues at an early stage.

11.7.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

11.7.12 Findings summary

Table 11.38: Summary of the impact assessment for use of road network during the Sea Lion Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity[1]	Severity[1]	Likelihood[1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Use of existing road network	Increased number of vehicles and use of infrastructure	Degradation in air quality	Planned	1, 2a, 2b & 3	Moderate	Slight	n/a	**Low (3)**	**Low (3)**	**Probable**	**Industry-standard:** Adherence to vehicle and road statutory requirements. Specific applications for abnormal road movements including signage and warning devices. HSE driving policy, risk assessment and local training. All non-critical activities coordinated to avoid peak periods. **Project-specific:** Traffic Management Plan. Accommodation with off-street parking will be a preference.
		Potential for nuisance to human population e.g., congestion	Planned	1, 2a, 2b & 3	Moderate	Minor	n/a	**Moderate (6)**	**Moderate (6)**	**Probable**	
		Degradation of road surfaces			Low	Minor	n/a	**Low (4)**	**Low (4)**

11.8.1 Introduction

The Phase 1 & 2 Development will use the supply base and Temporary Dock Facility (TDF) in Stanley. Additionally, Berkeley Sound will be used to host up to two Large Transport Vessels (LTVs) at any one time as storage and supply vessels for a total combined and non-consecutive duration of 13 months during the installation phase. All of these inshore, onshore and at-shore activities have the potential to create light pollution for the local residents. As shown in Chapter 6, lighting levels during operations were raised by stakeholders during informal scoping consultations.

This chapter specifically assesses the potential for artificial light to disturb the residents of Stanley and Berkeley Sound.

Note: Other impacts associated with the LTV storage and supply vessels, activities at the supply base and TDF are described elsewhere in this document, as described in Table 2.2.

11.8.1.1 Relevant legislation

There is currently no legislation in the Falklands relevant to light as a nuisance or disturbance.

The main piece of legislation concerning light pollution in the UK is:

- Environmental Protection Act 1990 (EPA '90), Part III: The Nuisance Provisions.

Also, while not directly related to the impact of artificial light, it is important to understand during this assessment that mitigation measures will be limited by the need to ensure the use of sufficient lighting for safety reasons. Specifically, offshore installations are required to be lit in line with the:

- International Regulations for the Prevention of Collisions at Sea (ColRegs) (Rule 22 and Annex 1).

11.8.1.1.1 The Nuisance Provisions: Disturbance from light

Under the Environmental Protection Act 1990 (EPA '90), a 'statutory nuisance' is defined based on its ability to cause disturbance. In order for an activity to cause disturbance, it must do one of the following:

- Unreasonably and substantially interfere with the use or enjoyment of a home or other premises,
- Present a long-term and sustained impact to local residents' quality of life, and / or
- Injure health or be likely to injure health.

With regard to light from the Sea Lion Development activities, it is recognised that only the first two definitions above may apply.

11.8.2 Sources of light disturbance to Falkland Island residents

The following Phase 1 & 2 activities have the potential to cause disturbance to local residents:

- Use of the onshore supply base at Gordon Lines in Stanley,
- Use of the TDF in east Stanley, and
- Mooring of up to two LTVs at any one time in Berkeley Sound to support the installation operation.

The sources of light disturbance at various stages of the Development are presented in Table 11.39 below.

Table 11.39: Sources of light disturbance from operations in Stanley and Berkeley Sound during the three stages of the Development

Location of disturbance	Source of light	Stage 1	Stage 2a&b	Stage 3
Stanley	Vessel deck lighting and navigation lights, both on vessels and on the TDF, Deck and office lighting on the TDF, and Yard and office lighting at the supply base.	✓	✓	✓
Berkeley Sound	Deck lights on the LTVs used as floating logistics vessels anchored in inshore waters in Berkeley Sound.	✓	✓	

11.8.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshops were used to identify the specific receptors upon which the impacts and / or risks of light disturbance warranted further investigation (Chapter 9). This chapter, focusing on the human population, identified the following receptors that may be impacted during the Phase 1 & 2 Development:

- Human population (Section 7.7.2):
  - Residents living in the vicinity of the TDF and supply base (Stanley):
    - The east end of Stanley (Gordon Lines area), where the TDF and supply base are located is generally an industrial area although there are a small number of houses in the vicinity (*c.* 1 km to the west).
  - Residents living in the vicinity of the proposed LTV site (Berkeley Sound) (Section 7.7.2.3):
    - There are four settlements / farmsteads around the Sound (*c.* 9 km from the proposed LTV location), with residents living and working in the area, as well as visitors and tourists.

11.8.4 Characterising and quantifying the impact of light disturbance

When characterising and quantifying the impact of light disturbance it is necessary to consider the:

- Nature of the impacts upon the human population,
  - Opinion of stakeholders.
- Quantification of the disturbance in both Stanley and in Berkeley Sound e.g.:
  - The number of sources of light (e.g., sites) and duration of exposure,
  - The location of sources of light (e.g., site),
  - The number of lights at each site, and
  - Orientation of lights at each site.

11.8.4.1 Nature of the impact

Light pollution is the alteration of natural light levels in the night environment produced by the introduction of artificial light. Exposure to light at night has been shown to disrupt melatonin levels, which can impact on sleep and blood pressure, along with a number of other health issues (Falchi, *et al.,* 2011). There are no set thresholds above which light can be considered a statutory nuisance in the UK (Section 11.8.1.1.1). However, guidelines (Section 11.8.5) suggest that acceptable levels of artificial light are dependent on the level of light found at the location prior to the artificial lights being introduced (Defra, 2015). For example, in areas that are 'intrinsically dark', people are less tolerant of artificial light being introduced, compared to large towns or city centres with high levels of nighttime activity (Scottish Executive, 2007).

Light pollution can also affect our enjoyment of the night sky when observing the stars, planets and galaxies (CIRES, 2016). The New World Atlas of Artificial Brightness shows that the Falklands are a relatively dark sky area, with the majority of the population living with very little light pollution (CIRES, 2016).

Regardless of the above however, the impact of light is largely subjective and it is therefore useful to consider the input of local residents and stakeholders (i.e., those that may be affected).

11.8.4.1.1 Opinion of stakeholders

Light pollution in Stanley did not come up as a specific issue during scoping for the Sea Lion development in August 2016 or December 2023 (Chapter 6) but it was noted during previous exploration scoping consultations that light from the TDF, vessels and yard is noticeable to Stanley residents. A community complaint was also made to POEPL during the 2015 exploration drilling campaign regarding the lighting from vessels moored up at the TDF at night.

The issue of light, particularly in Berkeley Sound, was discussed during the scoping consultations held by POEPL in 2016 and Navitas in 2023 (Chapter 6). The majority of stakeholders noted that the current levels of light in Berkeley Sound are quite high in jigger season (Section 7.7.3.2.1.2) and complaints about light from jiggers have been noted.

11.8.4.2 Quantification of the disturbance

11.8.4.2.1 Light in Stanley

11.8.4.2.1.1 Source and duration of light exposure

POEPL (now Navitas) made a successful application in January 2018 to the Falkland Islands Government (FIG) to vary the planning consent for the TDF to cover the duration of the Phase 1 & 2 activities. Navitas may propose further modifications to improve the dock's functionality in the future (Section 5.11.1.1.1) and any further proposals to upgrade TDF facilities will have to go through the process of planning consent, which may, at the planning officer's discretion, be accompanied by a full EIA. At this time however, it is assumed that the TDF operations will be similar to operations during the 2015 exploration campaign.

Therefore, it is estimated that light sources at the TDF and supply base will include:

- Deck and navigation lights from vessels at the TDF,
- Deck and navigation lights from the TDF,
- Office lighting on the TDF,
- Crane lights on the TDF,
- Street lighting along the TDF causeway,
- Floodlights at the supply base, and
- Office lighting at the supply base.

All of these light sources will be required throughout the Phase 1 & 2 Development (*c.* 30 years).

Both the TDF and supply bases may be operational 24 / 7 and will be illuminated during the hours of darkness.

11.8.4.2.1.2 Location of light sources

The TDF is located east of FIPASS, over one kilometre from the nearest residences (see Section 11.8.1.1.1). Vessel activity at the TDF will be limited to a maximum of two vessels berthing at any one time, due to space constraints.

The supply base is likely to be based in close proximity to the TDF, although the specific area has not yet been defined.

11.8.4.2.1.3 Number of lights

At the time of writing the specific lighting arrangements are not known for the supply base but are likely to be very similar to the lighting arrangements at the yards used during the exploration drilling campaigns. Lighting arrangements at the TDF are already in place.

The supply base will be larger in Stages 1 & 2 than the yard that was used during the 2015 exploration drilling campaign (Section 5.11.1.2). However, in Stage 3, steady state production, the overall yard space used will be smaller than that used during the 2015 exploration campaign. For the purposes of this EIS, it has been assumed that the number of lights will be proportional to the area of the yard. The yard will be similarly lit to the 2015 exploration campaign yard and it has been assumed that lights will be evenly spaced throughout. The area used for the exploration yard covered an area of 51,000 m^2 and the increase in area of the yards during each Stage of the Phase 1 & 2 Development is shown below in Table 11.40.

Owing to the differences in the areas of yard space required during the different stages, it is estimated that during Stage 1 and 2, the number of lights will be greater than residents have been used to during drilling and that during Stage 3, the lit areas will reduce in proportion. It should also be noted that much of the yard space, as with the yards used during the 2015 exploration campaign, will be covered sheds. As such the whole area will not be floodlit, only those areas outside the covered areas.

The lighting on the TDF will remain the same throughout the Phase 1 & 2 development, with a maximum of two vessels (e.g., two supply vessels) berthing at the TDF at any one time due to berthing space.

Table 11.40: Proposed area of yard space required for the Phase 1 & 2 Development in comparison to 2015 exploration drilling campaign yard space

Stage (and duration)	Area required (m^2)[1]	Difference in area to 2015 exploration yard area (51,000 m^2)	Comparison to 2015 exploration yard area
1, 2 a & 2b (*c.* 5 years)	127,500	76,500 m^2 more	Approximately 2.5 times greater
3 (*c.* 27 years)	20,000	31,000 m^2 less	*c.* 2/5th of the area

[1] Note that the area required for the specialised storage of explosives, NORM and radioactive sources (required throughout Field Life) is as yet unknown.

11.8.4.2.1.4 Orientation of lights

Some lights, such as office lighting, are not likely to be intrusive as the lights will be of a low level and inside buildings. These will be comparable to other residences and offices in Stanley.

The highest intensity lights will be the TDF deck and yard floodlights, which are generally orientated to illuminate any operational activity being undertaken on the deck of the TDF or in the yard.

11.8.4.2.2 Light in Berkeley Sound

11.8.4.2.2.1 Sources and duration of light exposure

The short-term sources of light that will be present in Berkeley Sound over the various stages of the Phase 1 & 2 Development are shown below in Table 11.41.

.

Table 11.41: Source and duration of lights in Berkeley Sound during the Phase 1 & 2 Development

Phase 1 & 2 Development Stage	Activity in Berkeley Sound	Duration of Presence in Berkeley Sound	Approximate number of light sources in Berkeley Sound
Stage 1: Mobilisation and installation of materials and equipment to support pre-First-Oil drilling by MODU[1], FPSO[2] moorings installation and construction	Up to 2 LTVs anchored in Berkeley Sound at any one time. 2 x Offshore Construction Vessels (OCVs) transiting between the LTVs in Berkeley Sound and the field location.	Ability to maintain a 24 hr operation over a total of seven months (in two periods) as and when operationally required	Deck lighting and navigation lights from installation vessels and LTVs (up to two vessels *in situ* at any time)
Stage 2a & 2b: Post First-Oil drilling by the MODU, concurrent production operations by the FPSO, oil export and construction	2 x LTVs anchored in Berkeley Sound 2 x OCVs transiting between the LTVs in Berkeley Sound and the field location.	Ability to maintain a 24 hr operation over a total of six months as and when operationally required	Deck lighting and navigation lights from installation vessels and LTVs (up two vessels *in situ* at any time)

[1] Floating Production, Storage and Offloading Vessel.
[2] Mobile Offshore Drilling Unit.

11.8.4.2.2.2 Location of light sources

Most of the installation vessel activity that requires deck lighting will be based around the LTVs in Berkeley Sound and each vessel will have its own individual 500m exclusion zone as described in Section 5.5. The construction vessels will spend minimal amounts of time in the Sound while they collect equipment from the LTVs. While on-station, deck lighting will have to be maintained by all vessels throughout the 24hr operation to provide a safe working environment.

11.8.4.2.2.3 Number of lights

The intensity of light emitted by each vessel will vary depending on activity. At the time of writing, the identity of the specific vessels involved is unknown. Nonetheless, some comparisons can be made with other vessels operating in Berkeley Sound and it is expected that lighting arrangements on the LTVs will be similar to the supply vessels utilised during the exploration drilling campaign.

11.8.4.2.2.4 Orientation of lights

Some lights, such as navigation lights, are designed to be seen by other vessels and therefore are orientated to face out-board. However, these are usually low intensity lights.

The highest intensity lights are the deck floodlights, which are generally orientated to illuminate:

- Any operational activity being undertaken on the deck of the vessel,
- To assist safe access and egress, and
- The surrounding water.

11.8.5 Industry-standard mitigation

Various guidance is available on minimising light pollution:

- Scottish Executive 'Controlling Light Pollution and Reducing Lighting Energy Consumption' (2007),
- The Institute of Lighting Professionals Guidance Notes (ILP, 2021), and
- International Commission on Illumination (CIE) Report 150: Guide on the Limitation of the Effects of Obtrusive Light from Outdoor Lighting Installations (CIE, 2003).

- Department for Environment, Food and Rural Affairs (Defra) Guidance: Artificial Light Nuisances, How Councils Deal with Complaints (Defra, 2015).

In Stanley at the TDF and supply bases, light will be minimised where possible by design, through good working practice and the use of black out blinds, which aim to reduce potential nuisance to local residents.

With regard to Berkeley Sound, good working practice and design will help to limit the amount of light the vessels emit, particularly the design of vessels' lighting arrangements and use of black out blinds. The vast majority of light emitted will be focused on the vessel decks and immediate area surrounding the vessels.

11.8.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

A summary of the impact assessment outcomes for this Development is tabulated in Section 11.8.12 which shows the worst-case impact for each activity and receptor and details are provided below.

11.8.6.1 Impact assessment of light in Stanley

Light was raised as an issue during the earlier scoping consultations (pre-2016) and a single complaint was been received during the 2015 exploration campaign, relating to the lighting of vessels at the TDF. However, there are already lights in the Gordon Lines industrial area at the east end of Stanley. Therefore, on balance, the sensitivity of receptor is considered to be '**Moderate**'.

Lighting used at the TDF will result in very similar levels of light experienced during the exploration campaign in 2015. However, the yard space will be 2.5 times greater (Section 11.8.4.2.1.3), albeit for a short time, before reducing to an area approximately 40 % of that used for the exploration campaign. As such, lighting is expected to increase initially for a short period (approximately five years) before decreasing during steady state operations. Therefore, on balance, the severity of effect is considered to be '**Minor**'.

Therefore, the overall significance of the impact is considered to be '**Moderate (6)**', and project-specific mitigation measures to reduce the significance will be developed and implemented.

11.8.6.2 Impact assessment of light in Berkeley Sound

There are a number of light sources in Berkeley Sound from both fishing vessels and permanent navigation lights. While the fishing vessels are seasonal, complaints have been noted about the light pollution. The issue of light was also raised by stakeholders during the pre-2016 scoping consultations and therefore, on balance, the sensitivity of receptor is considered to be '**Moderate**'.

The relatively short-term nature of the light impact from the LTV operation combined with the distance of residences to the light source (greater than 10 km) indicate the severity of effect is considered to be '**Minor**'.

Therefore, the overall significance of the impact of light disturbance in Berkeley Sound from the LTV operation is considered to be '**Moderate (6)**'.

11.8.7 Project-specific mitigation measures

11.8.7.1 Light impact in Stanley

Minimum levels of lighting are required on the TDF and at the supply base to ensure a safe operation. However, it will be normal practice to switch off any operational lighting that is not required. For example, operational and office lights will be switched off each evening once operations have finished

for the day. The following measures will be taken, where possible, to reduce the light impacts from the supply base, TDF and vessels alongside the TDF:

- Deck lights and yard lights will face inwards, and
- Vessel lights to be turned off when not required, particularly deck lighting.

11.8.7.2 Light impact in Berkeley Sound

Minimum levels of lighting are required on the LTVs to ensure a safe operation and in line with legislation (Section 11.8.1.1). However, the following measures will be taken, where possible, to reduce the light impacts from the LTVs:

- Deck lights will face inwards, and
- Vessel lights to be turned off when not required, particularly deck lighting.

11.8.8 Residual impacts and risks

11.8.8.1 Light impact in Stanley

Implementing the proposed mitigations to reduce the impact of light nuisance from the supply base, TDF and vessels moored at the TDF have the potential to lessen the severity of effect. However, these mitigations were implemented during the 2015 exploration drilling campaign and a complaint was still received.

As such, even with project-specific mitigation measures in place, the significance of the residual impact of light in Stanley remains '**Moderate (6)**'.

11.8.8.2 Light impact in Berkeley Sound

Implementing the proposed mitigations to the LTVs anchored in Berkeley Sound has the potential to lessen the severity of effect. However, it is unclear whether these will have the desired effect and the LTVs will be *in situ* for longer than jigger vessels in the Berkeley Sound area and are likely to be present out-with jigger season, so the duration of impact is not changed.

As such, with the proposed project-specific mitigation measures in place, the significance of the residual impact of light in Berkeley Sound remains '**Moderate (6)**'.

11.8.9 Cumulative impact

Places of human settlement and industry ashore represent permanent, or at least regular, sources of light. In the Falklands, these are primarily associated with the two major population centres, Stanley and Mount Pleasant (MPC). Additionally, Berkeley Sound (the LTV site) is used as an anchorage for the trans-shipment of fish and so is also a significant seasonal source of light pollution.

11.8.9.1 Stanley

Sources of existing anthropogenic light in Stanley include all housing, industry and human activity in the town. At the east end of Stanley, where the TDF and supply base will be operating, the area is already designated for 'a mixture of heavy and light industrial, warehousing and storage' within the Stanley Town Plan (FIG, 2015d). The area is currently used as yard space and the TDF is already in place, although, at the time of writing, not in operation.

The peak of activity in Stages 1, 2 (a & 2b), will add in 'concentration' (Section 8.9.1) to the light in the area, particularly from vessels visiting the TDF. This period will last approximately five years, in two tranches of approximately 2.5 years each.

Once into steady state operations the activity, and hence light, will reduce to below levels experienced during the exploration drilling campaign, though these are still above the baseline levels experienced in Stanley on a day-to-day basis.

11.8.9.2 Berkeley Sound

Sources of existing anthropogenic light within Berkeley Sound are summarised in the chapter on the environmental (as opposed to social) impacts of artificial light (Section 10.1.9.2). Notably, the jiggers utilise Berkeley Sound to trans-ship their catches to reefer vessels and to refuel. Although the full rig of jigging lights are not deployed in Berkeley Sound, there is a considerable amount of light emitted from these vessels, the glow from which can be seen from Stanley (A. Black, *pers. obs.*). In addition to the jiggers, other vessels use Berkeley Sound as an anchorage, primarily for the trans-shipment of fish catches.

Although vessels can be present in all months of the year, activity peaks between March and June, when tens of vessels can be present, but this varies considerably from year-to-year. Combined, these vessels represent a large source of anthropogenic light. Navitas plan to avoid peak fishing season as much as practicable to avoid competition for sea room (Section 5.5.1). At peak times, the LTVs and construction vessels will have less of a cumulative impact as they will be one of many vessels in the Sound (adding to the concentration). At other times of the year, there may be very few vessels using Berkeley Sound and therefore, darker skies (Section 11.8.4.1). The LTVs and construction vessels will be in place for up to 7 months in Stage 1 and around 6 months in Stages 2a & 2b, adding considerably to the ambient level of light pollution (increasing the duration of the impact) albeit that the level of light will be far less than residents are accustomed to when jiggers are present.

11.8.10 Confidence

While the approximate timing of activities and type of vessels used during the Phase 1 & 2 Development of the Sea Lion Field is known, the intensity and orientation of lights on the vessels and supply base are not quantified, and analogous examples have been used in this assessment.

The nature of the impact on the receptor (people) is understood, however, it is very subjective and so it is difficult to predict the impact. The pre-2016 scoping consultations highlighted that light may be considered an issue by some and a complaint was received during the previous exploration drilling campaign.

With the available data, the level of confidence in the impact predictions (in terms of the nature of the impact and its level of significance) is considered to be **'Probable'**. Additionally, the data gaps are not considered to have the potential to significantly change the outcome of the assessment.

11.8.10.1 Monitoring required

The two key areas where monitoring will be focused is:

- Understanding the baseline, and
- Understanding tolerance of the local residents.

11.8.10.1.1 Understanding the baseline

Further monitoring of light will be conducted to establish baseline levels.

During operations, periodic site environmental monitoring will include community and site surveys.

11.8.10.1.2 Understanding tolerance of local residents

Performance of key activities that have the potential to lead to disturbance will be monitored and managed through periodic monitoring at relevant sites.

Further, during Phase 1 & 2, Navitas will develop and implement a complaints mechanism, whereby members of the public can make a complaint, comment or observation directly. A point of contact will be identified in the Islands to receive any complaints and act as community liaison.

Complaints will be monitored and reported to FIG on a monthly basis (at a minimum). If it is determined that any complaints have similar contributing factors, or a trend is identified, the most appropriate mitigation measure will be identified and implemented using the Navitas Management of Change process (Section 3.2.16).

All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 SEMMP.

11.8.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

11.8.12 Findings summary

Table 11.42: Summary of the of the social impact assessment for light disturbance during the Sea Lion Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity[1]	Severity[1]	Likelihood[1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Operations at the TDF and supply base	Vessels, TDF and yard lighting	Annoyance, sleep disturbance to Stanley residents	Planned	1, 2a, 2b & 3	Moderate	Minor	n/a	**Moderate (6)**	**Moderate (6)**	**Probable**	**Industry-standard:** Good working practice and design, and Black-out blinds will be used on the vessels, TDF offices and yard offices. **Project-specific:** Deck lights and yard lights will face inwards, and Vessel lights to be turned off when not required, particularly deck lighting.
LTV operations	Deck and accommodation lights	Annoyance, sleep disturbance, impairment of dark skies	Planned	1, 2a & 2b	Moderate	Minor	n/a	**Moderate (6)**	**Moderate (6)**	**Probable**	**Industry-standard:** Good working practice and design e.g., focusing deck lighting, and Black-out blinds will be used on the vessels. **Project-specific:** Deck lights will face inwards, and Vessel lights to be turned off when not required, particularly deck lighting.

[1] See Chapter 8 for definitions of sensitivity, severity, likelihood and significance.

11.9 Disturbance to human population – Helicopters and Noise

11.9.1 Introduction

Throughout the Phase 1 & 2 Development it will be necessary to use helicopters, the supply base and port facilities in Stanley, and also Berkeley Sound for the Large Transport Vessels (LTVs) and Offshore Construction Vessels (OCV's). All of these activities have the potential to create a noise nuisance. As shown in Chapter 6, noise from operations and helicopter overflights were raised by stakeholders during the informal scoping consultations.

This chapter assesses the potential for noise to impact upon local residents and livestock specifically. The impacts of helicopter noise on wildlife are assessed in Section 10.2.

11.9.1.1 Relevant legislation

11.9.1.1.1 Helicopter use

There are numerous pieces of International and Overseas Territory legislation in place to govern air safety, which are outwith the scope of this EIA.

As is also described in Section 10.2, aviation activities within the Falklands are overseen by Falkland Islands Civil Aviation Department (FICAD). Their work is principally governed by the following:

- Air Navigation (Overseas Territories) Order (AN(OT)O) (2013), and
- International Conventions and Standards ('Rules of the Air').

While no legislation is in place specifically with regards to the social impacts of noise disturbance, due to concern over disturbance to wildlife and livestock from low flying aircraft, guidelines have been developed in the Falklands, and elsewhere, to minimise the impact. These are described in Section 11.9.5.1 below as Industry-Standard mitigations.

11.9.1.1.2 Noise legislation

The main pieces of legislation governing noise pollution in the UK are:

- The Nuisance Provisions, under part III of the Environmental Protection Act 1990 (EPA 1990).
- The Environmental Noise (England) Regulations (2006).
- The Noise Abatement Act (1960).
- MARPOL Convention on the International Regulations for Preventing Collisions at Sea, (ColRegs) (1972).

11.9.1.1.2.1 Disturbance from noise

Disturbance in general is based on the definition of a 'statutory nuisance' in the Environmental Protection Act (EPA) 1990. For an activity to qualify as a source of disturbance it must do one of the following:

- Unreasonably and substantially interfere with the use or enjoyment of a home or other premises,
- Present a long-term and sustained impact to local residents' quality of life by an otherwise unwanted aspect, and / or
- Injure health or be likely to injure health.

With regard to the type of noise exposure anticipated in the Phase 1 & 2 Development, it is recognised that only the first two definitions above may apply.

11.9.2 Sources of noise disturbance

The following activities have the potential to cause disturbance to local residents:

- Use of helicopters:

- To carry personnel and / or equipment to and from the Mobile Offshore Drilling Unit (MODU) and the Floating Production, Storage and Offloading (FPSO) vessel,
- To carry a Falkland's marine pilot to and from the purchaser's Conventional Trading Tanker (CTT) prior to approaching the FPSO, and
- For Search and Rescue (SAR) exercises, test flights and any SAR response required.

- Use of the onshore supply bases and accommodation in the Stanley area,
- Use of the Temporary Dock Facility (TDF) in east Stanley, and
- Anchoring of up to two LTVs at any one time in Berkeley Sound to support the subsea and FPSO installation operation using OCVs.

The specific sources of noise disturbance as they apply during the various stages of the Development are presented in Table 11.43 below.

Table 11.43: Sources of noise disturbance from helicopter operations, operations in Stanley and operations in Berkeley Sound during the three stages of the Development

Location of disturbance	Source of noise	Stage 1	Stage 2a &b	Stage 3
Under flight paths	Helicopter engine noise.	✓	✓	✓
Stanley	Operation of the TDF: engine noise from vessels, vehicles, cranes, generators, lifting and loading of cargo from the TDF onto vessels and *vice versa*.	✓	✓	✓
	Operation of the supply bases: engine noise from vehicles, generators, forklifts, reversing alarms on vehicles.	✓	✓	✓
Berkeley Sound	Engine noise from the LTVs during anchoring.	✓	✓	-
	Noise from the LTVs during crane-lifting of infrastructure onto the associated OCVs.	✓	✓	-
	Engine and pump noise from LTVs and OCVs.	✓	✓	-

11.9.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify the specific receptors upon which the impacts of noise disturbance warranted further investigation (Chapter 9). This chapter, focusing on the human population, identified the following receptors that may be impacted during the Phase 1 & 2 Development:

- Human population:
  - Residents living in the vicinity of the TDF and supply base (east Stanley) (Section 7.7.2):
    - The population of the Falklands is concentrated within Stanley with the heliport located within Stanley Airport, approximately 3.5 km from the nearest housing,
    - The Gordon Lines area to the east end of Stanley, where the TDF and supply base are located, is generally an industrial area although there are a number of houses in the vicinity, albeit >1 km away, and
    - The north of East Falkland is dotted with small settlements and farms on potential flight routes.
  - Residents living in the vicinity of the proposed OCVs / LTV site in Berkeley Sound (Section 7.7.2.3):
    - There are four settlements / farmsteads around the Sound, with residents living and working in the area, as well as visitors and tourists.
- Aggregations of livestock (Section 7.7.4.7):

- Following the austral winter, local farmers are concerned about the condition of their livestock and the likelihood of a poor lambing season (mid-September to end October). Further, livestock is corralled during the shearing season that runs from November to February, potentially making it more vulnerable to disturbance (FILFH, 2024).

11.9.4 Characterising and quantifying the impact of noise disturbance

When characterising and quantifying the impact of noise disturbance on the local population and livestock, it is necessary to consider the:

- Nature of the impact upon the human population and livestock,
- Baseline noise levels in Stanley and Berkeley Sound,
- Quantification of disturbance from helicopters during Phase 1 & 2,
- Quantification of disturbance from other Phase 1 & 2 noise sources in Stanley, and
- Quantification of disturbance from other Phase 1 & 2 noise sources in Berkeley Sound.

11.9.4.1 Nature of the impacts

Noise disturbance may affect the human population by directly impacting upon residents and / or by impacting upon livestock.

11.9.4.1.1 Human population

The most commonly reported effects of noise exposure are annoyance and sleep disturbance, both of which can impact on quality of life (WHO, 1999). Unlike many other pollutants, noise pollution depends not just on the physical impact of the sound itself, but also the human reaction to it (Defra, 2010).

Annoyance is defined by WHO (1999) as:

> *'a feeling of displeasure, associated with any agent or condition, known or believed by an individual or group to adversely affect them'.*

Factors determining how 'annoying' the noise is to humans include:

- The individual's attitude to the noise source,
- The tonality, impulsivity, and intermittency of a noise,
- When the noise is occurring, and
- A feeling that the noise could be avoided.

Different levels and types of noise can cause different magnitudes of annoyance in different individuals depending upon their hearing and tolerance. To account for this, British Standard 4142 and the WHO add 'penalty' decibels (dBs) to measurements to account for those noises that are particularly annoying. For example, an intermittent sound that is clearly perceptible is considered in BS 4142 to be more annoying than a continuous noise at the same level and thus incurs a penalty of +3 dB (BS4142, 2014).

Additionally, studies have shown that much greater annoyance results when sleep is disturbed compared with daytime activities (Passchier and Passchier, 2000; NoMEPorts, 2008). As such, there are different exposure thresholds for noise to reflect the varying sensitivity to noise during the day and at night. To ensure a 'good night's sleep' the WHO (1999) recommend that continuous background noise levels should not exceed 40 dB(A). The '(A)' refers to an 'A-weighting' which is applied to sounds that have been measured by instruments in an effort to account for the loudness, as perceived by the human ear. Essentially, between 500 Hz and 6 kHz, the human ear is much more sensitive, but above and below these frequencies, the human ear is not particularly sensitive and the 'A-weighting' takes these sensitivities into account.

The WHO recommend that sound levels during the evening and night should be 5-10 dB(A) lower than during the day (WHO, 1999) (Table 11.44). As sound levels vary over the course of a day, an average ambient sound level is normally used for determining acceptable thresholds; this is referred to as the Equivalent Continuous Level. Most commonly this is 'A-weighted' (to account for human perception) and is expressed as the 'LAeq' (NoiseNet, 2008).

The WHO Guidelines for Community Noise (1999) state that during the day:

> *'few people are highly annoyed' at LAeq levels below 55 dB(A), and 'few are moderately annoyed' at LAeq levels below 50 dB(A)'*

These WHO thresholds are used to determine the noise levels that should not be exceeded in various settings (Table 11.44).

To summarise the above:

- A penalty (in dB) is added to account for the particular annoyance of different types of sound e.g., tonality, intermittent *vs.* continuous,
- An A-weighting (e.g., dB(A)) accounts for the sensitivity of human hearing, and
- The LAeq refers to the average ambient noise level over the course of a day to enable comparisons between the dB(A) of noise during the night-time, when people are less tolerant, with that of the daytime.

Table 11.44: WHO guideline thresholds for noise in specific environments[1]

Specific environment	Critical nuisance effects	LAeq dB(A)
Outdoor living area	Serious annoyance daytime and evening	55
Outdoor living area	Moderate annoyance daytime and evening	50
Outside bedrooms	Sleep disturbance, window open (outside value)	40

[1] **Note:** WHO (1999 & 2009) do not give guideline thresholds for 'no annoyance'.

11.9.4.1.2 Livestock

Generally, in the Falkland Islands, livestock is widely spread at low densities and therefore a small proportion of animals would be subject to disturbance from helicopters at any one time. However, when animals are corralled, the reaction by livestock that have been startled by aircraft is similar in nature to that of wildlife and is one of mass panic, which can lead to animals being trampled or to reduced lambing success (FILFH, 2024). Further, corralling of livestock is usually associated with times when animals may already be experiencing stress, such as during lambing or shearing. Given that the same animals are unlikely to be exposed to repeated overflights and may only experience helicopters when corralled in certain locations, it is unlikely that animals exposed to such disturbance events will become habituated and thus de-sensitised.

11.9.4.1.3 Opinion of stakeholders

Noise was noted during scoping consultations carried out by the previous operator (POEPL); stakeholders also mentioned that activities in Berkeley Sound can already be heard by local residents and complaints are made about noise when incumbent boats are loading and offloading.

Noise as a potential disturbance from the TDF and supply base in Stanley was noted during the 2015 exploration drilling scoping consultations, though not during those for the Sea Lion Development in 2014, 2016 or 2023 (Chapter 6).

During the scoping consultations it was noted that livestock are disturbed by helicopters but also that they may become habituated to the sound. There was also concern raised as to whether the guidelines in the Falkland Islands Low Flying Handbook are followed by all pilots.

11.9.4.2 Baseline levels of noise in Stanley and Berkeley Sound

As detailed in the Environmental and Social Baseline chapter (Section 7.7.5.1.1) noise measurements were previously conducted in Stanley on behalf of:

- Workboat Services Ltd. in March 2013, and
- Noble Energy Falklands Ltd. in March 2014.

POEPL also conducted a short noise survey in August 2016 for a period of 48 hours and some additional spot measurements in February 2017. Locations of the Workboat (2013), Noble Energy (2014) and POEPL (2016) surveys are shown in Figure 11-9.

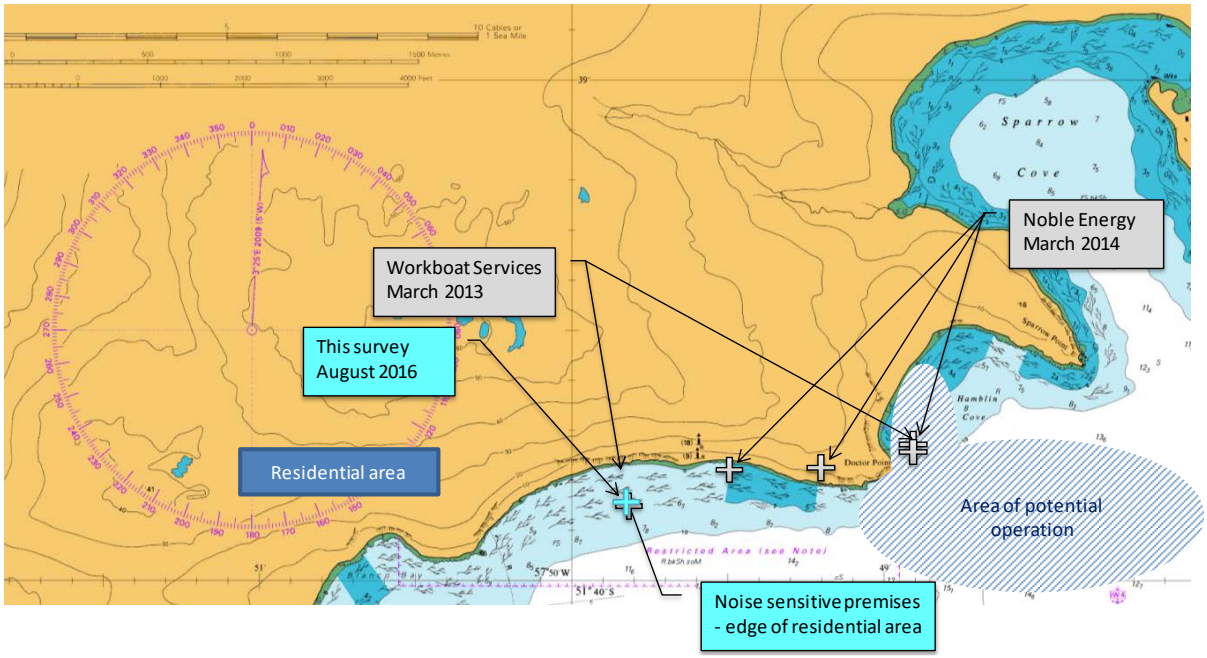

Figure 11-9: Location of noise monitoring points in Stanley. Note: 'This Survey' refers to the 2016 survey carried out by POEPL (Section 7.7.5.1.1.1)

11.9.4.2.1 Baseline noise in Stanley

In summary, wind and traffic play key roles in the noise profile in Stanley. Sound levels rarely dip below 40 dB(A) either during the day or at night, with an average noise level over the 2016 measurement period of 41.7 dB(A). The quietest period is between 11 pm and 6 am. Peaks in noise level reflect daily activities, with increases in noise levels between 6 am and 9 am and again between 3 pm and 5:30 pm. The minimum noise level recorded was 31.9 dB(A) and the highest was 106.3 dB(A), during a military overflight. The highest noise level spot measurements were recorded outside the power station (72.5 dB).

More detail on noise baseline monitoring in Stanley is available in the Environmental Baseline Description (Section 7.7.5.1.1).

11.9.4.2.2 Baseline noise in Berkeley Sound

Noise measurements were taken in Berkeley Sound near Long Island Farm, facing the Sound, over a period of 30 hours. Unfortunately, the initial recording was affected by wind. By convention, noise measurements taken above wind speeds of 5 m/s are not deemed reliable for noise assessments due to the effect of wind on ambient noise levels and, more specifically, the effect of buffeting on the microphone.

A second monitoring period at Long Island Farm was conducted in February 2017 which measured baseline noise levels in the absence of strong winds. Although winds were not monitored continuously, they were subjectively very low at the start and end of the measurement and no significant changes in weather were noted at the time. This reflects conditions when added noise from the proposed Project activities may cause the most annoyance. In this area, wind noise is a common and very apparent feature most of the time, and it was difficult to identify a period of more than a few hours when winds were low. The results should be read in this context, that they represent unusually 'quiet' conditions and do not reflect long term averages.

Daytime noise levels average around 40 dB(A), and night-time background levels averaging around 30 dB(A) for significant periods were recorded. Periodic loud noise events are observed lasting for 1-2 minutes. These are unidentified, but are unlikely to be passing local vehicles given the location of the meter and would be consistent with passing aircraft.

11.9.4.3 Quantification of disturbance from helicopter use

When quantifying the potential impacts of helicopter noise, it is necessary to consider the following:

- The proposed helicopter activity during the Development,
- Helicopter noise levels,
- The distribution of the susceptible residents and livestock, and
- The overlap between helicopter flight paths and residential and livestock areas.

11.9.4.3.1 Proposed helicopter activity during the Phase 1 & 2 Sea Lion Development

The level of helicopter activity throughout the Development is described in detail in Section 10.2.4.2.1. However, Table 11.45 is repeated below as a summary. The distribution of human and livestock receptors and the overlap between these and flightpaths are described below in Section 11.9.4.3.4.

Table 11.45: Number of helicopter flights during the Phase 1 & 2 Development

Helicopter activity[1]	Stage 1 (31 months, 942 days)		Stage 2a & b (35 months, 1,064 days)		Stage 3 (325 months, *c.* 27 years)	
	Frequency of flights	Number of flights[1]	Frequency of flights	Number of flights[1]	Frequency of flights	Number of flights[1]
Crew change to MODU	10 / fortnight	670	10 / fortnight	750	-	-
Crew change to FPSO					2 / week	2,795
Berthing crew transfer to CTT	n/a	n/a	Per direct offtake (average every 10 days)	106	Per direct offtake (average of 36 / year over Field Life)	972
SAR training	6.7 / month[2]	208	6.7 / month[2]	235	6.7 / month[2]	2,178
Total number of flights per Stage	**-**	**878**	**-**	**1,091**	**-**	**5,945**
Total	**7,914**					

[1] Based on an average of 30.4 days per month, and an average of 4.3 weeks per month.
[2] Based upon 20 hours flying per month and an average of 4.3 weeks per month.

11.9.4.3.2 Helicopter noise levels

Detail on the sound levels generated are described in Section 10.2.4.2.2. However, a summary of the sound levels, as well as noise levels of day-to-day activities for comparison, are repeated below in Table 11.46.

Table 11.46: Sound level from helicopter activity experienced at ground level *(adapted from Norske Olje and Gass, 2014; BMT, 2005)*

Activity	Maximum sound level at distance from sound source (dB(A))[1]			
	Equivalent at 1 m	Approx. 100 m	600 m	3,500 m
Super Puma EC225[2] (idling)	>114	-	*c.* 68	*c.* 43
Sikorsky S92 (idling)	>110	-	*c.* 54	*c.* 39
EC155 (overflight)	133	-	77	48
Sikorsky S61[2] taking off (recorded at MPN)	-	145	-	-
FIGAS Britten-Norman Islander (recorded at Stanley Airport)	-	148	-	-
Comparison with typical noise levels experienced by the public[3]	Chainsaw (120 dB)	-	Conversation (60 dB) Small penguin colony (65 – 69 dB)	Street in the evening (41 dB)

[1] An 'A-weighting' is normally applied to sounds measured by instruments in an effort to account for the 'loudness' as it is perceived by the human ear. Essentially, between 500 Hz and 6 kHz the human ear is much more sensitive, but below and above these frequencies the human ear is not particularly sensitive and the 'A-weighting' takes these sensitivities into account.
[2] Superpumas and S-61s are no longer used in the O&G industry.
[3] After NoMEPorts, 2008.

11.9.4.3.3 The distribution of the potentially affected residents and livestock

The only notable areas of dense human habitation in the Falkland Islands are found in Stanley and Mount Pleasant Complex (MPC). Heliports will be[95] located close to these communities and therefore air traffic and the human population converge here.

The distribution of Camp settlements and farms on the north of East Falkland is shown in Figure 11-10. Although livestock is widely spread at low density throughout much of the year, livestock corrals are generally associated with the settlements.

11.9.4.3.4 Overlap between helicopter flight paths and residential and livestock areas

Figure 11-10 highlights the distribution of sensitive environmental receptors and community settlements in the north of East Falkland.

11.9.4.3.4.1 Flights to the Sea Lion Field

Direct flightpaths between the two main heliports and the Sea Lion Field are indicated by the arrows. The flightpath from Stanley to the Sea Lion Field is on a bearing of 340° (I. Ewen, *pers. comm.*).

Direct routes to the Sea Lion Field from both Stanley and Mount Pleasant Airport (MPN), and between the two, will pass over three farms and settlements (Figure 11-10).

11.9.4.3.4.2 Flights to the CTT

A berthing crew will be transported from Stanley Airport by helicopter to the CTT at a safe distance from the FPSO and at least 12 nm from the Falkland Islands, using a similar approach route to that anticipated for normal FPSO crew change flights.

11.9.4.3.4.3 SAR Test Flights

SAR test flights may occur from MPN or from Stanley Airport, as occurred during the 2015 exploration campaign.

[95] Navitas intends to develop a heliport at Stanley airport in conjunction with FIG and this will be constructed in time to support Sea Lion Phase 1 & 2 operations. Stanley Airport has previously supported helicopter operations for the various exploration drilling campaigns.

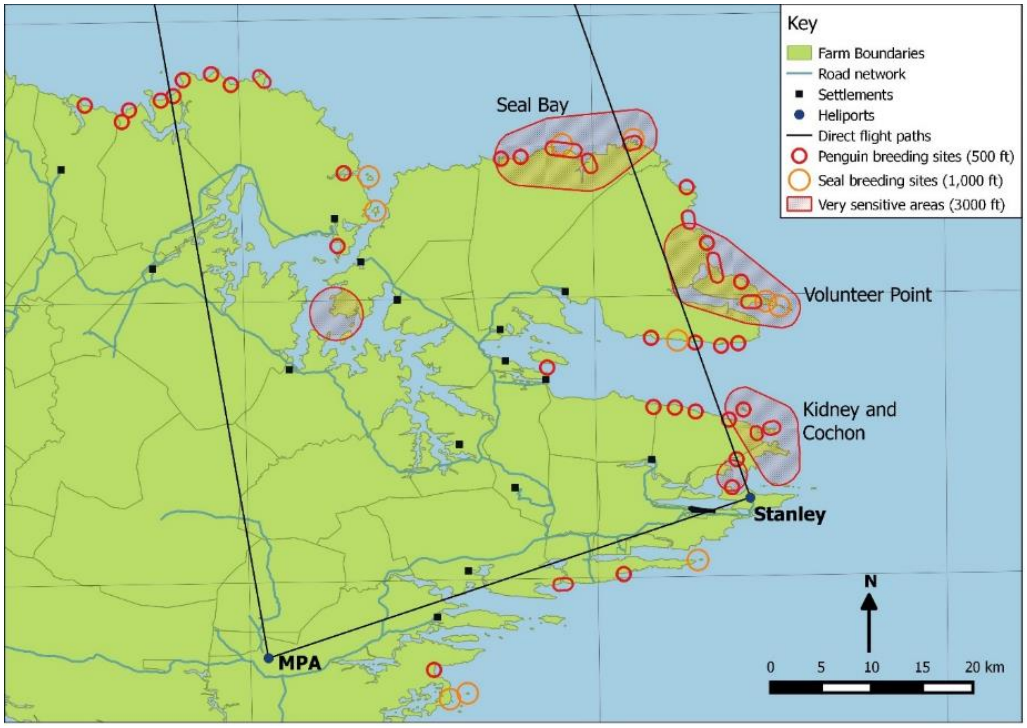

Figure 11-10: The distribution of sensitive wildlife receptors (see Section 10.2) and settlements in relation to the most direct helicopter flightpaths. Note: the arrows heading out to sea ultimately converge at the Sea Lion Field 220 km offshore. MPA refers to Mount Pleasant Airport

11.9.4.4 Quantification of other Phase 1 & 2 noise sources in Stanley

When characterising and quantifying the impact of noise in Stanley it is necessary to consider the:

- Type, location and timing of the Phase 1 & 2 noise sources near Stanley,
- Comparison of Phase 1 & 2 noise sources and duration with 2015 exploration campaign, and
- Estimation of Phase 1 & 2 noise levels near Stanley.

11.9.4.4.1 Type, location and timing of Phase 1 & 2 noise sources near Stanley

Noise types at the TDF and supply base during Phase 1 & 2 might include:

- Vessel engine noise,
- Lifting and loading at the TDF,
- Operation of the drilling mud and bulk mixing plant,
- Vehicles in the yard, including reversing alarms, and
- Lifting and moving equipment in the yard.

The previous operator of the Sea Lion Field, POEPL, made a successful application in January 2018 to the Falkland Islands Government (FIG) to vary the planning consent for the TDF to cover the duration of expected Phase 1 & 2 activities. Navitas is proposing future modifications to improve the dock's functionality. As described in Section 5.11.1.1.1, any proposals to upgrade the TDF facilities will have to go through the planning consent process. At the Planning Officer's discretion such applications may be accompanied by a full EIA. For the purposes of this EIS however, it is assumed that the TDF operations will be the same as they were during the 2015 exploration campaign.

The supply base is likely to be based in close proximity to the TDF, and outline planning permission has been granted by FIG as described in Section 5.11.1.2.

Both the TDF and supply bases may be operational 24 / 7 and thus may generate noise during the night.

A summary of the location and timing of Phase 1 & 2 noise sources, as compared to the 2015 exploration campaign is provided in Table 11.47 below.

11.9.4.4.2 Comparison of noise with 2015 exploration campaign

Specific data on anticipated Phase 1 & 2 noise levels from the varying sources are not available. Therefore, a comparison with the number and duration of noise sources during the 2015 exploration drilling campaign was made as it is assumed that the types of activity carried out during the Phase 1 & 2 Development activities at the TDF and the supply bases will be similar. Table 11.47 below summarises the number of sources and duration of noise at the TDF and at the supply base during the Phase 1 & 2 Development as they compare to the 2015 exploration campaign.

Following extrapolation of the number of vessels required and the area of yard space used during the 2015 exploration campaign, it is anticipated that during Stages 1 2a & 2b of the Phase 1 & 2 Development, the sources of noise from the yards could be greater, albeit not proportionally (Table 11.47). This will be for a period of approximately five and a half years. When the project progresses into steady state production (Stage 3), noise is likely to be less than that experienced during the exploration campaign.

Table 11.47: Source and duration of noise at the TDF and in the supply base during the Phase 1 & 2 Development as compared to the 2015 exploration campaign

Operation	Duration	Location	Activity at TDF and supply base	Comparison with 2015 exploration campaign	Potential implications for noise levels
Exploration drilling campaign					
2015	12 months	Current TDF location	2 supply vessels, 1 tug and 10 coasters (6 one way, 4 also counted on the return)	n/a	n/a
		Exploration drilling yard	51,000 m^2 of yard space		
Phase 1 & 2 Development					
Stage 1: Mobilisation and installation of materials and equipment, pre-First-Oil drilling by MODU, installation, HUC of the FPSO and 'First-Oil'	*c.* 2.5 years	Current TDF location	*c.* 10 vessels transiting to and from TDF	0.8 times number of vessels (including engine noise, lifting, loading and unloading from the TDF)	Vessel activity at the TDF is limited to 2 vessels, such that the noise level at any given time is unlikely to differ
		Operations Base location	127,500 m^2 of yard space	*c.* 2.5 times more yard space (including noise from vehicles, cranes, reversing alarms)	Potential for noise levels to be higher than during the 2015 campaign
Stage 2a & 2b: Post First-Oil drilling by the MODU (up to 15 wells), and concurrent production	*c.* 3 years	Current TDF location	*c.* 9 vessels transiting to and from TDF	0.7 times number of vessels (including engine noise, lifting, loading and unloading from the TDF)	Vessel activity at the TDF is limited to 2 vessels, such that the noise level at any given time is unlikely to differ

Operation	Duration	Location	Activity at TDF and supply base	Comparison with 2015 exploration campaign	Potential implications for noise levels
operations by the FPSO and oil export		Operations Base location	127,500 m^2 of yard space	*c.* 2.5 times more yard space (including noise from vehicles, cranes, reversing alarms)	Potential for noise levels to be higher than during the 2015 campaign
Stage 3: Steady phase production	*c.* 27 years	Current TDF location	*c.* 7 vessels transiting to and from the TDF per annum	*c.* 0.5 the number of vessels (including engine noise, lifting, loading and unloading from the TDF)	Potential for noise levels to be lower than during the 2015 campaign
		Operations Base location	20,000 m^2 of yard space	*c.* 0.5 the yard space (including noise from vehicles, cranes, reversing alarms)	Potential for noise levels to be lower than during the 2015 campaign

11.9.4.4.3 Estimation of Phase 1 & 2 noise levels near Stanley

In order to predict whether noise levels at the TDF and supply base might be acceptable based on commonly accepted standards (BS4142) (Section 11.9.4.1.1), noise attenuation calculations were undertaken. These were used to predict the attenuation that would be expected over a *c.* 1 km distance from the nearest residential location to the supply base / TDF, using appropriate assumptions for sound and environmental properties (Table 11.48).

These calculations show, for example, that a noise source with a sound power level of 110 dB(A), such as a diesel generator at the supply base, would result in a received noise level at the residential properties of 36.6 dB(A). A 6 dB(A) penalty for any potentially annoying characteristics of the sound tonality is added, giving a total received noise level at the residential properties of 42.6 dB(A). This is 0.9 dB above the average noise level during night and day (41.7 dB) measured by POEPL at Liberty Lodge (Section 11.9.4.2).

The British Standard 4142 states that if the commercial / industrial noise is around 5 dB higher than the background noise level, then this activity should be avoided (remembering that decibels are on a logarithmic scale such that an increase in sound level of 10 dB is equivalent to a doubling in the sound level). It also notes that if the noise is lower than the background, this is normally acceptable. An increase in background levels of around 0.9 dB therefore, may be acceptable to some but may disturb others (BS 4142). It is acknowledged that this is a guide only as, due to the subjective nature of disturbance from noise, some noises may still give rise to disturbance, despite being below the threshold.

Although all the received sound levels are below the WHO LAeq threshold of 50 dB(A), and as such are below the level likely to cause 'moderate annoyance in daytime and evening' (Section 11.9.4.1.1), the results in Table 11.48 indicate that unmitigated noise levels from certain activities could be near to 50 dB(A) and therefore could give rise to nuisance. Similarly, those that exceed the WHO night-time LAeq of 40 dB(A) could be more inclined to cause disturbance (Table 11.48).

Table 11.48: Example noise sources[1] from the supply base and TDF and the calculated received sound at nearest residences

Source example	Main frequency (Hz)	Sound power level (dB(A))	Received sound pressure level at nearby residences (dB(A))[2]	Received sound pressure level at nearby residences (dB(A)) + 6dB(A) penalty[3]	Difference to measured average background noise level (dB(A))	Potential outcome
75 kVA Diesel generator (BS5228-1:2009)	100	110	36.6	42.6	+2.1	Low to adverse impact
Inshore support vessels (as above)	63-100	96.8	23.4	29.4	-11.1	Low impact, normally acceptable
7.5 kW water pump (BS5228-1:2009)	125	106	32.5	38.5	-2	Low impact, normally acceptable
Reversing alarm (medium duty, manufacturer data)	1,000	114	40.2	46.2	+5.7	Adverse impact, should be avoided, if possible

[1] Note that there will be other smaller sources of noise from the supply base and TDF operations such as, for example, cars, lorries, tipper trucks and forklifts.
[2] Results calculated for 20 °C, 70 % humidity, mixed ground cover, no elevation difference.
[3] Although a 6 dB(A) penalty has been assumed, the penalty can be higher or lower depending on any specific unpleasant characteristics.

11.9.4.5 Quantification of other Phase 1 & 2 noise sources in Berkeley Sound

When characterising and quantifying the impact of noise in Berkeley Sound it is necessary to consider the:

- Location and timing of the noise sources in Berkeley Sound,
- Number of noise sources and duration of exposure in Berkeley Sound, and
- Airborne noise modelling.

11.9.4.5.1 Location and timing of noise sources in Berkeley Sound

Most of the OCV activity will be based around the LTVs in Berkeley Sound; each vessel will have its own individual 500 m exclusion zone. Navitas will work with FIG / Fisheries to identify optimum locations within Berkeley Sound that will cause the least disruption to other users and will strive to avoid periods of high marine traffic in the Sound. The OCVs will spend minimal amounts of time in the Sound while they collect equipment from the LTVs.

11.9.4.5.2 Number of noise sources in Berkeley Sound

The expected sources and duration of noise in Berkeley Sound during the Phase 1 & 2 Development are shown below in Table 11.49.

Table 11.49: Number, source and duration of noise in Berkeley Sound during the Phase 1 & 2 Development

Phase 1 & 2 Development Stage	Activity in Berkeley Sound	Duration of Presence in Berkeley Sound	Approximate number of noise sources in Berkeley Sound
Stage 1: Mobilisation and installation of materials and equipment, pre-First-Oil drilling by MODU, installation, HUC of the FPSO and 'First-Oil'	Up to 2 x LTVs anchored in Berkeley Sound 2 x OCVs transiting to and from the LTVs in Berkeley Sound	7 months	4 vessels (engine noise and lifting and loading noise from OCVs and LTVs)
Stage 2b: Post First-Oil drilling by the MODU, and concurrent production operations by the FPSO and oil export	Up to 2 x LTVs anchored in Berkeley Sound 2 x OCVs transiting to and from the LTVs in Berkeley Sound	5 months	4 vessels (engine noise and lifting and loading noise from OCVs and LTVs)
Stage 3: Steady state production		1 month[1]	

[1] Note the 1 month of this activity in Stage 3 happens in the 'interim Stage 3' between Stages 2a & 2b such that it directly precedes the 5 months of LTV activity in Stage 2b.

11.9.4.5.3 Airborne noise modelling

Noise modelling was carried out in Berkeley Sound as there is no point of comparison for the O&G industry as there is for Stanley, which has experienced noise from previous drilling campaigns. The activities planned for Berkeley Sound that may create additional noise are associated with the LTVs that will be anchored there and the associated visits of the OCV.

To enable brevity, the following sections provide only the information required to ensure appreciation and understanding of the modelling results and the impact assessment.

The following sections describe the:

- Modelling assumptions,
- Modelling of vessel noise around the proposed LTV anchorage location, and
- Summary of results.

11.9.4.5.3.1 Modelling assumptions

Given the standardisation of many vessel types according to their function and class requirements, it is possible to achieve reasonable correlations for noise output by different vessel classes. Therefore, a corresponding frequency profile was drawn from the Danish Ministry of the Environment (2010) which gives a noise profile from a Wartsila W6L32 engine exhaust stack. This type of engine is considered representative of the types of the vessels likely to be used. While there will be some noise from lifting and loading on the vessels, the majority of noise is generated by these engines. Table 11.50 provides a summary of the assumptions used in the model and the levels of noise modelled for each vessel.

Table 11.50: Main source assumptions used for modelling

Description	OCV[1]	LTV[1]
X coordinate (km) relative to the LTV anchorage	0.000	0.000
Y coordinate (km) relative to the LTV anchorage	0.000	-0.050
Elevation (m)	30	30
Source Noise Level, broadband sound power level dB(A)[2]	112.7	112.7

[1] OCV = Offshore Construction Vessel, LTV = Large Transport Vessel.
[2] Source levels are calculated from correlations in Danish Ministry of the Environment (2010).

11.9.4.5.3.2 Modelling of vessel noise in Berkeley Sound

Figure 11-11 plots the predicted noise levels (in dB(A)) from all vessels over an area 12 km by 24 km wide including the north and south shorelines of Berkeley Sound and receptors in line-of-sight to the west (Long Island Farm). Modelling shows that received levels from vessel noise are predicted to be up to 38 dB(A) at either shoreline and, since this is similar to existing vessel noise, and is below the WHO LAeq of 50 dB(A), it has been assumed that there would be no specifically annoying characteristics. The noise levels for assessment are 12 dB(A) lower than the level at which people experience 'moderate annoyance during the day', and 2 dB(A) lower than the WHO night-time level for sleep disturbance (Table 11.44 above). At the closest residence in this area (Long Island Farm), received noise levels from vessels are predicted to be around 24 dB(A).

Further, it should be noted that the noise modelling uses an attenuation method (ISO9613-2) that is widely used over open ground but which does not take account of topographical barriers. Relatively steep hills of around 100 m elevation or more exist to the north and south of Berkeley Sound which would dramatically attenuate (lessen) the noise heard in those directions e.g., towards Murrell Farm and Stanley. As such, noise levels in those directions are considered to be substantially less than those modelled at Long Island Farm.

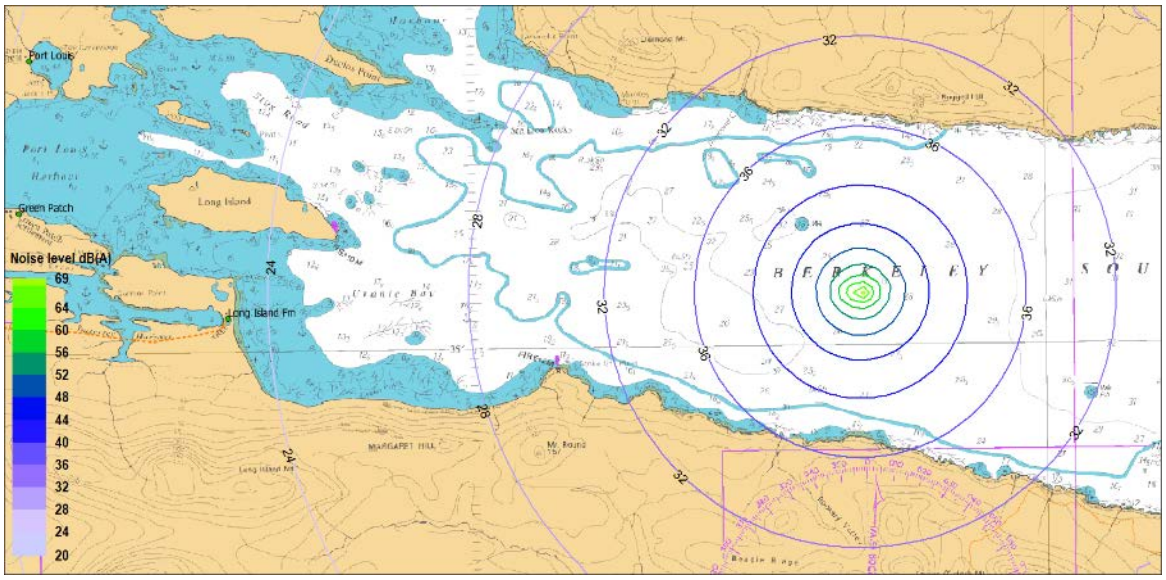

Figure 11-11: Received noise levels at a height of 1.5 m above ground from vessels operating around the proposed LTV Anchorage

11.9.4.5.3.3 Summary of modelling results

Table 11.51 compares the noise of the vessels operating, to the WHO Guidelines for Community Noise (1999) and the WHO Night Noise Guidelines for Europe (2009) (Section 11.9.5).

The noise levels received from the vessels at the Berkeley Sound shoreline and at Long Island Farm do not exceed the day or night-time thresholds. It is therefore considered unlikely that the current proposed operation will cause disturbance.

To further confirm whether noise sources in Berkeley Sound are acceptable or otherwise based on the WHO standards, further noise monitoring of the baseline in Berkeley Sound will be conducted throughout the Development and the results compared again to the WHO standards as per Table 11.51. For further detail on this monitoring, see Section 11.9.10.3.

Table 11.51: Berkeley Sound noise modelling results in comparison to WHO recommended levels

Noise Source	Modelled noise level received at Berkeley Sound shoreline	Modelled noise level received at Long Farm	WHO recommended level for daytime (WHO, 1999)	WHO recommended level for night-time (WHO, 1999 and WHO, 2009)
Vessels at the LTV Anchorage	38 dB(A)	24 dB(A)	50-55 dB(A)	40 dB(A)

11.9.5 Industry-standard mitigation

Relevant guidance on noise pollution includes:

- The International Finance Corporation (IFC) Environmental, Health and Safety (EHS) Guidelines: Noise Management (IFC, 2007a),
- Noise Management in European Ports (NoMEPorts): Good Practice Guide on Port Area Noise Mapping and Management (NoMEPorts, 2008),
- World Health Organisation (WHO) Guidelines for Community Noise (WHO, 1999),
- WHO Night Noise Guidelines for Europe (WHO, 2009),
- British Standard 4142:2014: Methods for rating and assessing industrial and commercial sound (BS4142, 2014),
- British Standard 5228:2009: Noise and Vibration Control on Construction and Open Sites (BS5228, 2009),
- Falkland Islands Low Flying Handbook (FILFH) Guidance (FILFH, 2024), and
- The Ministry of Defence's (MoD's) Falkland Islands Range and Avoidance Areas (5-GSGS) map (MoD, 2014).

Good working practice, in accordance with the above, will help to limit the amount of noise from the LTV operation as well as operations at the supply base e.g., maintaining vessel engines, design and layout of the base. Similarly, the design and working practices of the LTVs anchored in Berkeley Sound for the installation phase will aim to reduce any potential nuisance to local residents.

11.9.5.1 Mitigating the impact of helicopter use on livestock

While no industry-standard mitigations exist with regard to helicopter use in the O&G industry specifically, the FILFH Guidelines listed above which are specific to overflights have been developed in the Falklands to minimise the environmental impacts of disturbance from helicopters.

As described in Section 10.2, the simplest and most effective way to mitigate the effects of noise from helicopter overflights is to route helicopters away from aggregations of livestock. Following the example set by the MoD (MoD, 2014), and on other islands such as South Georgia, impact reduction methods (e.g., flight avoidance maps) can be used, which generally have a history of successful use and acceptance.

The key livestock avoidance areas are marked on the FILFH avoidance maps and the FILFH (2024) lists the following guidance:

- Sheep and Livestock Avoids - all aircrew, and particularly helicopter aircrew, are to be aware of the locals' concerns and are to avoid unnecessary over flight of livestock or known livestock grazing areas.

It is understood that during shearing season large flocks of sheep are gathered in preparation for shearing. The Military will invite landowners to notify HQ BFSAI (Mount Pleasant) of these areas of sheep concentrations and then promulgate them as temporary Notices To Airmen (NOTAMs), which

will be followed by Navitas' helicopters. Further, as the above is considered standard within the Falklands, Navitas will develop an approved project-specific flight plan which should be sufficient to mitigate the impact of helicopter disturbance to livestock (Section 11.9.4.1.2). Navitas will use the flight avoidance map as the basis for flight planning, following the Falkland Islands Low Flying Handbook Guidance (FILFH, 2024). All helicopter pilots will:

- Be briefed on flight avoidance protocols for sensitive areas prior to flying,
- Sign a document indicating that that the FILFH (2024) has been read and understood,
- Be accompanied by a pilot experienced in the area on their first flight, and
- Be issued with an approved flight path.

The above mitigation measures are taken into account during the initial impact assessment of helicopter noise described below (Section 11.9.6.1.2).

11.9.6 Impact assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of planned activities.

A summary of the impact assessment outcomes for this Development is tabulated in Section 11.9.12 which shows the worst-case impact for each activity and receptor and details are provided below.

11.9.6.1 Impacts of helicopter use

11.9.6.1.1 Disturbance to human population

Direct flight lines between MPN and the Sea Lion location, and those between MPN and Stanley Airport will pass over three settlements. However, the use of aircraft to transport passengers is an everyday occurrence in the Falklands so there is already a high degree of tolerance from people subjected to mild noise disturbance. Based upon the level of exposure, the sensitivity of the local population as a receptor to helicopter disturbance is therefore considered to be '**Low**'.

Stanley airport is sufficiently far from the nearest housing to negate the effect of helicopter noise. At times, it may be possible to hear the helicopters but the sound level experienced will be comparable with background noise. Equally, the SAR test flights may be carried out around MPN or around Stanley. Therefore, there should be no need for helicopters to overfly Stanley during normal operations, although this may happen in the case of a medivac situation when delivering patients to the King Edward VII Memorial Hospital (KEMH).

While every effort will be made to ensure that helicopters do not fly unnecessarily close to settlements, the impact of helicopter noise will be localised and short-term resulting in a barely detectable impact on the local population. Therefore, the severity of effect on Falklands' residents is considered to be '**Minor**'.

The overall significance of the impact of helicopter noise on Falklands' residents is therefore assessed as '**Low (4)**'.

11.9.6.1.2 Disturbance to livestock

Where animals are gathered e.g., for shearing or lambing, there is the potential to impact a high proportion of any one farms' livestock (Section 11.9.4.1.2). Direct flight lines from MPN to the Sea Lion Field and between MPN and Stanley Airport would also pass directly over, or close to, three settlements at which livestock may be corralled (Figure 11-10). Therefore, the sensitivity of receptor could be considered to be 'Very High'. However, as a flight plan, in line with the FILFH (Section 11.9.5.1), will be in place to ensure the avoidance of areas containing corralled livestock, the animals

will not actually be exposed to the helicopter noise. Therefore, the sensitivity of the receptor to the impact of helicopter noise can be considered to be '**Low**'.

As the FILFH compliant flight plan will prevent one-off or chronic exposure of corralled livestock to helicopter noise, the severity of effect of helicopter disturbance on livestock is considered to be '**Minor**'.

The overall significance of the impact of helicopter noise on livestock is therefore assessed as '**Low (4)**'.

11.9.6.2 Impact of noise disturbance in Stanley

While there is already a certain level of noise in the Gordon Lines area of Stanley (Section 11.9.4.1.1), noise was raised as an issue during the scoping consultations and it was noted that there have been complaints when boats are loading and unloading at FIPASS. Therefore, the sensitivity of receptor is considered to be '**Moderate**'.

Noise levels during the Sea Lion Phase 1 & 2 will be highest during the drilling and installation periods (Stages 1, 2a & 2b) when there will be the highest levels of vessel traffic in Stanley Harbour and most activity at the supply base (Section 11.9.4.1.1). Stages 1, 2a &2b will last for approximately five and a half years. Once into steady state production (Stage 3) which is the longest Stage of the operation, noise levels will decrease and level out. Therefore, on balance, the severity of effect is considered to be '**Minor**'.

Therefore, the overall significance of impact is '**Moderate (6)**', and project-specific mitigation measures to reduce the significance will be developed and implemented.

11.9.6.3 Impact of noise disturbance in Berkeley Sound

There are currently a variety of noise sources in Berkeley Sound from the fishing vessels and other vessels that use the Sound. However, noise was raised during the scoping consultations as a potential issue, and it was noted that there have been complaints about noise in the past. Therefore, the sensitivity of receptor is considered to be '**Moderate**'.

Noise modelling shows that the noise from the vessels involved is unlikely to pose a disturbance to the local residents as the sound of the vessels at the shoreline is lower than the WHO daytime and night-time thresholds (Section 11.9.4.1.1 above). The noise from the LTVs and associated operations will be short-term and intermittent however, the exact location of the LTVs is, as yet, undecided and therefore, to ensure a precautionary approach the Severity of Effect is considered to be '**Minor**'.

Therefore, the overall significance of impact is '**Moderate (6)**', and project-specific mitigation measures to reduce the significance will be developed and implemented.

11.9.7 Project-specific mitigation measures

11.9.7.1 Impact of helicopter use

As the impact of helicopter noise on humans and livestock is considered to be '**Low (4)**', there is no need to consider any additional project-specific mitigation measures.

11.9.7.2 Noise impact in Stanley

The introduction of operations at the TDF and the supply bases in east Stanley will increase noise levels in the area, particularly during the early stages of the Development. The following measures will be taken, where possible, to reduce noise impacts from the supply base, TDF and vessels alongside the TDF:

- Optimising the layout of the supply base to minimise sound propagation towards Stanley,

- Designing and managing construction and operations to minimise noise sources e.g., choice of site layout to minimise the travel of reversing alarm sounds or the use of white-noise reversing alarms,
- Application of specific mitigations for site equipment, based on noise calculations e.g., engine specification, enclosure and shielding of engines, auto-adjusting reversing alarms which alter output to suit the ambient noise level, or 'night-shift' alarms with lower output,
- Restrictions on the types of operations that can be undertaken at night to minimise night-time disturbance, and
- Loading of cargoes at the TDF will be prioritised for daytime operations.

11.9.7.3 Noise impact in Berkeley Sound

It is likely that the noise impact of the LTVs and associated operations will be minimal. However, the initial impact assessment retains a conclusion of '**Moderate (6)**' as a precautionary approach given that the final location of the LTVs is currently undecided. Therefore, noise impact from these operations shall be mitigated using the following methods:

- LTV engine use will be minimised,
- OCVs will, by preference, moor to the LTVs for cargo transfer, and avoid the use of dynamic positioning, and
- Cargo transfer operations will avoid, where practicable, between the hours of 11pm to 6am.

11.9.8 Residual impacts

11.9.8.1 Impact of helicopters

No residual assessment was carried out for impacts to the human population or livestock for which the impact assessments were considered to be '**Low (4)**'.

11.9.8.2 Noise impact in Stanley

The minimisation of noise where possible at the TDF and supply bases will reduce the severity of the impact to '**Slight**'.

With project-specific mitigation measures in place therefore, the significance of the residual impact of noise disturbance in Stanley is reduced to '**Very Low (3)**'.

11.9.8.3 Noise impact in Berkeley Sound

The minimisation of noise where possible within Berkeley Sound will reduce the severity of the impact to '**Slight**'.

With project-specific mitigation measures in place therefore, the significance of the residual impact of noise disturbance in Stanley is reduced to '**Very Low (3)**'.

11.9.9 Cumulative impact

Human settlements and industry onshore will always be sources of noise pollution. In the Falklands, these are primarily associated with the two major population centres, Stanley and MPC. Additionally, Berkeley Sound (the proposed LTV site) is used as an anchorage for the trans-shipment of fish and is also a seasonal source of noise. The following sections assess the potential for cumulative impacts at these two sites.

11.9.9.1 Stanley

Sources of existing anthropogenic noise in Stanley include all housing, industry and human activity in the town. At the east end of Stanley, where the TDF and supply base will be operating, the area is

already designated for 'a mixture of heavy and light Industrial, warehousing and storage' within the Stanley Town Plan (FIG, 2015d). The area proposed as the Operation Base is located adjacent to other operating yards and the TDF is already in place, although, at the time of writing, not in operation.

The peak of activity in Stages 1, 2a & 2b, will add in 'concentration' (Section 8.9.1) to the noise in the area. This period will last for approximately five and a half years.

Once into steady state operations (Stage 3) the activity, and hence noise, will reduce to below levels experienced during the 2015 exploration drilling campaign.

11.9.9.2 Berkeley Sound

Sources of existing anthropogenic noise within Berkeley Sound are summarised in Section 11.9.4.2.2. It was noted during the scoping consultations that the jiggers can be heard from local settlements around Berkeley Sound. In addition to the jiggers, other vessels use Berkeley Sound as an anchorage, primarily for the trans-shipment of fish catches.

Although vessels can be present in all months of the year, activity peaks between March and June, when tens of vessels can be present, but this varies considerably from year-to-year (Section 7.7.3.2.4). The LTVs and OCVs will, where practicable, avoid this period and so will not add to this in terms of 'increased concentration' and 'increased extent and proportion' (Section 8.9.1). This approach will however lead to an 'increased duration' (Section 8.9.1). At peak times, Navitas' activities will have less of an impact over and above the existing baseline as they will be one of many vessels in the Sound. At other times of the year, there may be very few vessels using Berkeley Sound and therefore Navitas' activities will add incrementally to the current baseline noise level and thus may have a more discernible impact.

11.9.10 Confidence

11.9.10.1 Helicopter use

The project activities are clearly defined in terms of the:

- Start and end points of flights,
- Frequency of flights, and
- Adherence to project-specific flight plans.

Equally, the locations of receptors (e.g., human populations and corralled livestock) are known.

Nonetheless the impact of noise on the human population is highly subjective such that the confidence in the assessment of impacts to humans is considered to be '**Probable**'.

While the long-term consequences of the impact of noise on livestock are not fully understood, the use of the flight plan will take account of tried and tested mitigation measures such that the confidence in the assessment of impacts to livestock is considered to be '**Certain**'.

11.9.10.2 Noise in Stanley and Berkeley Sound

The approximate timing of activities and type of vessels anticipated for use during the different options for the Phase 1 & 2 Development of the Sea Lion Field are well understood whilst the noise that may be emitted from the LTVs, supply base and TDF is not.

The nature of the potential impact on the receptor (people) is understood but it is a very subjective issue and is therefore difficult to predict. Scoping consultations highlighted that noise may be considered an issue by some. Further consultations may be required to better understand the sensitivity of local residents to noise and, once operations start, a clear complaints procedure will be in place, as well as a monitoring programme to record baseline noise levels (Section 11.9.10.3 below).

There is some uncertainty in the modelling conducted in that there are certain rare weather conditions, i.e., temperature inversions over water, in which sound levels may be higher than predicted by the model and it is not known how often these weather conditions may occur.

With the available data, the level of confidence in the impact predictions (in terms of the nature of the impact and its level of significance) is considered to be '**Probable**'.

11.9.10.3 Monitoring required

In order to confirm whether noise sources at the TDF, supply base and Berkeley Sound might be acceptable based on commonly accepted standards (BS4142), further noise monitoring of baselines and typical noise levels created by normal activities at the TDF, supply base and Berkeley Sound will be conducted. Further baseline monitoring will be undertaken to strengthen the basis of the assessment and to inform operations and monitoring programmes.

Performance of key activities that have the potential to lead to disturbance will be monitored and managed through periodic monitoring at relevant sites as is described in the Disturbance from Light chapter (see Section 11.8).

Detailed monitoring requirements have been established during the Environmental Monitoring and Management Plan (EMMP) workshop. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 EMMP (an outline EMMP is provided in Chapter 15).

11.9.11 Offsetting

For significant residual and impact and risks ('Moderate' or above), offsetting *via* a Carbon and Biodiversity Offsetting Fund is proposed, see Section 8.11 for further details.

11.9.12 Findings summary

Table 11.52: Summary of the of the social impact assessment for noise disturbance during the Sea Lion Phase 1 & 2 Development

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity[1]	Severity[1]	Likelihood[1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Helicopter use	Helicopter noise	Annoyance, sleep disturbance	Planned	1, 2a, 2b & 3	Low	Minor	n/a	**Low (4)**	**Low (4)**	**Probable**	**Industry standard:** Flight plan Follow FILFH Guidelines Be accompanied by an experienced pilot on their first flight **Project-specific:** n/a
		Disturbance to livestock			Low	Minor	n/a	**Low (4)**	**Low (4)**	**Certain**	
Operations at the TDF and supply base	Vessel, TDF and yard noise	Annoyance, sleep disturbance to Stanley residents	Planned	1, 2a, 2b & 3	Moderate	Minor	n/a	**Moderate (6)**	**Very Low (3)**	**Probable**	**Industry-standard:** Good working practice and design e.g. Maintaining engines, design and layout of the base. **Project-specific:** Optimising layout to minimise noise disturbance, Equipment specifications to minimise noise, and Daytime loading of cargoes at the TDF prioritised.
LTV / OCV operations	Vessel noise	Annoyance, sleep disturbance	Planned	1 & 2	Moderate	Minor	n/a	**Moderate (6)**	**Very Low (3)**	**Probable**	**Industry-standard:** Good working practice and design e.g., Maintaining vessel engines, **Project-specific:** Engine use minimised,

12.1.12 Findings summary 1225

12.1.1 Introduction

The marine environment is contaminated with both anthropogenic (man-made) and natural sources of hydrocarbons. The main anthropogenic inputs include direct spills of petroleum products and atmospheric deposition from combustion. Natural sources include atmospheric deposition from forest fires and volcanic eruptions. Oil pollutants have greater impacts in enclosed and semi-enclosed marine environments than in the open sea.

Along with the potential environmental impacts from planned development activities, impacts may arise from unplanned / accidental events and this was raised as a concern by stakeholders during the 2014, 2015 & 2016 scoping consultations (Chapter 6). Crude oil and fuel spills are unplanned events, which would result in environmental impacts if they occurred. The nature, extent and significance of these impacts will depend on a number of variables associated with the event, including, for example, the properties of the oil released, the size of spills, prevailing weather conditions and the sensitivity, density and distribution of environmental receptors in relation to the spill.

This chapter assesses the risks and potential impacts on environmental receptors in the offshore marine environment of seven scenarios, including five specific oil spill scenarios as well as those associated with low-level but chronic oil pollution and a loss of marine riser contents during drilling.

Note: the impacts associated with other discharges to sea are described elsewhere in this document, as outlined in Table 2.2.

Note: oil spill waste and the procedure for dealing with oil spill clean-up waste is described in Section 10.10.2.2.3.

12.1.1.1 Legislation relevant to oil and diesel spills

Much of the legislation applied to the Oil and Gas (O&G) industry is in place to prevent accidental events and is therefore relevant to oil spills. More specifically, the following legislation is related directly to discharges and spills in the marine environment.

- International legislation:
  - International Convention on Oil Pollution Preparedness, Response and Co-operation (OPRC Convention).
  - International Regulations for Preventing Collisions at Sea (ColRegs) (1972).
  - International Convention for the Prevention of Pollution from Ships (MARPOL) 73/78 Annex I on the Prevention of Pollution by Oil.
- UK legislation:
  - The Offshore Petroleum Production and Pipelines (Assessment of Environmental Effects) Regulations 2020.
  - The Offshore Petroleum Activities (Oil Pollution Prevention and Control) Regulations 2005 (as amended Regulations 2011).
  - Offshore Installations (Emergency Pollution Control) Regulations 2002.
  - Merchant Shipping (Oil Pollution Preparedness, Response & Co-operation Convention) Regulations 2015.
- Falkland Islands legislation:
  - Maritime Ordinance 2017 (and Amendments).
  - Maritime (Oil Pollution Preparedness, Response and Co-operation Convention) Regulations 2019.
  - Harbours and Ports Ordinance 2017.

- Merchant Shipping (Regulation of Ships) Regulations 2001.
- Offshore Petroleum (Licensing) Regulations 1995.
- Offshore Petroleum (Licensing) Regulations 2000 (as amended).
- Offshore Minerals Ordinance 1994 (as amended).
- Oil in Territorial Waters Ordinance 1960.
- Maritime (Ship to Ship Transfer) Regulations 2023.
- PON 08 Oil Pollution, requires that all release of oil to the sea must be reported as soon as possible to:
  - The Department of Mineral Resources as regulator, and
  - The Falkland Islands Maritime Authority (FIMA) as incident commander under the National Oil Spill Contingency Plan (NOSCP).

12.1.1.1.1 National Oil Spill Contingency Plan (NOSCP)

The FIMA is the lead agency charged with the safety of seafarers, the safety of ships and protection of the marine environment, as well as responding to marine oil spills within the 12 nautical mile (nm) territorial limit and 200 nm Exclusive Economic Zone (EEZ). The NOSCP currently reflects the most likely type of spill expected, namely minor spills within the harbours. Oil spill response equipment is stored at the Falklands Interim Port And Storage System (FIPASS) to counter this risk. Offshore, the NOSCP (FIG, 2022b) relies on the use of dispersants providing that the oil and environmental conditions are suitable.

Due to the limited response capability in the Falkland Islands, O&G operators are obliged to provide equipment and contingency plans to mount an effective response to oil spilled from their facilities. Oil Spill Emergency Plans (OPEPs) submitted to the Falkland Islands Government (FIG) are required to be compatible with the NOSCP.

12.1.1.1.2 Offshore Oil Spill Strategy

An Offshore Oil Spill Strategy for the Sea Lion Development was previously developed (Premier, 2019b), which identified the essential components of spill response for the project.

12.1.1.1.3 Oil Pollution Emergency Plan (OPEP)

Navitas will submit an OPEP as a separate document, which contains specific operational information such as detailed action lists and contact details for personnel. As described below, the OPEP will outline the responsibilities, actions, reporting requirements and resources available to ensure the effective and timely management of an accidental spill, and will be compatible with the NOSCP.

The OPEP will consist of a tiered response framework that is related to the magnitude of any spill event. Response and preparedness levels will be organised according to the International Petroleum Industry Environmental Conservation Association (IPIECA) / IMO international standard model of 'Tiered preparedness and response', defined as follows:

- **Tier 1 Spills:** An oil spill that will be mitigated solely using the local offshore response resources held by Navitas as defined within the OPEP.
  - Tier 1 spills will either be contained using local recovery equipment or monitored as it dissipates. A boom system and a skimmer[96] will be deployed on the Multi Role Support Vessel (MRSV) and Anchor Handling Tug Supply (AHTS) vessels, also referred to as an

[96] Note that the CEDRE investigation into the Sea Lion crude concluded that neither oleophilic nor weir skimmers would be effective for Sea Lion crude and that belt skimmers should be considered the most appropriate equipment (CEDRE, 2017). Oleophilic weir skimmers will only be deployed for response to MGO spills.

Anchor Handling Vessels (AHVs). Recovered oil will be stored in storage bladders and returned *via* a specifically mobilised recovery tanker for final disposal. Surveillance will be carried out either using aerostat balloons, drones and / or helicopter.

- **Tier 2 Spills:** An oil spill requiring support and resources from other local Navitas resources, oil operators / stakeholders in the Falkland Islands. The spill will be reported and Navitas will consult with the FIG NOSCP incident command, as required.
  - Tier 2 spills will be contained using the Tier 1 and 2 local equipment as described in Section 5.11.1.2.3. These resources will be supported by an *additional* AHTS or MRSV. Assuming that one Navitas vessel is already engaged in response, the Tier 2 response will be drawn from the remaining 1-3 Navitas MRSV / AHTS vessels present in the area. All such vessels would be classified to operate in the offshore location and equipped with identical specification response equipment, and
  - Surveillance will be carried out either using aerostat balloons or helicopter (MGO only). For Sea Lion crude, long-wave infra-red surveillance equipment, and satellite surveillance will be made available for use.
- **Tier 3 Spills:** An oil spill incident requiring international resources. The FIG NOSCP will be activated with national and, where necessary, international resources being deployed. These resources will be made available from the appointed international spill response provider stockpile within 96 hours of request; personnel might be deployed more quickly. In addition to the Tier 1 and Tier 2 resources already described, Navitas will have arrangements in place to mobilise resources from international oil spill response providers and local contractors if necessary to:
  - Supply offshore containment and recovery services: at sea recovery may not always be feasible in the Falkland Islands due to prevailing sea conditions,
  - Request satellite surveillance and conduct oil spill modelling,
  - Prepare for any shoreline response, if required: equipment is available for shoreline protection and clean-up, and
  - Aerial surveillance would be conducted using local aviation resources but might be bolstered by experienced observers from international oil spill providers.
- All spills are reported *via* a PON8 (Section 12.1.1.1.5).

12.1.1.1.4 Wildlife Response

Navitas has previously investigated optimal arrangements and providers for wildlife response and the OPEP will detail these arrangements. A wildlife response plan will also be developed and be in place before commencement of operations.

12.1.1.1.5 Spill reporting and the PON8

In line with the Offshore Petroleum (Licensing) Regulations 1995 and 2000 (Model Clause 21(8) of Schedule 2), the PON8 sets out the requirements for notifying the authorities of any oil spill (regardless of size) and provides a *pro forma* template, with contact details, to be completed.

In summary, spills of any size must be reported, *via* the PON 8 to the:

- FIG Department of Mineral Resources as regulator, and
- FIG FIMA as incident command for the NOSCP.

Note that the PON8 also requires information on oil sheens associated with produced water to be reported (Section 3.1.7.4).

12.1.2 Sources of potential offshore oil spills

Sources of oil pollution from the O&G industry are many and varied and include catastrophic spill events as well as small scale and chronic releases.

During the ENVironmental Impact Identification (ENVIID) workshop, a number of oil spill scenarios were identified and selected for further assessment. These include:

- Large oil spills:
  - Scenario 1: A subsea well blow-out,
  - Scenario 2: The complete loss of the Floating Production, Storage and Offloading (FPSO) vessel's crude oil inventory plus two tanks of the offload tanker,
  - Scenario 3: A crude oil transfer spill during FPSO offloading to the purchaser's Conventional Trading Tanker (CTT),
  - Scenario 4: The loss of the Mobile Offshore Drilling Unit's (MODU's) diesel (or Marine Gas Oil (MGO)) inventory, and
  - Scenario 5: An MGO bunkering spill.
- Small scale / chronic oil releases, and
- Loss of MODU riser contents containing NADF.

12.1.2.1 Large oil spills

12.1.2.1.1 Scenario 1: subsea well blow-out

In the unlikely event that all the preventative industry-standard safeguards and controls fail (Section 12.1.5), it is possible that crude oil could 'kick' into the wellbore leading to an uncontrolled release or 'blow-out'. Once drilling finishes the likelihood that a well blow-out may occur decreases (Section 5.4.9).

12.1.2.1.2 Scenario 2: loss of the FPSO crude oil inventory

While it is possible that extreme and freak weather conditions could impact the FPSO, the FPSO will be designed to ensure it is able to withstand the range of environmental conditions in the North Falkland Basin (NFB).

In addition, the FPSO will be anchored *via* a detachable turret and therefore, will be able to move off-station, if considered necessary. Therefore, although highly unlikely to occur, the only credible events that could lead to a scenario in which the FPSO loses its entire crude oil inventory would be a collision with a large vessel transiting through the area (Section 11.1) or a collision with an iceberg. Collision risk assessments have been conducted for both of these scenarios and are presented in Anatec (2024b) 'Sea Lion Offshore Development Vessel Collision Risk Assessment' (Ref: A5274-NVP-VCRA-1). Navitas will also have an Iceberg Management Plan in place prior to commencement of operations.

UK OPEP Guidelines (BEIS, 2022a) have been followed which requires that loss of the full FPSO inventory has been assessed.

12.1.2.1.3 Scenario 3: crude oil transfer spill

Following production and processing, crude oil will be stored on the FPSO. Once full, it will be necessary to offload the crude from the FPSO to a CTT. Offloading to the CTT may occur twice in any given export cycle to ensure that the CTT is full prior to its departure.

While offloading operations are a planned activity, there is the potential for a failure of the transfer hose and the resultant loss of crude at the offshore location during the transfer process. While such

spills would most likely be small as the offloading process would cease as soon as any leak or spill was detected.

The likelihood of any failure modes that can lead to a hose failure are discussed further below (Section 12.1.6.3.2) and a potential worst-case is assessed in this chapter.

12.1.2.1.4 Scenario 4: loss of the MODU MGO inventory

As with the FPSO in Scenario 3, the only credible scenarios which could lead to the loss of the entire MGO inventory from the rig would involve a catastrophic impact from a large vessel or iceberg. This scenario could equally apply to the FPSO; however, the MODU was modelled as it has a larger MGO inventory.

12.1.2.1.5 Scenario 5: MGO bunkering spill

While all industry-standard safeguards will be in place (Section 12.1.5), there is the potential for spills of MGO to occur during bunkering operations. While such spills would most likely be small as the bunkering process would cease as soon as any leak or spill was detected, this chapter assesses the potential worst-case scenario.

12.1.2.2 Small scale releases

Chronic oil pollution refers to the accumulation of oil from numerous sources (NRC,1985 and 2003).

Specifically, chronic oil pollution can result from:

- Legally compliant operational discharges with low-level oil in water (OiW) concentrations e.g., drainage, bilge and produced water discharges,
- Discharge of off-specification operational discharges between samples, and
- Small and discrete accidental oil spills.

Note: the potential impacts of oil sheens forming from legally compliant or off-spec operational discharges, and their contribution to chronic oil pollution, are described in Section 10.7.

12.1.2.3 Loss of MODU riser contents containing NADF

During the 2015 exploration drilling campaign, the MODU lost station due to failure of the Dynamic Positioning (DP) system which resulted in the loss of the riser contents to the sea. This resulted in the loss of 450 kg of Water-based Mud (WBM) to sea. Some sections of the Phase 1 & 2 Development wells will be drilled with a Non-Aqueous Drilling Fluid (NADF), which would cause greater environmental impact than WBM if released. However, the MODU will be anchored to the seabed and will not be maintained on station by DP. The risk of losing station is therefore greatly reduced and the loss of riser contents due to an emergency disconnect has been scoped out of this assessment as is indicated in the ENVIID report (Chapter 9).

Nonetheless, it is possible that the contents of the riser (approximately 60 m^3 of NADF) may be lost due to other reasons and as such, is included in the assessment below.

12.1.3 Potential environmental receptors

The ENVIID workshop was used to identify those receptors upon which the impacts and / or risks of oil spills warranted further investigation (Chapter 9). These include:

- Water quality and plankton (Section 7.4.1),
- Sediment quality and benthic communities (Section 7.4.3),
- Fish and squid (Section 7.4.4),
- Seabirds (Section 7.4.6),

- Marine mammals (Section 7.4.5),
- Coastal communities / ecology including marine flora (Section 7.6),
- Fisheries (Human population) (Section 7.7.3.1), and
- Tourism (Human population) (Section 7.7.4.6).

These receptors may be impacted upon as they either exist in, or spend time in, the area that could be influenced by an accidental release of oil into the marine environment.

12.1.4 Characterising and quantifying the risk of oil spills

When characterising and quantifying the impacts of oil spills, it is necessary to consider the following:

- Influencing factors:
  - Type and composition of oil, and
  - The fate of oil in the marine environment.
- The nature of the impact on each of the different receptors (Section 12.1.3),
- Spill modelling parameters, and
- Spill modelling results for:
  - Scenario 1: Well blow-out,
  - Scenario 2: Loss of FPSO crude inventory,
  - Scenario 3: Spill during crude oil transfer,
  - Scenario 4: Loss of MODU MGO inventory, and
  - Scenario 5: MGO bunkering spill.

12.1.4.1 Influencing factors

12.1.4.1.1 Oil type and behaviour

The type of oil can influence the nature of the impact to receptors. Some receptors are more vulnerable to the physical impacts of heavier crudes, others to chemical toxicity of lighter oils and NADFs, while others still are relatively resilient.

In general, heavier crude oil is more likely to cause fouling but is less toxic than refined oils. Toxic effects occur when oil components are bioavailable to the organisms being exposed. Volatile aromatic compounds, such as benzene, toluene and Poly-Aromatic Hydrocarbons (PAH), are highly toxic, can cause internal damage and can bioaccumulate in food chains. In the water column they are relatively short-lived, e.g., 98 - 99.9 % biodegradation of dissolved PAH in 28 days (SINTEF oil weathering database), whereas once in sediments, they can persist for much longer. In coastal waters, PAHs are concentrated in marine sediments where squid and other molluscs are particularly subject to exposure, and PAHs can be persistent in marine sediments or in the tissues of some animals.

12.1.4.1.1.1 Sea Lion crude

Sea Lion crude is an atypical oil given its extremely high wax content (42.3 % (Section 5.3)), which is greater than any analogue in the oil weathering databases held by the international research centres at CEDRE and SINTEF. Crude oils with high wax contents tend to solidify rapidly on release as the oil cools to ambient temperatures. Tests were undertaken to determine the weathering, behaviour and potential impacts of Sea Lion crude. A summary of results (Table 12.1) and some representative images are presented below (Figure 12-1). For full details see CEDRE (2017).

The behaviour of oil / wax particles resulting from a release were tested at CEDRE in simulated conditions of the NFB marine environment over a seven day period, and also with breaking wave conditions for a further three days. The oil masses that initially formed from pouring the oil into cold

water were in the size range of centimetres and showed little breakdown in particle size over time (CEDRE, 2017). The initial conditions of any release will determine the initial size and shape of cooled oil masses. For example:

- A subsea blow-out will tend to result in small oil masses due to the high turbulence and shear forces including gas at the wellhead (seen in small scale trials (CEDRE, 2017)),
- Small spills similarly may result in small oil masses (CEDRE, 2017), and
- Large spills will tend to form larger masses.

Table 12.1: Summary of results of CEDRE Sea Lion crude oil tests (CEDRE, 2017)

Aspect	Test results	Implication for risk assessment and / or spill response
Specific Gravity (s.g.)	S.g. is 0.833, i.e., the density is 0.833 tonnes per cubic metre	Less dense than seawater (s.g. 1.027) and readily floats
Wax content	Very high wax content of 42.3 % measured by the wax crystallization method	The crude is solid at ambient temperature and resists physical breakup into smaller particles
Pour point	Oil remains solid until heated to 36 °C	The crude is solid at ambient temperature and on the sea surface and does not spread once cooled. It must be heated to >36 °C to flow under the action of gravity. At higher pressures it can be pumped at lower temperatures e.g., 25°C for oil recovery.
Physical state when in contact with water / ambient air temperature	Immediately solidifies in contact with water at Falklands seawater temperature (Figure 12-1).	As above. Individual oil masses do not tend to coagulate together once cooled.
Evaporation	True Boiling Point data indicate that at 140 °C up to 2.8 % volume of the crude evaporates (this is extrapolated to the fraction lost over a weathering period of approximately 0.5 – 1 day in reality). The maximum evaporation was found to be 11.7 % volume, which represents evaporation over 3-7 days weathering in reality.	In the event of a spill, very little will evaporate so the mass of oil spilled will not reduce greatly as the crude weathers at sea. The density of the oil will increase slightly by evaporation, but not enough to sink in seawater.
Dispersion	In a test environment, the oil was released in simulated open sea conditions: Approximated to Beaufort sea state 3 (corresponding parameters in the 'polludrome' (test environment) were wave height 20 cm, mean period 3 seconds, current speed 40 cm/s, wind speed 5 m/s, volume of seawater 7 m^3), Sea temperature 8 °C, Solar energy was created using UV light, and Water was continuously circulated for 7 days. No dispersion of the oil into the water column, or significant breakup of the oil masses, was recorded. The test environment energy was then increased to breaking wave conditions for 3 days, and no difference in the oil behaviour was observed.	Masses of oil from an oil spill would not break up after weathering at sea but remain in discrete clumps.
Response to chemical dispersion	The oil does not respond to chemical dispersants. Dispersants did not penetrate the surface of cooled oil.	Chemical dispersants will not be effective on spilled Sea Lion crude oil and are not recommended.

Aspect	Test results	Implication for risk assessment and / or spill response
Biodegradation	The high alkane content of the oil means it will biodegrade but due to the high wax content this is expected to take some time.	If not recovered, the oil would remain in the environment as solid components (for at least seven days) until eventually breaking up and biodegrading.
Interaction with suspended solids	Tests at 5 and 100 parts per million (ppm) showed that after 5 days there was no interaction between the oil and the suspended solids at 5 ppm, and some particles were adsorbed onto the surface of the oil at 100 ppm, but the oil remained floating.	This indicates that at low concentrations such as at sea, the oil is unlikely to interact with suspended solids and fall into the water column. At much higher concentrations there will be some interaction, and over long periods of exposure to suspended solids e.g., near beaches, the oil may eventually sink to the seabed.
Adhesion to feathers	Adhesion of oil to feathers (Figure 12-1) was tested for nine species found around the Falklands. These were: black-browed albatross, sooty shearwater, thin-billed prion, Antarctic fulmar, Wilson's storm-petrel, South American tern, imperial shag, king penguin and gentoo penguin. For each species, the adhesion of oil to feathers was assessed in respect of two oil spill scenarios and one produced water discharge scenario: **Spill scenarios:** Feathers were dipped into a concentration of 100g/m^2 oil in seawater: No oil was adsorbed by feathers, and No structural damage was observed. At a concentration of 1 kg/m^2: All feathers were stained by the oil and two species (thin-billed prion and imperial shag) had microparticles stick to them, but No structural damage was observed. **Produced water scenario:** At a concentration of dispersed oil at 10 mg/l with oil droplets of *c.* 100 microns: Oil particles were observed on all feathers, All species adsorbed similar amounts of oil, but No structural damage was observed.	In the event of a spill, the concentration of oil will affect the amount of oil adsorbed by birds' feathers. At concentrations of 1kg/m^2 all species tested were stained but thin-billed prion and imperial shag feathers showed a greater degree of oil adhesion, suggesting these species may be more susceptible once exposed Emulation of produced water discharge caused adhesion of oil particles to all species of feathers tested. However, in all scenarios tested, no structural damage to the feathers was observed although the barbules (the 'feathery' linkages in between the feather structure) were dis-arranged. The above tests were also completed for an alternative crude oil with a lower pour point and indicated a much higher adhesion of oil to the feathers.
Pelt and fur adhesion	Tests are planned for pelt and fur adhesion (Section 15.7.6).	Gives greater confidence in response decision-making around oiled birds and mammals.
Sheen formation and visibility	Hot oil (55°C) released into 18°C calm seawater resulted in a slight sheen being observed by the naked eye for approximately ten minutes. The oil could be perceived by an infrared camera even when cooled, though sheens were not	Sheen formation is very limited around a spill of Sea Lion crude and would only be visible in very calm conditions. It is possible that the temperature of the seawater during

Aspect	Test results	Implication for risk assessment and / or spill response
	easily identifiable with the camera and could only be seen in the early stages of the spill. Testing of water samples did not show any difference between the samples collected after the oil release (near the oil patches) and the background level of the basin.	the test (18°C) could have influenced the creation of a sheen and the water temperatures in the NFB are considerably lower (8°C). While the outdoor test basin was warmer than NFB, CEDRE drew a firm conclusion from the experiment that sheens were very limited, and the longer-term behaviour in the form of waxy masses was shown in the 9-day flume test at 8 °C (see above). Calm conditions at the Sea Lion field are anticipated to occur <3 % of the time and in wave conditions, sheens will be dispersed.
Emulsification	See above test conditions for 'Dispersion'. Around 5 % emulsification was observed, although in the form of water trapped in solid oil rather than a true emulsion.	During release, and to some extent during dispersion, the volume of oil is likely to increase by around 5 % due to water trapped in the oil. This is a relatively lower value – many oils emulsify to a much larger extent, significantly increasing their volume in the marine environment (e.g., by up to 5x).
Dissolved fractions in the water column	See above test conditions for 'Dispersion'. No PAH dissolved into the water column after seven days of monitoring.	Water column impacts are more likely to arise from ingestion of oil rather than contamination of the water column from any dissolved components of the oil. Low risk to shellfish which tend to accumulate PAH.
Ecotoxicity (diatoms)	Tests on the marine algae *Skeletonema costatum* were carried out for 72 hours to determine the concentration which results in 50 % (EC_{50}) inhibition of growth rate. Diatom growth was not affected by Sea Lion crude.	Sea Lion crude is unlikely to impact upon phytoplankton.
Ecotoxicity (copepods)	Tests on the copepod *Arcatia tonsa* were carried out for 48 hours to determine the lethal toxicity of the crude to copepods. 20,700 mg/l of Sea Lion crude in seawater is the concentration at which 50 % of test organisms died when compared to a control. This is expressed as 'LC_{50} 48 hours > 20,700 mg/l'.	This indicates that Sea Lion crude may impact upon zooplankton in the water column in the event of a spill, dependent on the concentration of oil - e.g., there could be 50 % mortality of organisms if exposed to >20,700 mg/l for 48 hours.
Ecotoxicity (amphipods)	Tests on the amphipod *Corophium sp*. were carried out for 10 days to determine the lethal toxicity (LC_{50}) of the crude to amphipods. 392 mg/kg of oil in sediments is the concentration at which 50 % of the test organisms died when compared to a control. This is expressed as 'LC_{50} 10 days >392 mg/kg'.	This indicates that Sea Lion crude may impact upon benthic assemblages in the event of a spill, but at a relatively high concentration of oil in the sediments.

Aspect	Test results	Implication for risk assessment and / or spill response
		Amphipods are recognised as good indicators of oil pollution.
Ecotoxicity (fish eggs)	Tests on embryonic zebra fish (*Danio rerio*) were carried out for 96 hours to determine the LC_{50} of the crude to fish eggs. At all concentrations tested no toxic effects were observed on the fish eggs when compared to a control. Slight subacute toxicity (<3 %) was noted.	This indicates that Sea Lion crude is unlikely to impact fish eggs in the event of a spill.
Adhesion to seaweed	Three types of seaweed were tested for oil adhesion. These were: sea lettuce (Ulva), *Laminaria* and *Fucus* (Figure 12-1). Adhesion to the three seaweeds was tested with hot oil to emulate a spill of crude directly onto the beach at low tide, though it should be noted that this scenario is very unrealistic as any spills at sea would mean the oil solidifies before reaching the shore, even in the case of a tanker grounding, the vessel would ground a distance from the shore due to its hull depth. Oil that had solidified and cooled having been spilled to sea (to emulate a spill which had drifted onto the beach at high tide) was also tested. Adhesion of hot oil to the seaweed at low tide can be substantial but at high tide interaction was very limited. At high hide, the hot oil remained on the surface of the water and did not stick to the seaweed. For cold oil, adhesion to sea lettuce and *Laminaria* was strong but less so with *Fucus*. Hot oil directly applied to the seaweed adhered well to sea lettuce and *Fucus* but not as much to *Laminaria*, with the roughness of the seaweed being an important factor in the amount of oil adhesion.	Spills that are direct to the beach, and with the oil still hot, would mean substantial adhesion to seaweed, however, this scenario is very unrealistic. Spills to water, which then drift onto the beach are unlikely to adhere to the seaweed if they reach the shore at high tide or if they reach seaweed that is permanently immersed in seawater. If cold oil reaches shallow water at the shore at low tide (i.e., where waves are mixing oil and seaweed on a beach) it may strongly adhere to exposed sea lettuce and *Laminaria*. Roughness of the seaweed plays a role in the adhesion of the oil.
Adhesion to shoreline	Tests were carried out to assess the oil adhesion to different substrates (Figure 12-1). These simulated hot oil being discharged onto or near the shoreline, although this is not a credible scenario within the current proposals. Nevertheless the behaviour of solidified crude reaching a shoreline can still be inferred. When the hot crude was spilled at high tide (i.e., to water), the oil solidified on contact with the water and no contact occurred between the oil and sediments. After two tidal cycles, no adhesion was observed and the oil stayed on the water's surface.	Oil approaching the coastline will be solidified and will predominantly stay on the surface of the water with little adhesion to the shoreline.

Aspect	Test results	Implication for risk assessment and / or spill response
	When the hot crude was spilled at low tide (i.e., directly onto the substrate which, as noted above is very unrealistic) the oil stayed stuck to the rocky and cobbled shores and was laid on the sandy sediment. After three hours, the oil lifted off the sandy sediments but stayed stuck to the rocky and cobbled shores. After one week a small amount of oil resurfaced from the rocky sediment but the majority of oil stayed stuck. After one week the majority of oil resurfaced from the cobbled sediment but a small portion remained stuck. After one week no adhesion was observed to the sandy sediment and all oil remained on the surface of the water. A sample of the oil face in contact with sediment was also taken and it was identified that sediment had penetrated the surface; a 5 g sample showed 31 % of the sample by weight was sediment.	
Removal of oil from rocky shores	Hot oil was spread onto standardised granite tiles manually and allowed to cool. Pressure washing was carried out at 15 °C, 50 °C and 50 bar and 100 bar pressures. Pressure did not seem to play an important role for any of the oils but hot water was much more efficient. Cleaning efficiency seemed to be slightly better for the Sea Lion crude oil than more commonly encountered oils of a similar density.	If spilled directly on rocks (very unlikely), the Sea Lion crude oil could be efficiently treated by using a high pressure water washer by using hot water (50 °C). It should be noted that, in real conditions, rocks are not totally cleaned and an oil film will remain, to be weathered over time.

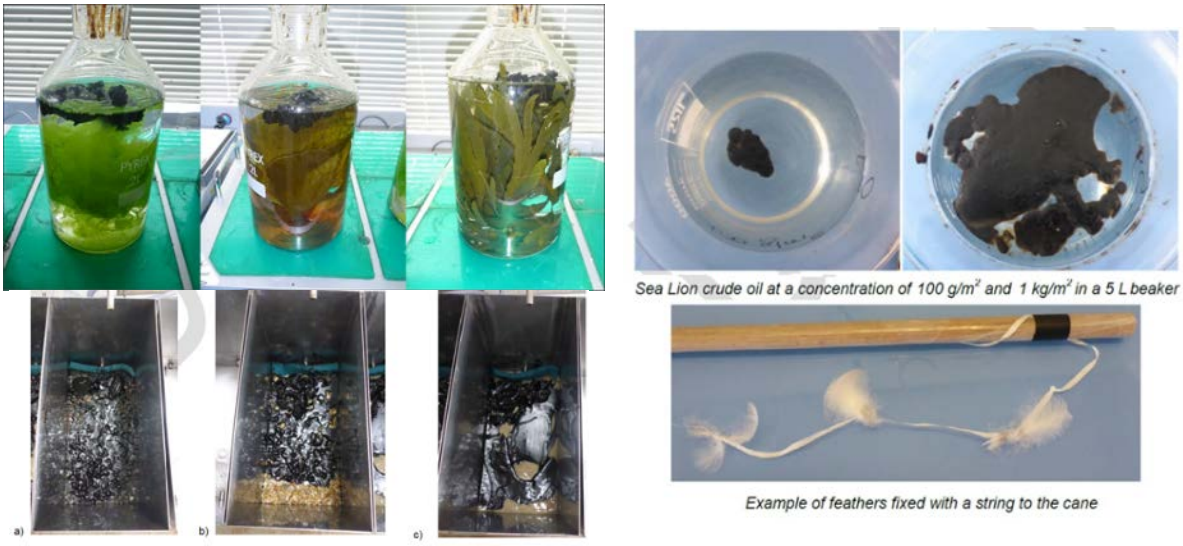

Figure 12-1: Examples of testing images from tests on seaweed, shoreline and feathers (CEDRE, 2017)

12.1.4.1.1.2 Marine diesel or Marine Gas Oil (MGO)

The project vessels will use MGO as fuel, sometimes referred to as marine diesel. MGO contains a much higher proportion of light volatile hydrocarbons than heavier crude oils and therefore evaporates and dissolves more readily when spilled on water, MGO spreads very quickly to a thin film that can manifest as dull or dark colors or as a rainbow and silver sheen as the layer thins.

MGO is less dense than water and therefore it is not possible for diesel to sink and accumulate on the seafloor as pooled or free oil unless adsorption occurs with sediment. However, it is possible for the diesel oil that is dispersed by wave action to form droplets that are small enough be kept in suspension and moved by the currents. When diesel dispersed in the water column does adhere to fine-grained suspended particles, these can settle out and reach the seafloor, although this is less likely to occur in open marine settings.

In terms of toxicity to water-column organisms, diesel is considered to be one of the most acutely toxic oil types. Diesel fuels, such as MGO, contain volatile aromatic compounds, some of which, including alkylbenzenes, toluene, naphthalenes, and PAH, are known to have acute toxic effects on marine life in the water column. Given its volatile nature however, diesel breaks down more rapidly than crude oil and generally poses shorter exposure risk to environmental receptors. Nonetheless, potential impacts on vertebrates include damage to the liver, kidneys, heart, lungs, and the nervous system. Increased rates of cancer, immunological, reproductive, fetotoxic, genotoxic effects have been associated with diesel contamination (Irwin, *et al.,* 1997). PAHs are relatively long-lived in the environment and bioaccumulate in the fatty tissues of animals, resulting in vital organ malfunction (particularly the liver and kidney).

12.1.4.1.1.3 Non-Aqueous Drilling Fluids

The most likely place for a failure of the riser, which could lead to a loss of NADF and any associated cuttings in circulation, is at the base of the riser at the lower marine riser package as this section experiences the most stress from the rig moving above and loading from currents. If disconnection happens whilst drilling with NADF, the drilling fluid will flow out over the seabed around the well and in a relatively cohesive mixture (a result of the drilling fluid being specifically designed to prevent separation of oil, water and solids). The NADF is quite dense and would disperse very little into the water column.

The area directly covered by the NADF will be impacted as the mud itself would be very toxic to local sediments and benthic communities. There is also likely to be an element of smothering, although less so than with cuttings piles as the NADF liquid is assumed to settle out to *c.* 1 cm thickness.

The NADF would biodegrade over time and release particles into the water column but this will be a slow steady process. The components of NADF are somewhat biodegradable and have to pass CEFAS (Centre for Environment, Fisheries and Aquaculture Science) tests so it would be reasonable to expect the area would recover after a number of years. Deposits of NADF and associated cuttings are well studied in the North Sea. Breuer *et al.* (1999) noted that eight years after NADF cuttings piles were deposited, biological effects were still noticeable. Change of benthic habitat has also been seen on and around NADF cuttings piles near historic North Sea wells over a period of years (Olsgard and Gray, 1995).

12.1.4.1.2 Fate of oil in the marine environment

As oil is released into the sea it undergoes a number of physical and chemical changes (Figure 12-2). These changes are dependent on the type and quantities of oil spilled and the meteorological and oceanic conditions to which the oil is exposed over time. Detail on the processes which influence the behaviour and fate of oil at sea following a spill are described in Table 12.2.

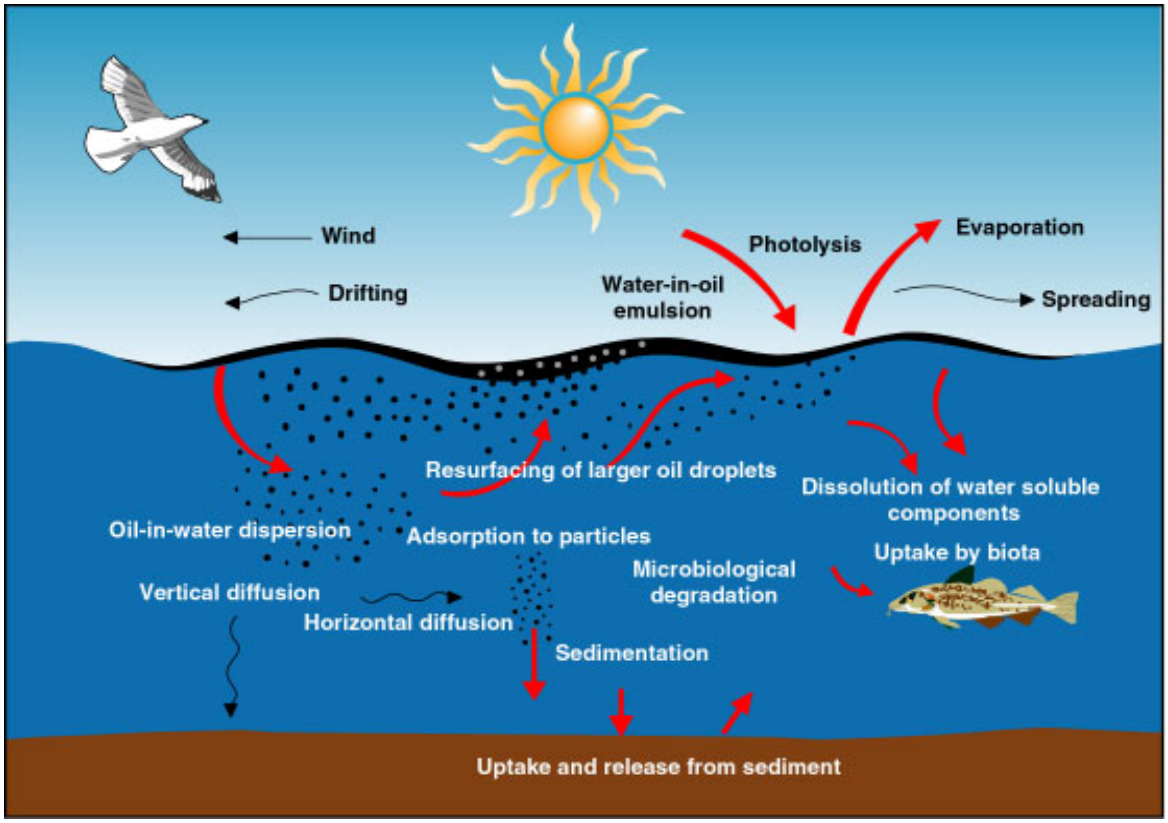

Figure 12-2: Behaviour and fate of oil in the marine environment (after Andreassen and Sørheim, 2013)

Table 12.2: Fate of oil in the marine environment

Oil behaviour	Description
Spreading and advection	When spilled at the surface, oil spreads out on the surface of the water. This increases the surface area of the oil but reduces the thickness. Sea Lion crude is unlikely to spread out thinly as a 'normal' oil. From behaviour observed during testing of the crude, a 'terminal film thickness' of between 1 and 5 mm has been assumed, dependent on the type of spill (see Section 12.1.4.1.1.1).
Evaporation	Evaporation is the main mechanism by which the mass of oil is reduced immediately after a spill and is enhanced by warm air temperatures and moderate winds. It also causes considerable changes in the density, viscosity and volume of the spill over time. The light fractions of the oil (aromatic compounds such as benzene and toluene) evaporate quickly. As noted above (Section 12.1.4.1.1.1), a large percentage of Sea Lion crude is not expected to evaporate (CEDRE, 2017).
Dissolution	Some of the lighter components of the oil will go into solution in the surrounding water; however, this only accounts for a very small proportion of the overall spill. As noted above (Section 12.1.4.1.1.1), in the CEDRE tests no PAH were observed dissolving into the water column from Sea Lion crude after 7 days (CEDRE, 2017).
Natural dispersion	Once the lighter fractions have evaporated from the oil spill the evaporation process slows down and natural dispersion becomes the dominant mechanism in reducing surface oil volume. Dependent upon sea surface turbulence, and therefore weather conditions, oil breaks up into droplets in the water beneath the surface oil and disperses in the water column. As noted above (Section 12.1.4.1.1.1), Sea Lion crude is not expected to naturally disperse to any great extent (CEDRE, 2017).
Emulsification	Oil and water combine to form a mousse. The tendency to emulsify depends on the asphaltene content of the oil. Sea Lion crude is likely to absorb around 5 % water (see Section 12.1.4.1.1.1) (CEDRE, 2017).
Photo-oxidation	Sunlight transforms some oil components into new by-products, which may be more toxic and water-soluble than the original components.
Sedimentation	Oil adheres to particles in the water column and sinks to settle in the sediment. Once in the sediment, further degradation slows. As noted above (Section 12.1.4.1.1.1), Sea Lion crude is unlikely to interact with particles at sea, but may interact with them in the water column at particle concentrations of around 100 ppm e.g., at beaches, and increase in density over a period of days and weeks (CEDRE, 2017).
Stranding	Oil that reaches the shore-line is said to have stranded.
Biodegradation	Biodegradation can occur at the surface, in the water column and within sediments. Oil is slowly broken down by resident bacteria, and other microbes, into water and carbon dioxide. The microbes concerned rapidly multiply in the presence of excess food and produce by-products that can themselves be toxic to other marine organisms. Sea Lion crude is expected to biodegrade eventually but it is thought this will take a long time (see Section 12.1.4.1.1.1) (CEDRE, 2017).

12.1.4.2 Nature of the impacts

The impacts of oil spills on marine organisms are well documented and have been the focus of numerous studies, and extensive review (e.g., Moore and Dwyer, 1974; Burger, 1993; Gubbay and Earll, 2000; Kingston, 2002; Barron, 2012; Beyer, *et al.,* 2016).

There are four main routes of oil contamination. These include:

- Direct contact,
- Ingestion,
- Inhalation, and
- Absorption through skin or respiratory membranes.

The extent of oil spill impacts will be influenced by the environmental conditions and the spreading and dispersion of oil experienced in the period following any spill. Further, the size of a spill is not necessarily the most important factor influencing the extent of impacts on environmental receptors. Small spills can impact disproportionately large numbers of individual receptors if they are present in the affected area at the time. The nature and significance of impacts at a population-level will differ across the range of environmental receptors, and will depend on the type of oil (Section 12.1.4.1.1) and the distribution, density, ecological and life-history attributes and the behaviour of each of the receptors at the time of a spill.

12.1.4.2.1 Plankton

Plankton plays a critical role in marine food web dynamics, biogeochemical cycling and fisheries recruitment. Despite their importance in the marine environment our knowledge of the interactions between plankton and anthropogenic pollutants is limited.

Although it is known that low concentrations of hydrocarbons (<0.05 mg/l) may stimulate phytoplankton growth (for some species), higher concentrations are likely to inhibit growth or kill phytoplankton (Boyd, *et al.,* 2001). Given that phytoplankton form the base of the food chain, bioaccumulation of hydrocarbons through the planktonic food web would increase exposure of higher trophic-level organisms (Meador, 2003). Further, lethal contamination could change the distribution and reduce the abundance of plankton communities, and hence the availability of food sources up the food chain.

The oceanography and topography of the southern Patagonian Shelf creates an area of very high zooplankton productivity immediately to the north of the Islands (Section 7.4.1). While the distribution and abundance of plankton in the waters of the Falkland Islands varies on a seasonal basis, it is expected that any impacts of oil spill will be greatest during summer when the area of the shelf-break to the south of the Sea Lion Field supports higher densities of plankton. *Themisto gaudichaudii* provides an important ecological link between small zooplankton and top consumers around the Falkland Islands. *Themisto gaudichaudii* is a voracious predator of anything smaller than itself, and occasionally of animals its own size or larger with adults preferentially consuming prey in the size range 1 to 4 mm (Pakhomov and Perissinotto, 1996). Other important plankton species in the Falklands include species in the order Euphausiacea (e.g., *Euphausia lucens*, *E. vallentini* and *Thysanosessa gregaria*) and lobster-krill (*Grimothea gregaria*) (Agnew, 2002; van de Grient, *et al.,* 2023).

Further, eggs and larvae in the zooplankton appear seasonally and many have been shown to be vulnerable to oil during laboratory experiments (Almeda, *et al.,* 2013) as the latter can ingest oil droplets directly (Lee, *et al.,* 2012; Almeda, *et al.,* 2014). For eggs, on the other hand, only small molecules can cross the outermost membrane around the embryo such that these are less vulnerable than zooplankton. Testing of the Sea Lion crude (Section 12.1.4.1.1.1) on zooplankton (*Acartia tonsa*) and phytoplankton (*Skeletonema costatum*) indicates that the crude is unlikely to impact upon the phytoplankton species tested but that concentrations of around 20,700 mg/l will have lethal effects on up to 50 % of zooplankton organisms tested after 48 hours of exposure (CEDRE, 2017).

There are three main types of interactions between zooplankton and pollutants:

- Pollutants can have direct toxic effects on zooplankton, which may have lethal or sub-lethal consequences (Walsh, 1978),
- Zooplankton may influence the physicochemical characteristics of the pollutants in the water column by absorption, transformation and elimination (Walsh, 1978; Fisk, *et al.,* 2001; Muschenheim and Lee, 2002), and / or

- Zooplankton may play an important role in the bioaccumulation of pollutants in food chains and webs.

Therefore, understanding the interactions between pollutants and zooplankton is crucial to understanding the fate of pollution in the pelagic zone and its impacts on marine environments.

Further, in all of the potential impacts described, there is increasing evidence that sunlight, mainly ultra violet radiation, can increase the toxicity of petroleum hydrocarbons to marine organisms (e.g., Alloy, *et al.,* 2016; Almeda, *et al.,* 2016).

12.1.4.2.2 Benthic communities

Contamination of the benthos in a low energy environment may have long-lasting impacts, as physical breakdown and biodegradation are reduced. Invertebrates vary greatly in their sensitivity to oil contamination, but it is known that many are unable to metabolise petroleum (NOAA and API, 1994) and may therefore accumulate toxins in their bodies.

Among the invertebrates, corals are known to be one of the most sensitive groups. Similarly, shellfish may accumulate oil residues with attendant secondary effects, particularly relating to health (OSPAR, 2009a). Infaunal organisms (i.e., those actually living within sediments) are particularly susceptible to oiling whereas some barnacles and limpets may withstand a degree of oiling. The sub-lethal effects of contamination on the above may include growth reduction, feeding impairment, and behavioural changes. For vertebrates that might be in physical contact with hydrocarbons on the seabed, such as skates, the impacts are generally sub-lethal, including changes in feeding, growth, development, and recruitment (Boyd, *et al.,* 2001).

To date, surveys in the Sea Lion Field have indicated that the benthic environment is fairly uniform, in terms of habitat classification (Section 7.4.3.2). The results of surveys, in the Isobel / Elaine area approximately 40 km south of the Phase 1 & 2 Development, indicate that there are some very localised differences in the habitats and species encountered in the NFB, which are largely due to the presence of erratic rocks (iceberg drop stones) that provide habitat for corals and other encrusting organisms (Section 7.4.3.2).

12.1.4.2.3 Fish and squid

Impacts on fish and squid from oil spills may include:

- Displacement of adults from feeding grounds, and
- Contamination of adult fish, eggs, larvae and juvenile stages.

12.1.4.2.3.1 Displacement from feeding grounds

Typically, adult fish are considered sensitive to impacts of oil spills however, they are mobile and are able to detect areas of heavy contamination or poor water quality and avoid them, particularly in the open ocean (Hjermann, *et al*., 2007). However, such avoidance behaviour may serve to displace them from important feeding areas. The Phase 1 & 2 Development is situated within the Falkland Islands Northern Slope habitat zone which has been identified as an important feeding area for a number of fish species, whose abundance varies with season (Section 7.4.4.2.2). As a spill could occur at any time throughout the operations, it could coincide with recorded high abundances of numerous fish species (Section 7.4.4.2.2).

Cephalopods are sensitive to environmental conditions, which can affect their abundance and distribution widely (Pierce, *et al.,* 2008; Arkhipkin, *et al.,* 2004a). Squid exhibit high growth rates and the majority have short life spans such that the accumulation of pollutants in their tissues can reflect the pollutant bioavailability in the immediate environment over a relatively short time period. Therefore, in addition to the importance of squid in commercial fisheries and as prey and predators in

the marine environment, they have the potential to act as bioindicator species in environmental monitoring studies. However, the mobile nature of some species can limit their potential as bioindicators, as may the fact that, for example, superbull loligo males can provide temporal connectivity that arises through phenotypic plasticity[97] enabling them to live longer, thus connecting cohorts. Please note however, that such males represent a small proportion of the population (Jones, *et al.,* 2019).

It is important to note that in relative terms, there is a small fraction of fishing effort in the Sea Lion area. There are years where catches have been reported in XFAK. However, analysis has shown that although catch by a few vessels have been attributed to XFAK with either their mid-day or midnight position, in actual fact the vessels did not enter this grid square at all, as evidenced from Marine Satellite -based AIS. These are likely to be rare, accidental misreportings. Almost all of the fishing effort is based around the shelf break at 200m.

12.1.4.2.3.2 Contamination of adult fish and squid, eggs, larvae and juvenile stages

The ability to avoid areas of oil contamination does not negate the sensitivity of fish to associated ecosystem and long-term effects (Balk, *et al*., 2011; Ainsworth, *et al*., 2018; Cave and Kajiura, 2018; Grosell and Pasparakis, 2021).

For example, a biogeochemical ecosystem model that was used to assess the impacts from the Deepwater Horizon oil spill on fish suggested that the biomass of large reef fish decreased by 25-50 %, and large demersal fish by 40-70 % (Ainsworth, *et al*., 2018). This was a result of the impacts on reef and demersal foraging areas leading to starvation. Similarly, in the North Sea Balk *et al.* (2011) found that haddock and Atlantic cod populations were under significant environmental stress due to the chronic effects of oil-related pollution. Studies carried out in control areas (e.g., a North Sea area without oil production and remote Icelandic waters) indicated significant background pollution in the North Sea. However, as a light and more volatile crude, the characteristics of the oil in the Deepwater Horizon incident were very different to those of the Sea Lion crude. Further, the chronic pollution levels in the North Sea are more likely attributable to > 40 years of produced water discharge from numerous installations than to the impact of oil spills. Of importance, the base-case design of the Sea Lion Development is to reinject, rather than discharge, produced water (Section 5.8.5.8 and Section 10.7).

Adverse impacts of oil spills on adult fish are most likely to be observed in the shallow coastal areas of the sea where oil could accumulate and the potential to 'escape' is limited by the land and / or the species' habitat requirements. Fish eggs and larvae are considered to be more susceptible to the toxic effects of oil than adults, due to their reduced ability to avoid contaminated water. However, testing the impact of Sea Lion crude on a test organism (zebra fish (*Danio rerio*) eggs) found that the crude is unlikely to impact these fish eggs in the event of a spill (CEDRE, 2017).

If contaminated, adult fish are able to metabolise small quantities of hydrocarbons, although the toxic effects of the ingested oil may lead to organ damage (OSPAR, 2009a). In particular, fish are susceptible to the water-soluble fractions of oil, such as Benzene, Toluene Ethylbenzene and Xylenes (BTEX), which have been shown to cause cardio-edema in larval fish (Incardona, *et al.,* 2013). Other toxic components in crude oil such as the PAHs can be mutagenic and carcinogenic in fish. Testing of the Sea Lion crude has shown that PAHs were not observed dissolving into the water column during the seven days of monitoring following the simulated spill, so are unlikely to be present in high concentrations after a spill to sea (CEDRE, 2017). Although squid are unable to metabolise oils, there is little evidence of direct mortality of adult squid following contamination.

[97] The ability of an organism to change its phenotype in response to environmental conditions. This can include changes in behavior, physiology, morphology, growth, and life history.

Cephalopods have received some attention on account of their capacity to accumulate contaminants and the resultant implications for human health (Gomes, *et al.,* 2013; Morais, *et al.,* 2013; Section 12.1.4.2.3.2). In particular, PAHs are of note due to the potential cytotoxic, mutagenic and carcinogenic properties of these chemicals.

Although these components may not be present initially after a spill (CEDRE, 2017), they could dissolve into the water column later if all oil is not recovered. PAHs can be absorbed into the water column from waterborne compounds and contaminated sediments but predominantly *via* the food chain. In marine food chains, molluscs (including squid) have the poorest capacity to metabolise PAHs, crustaceans are intermediate with fish displaying the best capacity (Gomes, *et al.,* 2013). The natural content of PAHs in fish tissues is lower than that in squid because fish are able to oxidise and further metabolise PAHs to water soluble compounds, which can be excreted *via* gall or urine. In squid, the highest concentrations of PAHs are found in the digestive glands but these compounds are found in all tissues.

The Northern Slope is used by many species of ecological importance, such as *Moroteuthopsis ingens* squid, myctophids and Falkland sprat (*Sprattus fuegensis*). These species are important food sources for predatory fish, seabirds and marine mammals. Grenadiers also occur in this area, particularly *Macrourus carinatus* and *Coelorinchus fasciatus*, the former of which is considered a potential fisheries resource for the Falkland Islands (Payá, 2009). Other species are resident within the Phase 1 & 2 zone of influence although, many of these, such as skate and eelpout, do not have planktonic egg or larval stages.

12.1.4.2.4 Seabirds

Seabirds are particularly susceptible to oil floating on the surface of the sea and millions of seabirds have been killed globally by oil pollution (e.g., Goldsworthy, *et al.,* 2000; García Borboroglu, *et al.,* 2006; 2010; Wolfaardt, *et al.,* 2009). Seabirds tend to be the most conspicuous group affected during oil spill events. When considering the impacts of oil spills on seabird populations, the volume of oil released is not necessarily the most important factor (Hunt, 1987; Tasker and Pienkowski, 1987; Burger, 1993), but rather the location of the spill relative to concentrations of vulnerable seabirds. A relatively small spill in close proximity to large numbers of vulnerable seabirds will likely have a much more severe impact than a larger spill in an area with few seabirds. Indeed, tens of thousands of birds can be killed by a relatively minor spill (e.g., Barrett, 1979). Equally, chronic oil pollution from operational discharges (Section 10.7) and small spills may have severe long-term effects on seabird populations (e.g., García Borboroglu, *et al.,* 2006). About half of the input of oil into the marine environment is due to chronic oil pollution (GESAMP, 2007), highlighting its potential to impact seabirds.

The effects of oil on birds include both immediate impacts on survival, and longer-term sub-lethal impacts that could affect individual birds and populations over many years (e.g., Camphuysen, *et al.,* 2005; Perez, *et al.,* 2009).

Impacts of large oil spills and / or small-scale unplanned but chronic releases include:

- Direct contamination and fouled plumage,
- Ingestion:
  - Direct ingestion e.g., from preening contaminated feathers, and / or
  - Indirect ingestion e.g., from consuming contaminated prey (Committee on Oil in the Sea, 2003).

The consequences of the above also depend upon the vulnerability of bird species, their behaviour and the feasibility of post-contamination treatment.

12.1.4.2.4.1 Direct contamination

Fouled plumage is recognised as the primary cause of mortality and stress in oiled birds (NRC, 1985; Leighton, 1991; there is a good deal of literature on this subject however for a recent review see King, *et al.,* 2021). Direct contact between seabirds and oil can contaminate feathers such that the barbules become bound together by oil which leads to a loss of feather condition and function. Plumage is essential for flight, heat insulation and waterproofing, and even small effects on any of these functions can compromise survival. Waterlogging and loss of buoyancy in oiled birds further exacerbate oil impacts and can rapidly lead to drowning. Additionally, oil can also directly affect reproductive success as eggs contaminated with oil from fouled feathers can have lethal effects on the embryo (King, *et al.,* 2021).

Along with environmental factors; such as sea state, the chemical and physical properties of the specific type of oil discharged will influence how the oil behaves in the environment and the effects it is likely to have on seabirds (Section 12.1.4.1.1).

Most of our knowledge of how oil spills contaminate seabirds is based on experiences with fluid oils that form slicks or sheens (O'Hara and Morandin, 2010). Observations from such incidents are not directly applicable to the current assessment however, because they do not reflect the waxy oil type found in the Sea Lion Field. The initial testing indicates that the highly waxy crude may pose less of a risk to seabirds in respect of feather contamination when compared to other crude oils tested in the same way (CEDRE, 2017). Testing of Sea Lion crude oil adhesion to feathers showed that adhesion was determined by the concentration of oil, with no oil adsorbed by feathers dipped into a concentration of 100 g/m^2 but staining and microparticles were observed at a concentration of 1 kg/m^2 (CEDRE, 2017). No structural damage was observed to any feathers tested, although the barbules were noted as 'messy' (CEDRE, 2017).

With regard to the far lighter diesel oils, seabirds can be oiled by direct contact although the higher volatility of diesel (MGO) means that the oil remains on the surface for a relatively short time, which may influence the number of birds affected. However, as described by O'Hara and Morandin (2010), the potential for these impacts to occur largely depends upon the degree of oil fouling, which is affected by the:

- Thickness of the sheen and the area of sheen that comes into contact with the bird,
- Oil type,
- Patchiness of the oil,
- Movement patterns of the bird at the sea surface, and
- Preening capacity.

While there are limited data on the thickness of sheen required to affect the microstructure of feathers in practice, it is believed that small quantities of oil contamination could have lethal consequences (O'Hara and Morandin, 2010). Laboratory based experiments determined that exposure to oil sheens at a thickness of only 0.1 µm could result in measurable oil transfer to feathers and thus impact upon their microstructure. Further, it was concluded that lethal consequences could result from a bird being exposed to as little as 10 ml of oil (O'Hara and Morandin, 2010). In order to become contaminated with 10 ml of oil, it is estimated by O'Hara and Morandin (2010) that a bird would have to swim through approximately 100 m^2 of a sheen of 0.1 µm thickness. Although hypothermia due to matted feathers does occur, the toxicity of MGO means that mortality is most commonly caused by ingestion during preening (NOAA, 2014).

Although the oil in water (OiW) concentrations of operational discharges are tightly controlled by legislation, chronic oil pollution, in the form of rainbow effects, and blue / silver / gray discoloration

(Fraser, *et al.,* 2006), may occur even at OiW concentrations of 25 mg/l when discharged on calm days (Wills, 2000). Potential sources of chronic oil pollution from legally compliant operational discharges e.g., produced water, are assessed in Section 10.7 while the contribution of small accidental spills are assessed here.

Once attached, oil of either form can be ingested, either directly, or through preening, leading to a number of toxic effects that compromise the health of the animal, and may eventually lead to its death.

12.1.4.2.4.2 Ingestion

It is likely that seabirds may ingest floating waxy oil masses (pellets), in much the same way that they ingest floating particles of plastic (BirdLife International, 2008). Whereas penguins and other seabirds that spend a lot of their time at the surface and dive to obtain their prey are particularly vulnerable to plumage contamination and ingestion of the oil, surface foraging Procellariiformes (albatrosses and petrels) would be particularly susceptible to ingesting the floating wax pellets, especially as many of the birds in this group habitually congregate around offshore vessels / structures. This stems from their scavenging nature, which also predisposes them to misdirected foraging - ingesting the wax pellets which they mistake for food. The wax pellets may also be ingested incidentally with prey in the same way fur seals ingest plastic incidentally *via* myctophid fish (Ryan, *et al*., 2016). Smaller petrels, such as prions and storm-petrels, filter feed or pick at planktonic organisms. These birds will all be vulnerable to ingesting oil masses of differing sizes and therefore the range of species potentially impacted will change as the oil masses break down and spread.

Although the issue of ingesting plastic and other debris, such as tar balls, is known to occur amongst a wide range of seabird species, there has been limited research to quantify the impacts of such ingestion (BirdLife International, 2008). However, the ingestion (through preening, consumption of contaminated prey and of oil) or inhalation of hydrocarbons has been documented, mostly through experimental studies, to cause a number of lethal and sub-lethal toxicological effects on seabirds. These include:

- Gastrointestinal irritation,
- Pulmonary congestion,
- Adrenocortical hyperplasia,
- Fluid and electrolyte loss,
- Detrimental effects on salt glands and osmoregulation, and
- Fatty liver and mutagenic (cancer causing) effects.

Further, the absorption of toxic components from the oil can lead to damage of the liver, pancreas and kidneys, amongst other organs. Where sub-lethal, these impacts may reduce reproductive rates, leave the animal open to secondary infection and act synergistically with other environmental stressors, leading to reduced survival in the medium to long-term (Boyd, *et al.,* 2001; Wolfaardt, *et al.,* 2008; 2009; King, *et al.,* 2021). On the basis of studies investigating the impacts of ingested plastic on seabirds, species that seldom regurgitate indigestible stomach contents and therefore accumulate large debris loads, are most susceptible to the adverse effects of ingesting these items. For example, immature petrels that would not be feeding chicks would be particularly vulnerable as they cannot offload their accumulated load (Drewery and Wolfaardt, 2017). Oil can also indirectly influence the survival or reproductive success of seabirds by affecting the distribution and / or abundance or availability of prey but this is much more difficult to assess.

12.1.4.2.4.3 Seabird vulnerability to oil pollution

Seabird species in the waters around the Falkland Islands differ in their susceptibility to contamination from oil pollution due to differences in foraging ecology, geographical distribution and other life history

traits, such as reproductive biology. Although a wide variety of seabirds may be affected, the greatest impact is generally observed in those species that spend a large amount of time at the sea surface, such as penguins and shags. Additionally, the behavioural traits of some species increase the likelihood that they will be attracted to vessels; due to the presence of artificial light (Section 10.1.4.2) discharged wastewater and food (Section 10.10); or simply to investigate a novel object in an otherwise uniform environment.

Although there are gaps in the data, a general picture of seabird distribution within the NFB has been, and continues to be, acquired through a combination of satellite tracking and visual surveys. However, the presence of the vessels associated with the Sea Lion Development will attract birds (see Wiese, *et al.,* 2001; Munro, 2011), which distorts the natural distribution of these species. This will result in elevated numbers of sensitive species in an area of high risk, in the immediate vicinity of Navitas chartered vessels, and it is these birds that are at greatest risk of being impacted by spilled MGO or other oils.

Albatrosses are the most threatened group of birds in the world (Croxall, *et al.,* 2012) and large numbers use the waters of the Falkland Islands. Although the most recent archipelago-wide surveys of black-browed albatross and southern giant petrel breeding in the Falkland Islands reveal that these populations are currently increasing, the populations of most ACAP (Agreement on the Conservation of Albatrosses and Petrels) listed species have declined significantly and continue to do so (e.g., Poncet, *et al.,* 2006; Poncet, *et al.,* 2017; Section 7.4.5.2.3). Moreover, several species that breed elsewhere, including wandering, southern and northern royal albatrosses, are regular visitors to the waters of the Falkland Islands (White, *et al.,* 2002). Albatrosses and petrels are therefore of considerable, and international, conservation concern, which is exacerbated by their life-history traits, such as: a long life-span, high adult survival rates, delayed sexual maturity and low fecundity. Given these extreme life-history attributes, impacts that contribute to adult mortality, such as oil contamination, have a significant influence on population trajectories, because the ability of these populations to recover quickly from such impacts is limited. Nonetheless, in respect of the numbers of birds affected, the impacts of oil spills on albatrosses and petrels appear lower compared with other seabirds, such as penguins, although birds oiled at-sea may go unobserved and unrecorded. In addition, pelagic seabirds, such as albatrosses and petrels are generally less successfully rehabilitated following oil spill events than penguins, such that it may not be possible to treat and rehabilitate many of the procellariiform species that occur around the Falklands.

To date, the birds most affected directly by oil pollution in the southern hemisphere have been penguins and shags (García Borboroglu, *et al.,* 2006; 2008; Altwegg, *et al.,* 2008; Wolfaardt, *et al.,* 2009). Although less likely to associate with vessels, at certain times the area of the NFB is utilised by several penguin species (Section 7.4.5.2.2). Given their foraging behaviour and ecology, and especially the amount of time they spend at the sea surface, penguins are particularly susceptible to becoming contaminated following an oil spill. There are five species of penguin breeding in the Falklands, although the macaroni penguin occurs in very small numbers. Amongst the four major penguin species breeding in the Falkland Islands, the rockhopper penguin is the species of greatest conservation concern (Section 7.4.5.2.3). The global population has exhibited a long-term decline. The species is currently classified as 'Vulnerable' under the IUCN threat designations and has been highlighted as a species of priority conservation concern (Crofts, 2014).

A preliminary assessment of seasonal vulnerability of seabirds to oil contamination within Falkland Islands waters was performed on data collected by the Joint Nature Conservation Committee (JNCC) to produce an Oil Vulnerability Atlas, (White, *et al.,* 2001). Further information and vulnerability maps from the Atlas are provided in Section 7.4.5.6. The area around the Sea Lion Field was not considered to be of 'very high' vulnerability during any period of the year, although adjacent areas of the

continental shelf - to the south, in January, and the south-west in September - were of 'very high' vulnerability.

12.1.4.2.5 Marine mammals

All marine mammals are afforded priority conservation status. Both pinnipeds (seals) and cetaceans (whales and dolphins) may be affected by oil spills in numerous ways. These include:

- Direct contamination through contact,
- Ingestion, and
- Inhalation of toxic fumes.

12.1.4.2.5.1 Pinnipeds

Like seabirds, pinnipeds (seals) may be impacted directly through contact with, or ingestion of, hydrocarbon pollution or indirectly through impacts to prey at lower trophic levels.

Marine mammals that rely on fur for insulation, such as fur seals, are vulnerable to oil contamination of their coats, which could lead to hypothermia. Fur seals groom extensively to maintain their coats and are therefore more likely to ingest hydrocarbons than other seals. The latter may not result in mortality in all but the most severe cases. However, it may lead to short-term disruption of breeding (Atlantic OCS, 1988) and to some level of bioaccumulation of trace metals and intermediate metabolites (Ridoux, *et al.,* 2004).

Phocids (true seals) are generally considered less sensitive to the effects of direct hydrocarbon fouling than otariids (eared seals - fur seals and sea lions) and seabirds. Although the pelage of phocids can be coated / fouled with oil, it is the sub-dermal fat layer that provides most of their insulation.

Besides hypothermia, there are a number of other potential impacts of oil pollution on seals. Exposure may cause severe eye watering (lacrimation), conjunctivitis, and corneal abrasions and ulcers if debris becomes mixed with encrusted oil. This may subside if exposure is short but prolonged exposure could result in more permanent damage (Atlantic OCS, 1988; Salazar, 2003). Severe fouling of their pelage may lead to an inflammatory response in the dermis and to skin ulcers following contamination but with subsequent recovery if contamination is of short duration (Atlantic OCS, 1988; Salazar, 2003). The greatest risk of mortality may result from inhalation of toxic volatile compounds from the surface of oil spills, which will be exacerbated if the animal is already stressed from the secondary effects of the spill and disturbance associated with response operations (Atlantic OCS, 1988; Jenssen, 1996).

12.1.4.2.5.2 Cetaceans

Cetaceans can be exposed to oil and oil-derived compounds through multiple pathways, including direct contact with the skin, ingestion of oil or contaminated prey, inhalation of volatilised or aerosolised oil components, and aspiration of oil into the lungs. There is a body of information highlighting the potential impacts of oil spills on cetaceans (Gubbay and Earll, 2000; Matkin, *et al.,* 2008; Schwacke, *et al.,* 2014; Venn-Watson, *et al.,* 2015; Frasier, *et al.,* 2020; Schwacke, *et al.,* 2022; Marques, *et al.,* 2023). Documented effects include poor body condition, calcium imbalance, inflammation, reproductive failure, organ damage (such as lung disease and failure, as well as adrenal gland dysfunction), altered hepatobiliary function, immune system changes leading to increased susceptibility to infections, impaired stress responses, and mortality.

Observations of cetaceans indicate that they are aware of slicks but the animals do not necessarily avoid contact with them. Compared to seabirds and pinnipeds, cetaceans generally spend longer periods submerged than at the surface of the water where contaminants are likely to be more concentrated. The behaviour, diet and habitat use of cetaceans will determine their level of contact with an oil spill (Wursig, 1988). Species that forage in mid- or deep-waters will be at lower risk than species that feed at the surface. Species such as right whales and rorquals that surface skim or lunge

feed, respectively, are therefore more sensitive and likely to consume surface oil directly than species that feed in deeper waters. This may also be true for some dolphins that 'chase' prey to the surface. Ingestion of oil by marine mammals can cause damage to the digestive system or affect the functioning of the liver and kidneys.

Of note, a recent set of tests involving whale baleen and six petroleum-based oils (Werth, *et al.,* 2019) indicated that whale baleen is oleophobic and does not adsorb oil, and that oil is readily rinsed from the baleen by flowing water. There was minimal wrinkling or peeling of the baleen's cortical keratin layers in the tests and filter porosity was not appreciably affected. Oil ingestion risks remain although particle capture studies suggest potentially greater danger to mysticetes (baleen whales) from plastic pollution than oil.

Where oil is in contact with the skin there is the potential for it to cause irritation to the eyes or to burn mucous membranes. Moreover, all cetaceans can be fouled or inhale the volatile components of hydrocarbons when they surface to breath and rest. In cetaceans, the respiration of volatile chemicals at the surface of a slick or the ingestion of oil may be lethal or chronic affecting longer-term foraging performance and susceptibility to disease, which may ultimately affect survival (Schwacke, *et al.,* 2014). The lighter BTEX fractions of crude are the most volatile (evaporate readily) and are also the most toxic. If inhaled, such hydrocarbons can impact the respiratory system, which is also a pathway for chemicals to enter the circulatory system. PAHs tend not to be accumulated in marine mammals but certain metallic trace elements present in oil can be transferred and bioaccumulate.

To date, the most comprehensive and detailed information on the impacts of oil exposure in cetaceans comes from research following the 2010 Deepwater Horizon oil spill in the northern Gulf of Mexico, which resulted from a drilling platform explosion (see Godard-Codding and Collier, 2018). However, Sea Lion Crude differs significantly from the Deepwater Horizon crude in several key ways. It is waxy and solid at ambient temperatures, making it unlikely to adhere to cetacean skin. Additionally, Sea Lion Crude is far less volatile than the Deepwater crude, reducing the likelihood of inhalation exposure to toxic vapours.

Nonetheless, many species of cetacean are late to mature and reproduce at a slow rate. Combined with complex social group structures, such as that displayed by killer whales, the loss of relatively few adult animals can lead to long-lasting impacts on family groups or sub-populations (Matkin, *et al.,* 2008).

Numerous species of cetacean have been recorded in the NFB. Species of note include the sperm whale (IUCN 'Vulnerable') and fin whale (IUCN 'Vulnerable') which were recorded acoustically throughout the year in the NFB, and sei whales (IUCN 'Endangered') are known to be seasonal visitors (Section 7.4.6.2).

A description of the spatial and temporal distribution of marine mammals in the NFB can be found in Section 7.4.6.2.2.1.

12.1.4.2.6 Coastal impacts

POEPL (now Navitas) conducted an environmental assessment of the sensitivity of the north Falklands coastline to the potential impacts of an oil spill (Premier, 2014a). This study used oil spill modelling (not the same as that described later in this chapter) to ascertain the potential distribution of oil in the unlikely event of a worst-case oil spill from the proposed Sea Lion Field Development. The North Falklands Coastline Environmental Sensitivity study has been used to identify the most sensitive sites along the north Falklands coastline in the event that a shoreline oil spill response operation needs to be initiated. The Environmental Sensitivity classification does not take into account sensitivity of the specific wildlife at the sites but is a more general ranking of sensitivity based on the physical

characteristics of the shoreline - ranging from high energy rocky shores to sandy beaches, mud flats and wetlands. These sites have been outlined in Section 7.6.

Throughout the year, inshore and coastal waters are important feeding grounds for numerous species. Inshore waters support large quantities of lobster krill and loligo squid, which in turn are major food resources for higher predators. At certain times of the year marine animals return to land to breed or moult, increasing the densities of vulnerable species in the coastal waters during these times. Further, inshore waters support seabird assemblages that were assessed by White, *et al.* (2001) as being of very high vulnerability to the potential impacts of oil pollution throughout the year (Section 7.4.5.6).

Section 7.5.2.3.1 identifies Important Bird Area (IBAs) around the Falkland Islands coastline. Of particular note are the Volunteer Point IBA and Seal Bay IBA on the North Falkland coastline, which are at a low risk of oil reaching shore as predicted in the following sections, and which contain bird species that use the inter-tidal area. In addition, the inshore area three nautical miles from the baseline is a proposed MMA (pMMA) and much of this area is also a Key Biodiversity Area (KBA) for sei whales and has KBA elements for a number of seabird and coastal bird species (see Section 7.5.2.3.4). The northern coastline of East Falkland is considered an IMMA for southern right whales and all of the Falklands inshore waters out to 100 m is considered a KBA for sei whales.

Laboratory results (CEDRE, 2017) and experience indicate that while tar balls are normally possible with waxy oils, they would take a long time to form as the cold oil shows little affinity for suspended solids or shoreline sediments and remains buoyant after losses to evaporation. Tar balls that do form over time will sink to near the seabed where they will move much more slowly, potentially travelling for long distances. While they do so they have relatively little interaction with the environment. Tar balls can then emerge on shorelines a long time after the initial release, where they cause nuisance and can break down in higher temperatures. Most reports of tar balls focus on their interference with human activities at coastlines when they adhere to shoes and clothes, and it is conceivable that other large mammals or seabirds (such as penguins and steamer ducks) could be impacted by smearing and ingestion on the shoreline. The likelihood of any oil reaching the shore remains very low, however, and oil would be significantly weathered. Tar balls are normally quite visible and affected areas can typically be manually cleaned without further damage.

Oil and diesel spills are known to modify macrobenthic assemblages at the intertidal zone (Zhou, *et. al*., 2019). However, as noted above, testing of the Sea Lion crude indicated that the crude may stick to seaweed if spilled directly onto the coastline (i.e., hot oil), although it is considered that this is not a realistic scenario given planned operations. Nonetheless, if oil were to reach the coast following a spill at sea it would no longer be hot and the adhesion will be limited, although roughness of the seaweed, for example if bryzoan colonies are attached to the kelp creating rough patches, means the oil is more likely to stick (see Section 12.1.4.1.1.1). Testing also indicated that oil reaching the coast from a spill at sea is not likely to stick to the shoreline; if oil spilled directly onto the coast (again not considered realistic), it will likely stick to rocky and cobbled shores (CEDRE, 2017).

12.1.4.2.7 Fisheries (Human population)

12.1.4.2.7.1 Spawning aggregations

Knowledge of the timing and distribution of spawning aggregations and egg and larval transport *via* oceanographic features is critical to understanding the potential impact of oil spills on fisheries in the Falkland Islands. While the understanding and knowledge of spawning grounds in the Falkland Islands is poor, many of the commercially fished species exploit Falklands waters for feeding rather than spawning (Arkhipkin, *et al.,* 2012b). Nonetheless, the following spawning sites have been identified:

- Loligo squid spawn in inshore waters around the Islands (especially the east coast),

- Southern blue whiting and red cod spawning sites south of Cape Meredith (Arkhipkin, *et al.,* 2010; Brickle, *et al.,* 2011), and
- Toothfish spawning on the southern and eastern parts of the Burdwood Bank (Laptikhovsky, *et al.,* 2006; Collins, *et al.,* 2010).

While the Development is therefore not located in areas that are known to be significant for spawning for commercial species, it is located in the broader area of the Northern Slope which is an important feeding area for numerous commercially important species (Section 7.4.4.2.2). Moreover, oil released into the marine environment would disperse and may overlap with the distribution of major finfish and *Illex* squid fishing grounds on the edge of the continental shelf.

12.1.4.2.7.2 Tainting and contamination of fish and squid

Pelagic fish that swim with their mouths open to maintain a continuous current of water across their gills (e.g., scombrid fish; Klinger, *et al.,* 2015) could experience increased oil exposure from suspended or sinking waxy crude (Drewery and Wolfaardt, 2017) and ingestion of hydrocarbons by fish can lead to tainting of the flesh. The degree of tainting depends on the type of oil, the species concerned and the exposure time but can persist even after the source of the contamination is removed. Unlike vertebrates, invertebrates, such as shellfish or squid, are less able to metabolise hydrocarbons (Section 12.1.4.2.3.2) and therefore tainting can persist for longer periods. In finfish, which have the enzyme systems necessary to metabolise petroleum (NOAA and API, 1994); tainting is not believed to persist for more than a few days following exposure (Boyd, *et al.,* 2001). However, even if it does not persist within finfish, the public perception of tainting may last longer and may have implications for commercial markets. Moreover, concentrations that do not lead to tainting may still affect the physiology of the fish.

The accumulation of hydrocarbons in squid tissue has implications for tainting and human health. In recognition of the risk of potential contamination of the human food chain, the European Union (EC Regulation 208/2005) established a maximum level of 5.0 µg/kg wet weight for benzo(a)pyrene (the marker used for PAHs carcinogenic risks) in cephalopods. Some studies have been carried out to look at the background level of contamination in several cephalopod fisheries around the world (Gomes, *et al.,* 2013; Morais, *et al.,* 2013), which found relatively high background levels in Loligo squid from the South Atlantic. Consequently, should a significant oil spill overlap with squid fisheries, this would pose a risk to human health. The impact may also be cycled through the food chain due to squid's pivotal role as a consumer and prey species. However, as noted above, the CEDRE analysis of the Sea Lion crude indicates that PAHs did not dissolve into the water column during the seven day monitoring period. As described above, PAHs could potentially dissolve into the water column over longer periods of time, but the intrinsic levels of PAH in the crude are still relatively low (0.15 % versus 0.3-0.5 % for many crudes).

Nonetheless, the persistence of these chemicals, which can be subject to long-range transport impacting areas a considerable distance from the point of discharge, may lead to long-lasting impacts to the fishing industry, including fishery closures and reduced confidence from consumers.

Although there is little direct fishing effort in the immediate vicinity of the Sea Lion Field (Section 7.7.3.1.1.1), the Field sits between two major fishing areas. Deeper waters (>600 m) to the north and north-east are subject to a longline fishery for Patagonian toothfish. Waters on the edge of the Continental Shelf to the south and south-west of the Development are targeted by finfish trawlers. The catch of these vessels is mixed but comprises predominantly Patagonian rock cod, hake, hoki and skate (Section 7.7.3.1.1.1). However, the commercially targeted Argentine shortfin squid migrates into deeper water in May and June, to access the Falkland Islands current to aid passage to their northerly spawning migrations (Arkhipkin, *et al.,* 2015), and a significant proportion of the South Patagonian Stock passes through the Northern Slope.

12.1.4.2.8 Tourism

The natural environment and abundant wildlife are amongst the main attributes that draw tourists to the Falkland Islands. Even if oil does not reach the coast following a spill, news of an oil spill in what is perceived to be a remote and wild destination will result in negative publicity. In a wildlife destination like the Falklands, this could adversely impact public perception and experience of the Islands and undermine its status as an internationally renowned eco- and wildlife destination.

12.1.4.3 Oil spill modelling

In order to assess the potential impacts of large oil spills on environmental receptors, five oil spill, or release, scenarios have been modelled.

The main aims of the modelling were to understand the:

- Probability of hydrocarbons accumulating on the surface or reaching the shore,
- Characteristics of hydrocarbons dissolved in the water column,
- Fate of the hydrocarbons in terms of the relative amounts dispersed, evaporated, beached, biodegraded and deposited in sediments, and
- Overall likely transport of oil at sea in terms of density, direction and time.

For the Sea Lion Phase 1 & 2 Development, using the most accurate oil properties and metocean data available, it is predicted that the Falkland Islands coastline is on the fringe of the maximum area that could potentially be reached by oil from a large release. The likelihood of such an outcome has a very low probability and consequently quite subtle changes in metocean data, location and release size can have apparently large effects on shoreline impacts. The predictions consistently show low (if any) probabilities and oil masses. A blow-out (Scenario 1) is predicted to result in a very small mass of oil to shore in 4 % of the metocean conditions modelled. It is predicted that an FPSO loss (Scenario 2) could also reach the coast of the Falkland Islands in 5.8 % of the metocean conditions modelled.

12.1.4.3.1 The OSCAR modelling approach

The SINTEF OSCAR software is a sophisticated multifunction model that computes surface and subsurface transport, behaviour, weathering and fate of oil, as well as potential ecological impacts. The OSCAR model has been developed by SINTEF, an independent Norwegian research organisation founded in 1950 that specialises in oil behaviour with extensive oil testing laboratories. The suite of models to which OSCAR belongs has been the subject of verification and calibration by numerous field experiments both on surface spills and subsea releases in offshore and nearshore locations, e.g., as described in Reed *et al.* (1995; 1996), Johansen *et al.* (2001), Hayes and Galley (2012), de Susanne (2015) and Niu *et al.* (2016). This validation confirms the model as a state-of-the-art method for predicting oil behaviour at sea. Since the modelling draws in a number of different datasets (currents, winds, bathymetry, shoreline types, oil characteristics and others), the outputs should be viewed as giving the best possible indication of oil behaviour that are reliable for drawing overall conclusions, while bearing in mind that there is an uncertainty around specific numerical outputs.

The OSCAR model was primarily written to predict the physical behaviour of Newtonian fluids, which includes the majority of crude oils. However, it is possible to input specified measured parameters for individual crude oils including the hydrocarbon characterisation and weathering parameters, which now includes Sea Lion Crude, following crude oil tests undertaken by CEDRE (2017).

The following describes only the information required to ensure appreciation and understanding of the modelling results. Of note, release 14.1 of OSCAR was the current version when the modelling was undertaken and was used for the modelling described below.

12.1.4.3.2 Discharge parameters and assumptions used in the modelling

The release parameters used in the oil spill dispersion modelling for each scenario are summarised in Table 12.3. These parameters are based on worst-case scenarios so as to set an upper boundary in relation to the potential effects.

Of note, there will probably be an upper limit in terms of the thermal properties of the release, i.e., a large mass of hot oil released will remain fluid potentially for some minutes, float and flow into a thinner layer, but it is expected that such a layer would not be strong enough to withstand wave action. To reflect this behavior, during the modelling undertaken for Sea Lion crude releases:

- The initial oil droplet size was set as large as possible, in the range of centimetres,
- The 'terminal film thickness' parameter was modified to prevent oil from continuing to spread on the sea surface,
- For subsea releases (e.g., a well blow-out) and smaller surface releases (e.g., crude oil transfer spill), the initial surface film thickness was set to 20 mm thickness and spreading was limited to 1 mm thickness, and
- For larger losses of inventory (e.g., loss of FPSO inventory), the initial surface film thickness was set to 50 mm and spreading is limited to 5 mm thickness.

Table 12.3: Parameters included in the oil dispersion modelling for the oil and diesel spill scenarios

Scenario	Fluids discharged	Release parameters					Model run duration	Worst-case assumptions
		Volume (tonnes)	Duration	Location	Temp. (°C)	Diameter		
1: Well blow-out scenario	Sea Lion crude oil	Worst-case declining rate: 1,980 – 1,291 t/d (32,295 tonnes total)	21 days[1]	Seabed	68	230 mm	111 days	Release duration assumes 21 days to employ a well capping device. Worst-case declining flow rate used.
2: FPSO crude oil inventory loss	Sea Lion crude oil	80,080	1 day	Surface release	60	n/a	91 days	Release volume based on total loss of FPSO inventory (605,000 bbl) at 60°C storage temperature over one day.
3: Crude oil transfer spill	Sea Lion crude oil	70	10 minutes	Surface release	60	n/a	30 days	Volume and duration reflect the fact that operations would cease as soon as a leak / spill was detected. Hose volume reflects the largest comparable spill recorded.
4: Diesel inventory loss (MODU)	MGO	3,936	1 hour	Surface release	8 (ambient)	n/a	14 days	Release volume based on total loss from an analogue MODU.
5: Diesel bunkering spill	MGO	20	10 minutes	Surface release	8 (ambient)	n/a	14 days	Volume and duration reflect the fact that operations would cease as soon as a leak / spill was detected.

[1] 21 days is calculated by Navitas on the basis of the upper durations estimated for the following tasks (i) decision to deploy capping stack; (ii) deploy Capping Stack by air to Falkland Islands; (iii) mobilise well control team; (iv) prepare Capping Stack for deployment offshore; (v) deploy Installation Vessel to field; (vi) deploy Capping Stack to field; and (vii) cap well.

12.1.4.3.3 Reporting thresholds defined in the model

In order to give meaning to the models, it is necessary to determine thresholds (based on industry best practice), below which the predicted levels of contamination are insignificant. Once a threshold is reached, the model terminates oil particles (assuming loss of mass to evaporation, decay or deposition) or ceases recording them.

The spill properties to which the thresholds apply include:

- Thickness / density of oil on the surface, and
- Total water column concentration.

The model generates output data (maximum oil concentrations, surface thickness etc.) by tracking numerous particles placed throughout a specified grid that is manually selected in the locality of the release site. Typically, this grid will be set to capture the majority of the plume as it disperses across the sea.

12.1.4.3.3.1 Thickness / density of oil on the surface

Significant, and relevant, surface thicknesses depend on the specific properties of the oil under consideration.

Sea Lion Crude

For the Sea Lion crude oil type, the overwhelming properties of the wax components mean that a surface thickness parameter is not meaningful, and a scale has therefore been devised to reflect the density of waxy oil droplets on the sea surface.

The scale of oil density chosen to represent the results is 1, 10, 100, and 1,000 grams per square metre (g/m^2). This unit has been used previously for similarly waxy crudes, for example, oil pollution emergency plans following the Montara oil spill in the Timor Sea in 2009 used a density of 10 g/m^2 (PTTEP, 2016). Here the chosen threshold is 1 g/m^2 and below this value the oil ceases to be shown in model outputs, although it remains present in the calculations in the model (Table 12.4). Importantly, the scale selected here is not intended to imply significance in terms of the impact assessment below, but to convey factual information regarding the model predictions and allow a means of visualising the results.

It is noted that in the laboratory tests, feathers exposed to 100 g/m^2 of oil showed no oil being adsorbed by the feathers, and no structural damage was observed. At an oil concentration of 1,000 g/m^2, all the feathers were stained by oil, and for two bird species, micro particles of oil adhered.

Diesel (Marine Gas Oil)

While there are some data on the effects on feathers of thicknesses of sheens or slicks from liquid oils such as MGO (Section 12.1.4.2.4.1), there is no consensus on thicknesses of surface oil that corresponds to impacts on the whole animal or on populations. For the MGO spill scenarios that have been modelled in this study, a surface thickness threshold of 0.3 µm has been adopted as a way of judging the onset of impacts (Table 12.4). Under the Bonn Agreement 'Oil Appearance Code of oil thicknesses' (Bonn Agreement, 2009), this thickness value corresponds to a rainbow sheen and any surface oil thickness below this value is unlikely to be visible.

12.1.4.3.3.2 Total water column concentration

Water column concentrations refer to dissolved hydrocarbons plus droplets. A threshold of 25 parts per billion (ppb) has been used in the models for all spill scenarios and oil types, below which the oil in the water column is not expected to have acute toxic effects (Table 12.4). This threshold reflects a worst-case and it is noted that 50 pbb is the lowest Predicted No Effect Concentration (PNEC) for acute

toxicity of the oil components in the OSCAR database and is also the mid-range of the concentrations of crude oil found to give sub-lethal effects (Patin, 2004).

12.1.4.3.3.3 Sediment concentration

Oil can reach the sediments either directly if a release is near to the seabed in turbulent water conditions or it can sink to the seabed if it adsorbs to suspended solids within the water column, thus becoming denser. The latter method has not been included within the modelling (Section 12.1.4.3.4.1).

Tests of Sea Lion crude on benthic organisms (*Corophium* sp. (Amphipod)) indicated that at concentrations of >392 mg/kg oil in the sediment, the oil is lethal to 50 % of organisms tested after 10 days (Table 12.1 above, CEDRE, 2017). A level of 50 mg/kg is a more general level of oil contamination where toxic effects may be discernible, referenced in OSPAR Recommendation 2006/5 on the management of drill cuttings piles and a more precautionary threshold of 10 mg/kg is put forward in Patin (2004) as being the zone of No Observable Effect Concentrations (NOEC) of crude oils (Table 12.4).

Table 12.4: Oil density thresholds used in the Sea Lion development oil spill modelling study

Scenario	Oil type discharged	Surface threshold	Water column concentration threshold	Sediment threshold
1: Subsea well blow-out	Sea Lion crude oil	1 g/m^2	25 ppb	>392 mg/kg[1] 50 mg/kg[2] 10 mg/kg[3]
2: FPSO inventory loss				
3: Crude transfer spill				
4: Diesel inventory loss	MGO	0.3 µm	25 ppb	n/a
5: Diesel bunkering spill				n/a

[1] Tests on the amphipod *Corophium sp*. were carried out for 10 days to determine the lethal toxicity (LC_{50}) of the crude to amphipods. 392 mg/kg of oil in sediments is the concentration at which 50 % of the test organisms died when compared to a control (Table 12.1).
[2] OSPAR Recommendation 2006/5 on the management of drill cuttings piles.
[3] Indicated by Patin (2004) as the zone of NOEC.

12.1.4.3.4 Understanding the model

Oil spill modelling incorporates the following two types of model run:

- **Stochastic modelling** - carried out by running individual discharge scenarios multiple times over different time periods (thereby utilising different wind and current conditions) and aggregating the results in order to report behaviour in some probabilistic or statistical manner. For each oil spill scenario, the aggregated stochastic modelling results present:
  - The probability (%) of hydrocarbons accumulating to levels above the stated thresholds:
    - On the sea surface,
    - In the water column, and
    - On any shorelines.
  - The minimum times taken (days) for hydrocarbons to arrive at any location at levels above the stated thresholds:
    - On the sea surface,
    - In the water column, and
    - On any shorelines.

- The maximum length of time (days) any area is exposed to oil at levels above the stated thresholds:
  - On the sea surface,
  - In the water column, and
  - On any shorelines.

- **Deterministic modelling** - conducted over a particular time frame which is selected based on the results of the stochastic model results, deterministic modelling is used to highlight hydrocarbon behaviour over a specific time frame. The time period for each deterministic run was selected to highlight either the worst-case mass of oil arriving on shore, or the largest mass of oil on the sea surface both of which are predicted by the stochastic modelling results. For each oil spill scenario, the deterministic modelling results present:
  - The predicted worst-case shoreline oiling concentrations (kg/m^2) (if applicable),
  - The maximum surface area affected by levels above the stated thresholds for a single spill scenario, and
  - The total hydrocarbon concentration (ppb) in the water column for a single spill scenario.

12.1.4.3.4.1 Model parameters

To assist the interpretation of model outputs and the conclusions drawn, the following points are noted.

Sedimentation of oil

There are two mechanisms by which oil can contaminate sediments. One is where oil in the water column becomes absorbed directly into seabed sediments through close contact near the seabed and occurs particularly when the water column is turbulent. Inclusion of this mechanism was not available in previous versions of the OSCAR modelling software but is now included within version 14.1 (used in this assessment).

The second mechanism is where oil in the water column attaches to suspended solid particles also in the water column. This makes the oil more dense so that it sinks more quickly to the seabed. The OSCAR model (version 14.1) allows for the entry of an ambient suspended solids concentration to account for this mechanism. However, this has not been applied in the modelling here because there are little data on suspended solids in the region, and laboratory testing indicated little uptake of suspended solids by the Sea Lion oil. By omitting it, there is confidence that the amount of oil in other compartments (e.g., surface layers or the water column) is not underestimated.

Emulsification of oil

In the scenario narratives below, the model outputs present oil masses that include a water content in the oil that is predicted by the model physics. This means the reported mass of oil across all compartments is slightly higher than the released mass.

Grid selection

Model results are collated and reported *via* a 3D grid, and for each scenario the grid layout has been chosen that maximises the accuracy of the outputs by focusing on the area occupied by the vast majority of oil particles for the period when they are most likely to present significant environmental impacts. Given available computing power, it is possible to increase the definition of outputs for the deterministic model, and in particular the resolution of the water column grid is increased so that the presence of oil in the water column can be reported at a higher resolution.

Where model particles exit the grid, such as to the north of the area for the blowout and FPSO inventory loss scenarios, they are recorded as 'outside grid'. The northern boundary for these two

scenarios has been chosen to be as far north as possible within the high-resolution NEMO PS4 currents dataset, and by the time oil exits this area, its environmental properties are known and relatively stable and conclusions on impacts can be drawn.

Model duration

Extensive modelling of potential offshore releases, including the results presented here, confirms that oil can reach the edge of the model domain in 30 days, and takes 60 days in the majority of cases. It is therefore considered conservative to allow a model run period of 90 days after the end of the release. For the smaller scenarios, a duration of 30 days is used for the crude transfer spill and 14 days for the MGO scenarios in proportion to the volume and persistence of the oil. Using 102 stochastic scenarios, the individual runs are spaced at approximately 10 day intervals across the 3-year metocean dataset, and periods being modelled overlap very significantly. For the blowout scenario, this means that oil is released at every time interval within the model dataset with subsequently at least 90 days to disperse to identify all possible trajectories. Experience has also shown that increasing the number of stochastic runs beyond this number does not significantly alter the results, which complies with UK government recommendations (BEIS, 2022a). This can be seen by the projection that while four scenarios for well blow-out reach the shore, they all occupy the same set of north winds in the metocean record, i.e., increasing the number of runs would not alter the proportion that occupy this set of winds.

12.1.4.4 Scenario 1: Subsea well blow-out - modelling results

12.1.4.4.1 Predicted behaviour of oil

The behaviour of Sea Lion crude released due to a well blow-out (worst-case 32,295 tonnes) is shown in Figure 12-3. These results represent the scenario giving rise to the maximum oil coming ashore and are also representative of the general oil behavior over a wide range of conditions. The ‘spikiness’ of the surface and dispersed oil values reflects periods of rough and calm weather, when oil moves between surface and water column, resurfacing when calm.

Since the well blow-out discharge is assumed to occur on the seabed, crude oil is not immediately present on the sea surface. However, due to the buoyancy of the oil, it is predicted to surface very quickly after it has been discharged. The modelling predicts that after 20 days from the start of the discharge, 35,250 tonnes of oil is accounted for (including emulsified water): 71 % (25,030 tonnes) will be found on the sea surface, 16 % (5,599 tonnes) will be dispersed in the water column, 7 % (2,537 tonnes) will have evaporated, and 2 % (673 tonnes) will have biodegraded. A maximum of 110 tonnes is predicted to be present in sediments at the end of the simulation (<1 %).

After approximately 60 days, model particles begin to leave the modelling grid. Model particles were only observed to leave the modelling grid initially *via* the northern boundary due to the strong northerly currents and then later also *via* the eastern boundary. It is expected that any oil that has travelled this far will be insignificant as it will be in a highly dispersed state, having been at sea for a minimum of 30 days. Thus, any oil that leaves the model grid is not expected to significantly affect the overall conclusions of the model predictions. It should also be noted that extending the model grid northwards is not practical since this boundary is set to coincide with the boundary of the NEMO PS4 currents grid. However, it is important to note that once the oil starts to leave the model grid, the fate of oil is unknown, therefore the total masses of oil in each fate category beyond 60 days may be larger than those shown in Figure 12-3 as the oil that leaves the modelling grid is not accounted for.

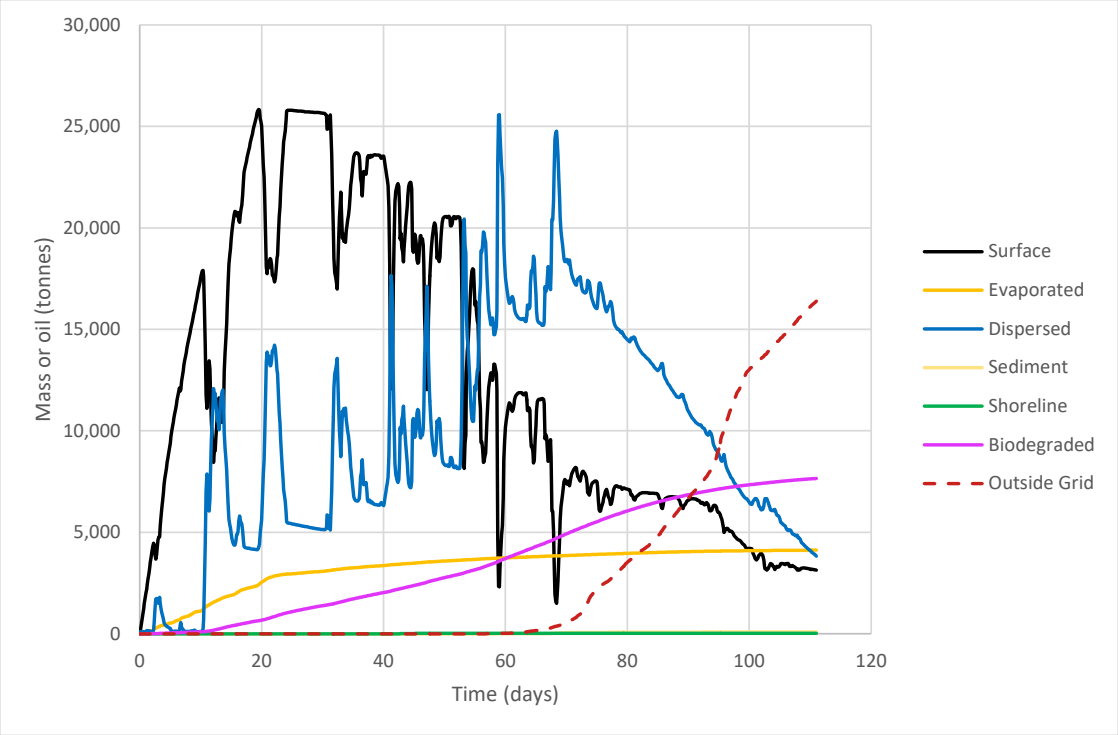

Figure 12-3: Behaviour of oil over time during the modelled blow-out

12.1.4.4.2 Subsea Well Blow-Out - Surface results

Figure 12-4 below shows the probability of oil appearing on the sea surface above the threshold of 1 g/m^2 following a subsea well blow-out throughout the whole model run. Because Sea Lion crude is a low density oil, and the oil masses that form after the oil is discharged to the marine environment are buoyant, there is a high probability that oil will appear on the sea surface above the threshold. There is a large area of the sea surface that has 100 % probability of surface oil above 1 g/m^2 (Figure 12-4). The oil is predicted to travel on the sea surface primarily in a northerly direction due to the predominant surface current direction. Some wax is also likely to be found to the south-east of the discharge location, as a result of wind driven Ekman currents. It is predicted that there is approximately a 4 % probability of oil reaching the coastline of the Falklands *via* the sea surface – that is, four out of 102 cases, oil is predicted to reach the shoreline, while in 98 out of 102 cases, no oil is predicted to reach the shore.

Figure 12-5 shows the minimum arrival times of Sea Lion crude above the threshold of 1 g/m^2 on the sea surface. In most conditions, the Sea Lion crude can potentially travel up to 30 km within one day of being discharged, 105 km within 5 days, and up to 260 km within 10 days. Although the crude oil can potentially travel very long distances within a relatively short period of time, it is predicted that after 10 days the oil will be in a highly dispersed state. The oil rises quickly to the surface and spends little time in the zone of strongest currents which is around 30 m below the surface, and after surfacing is driven by winds and prevailing currents. Oil takes at least 7.5 days to reach the outer boundary of the FOCZ.

Figure 12-6 shows the maximum time that any sea surface location is exposed to Sea Lion crude above the surface density threshold of 1 g/m^2. The sea surface around and to the east of the well blow-out discharge location can potentially be exposed to Sea Lion crude oil for up to 30 days. At locations further away from the discharge, the maximum exposure times decrease as the oil spreads and the likelihood of oil above 1 g/m^2 on the sea surface decreases. At locations outside of the FOCZ boundary

it is unlikely that the surface will be exposed to oil above the 1 g/m^2 threshold for more than three days and will probably be less than a day.

All of the outputs shown in these figures are based on an aggregation of results from all the stochastic model runs and therefore do not represent a single spill scenario, and certainly do not reflect the manifestation of oil on the sea surface at any single instance in time.

Tests on oiling of feathers were conducted at CEDRE (2017) looking at densities of 100 g/m^2 and 1,000 g/m^2; minor changes to barbules were noted at 100 g/m^2, and adhesion of oil and some feather staining was observed at 1,000 g/m^2 surface density.

In the blow-out scenario, very little area is predicted to be exposed to a concentration of more than 10 g/m^2 and there are no sustained areas predicted to be above 100 g/m^2 (Figure 12-7). Levels of 1,000 g/m^2 were necessary in the laboratory to induce oil staining and adhesion, with minor changes to barbules noted at 100 g/m^2 (Section 12.1.4.1.1.1). Note that due to averaging and contouring functions in the stochastic model, some individual cells may exhibit a transient concentration of above 100 g/m^2 but remain absent from the plots, which can be seen in the deterministic example in Figure 12-8 very close to the release. The conclusion remains that there is a negligible area of sea at risk of > 100 g/m^2 of crude oil on the surface at this scale.

Based on the stochastic simulation results of the worst-case well blow-out scenario, a single deterministic model run was conducted to demonstrate the predicted total impacted surface area for a single, worst-case, scenario. Figure 12-8a shows the total impacted surface area for the single deterministic model run, and shows the maximum oil densities on the sea surface that were observed at each geographical location throughout the whole model run duration of 137 days. This graphic illustrates every location where wax might be found throughout the entire model period. Again, this is not reflective of the extent of wax distribution at a single point in time. An example typical snapshot of surface wax densities for the single deterministic well blow-out model run is shown in Figure 12-8b.

12.1.4.4.2.1 Model predictions after oil has been at sea for long periods

It is normal to run scenarios for the entire duration of a blow-out, and for some time following the cessation of the release, to determine the behaviour and location of oil before taking a view on whether this poses a risk to receptors. There are reasons to view the longer-term surface predictions as conservative, as the particles at sea will eventually be biodegraded or combine with suspended solids and sink. It is also not certain that the model physics for very weathered oil masses is representative. The representation of the oil as a density, which appears to evenly cover grid cells of 2 km^2 in the well blow-out model run, is a reasonable way to envisage it during the early stages of a release but may lose relevance when the oil masses are extremely small and widely dispersed. It is possible to employ a higher threshold to 'screen out' smaller concentrations, but this has not been done in the interest of transparency.

Overall, the interpretation of results over long timescales should be done with caution and experience, and, in general, the model results may exaggerate the apparent impact of dispersed oil and are therefore considered to be conservative.

Figure 12-8: Surface results (deterministic) for worst-case well blow-out

12.1.4.4.3 Subsea Well Blow-Out - Water column results

Figure 12-9 shows the probability of oil accumulating in the water column above the threshold of 25 ppb for the worst-case well blow-out scenario. As expected, since the release is modelled to occur subsea for a duration of 21 days prior to being capped, there is a high probability that the water column will be exposed to crude oil above the concentration threshold of 25 ppb. The crude oil is predicted to travel predominantly in northerly and south-easterly directions, which is likely caused by currents and the predominant winds from the north-west dispersing surface oil into the water column. The oil released at the seabed is expected to rise through the water column quickly and there is a high probability that it will accumulate in the topmost layer (<60 m) of the water column in concentrations above 25 ppb.

Figure 12-10 shows the maximum times the water column will be exposed to >25 ppb, showing clearly that there are longer exposure times near the blow-out location.

A cumulative plot of water column concentrations of dissolved oil and oil droplets for the worst-case well blow-out is shown in Figure 12-11a. Figure 12-11b shows a cross section of the same results. However, given the very low solubility of Sea Lion crude, these concentrations are almost all small wax particles, and very little of the oil is present in the more hazardous dissolved form.

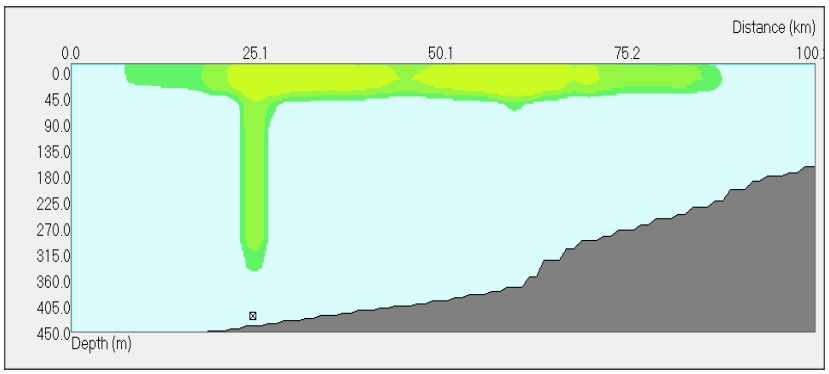
a) Cumulative water column concentration dissolved oil and oil droplets



b) Cross-section of cumulative water column concentration dissolved oil and oil droplets

Figure 12-11: Cumulative water column concentrations from a worst-case blow-out

12.1.4.4.4 Subsea Well Blow-Out - Shoreline results

Figure 12-12 shows the probability of oil reaching the Falklands coastline after a worst-case blow-out by identifying the initial beaching locations. The modelling results indicate that there is a low probability of crude oil reaching the shoreline. The northern coastline of East Falkland is predicted to be the most likely place where oil could beach and there is no possibility for any international beaching events. The greatest probability of shoreline oiling was observed to be 4 %, indicating that only four of the 102 individual stochastic simulations resulted in crude oil reaching the Falklands coastline. Examining the metocean record, this only occurs when there is a prolonged period of northerly winds for some weeks, and this has occurred only once in the record. Four scenarios had this weather episode

within their duration for long enough for oil to reach the coast. Consequently, in the event of a worst-case blow-out, shoreline oiling is possible, but highly unlikely. In 98 out of 102 cases, no oil is predicted to reach the shore.

Figure 12-13 shows the minimum arrival times for shoreline oiling for a worst-case blow-out indicating that, in the unlikely combination of conditions where oil is blown towards the Falkland Islands, arrival times are 32-52 days to reach the northern coast of East Falkland, with an average of 41 days.

Figure 12-14 shows the concentration of oiling on the shore for a deterministic scenario to predict the worst-case oiling on the shore. The maximum volume of oil predicted to reach the coastline is approximately 29 tonnes and the average amount of oil on shore (in the 4 % of scenarios in which oil does reach the shoreline) of 16.5 tonnes.

Figure 12-15 shows the forecast for any oil to reach the shoreline in terms of the mass of oil over time. It is predicted that any crude oil that eventually reaches the Falklands coastline would be in a highly dispersed state due to it having been at-sea for over 30 days before reaching the coastline. It is therefore likely that the oil would reach the shoreline as small masses and might not be easily detectable.

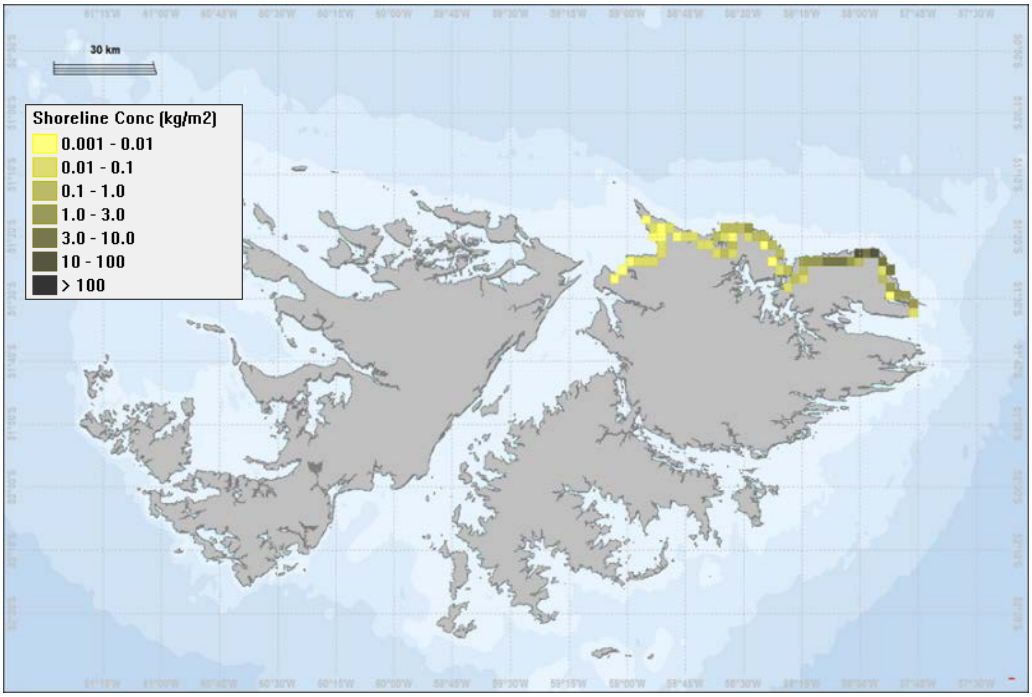

Figure 12-14: Concentration of oiling on the shoreline for a worst-case blow-out (deterministic)

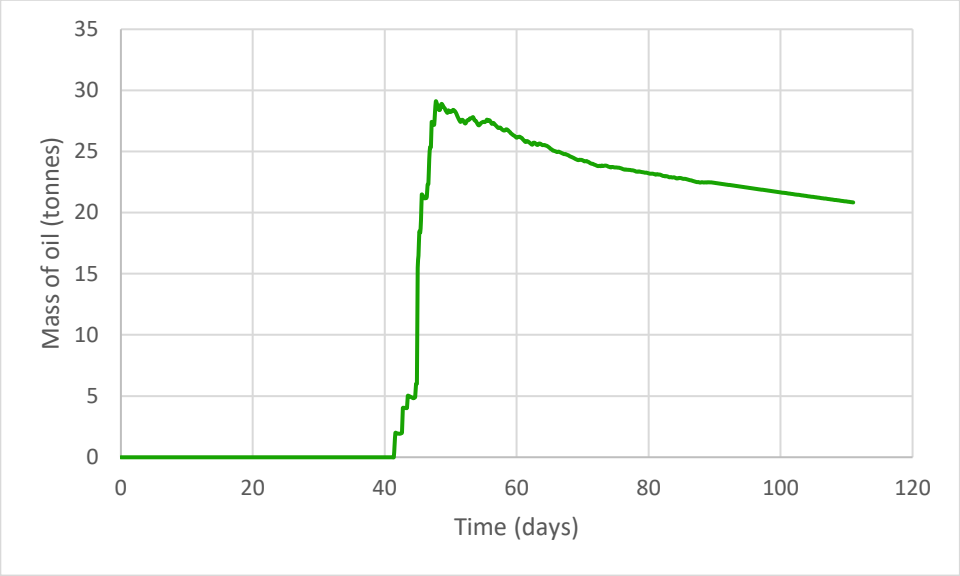

Figure 12-15: Forecast of oil arriving onshore in a worst-case blow-out scenario

12.1.4.4.5 Subsea Well Blow-Out – Sediment concentration

Tests on the Sea Lion crude indicate that a spill would impact upon on benthic species tested at concentrations >392 mg/kg in the sediments (Section 12.1.4.1.1.1). This is not predicted to occur anywhere following a well blow-out. A level of 50 mg/kg is a more general level of oil contamination where toxic effects may be discernible (Table 12.4 above). No predicted levels are above this threshold. A more precautionary threshold of 10 mg/kg is put forward in Patin (2004) as being the zone of NOEC, and 644 km^2 of seabed could be above this concentration, the maximum level predicted being 29.3 mg/kg assuming oil is mixed over a 5 cm layer.

12.1.4.4.6 Subsea Well Blow-Out - Effect of oil spill response measures

The OSCAR model has been used to predict the effectiveness of oil spill response measures. Oil containment and recovery is the principal means of response, as dispersants are ineffective (Table 12.1 above) and burning has not been evaluated. Oil containment and recovery has limited efficacy in offshore sea states where significant wave height is >2 m but the necessary resources for response will be available on support vessels, as will be described in the operational OPEP (Section 12.1.1.1.3). The assumptions around response resources are as follows.

- In the case of a blow-out, it is assumed that any vessels present would support rescue of personnel or source control activities for the first 24 hours, and there would be no immediate recovery,
- After that, it is assumed that two recovery units would be available using a boom system,
- Each recovery unit would have a boom encounter width of 15 m and a single skimmer[98] capable of recovering 30 tonnes per hour (if that much oil is encountered by the boom) and could operate at a wave height of up to 2 m,
- Each recovery unit would store 200 tonnes of oil and take two hours to offload into bladders or onto a suitable vessel,
- After 10 days, five recovery vessels contracted from the spot market in South America arrive on site, and it is assumed that each is able to recover 30 tonnes per hour, and

[98] Note that the CEDRE investigation into the Sea Lion crude concluded that neither oleophilic nor weir skimmers would be effective and that belt skimmers should be considered the most appropriate equipment (CEDRE, 2017).

- After 20 days, a further five recovery vessels contracted from the spot market in Africa arrive on site, and it is assumed that each is able to recover 30 tonnes per hour.

Note: recovered oil will initially be stored in bladders while a specific recovery tanker is mobilised (a Vessel Of Opportunity (VOO)).

In reality, more resources may be available depending on other activities and vessels of opportunity. During production, the MRSV/ERRV and AHTS/EERV will be available with spill response capability or if any other vessel were available offshore, tanks could be offloaded more quickly. For the purposes of the assessment, the predicted recovery is seen as conservatively small. There are also many uncertainties in these predictions, both potentially positive and negative.

Applying these resources to the spill scenario, a new set of outputs is obtained. Key comparison data are provided in Table 12.5. In this example, the response resources do not alter the shoreline oiling outcomes within the tolerances of the model. Figure 12-16 shows that the two recovery units initially on-site (labelled AHV1 and AHV2) are able to recover almost 1,000 tonnes of oil each, while the multiple third-party oil spill response vessels recover less. This is due to their later arrival time, and the fact that the blowout ceases at day 21 and thereafter, the oil present is more and more dispersed and difficult to recover. This helps to show the critical parameters for defining the oil spill response resources.

Although the assumed response has a very modest effect and recovers 6.3 % (2,231 tonnes) of the oil, it represents realistic recovery assumptions under challenging sea conditions. In an actual spill, the recovery units could likely be tasked more intelligently to tackle oil that was more likely to reach shorelines, rather than using the simple model algorithms. It should be noted that for a smaller volume spill, the available recovery rate remains the same and so the operation would be likely to recover a greater fraction of the oil. Actual recovery rates for 30 large oil spill incidents are reviewed in Etkin and Nedwed (2021), which concludes that 2-6 % mechanical recovery is experienced in practice.

Table 12.5: Summary of oil spill response effectiveness for worst-case shoreline oil

Parameter	No response	With response
Mass of oil on shore	60 -70 tonnes	60 -70 tonnes
Mass of oil recovered	-	2,231 tonnes
Proportion of oil recovered	-	6.3 %

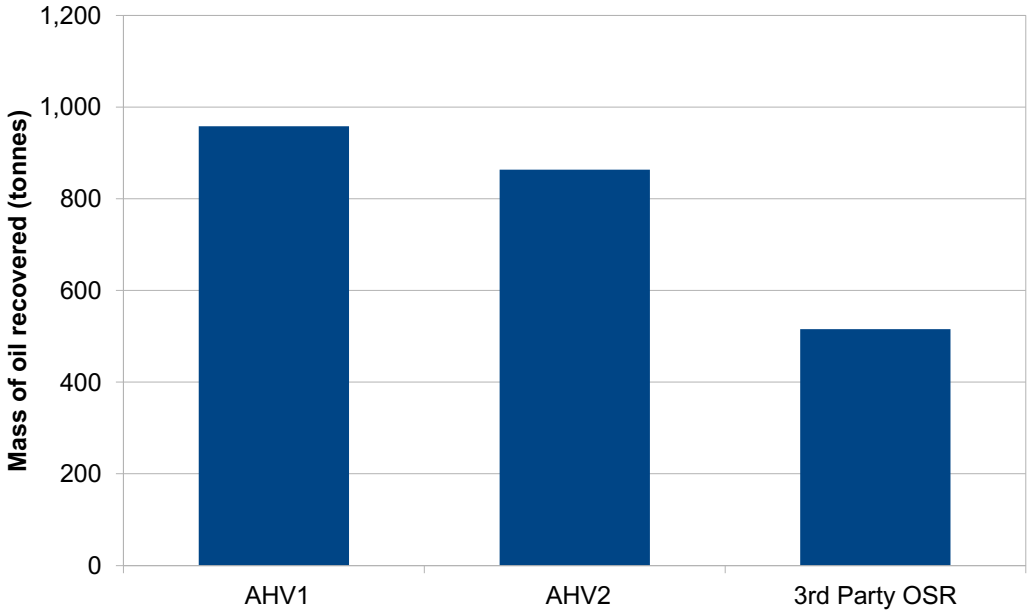

Figure 12-16: Mass of oil recovered by modelled response units

12.1.4.5 Scenario 2: Loss of FPSO crude oil inventory - modelling results

12.1.4.5.1 Predicted behaviour of oil

The predicted overall behaviour and fate of Sea Lion crude after a FPSO crude inventory loss (worst-case 80,080 tonnes) is shown in Figure 12-17. These results represent the scenario giving rise to the maximum oil on shore and are also representative of the general oil behavior over a wide range of conditions.

Initially, the largest proportion of Sea Lion crude is found on the sea surface, however this will start to decrease after the discharge ceases, as the oil disperses in the water column and evaporates. The modelling predicts that after 20 days from the start of the discharge, 71 % (25,030 tonnes) of the oil will remain on the sea surface, approximately 16 % (5,599 tonnes) will be dispersed in the water column, and 7 % (2,537 tonnes) is expected to have evaporated. A maximum of 18 tonnes is predicted to be present in sediments at the end of the simulation (<0.5 %).

Similar to the well blow-out scenario, Figure 12-17 indicates that crude oil begins to move outside the modelling grid after approximately 40 days. However, the fact that oil goes beyond the modelling grid does not affect the overall conclusions drawn from the model.

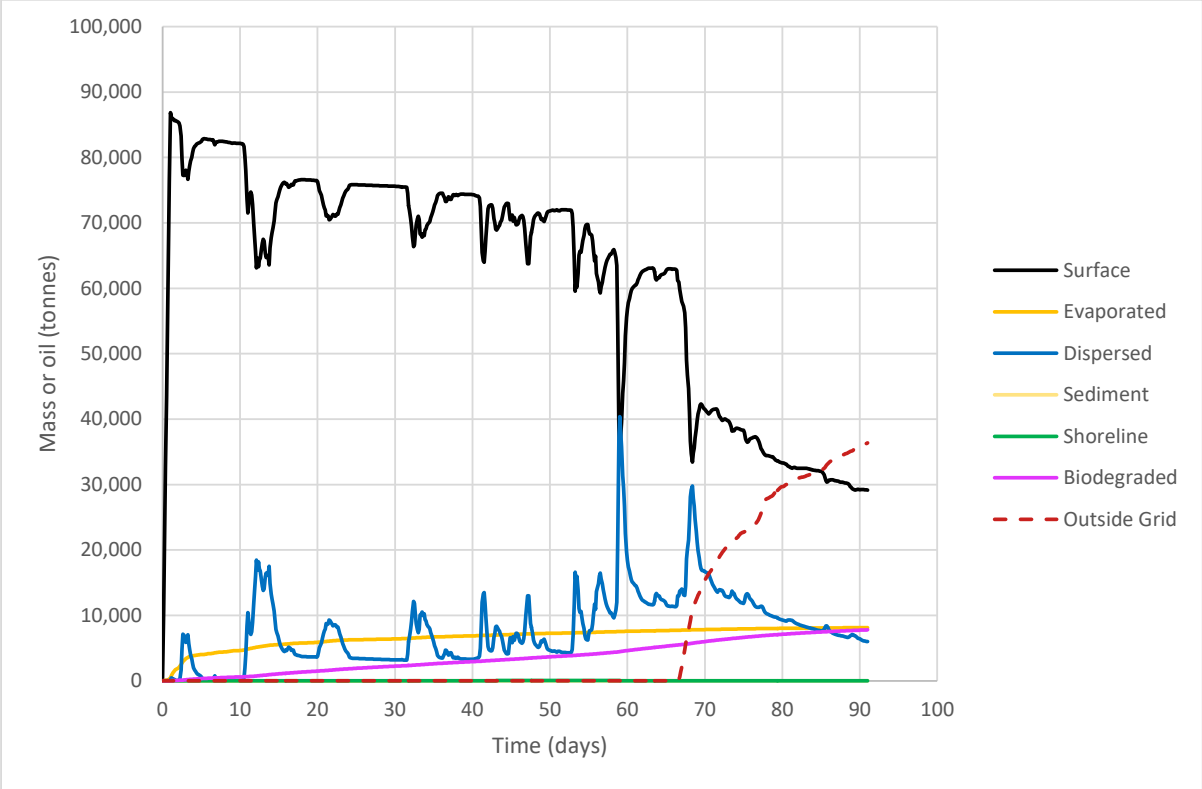

Figure 12-17: Predicted overall behaviour of Sea Lion crude oil after FPSO inventory loss

12.1.4.5.2 FPSO crude inventory Loss - Surface results

Figure 12-18 shows the probability of Sea Lion crude oil occurring above the threshold of 1 g/m^2 on the sea surface at any time throughout the entire model period. Because Sea Lion is such a low density waxy crude oil that is persistent and does not biodegrade quickly, there is a high probability that wax will be found on the sea surface at large distances from the initial discharge location. The modelling predicts that there is a greater than 90 % probability that wax could be found up to 220 km north of the FPSO location, and that surface oil is more likely to spread in a northerly direction from the FPSO. This is due to the predominant currents around the Sea Lion location, which travel in a northerly direction. Surface oil is also predicted to appear at locations to the south-east of the FPSO location, which is likely due to wind driven surface currents. The modelling predicts that, in the unlikely event of a full FPSO inventory loss, there is a high probability (above 90 %) that the crude oil will travel on the sea surface outside of the FOCZ and into international waters.

Figure 12-19 shows the predicted minimum time taken for oil above the threshold of 1 g/m^2 to arrive at any location on the sea surface after a full FPSO inventory loss. Due to the persistence and low biodegradation rate of Sea Lion crude, the oil can potentially travel very long distances. In the most mobile of conditions, the crude oil can travel up to 35 km within one day, 97 km within five days, and up to 350 km within 15 days from the start of the discharge. However, it is predicted that after 15 days the oil will be in a highly dispersed state. In the event of the loss of the full FPSO crude inventory, it is predicted that it would take at least five days for oil to cross the FOCZ boundary.

Figure 12-20 shows the maximum time that any sea surface location is exposed to crude oil above the surface threshold of 1 g/m^2. At locations close to the FPSO location, the sea surface could be exposed to oil for up to 23 days. Further away from the discharge location, the maximum exposure time decreases as the oil becomes dispersed due to wave action and weather conditions.

Figure 12-21 compares the probabilities that different levels of oil concentration are exceeded. The CEDRE laboratory results showed that oil adhesion to feathers was absent below 100 g/m^2, and some adhesion was usually observed above 1,000 g/m^2 (Section 12.1.4.1.1.1). It can be seen that the areas potentially affected at these two thresholds are far smaller than the area shown at 1 g/m^2, indicating that the potential for negative impacts on plumage is limited to an area much closer to the release – e.g., the 50 % probability contour extends to around 5 km for 100 g/m^2 level and is extremely localised to the release site for the 1,000 g/m^2 level.

The results in Figure 12-21 are based on an aggregation of results from all the stochastic model runs and therefore do not represent a single spill scenario.

Therefore, a single deterministic model run of the FPSO inventory loss scenario was conducted to show the behaviour of discharged oil for a single, worst-case, spill scenario. The total impacted surface area above the threshold of 1 g/m^2 is shown in Figure 12-22a, in which the maximum oil densities observed at any location throughout the whole modelling duration of 120 days are presented. An example snapshot of the surface wax after three days from the start of the discharge is shown in Figure 12-22b.

Figure 12-22: Surface results (deterministic) for FPSO inventory loss (at 30 days)

12.1.4.5.3 FPSO crude inventory Loss - Water column results

The probability of oil occurring in the water column above the threshold of 25 ppb is presented in Figure 12-23. The model predicts that in the event of the entire FPSO crude inventory being lost, there is high probability that large areas of the water column will have concentrations of crude oil above the 25 ppb threshold. The crude oil is carried predominantly northwards through the water column by the strong underlying Falklands Current (Figure 12-23).

It is predicted that a large volume of water around the discharge location will be exposed to water column concentrations exceeding 25 ppb for up to 16.5 days (Figure 12-24). At distances further from the discharge location, the water column exposure time declines significantly as the crude oil becomes more dispersed through wave action and sea conditions.

The probability and maximum water column exposure times shown in Figure 12-23 and Figure 12-24 represent the aggregation of results from the stochastic simulations that cover a wide range of metocean conditions, which influence the transport of released crude oil through the water column. These results should therefore not be misinterpreted as being representative of a single spill scenario.

A deterministic model was conducted to predict the total area in which the threshold of 25 ppb would be exceeded for a single run, based on the worst-case metocean conditions identified from the stochastic modelling. Figure 12-25a illustrates the maximum total water column concentrations that were observed at any time during the deterministic model run period of 91 days. The model predicts that, at some time after the start of the release, areas of the water column close to the discharge location could be subjected to water column concentrations in excess of 1,000 ppb (1 ppm). The cross-sectional plot in Figure 12-25b shows that crude oil is typically expected to reach depths of 50 m. Figure 12-25b shows a snapshot of the water column concentrations at a single instance in time.

The model also clearly shows that the water column concentrations of dissolved oils are contributing very little to concentrations of oil in the water column.

It is predicted that initial oil concentrations in the water column shortly after the release will be in the tens of parts per million. Such high concentrations result from the model setting the FPSO inventory loss / discharge to just one day, and the initial release of water-soluble components from the surface of the oil. It is predicted that the maximum oil concentrations in the water column will very rapidly decrease after this initial period of high concentrations.

Figure 12-25: Cumulative water column concentrations from an FPSO inventory loss

12.1.4.5.4 FPSO crude inventory Loss - Shoreline results

Figure 12-26 shows the probability of oil reaching the Falklands coastline after the loss of the entire FPSO crude oil inventory by identifying the initial beaching locations. The modelling results indicate that there is a low probability of crude oil reaching the shoreline and there is no possibility for any international beaching events. The northern coastline of East Falkland is predicted to be the most likely place where oil could beach. However, the greatest probability of shoreline oiling was observed to be 5.8 %, indicating that only three of the 51 individual stochastic simulations resulted in crude oil reaching the Falklands coastline. Consequently, in the event of the complete loss of the FPSO crude oil inventory, shoreline oiling is possible, but highly unlikely. The maximum mass of oil on shore was predicted to be 36 tonnes, and the average was 34 tonnes. Given the highly dispersed state of the oil when encountering shore and the long length of coast over which the oil is predicted to arrive, it is possible that this would not be detectable.

Figure 12-27 shows the minimum time taken for any oil to reach the shoreline in the worst-case oil beaching scenario, which was observed to be approximately 66 days. It is predicted that any crude oil that eventually reaches the Falklands coastline would be in a highly dispersed state due to it having

been at-sea for at least 66 days before reaching the coastline. It is therefore likely that only small individual masses of oil would reach the shoreline.

A single deterministic run of the FPSO crude inventory loss scenario was conducted to further investigate shoreline oiling. The time frame for this single deterministic run was selected to coincide with the stochastic simulation that resulted in the worst-case mass of oil arriving onshore. The predicted worst-case shoreline oiling is shown in Figure 12-28. The worst-case shoreline concentration at this instance in time was predicted to be 0.23 kg/m^2.

Figure 12-29 shows the temporal pattern of oil arriving onshore for the deterministic scenario for the most oil beaching. Again, this illustrates that only an extremely small proportion of the total mass discharged eventually reaches the shoreline. Note that there are some small differences between the stochastic and deterministic plots, which are a product of slightly simplified algorithms used in the stochastic runs and the sensitivity of the model to the very small amount of oil reaching shore in this case.

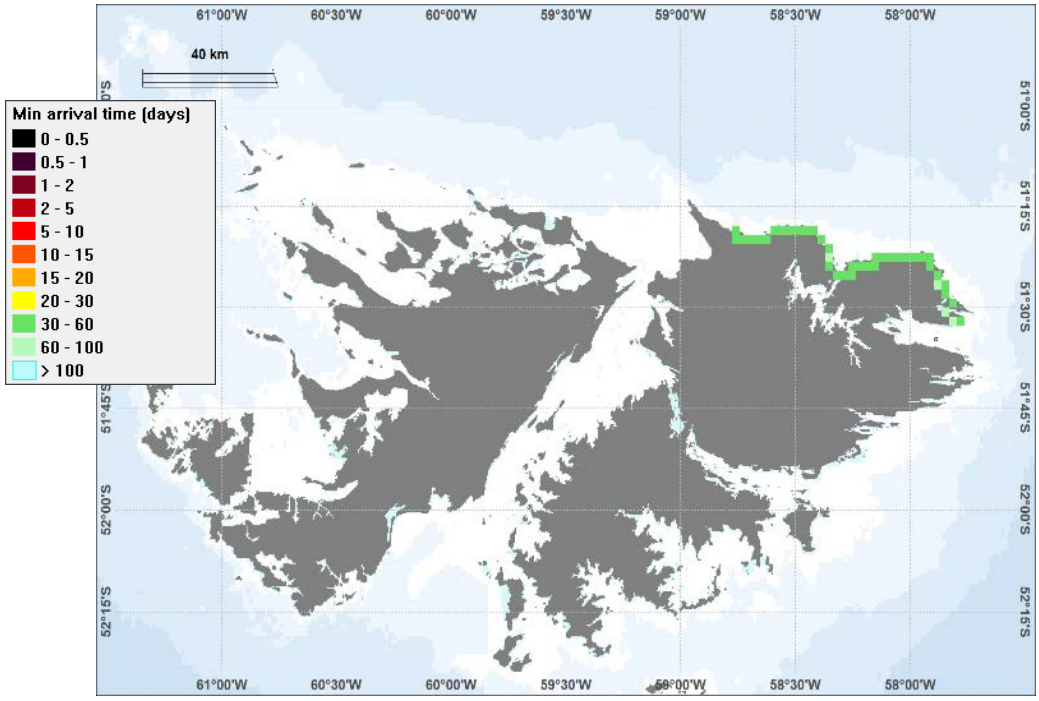

Figure 12-27: Minimum arrival times for shoreline oiling for an FPSO inventory loss

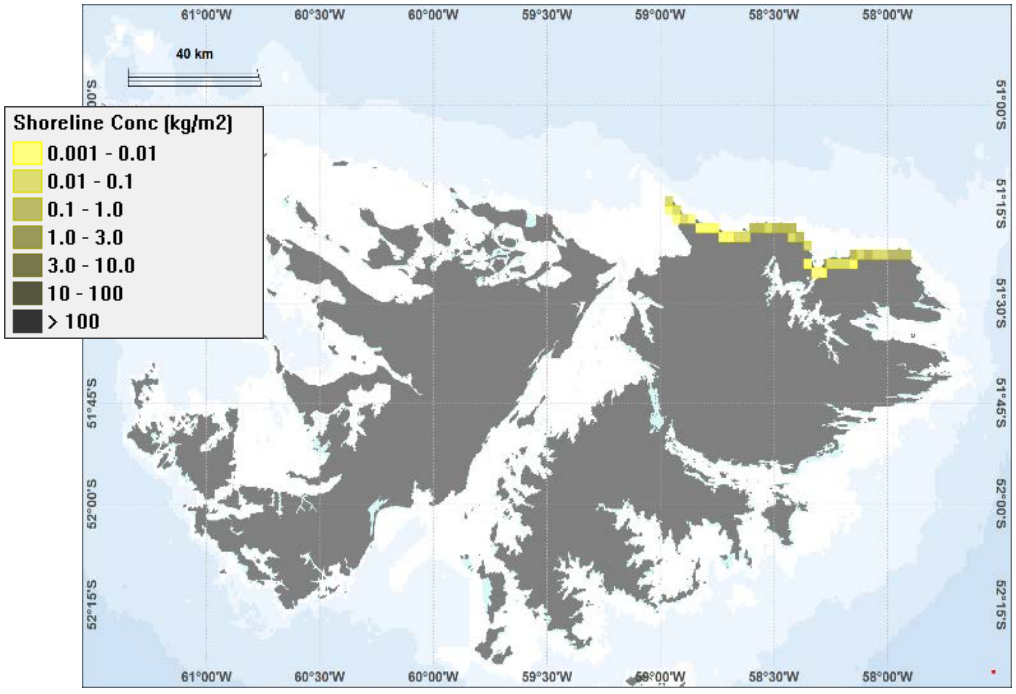

Figure 12-28: Concentration of oiling on the shoreline for an FPSO inventory loss (deterministic)

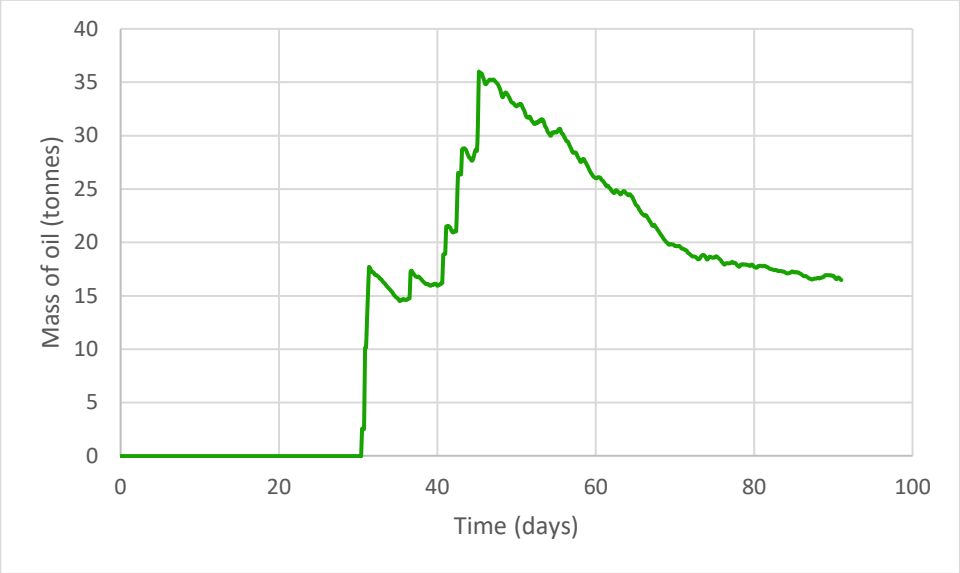

Figure 12-29: Time evolution of oil on shoreline for FPSO inventory loss (deterministic)

12.1.4.5.5 FPSO crude inventory Loss – Sediment concentration

The maximum predicted deposition concentration over a 5 cm mixed layer in the model grid is 1-2 mg/kg thus breaching none of the thresholds indicated in Section 12.1.4.3.3.

12.1.4.5.6 FPSO crude inventory Loss - Effect of oil spill response measures

The assumptions around response resources are the same as for the blowout scenario above (Section 12.1.4.4.5).

Applying these resources to the FPSO spill scenario, a new set of outputs is obtained. Key comparison data is given in Table 12.6 and a graphical comparison of surface oil probability and the path of the surface oil in the deterministic case is shown in Figure 12-30.

Although the assumed response has a very modest effect and recovers <2 % (1,146 tonnes) of the oil on average, it does improve the outcomes. The estimated recovery is close to the range of 2-6 % concluded by Etkin and Nedwed (2021) for large oil spills internationally and represents realistic recovery assumptions under challenging sea conditions. Recovery for this case is proportionally smaller because the inventory loss volume is much larger than the well blow-out volume and because the oil is largely dispersed by the time the Oil Spill Response (OSR) recovery vessels arrive. In this example, the response resources affect the shoreline oiling outcomes. Figure 12-31 shows that the two recovery units initially on-site (labelled AHV1 and AHV2) are able to recover around 300 tonnes of oil each. The multiple third-party oil spill response vessels recover over 500 tonnes, although since there are more such units it means their effectiveness per unit is much lower. The reason there is a lower recovery rate for this scenario than the blowout appears to be due to the response units having to follow the oil long distances while dispersion continues, whereas in the blowout case the oil is surfacing in a localised area for the first 21 days. The logistics of offloading oil, finding oil to recover and transiting to the location of the oil are therefore critical issues in improving performance. As for a blowout, if the release were smaller, the available recovery rate remains the same and so the operation would be likely to recover a greater fraction of the oil.

The improvement in shoreline oiling outcomes can be seen in Figure 12-30, whereby a smaller length of coastline is affected.

Table 12.6: Summary of oil spill response effectiveness for worst-case shoreline oil

Parameter	No response	With response
Maximum mass of oil onshore	30 - 40 tonnes	20 - 30 tonnes
Mass of oil recovered	-	1,146 tonnes
Proportion of oil recovered	-	1.43 %

Note: Due to the particle motion physics, response modelling can result in fragmentation of large oil masses and a larger number of small particles in the model which are available to reach more shoreline cells, and therefore occasionally more scenarios will reach shore when response is applied. This is an artefact of the model and overall the response modelling shows that response reduces the maximum and average volume of oil reaching shore.

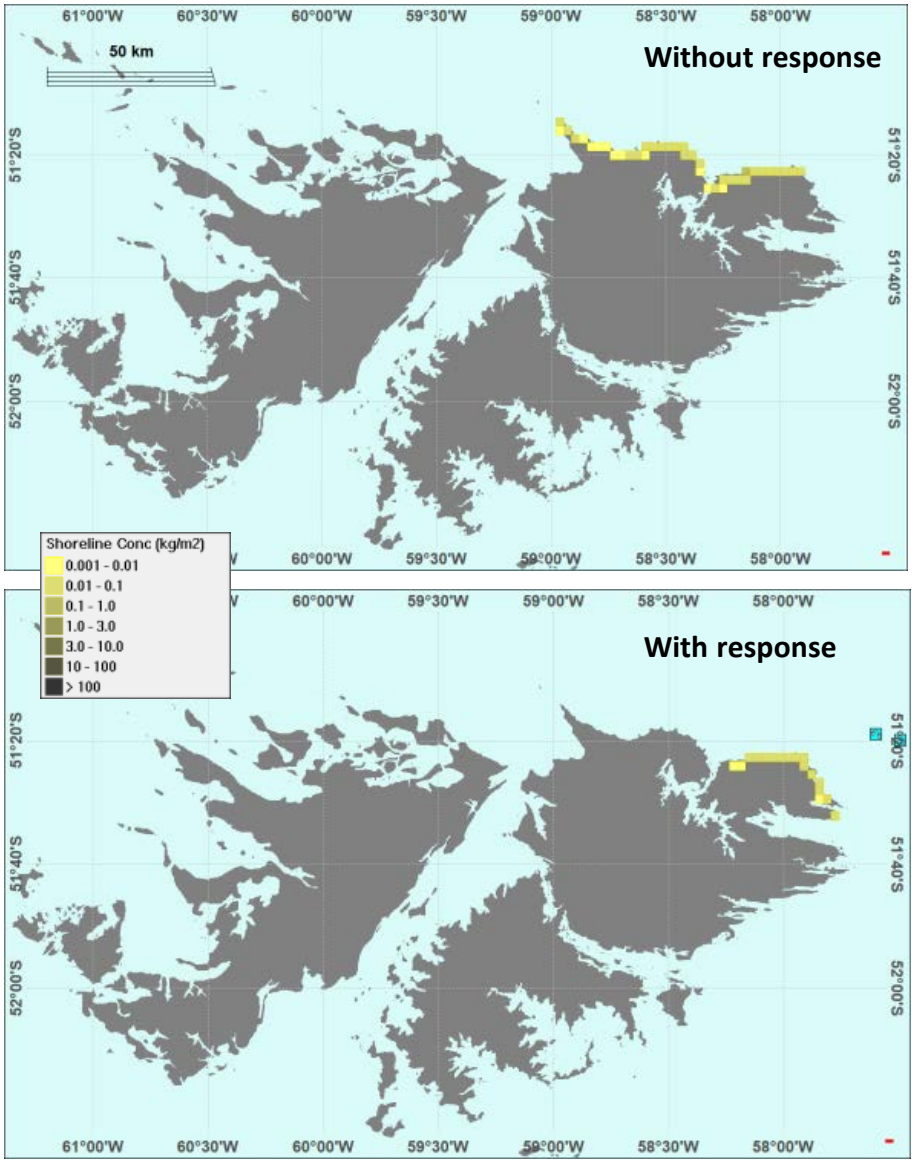

Figure 12-30: Comparison of shoreline oiling with and without oil spill response

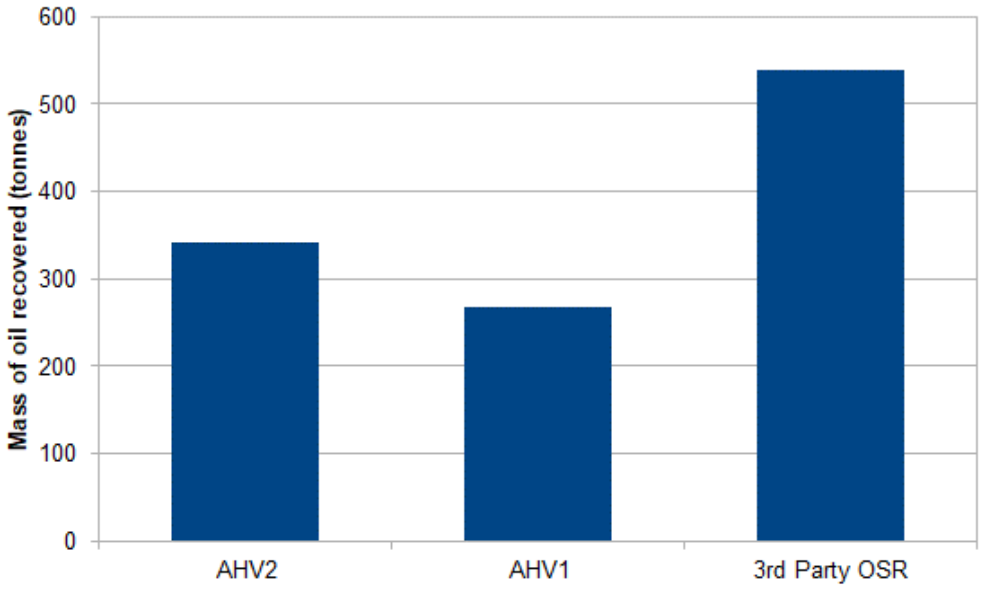

Figure 12-31: Mass of oil recovered offshore by modelled response units

12.1.4.6 Scenario 3: Crude oil transfer spill - modelling results

12.1.4.6.1 Predicted behaviour of oil

The predicted overall behaviour of the Sea Lion crude after an offshore crude transfer spill (worst-case 70 tonnes) is shown in Figure 12-32. The results here have been obtained by averaging masses over all the stochastic modelling runs. These results therefore do not represent a single model run, but serve to illustrate the expected overall behaviour of the discharged oil.

The discharge has been set to occur on the sea surface, so this is where the highest mass of crude oil will initially be found. After release, the crude oil is predicted to begin to evaporate from the surface, as well as being dispersed in the water column. Five days after the start of the discharge it is predicted that 95 % (66 tonnes) of the discharge will be left on the sea surface, with <1 % (0.3 tonnes) dispersed in the water column, and 5 % (3 tonnes) evaporated. Due to the Sea Lion oil being a persistent waxy crude, it is predicted that biodegradation will occur at a very slow rate. By the end of the model run duration (14 days), it is predicted that 89 % (62 tonnes) of the Sea Lion crude will still be on the surface at increasingly low densities, 6 % (4 tonnes) will have evaporated, 4 % (3 tonnes) will be in the water column, and biodegradation will have risen to 1 % (0.6 tonnes). A negligible amount is predicted to be present in sediments. This trend in behaviour would continue for many days with periodic enhancement in dispersion during higher sea states.

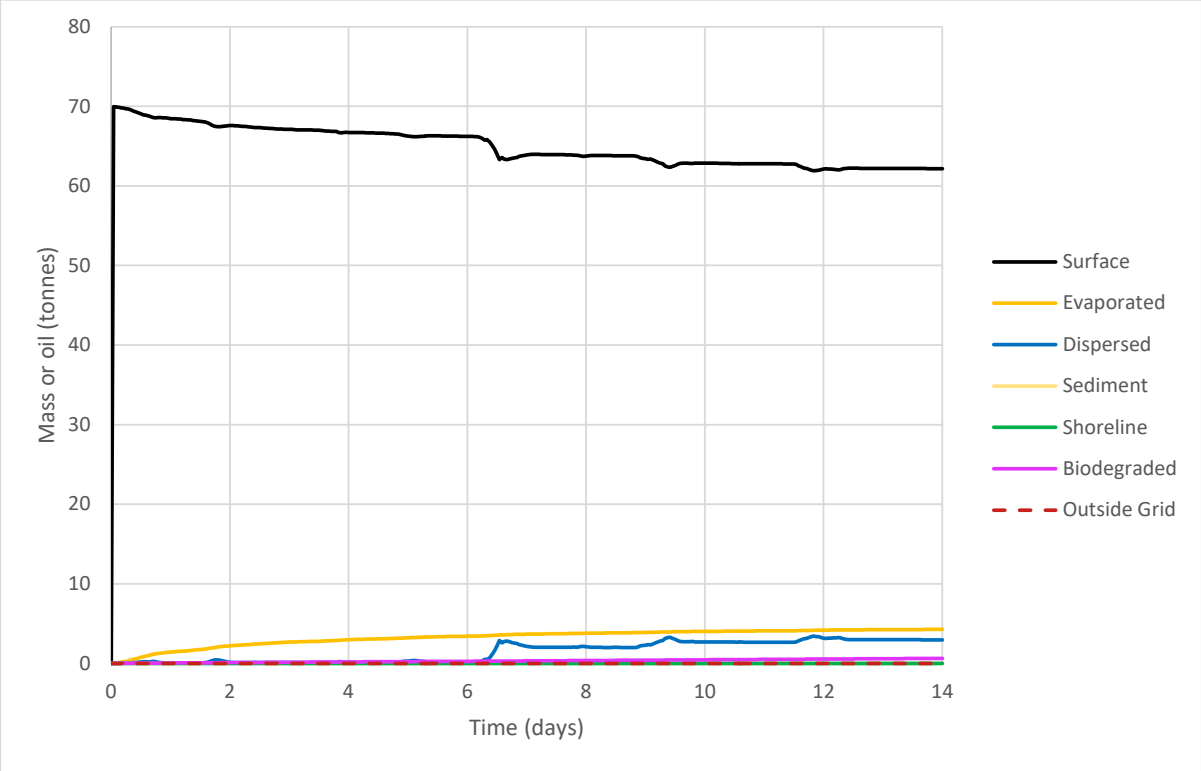

Figure 12-32: Predicted overall behaviour of Sea Lion crude oil after a crude transfer spill

12.1.4.6.2 Crude oil transfer spill - Surface results

Figure 12-33 shows the probability of oil contamination on the sea surface, the minimum time taken for oil to disperse on the sea surface, and the maximum time that any surface location is exposed to oil above the threshold of 1 g/m^2. These maps are based on the aggregation of results from different stochastic modelling runs and are not indicative of a single model output.

The probability of Sea Lion crude accumulating on the sea surface above the threshold of 1 g/m^2 is relatively low (Figure 12-33a), particularly in comparison with the larger well blow-out and FPSO inventory loss scenarios presented and discussed in the previous sections. The low probabilities illustrate that the relatively small volume of crude oil discharged (70 tonnes) is expected to disperse very quickly in the water column (see Figure 12-32 above), and a small fraction will evaporate from the surface.

Figure 12-33b shows the minimum time taken for oil from a crude transfer spill to arrive at any location on the modelling grid. In the most mobile of conditions, the Sea Lion crude oil could potentially disperse up to 20 km within one day, and up to 45 km within four days. The model predicts that after four days, most of the crude oil on the sea surface will either have evaporated or have been dispersed in the water column (Figure 12-33c).

Figure 12-34 shows the total surface area impacted above the threshold of 1 g/m^2 for a single deterministic run of the crude transfer spill scenario. This graphic shows the typical area that will be affected after a crude transfer spill of 70 tonnes. During calm weather, the oil would be amenable to recovery given the buoyant nature of the wax masses. Unlike the major scenarios of a blowout or an FPSO inventory loss, in the case of a crude transfer spill, the attendant vessels with spill response equipment would likely be able to deploy boom and skimmer equipment very quickly and achieve recovery of some of the oil.

12.1.4.6.3 Crude oil transfer spill - Water column results

None of the stochastic simulations resulted in oil concentrations in the water column exceeding the threshold of 25 ppb at any point during the model run duration (30 days). Water column concentrations are expected to decrease rapidly after the end of the discharge, with concentrations typically decreasing back to ambient conditions after a few days.

12.1.4.6.4 Crude oil transfer spill - Shoreline results

No shoreline oiling was predicted during any of the stochastic simulations of the crude oil transfer spill scenario. Due to the small volume of oil being discharged, and the large distance between the discharge location and the Falklands coastline, it is extremely unlikely that such a spill would result in any oil reaching the coastline of the Falkland Islands.

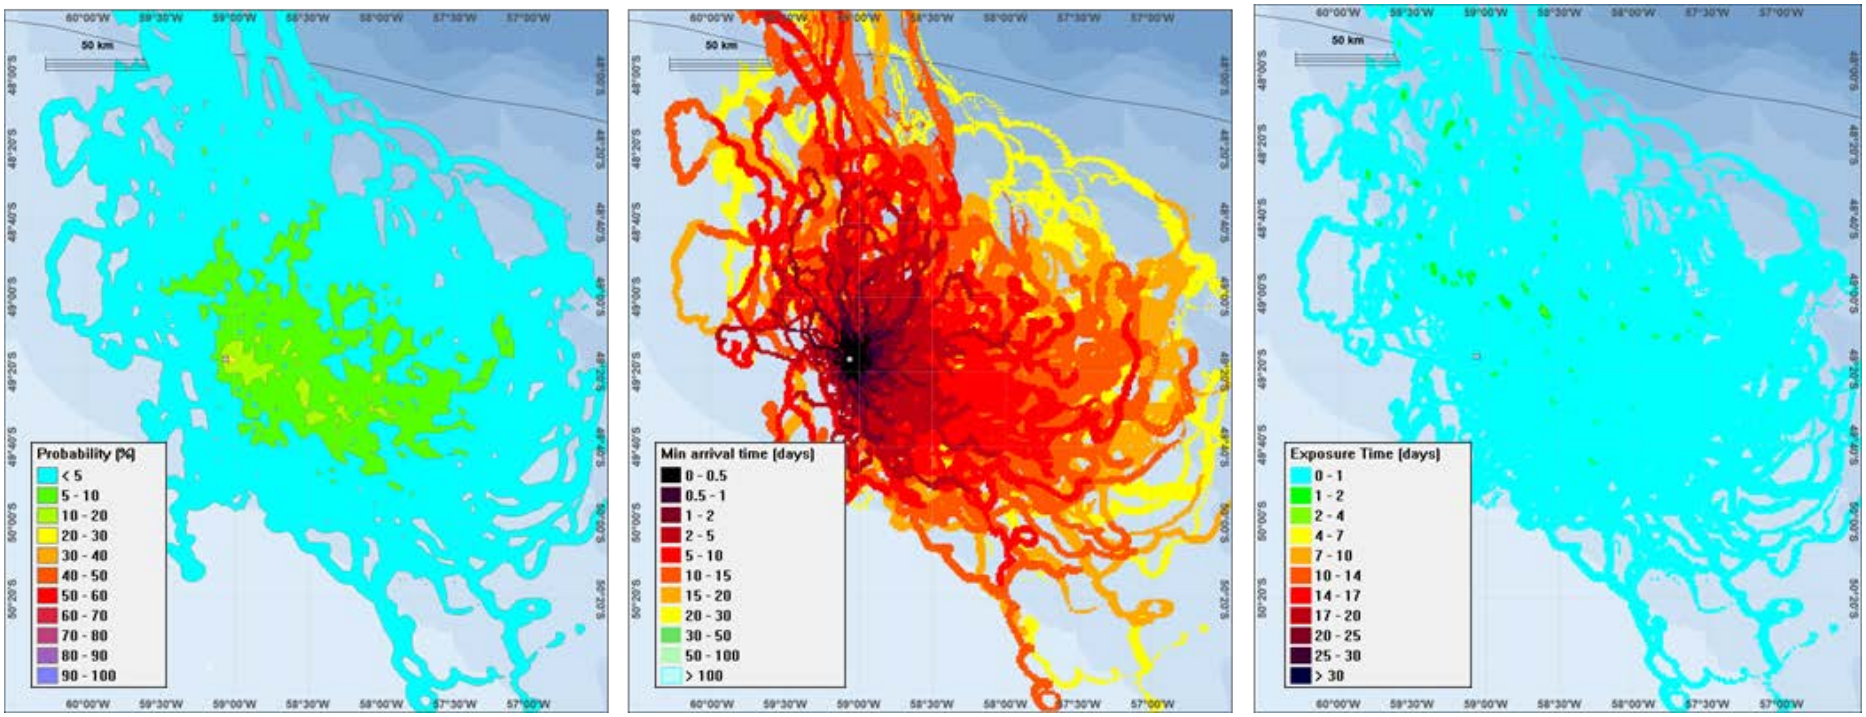

Figure 12-33: Surface results (stochastic) for crude transfer spill

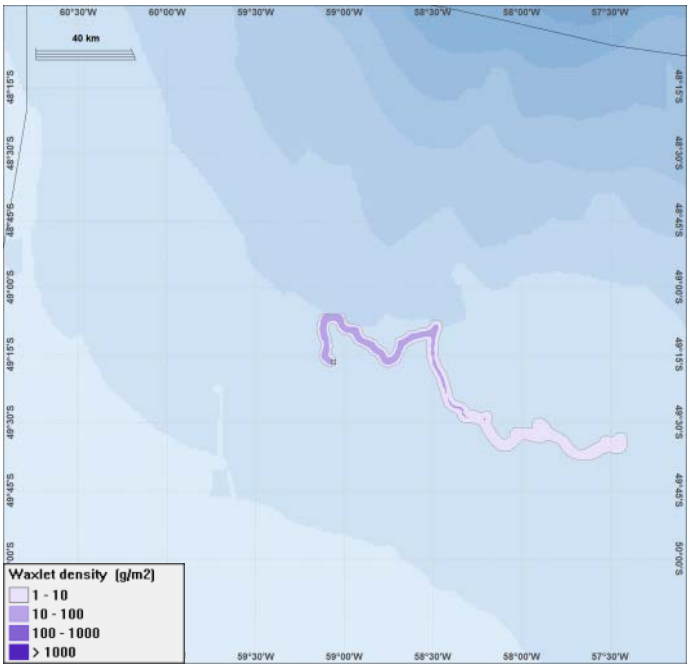

Figure 12-34: Total impacted surface area above threshold of 1 g/m² for single deterministic model run of crude oil transfer spill scenario

12.1.4.6.5 Crude oil transfer spill – Sediment concentration

Concentrations of oil in the sediment following a crude transfer spill were negligible such that impacts to benthic communities are not considered further.

12.1.4.6.6 Crude oil transfer spill - Effect of oil spill response measures

In this scenario, response has not been modelled as conclusions can be drawn on oil spill response effectiveness using observations from the previous cases and empirical data.

In this case, the incident itself is unlikely to trigger a personnel safety issue and so the MRSV/AHTS and ERRV/AHTS vessels that are equipped with oil recovery equipment will be able to attend to the spill very quickly and recover oil before it becomes significantly spread and dispersed over the sea surface. Further, the recovered oil is unlikely to fill the tanks of a single vessel, and so the vessel does not have to cease recovery in order to unload the tanks. Thirdly, the recovery operation is likely to be completed quickly while the oil is still close to the release point and so search and transit times are a much smaller factor and actual recovery time can be maximised.

These considerations mean that oil recovery is likely to be much higher in such an incident, and incidents of this size are also much more representative of a spill that might occur during the lifetime of the field. An example of oil spill response effectiveness in such a situation is documented in Engen (2005). In that case, an unplanned release of 500 - 800 m^3 of heavy oil in Norway waters was responded to by a vessel equipped with recovery equipment. 180 m^3 of oil was recovered mechanically by the vessel representing 30 - 60 % of the seaborne oil after evaporative losses were deducted.

12.1.4.7 Scenario 4: Loss of MODU MGO inventory - modelling results

12.1.4.7.1 Predicted behaviour of oil

Figure 12-35 shows the predicted behaviour and fate of MGO following the accidental loss of the full MODU inventory (worst-case 3,936 tonnes). These results are based on 99 stochastic model runs of the MGO inventory loss scenario.

Initially, most of the MGO will be found on the sea surface, after which it is likely to be quickly dispersed in the water column and evaporated or biodegraded from the sea surface owing to its higher volatility (Section 12.1.4.1.1.2). The modelling predicts that after 10 days, none of the discharged MGO will be left on the sea surface as 50 % (1,976 tonnes) of it will have evaporated, and 27 % (1,066 tonnes) of the total discharge will have biodegraded. Given the water depth, there is no predicted oil in sediments.

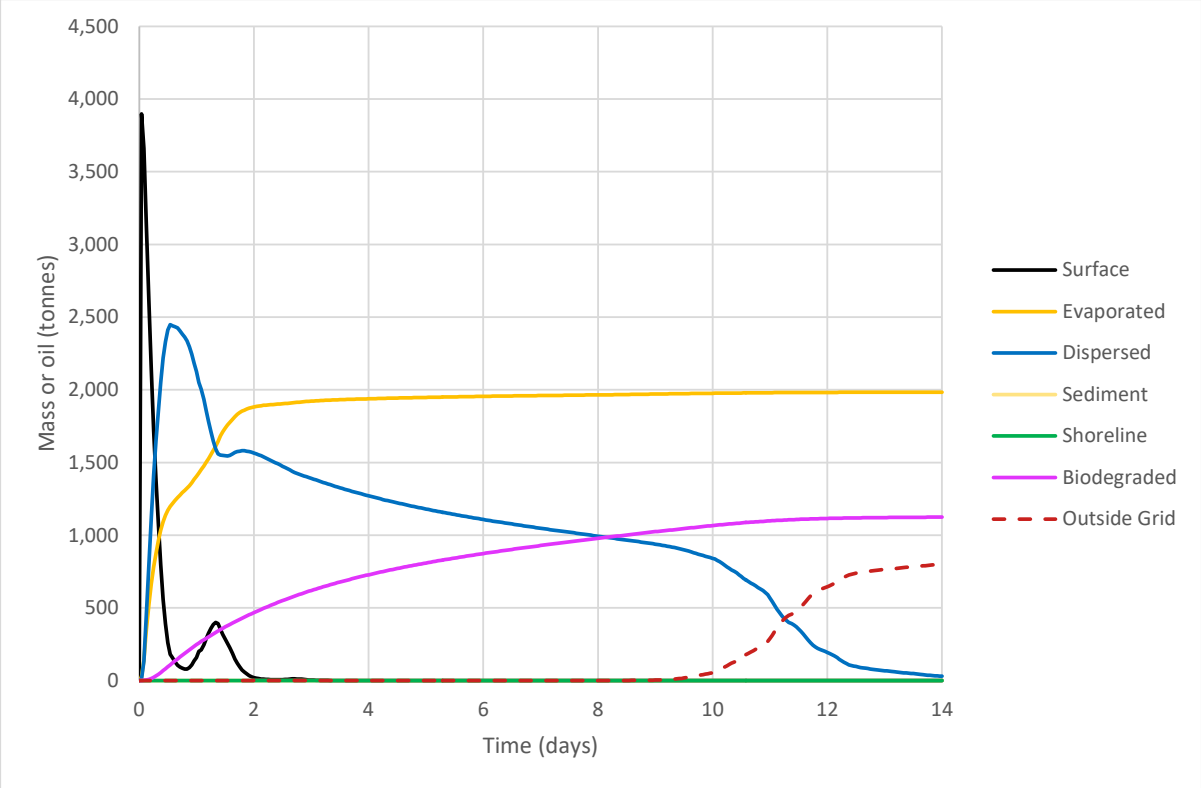

Figure 12-35: Predicted overall behaviour of MGO after full inventory loss

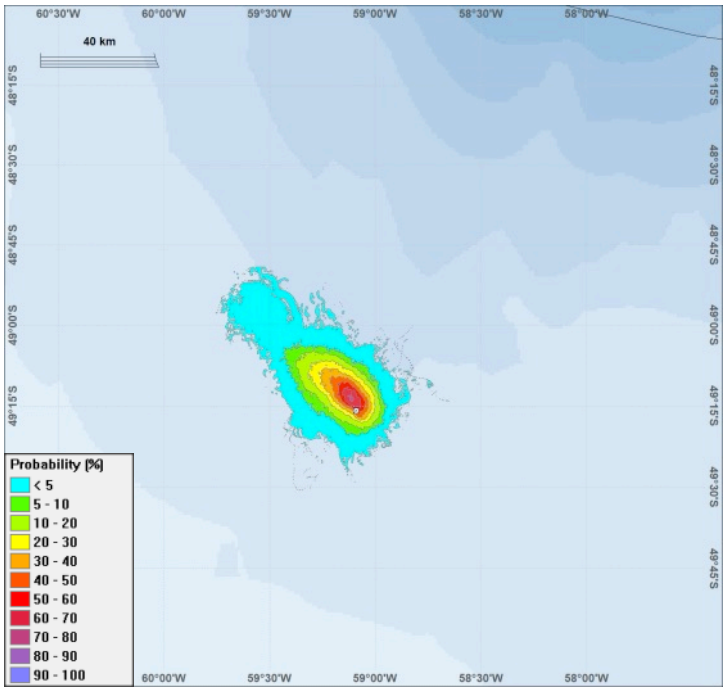
12.1.4.7.2 Loss of MODU MGO inventory - Surface results

Figure 12-36a shows the probability of diesel occurring above the threshold of 0.3 µm on the sea surface. The probabilities vary from 20-30 % near the discharge location to less than 5 % at locations further from the discharge site (beyond approximately 30 km). The low probabilities of MGO occurring above 0.3 µm on the sea surface is due to the diesel evaporating quickly and also being dispersed in the water column. The results in Figure 12-36a show that there is zero percent probability of MGO crossing the outer boundary of the FOCZ. In the most mobile of conditions, the diesel can travel up to 30 km within one day, up to 50 km within two days, and up to 90 km within five days. After approximately seven days, it is predicted that no MGO will remain on the sea surface.

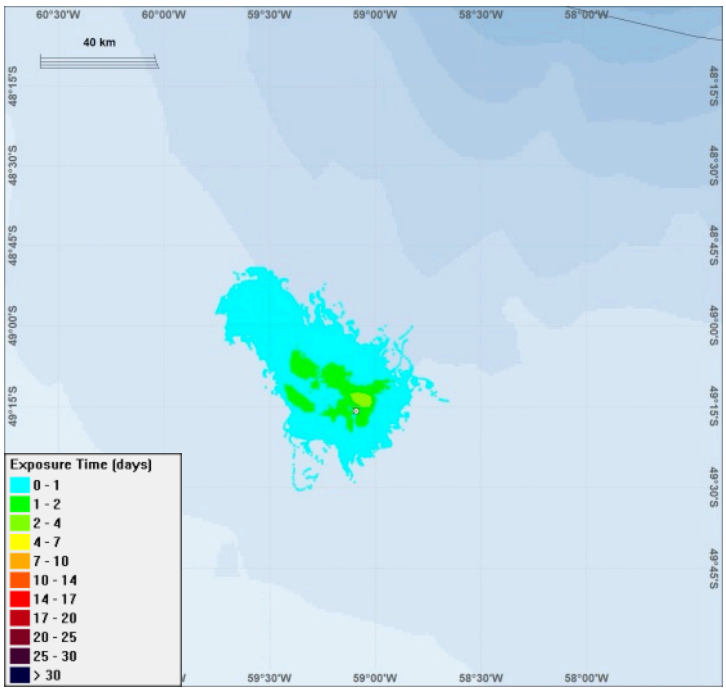
Figure 12-36b shows the maximum length of time that any location is exposed to MGO above the thickness threshold of 0.3 µm. The model predicts that in the event of a catastrophic discharge of the MODU's full MGO inventory, no surface location will be exposed to MGO for more than three days.

The results presented in Figure 12-36 are based on an aggregation of results from all the stochastic model runs and therefore do not represent a single spill scenario. To show the predicted surface area that will be impacted by a single spill scenario, a deterministic model run of the MGO inventory loss was conducted using the worst-case metocean conditions from the stochastic modelling. The total surface area predicted to be impacted by a single spill is shown in Figure 12-37 (note the much smaller

area of a single incident compared with the envelope in Figure 12-36). In the case of a single spill, it is predicted that a continuous sheen above the 0.3µm threshold will form in the immediate vicinity of the discharge location (approximately 55 km^2 at the maximum extent).



a) Probability of surface contamination above threshold of 0.3 µm



b) Maximum time surface is exposed to oil above threshold of 0.3 µm

Figure 12-36: Surface results (stochastic) for MGO inventory loss

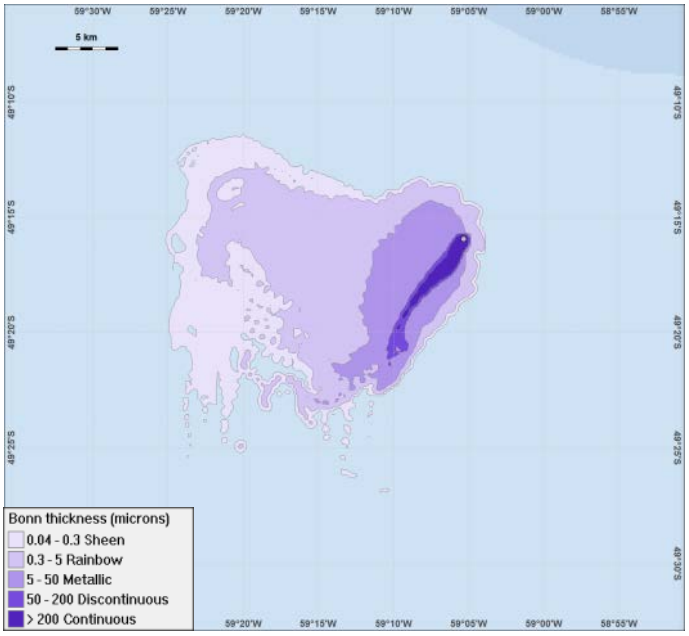


Figure 12-37: Total impacted surface area above threshold of 0.3 µm for a single deterministic model run of the MGO inventory loss scenario

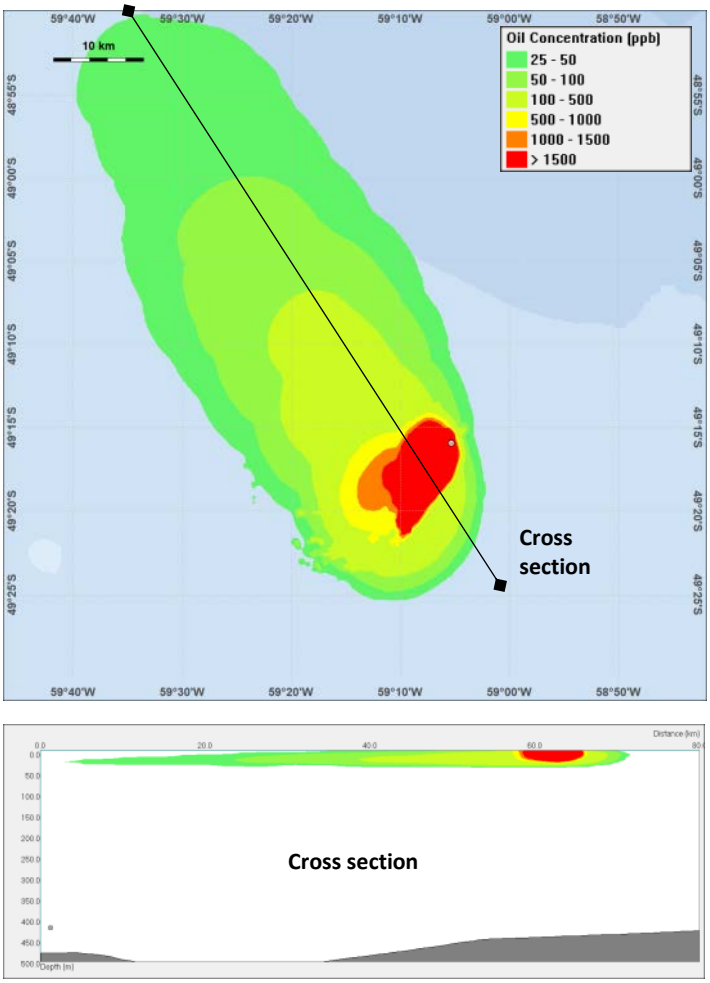
12.1.4.7.3 Loss of MODU MGO inventory - Water column results

A single deterministic model run of the MGO inventory loss scenario was conducted to show the total impacted water column for a single, worst-case, spill scenario. The maximum concentrations that were observed at any point during this run are shown in Figure 12-38. In the event of the MODU's full MGO inventory being discharged, water column concentrations exceeding 1,000 ppb (1 ppm) could be observed at locations near the discharge site. However, these concentrations would only be present for a short period of time after the discharge.

As shown in the plan and cross-sectional plot in Figure 12-38, MGO is most likely to occur in the water column above the threshold value (25 ppb) in the top 100 m of the water column. In the immediate vicinity of the discharge location and down to depths of 60 m, the water column could be exposed to concentrations in excess of 25 ppb for up to six days.

12.1.4.7.4 Loss of MODU MGO inventory - Shoreline results

No shoreline oiling was predicted from any of the stochastic simulations of the MGO inventory loss scenario. With the discharge occurring so far from the Falkland Islands, it is not credible that any MGO discharged will reach the coastline of the Falkland Islands.



a) Total impacted area above a threshold of 25 ppb for a single deterministic model run

Figure 12-38: Water column results (deterministic) for MGO inventory loss

12.1.4.7.5 Loss of MODU MGO inventory - Effect of oil spill response measures

In the case of an oil such as MGO that spreads rapidly on the surface, mechanical recovery is ineffective. It is also likely that prevailing sea states will break up surface oil into progressively smaller patches that hinder mechanical recovery, and dispersion into the water column will progress quickly as shown in Figure 12-35. Application of dispersants by aerial means or from a vessel are possible response measures which will accelerate the dispersion into the water column, but the natural dispersion processes are already rapid and dispersants themselves have environmental impacts that need to be considered.

The modelling suggests that natural dispersion processes will remove surface oil relatively quickly thereby minimising effects on seabirds that use the sea surface, and that recovery or dispersant intervention would not significantly alter this outcome. Biodegradation then breaks down the oil significantly over a timescale of days and weeks. Therefore, applying oil spill response measures is unlikely to alter the environmental impacts of such a scenario.

12.1.4.8 Scenario 5: MGO bunkering spill - modelling results

12.1.4.8.1 Predicted behaviour of oil

The predicted overall behaviour of MGO after it has been discharged to the sea following a bunkering spill (worst-case 20 tonnes) is shown in Figure 12-39. These results are based on the aggregated outputs of all the stochastic modelling runs, and do not therefore represent a single model run (spill scenario).

The overall behaviour of the discharged MGO is broadly similar to the larger MGO inventory loss scenario described above, but on a much smaller scale. It is predicted that a large proportion of the MGO will be on the sea surface immediately following the spill. However, this surface MGO is expected to decline very quickly, as it gets dispersed by wave action and also evaporates and biodegrades. The model predicts that after two days from the discharge, no MGO will remain on the sea surface. By four days, 31 % (6 tonnes) will have evaporated, 25 % (5 tonnes) will have biodegraded, and the remainder of the discharge will either be dispersed in the water column or dissolved. MGO also starts to exit the modelling grid at four days, and the trend of dispersed oil being biodegraded continues in the water column beyond this point, with no MGO predicted in sediments. See Section 12.1.4.3.4.1 for detail on model parameters and note that owing to the volatility of MGO and the highly dynamic environment at the Sea Lion location regarding wind and wave action, the grid size is selected to demonstrate the worst-case outcome of the MGO bunkering spill scenario.

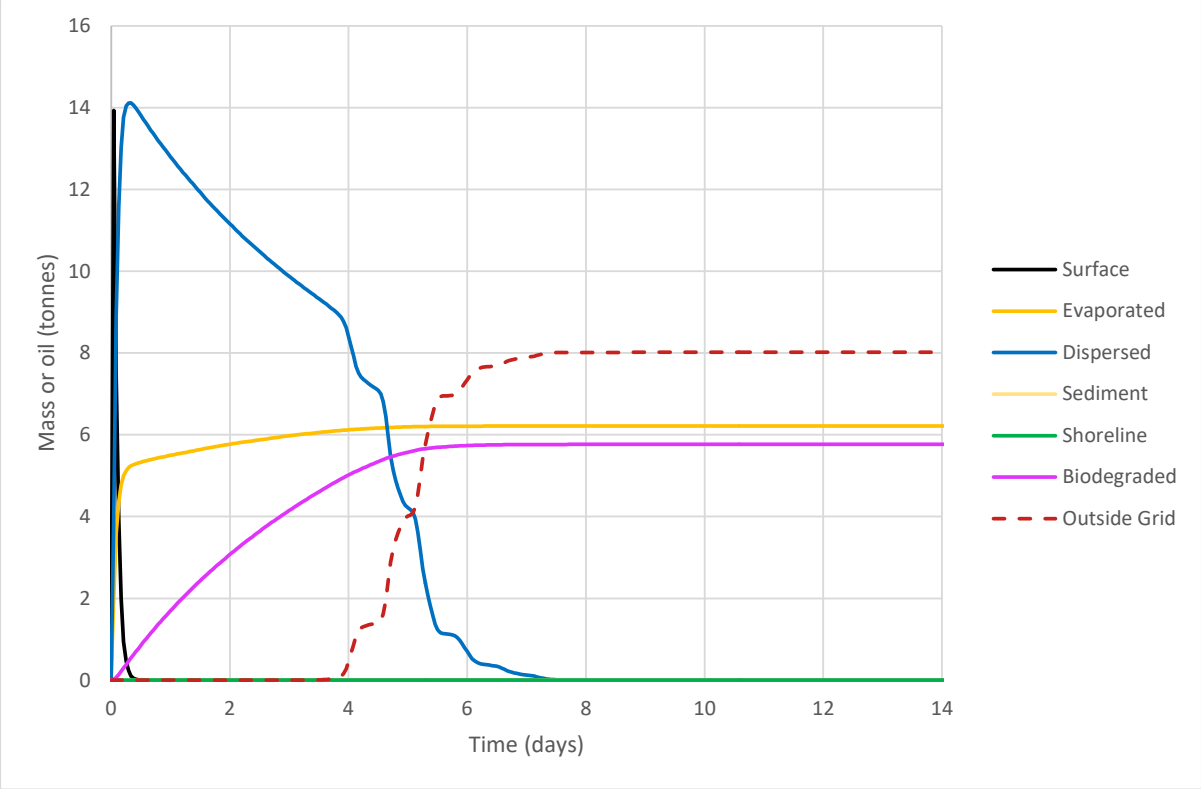


Figure 12-39: Predicted overall behaviour of MGO after a bunkering spill

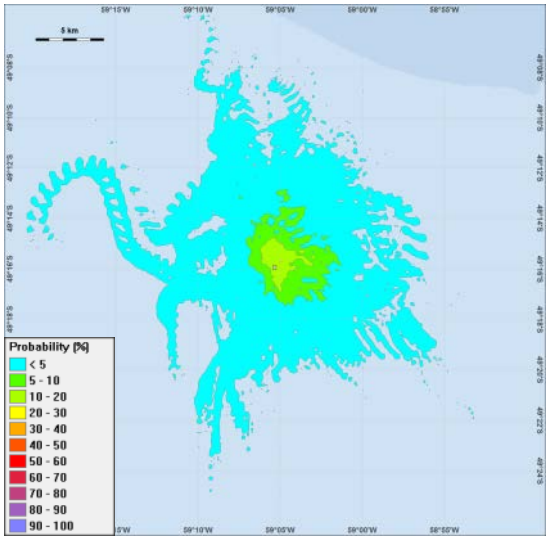
12.1.4.8.2 MGO bunkering spill - Surface results

Figure 12-40a shows the probability of MGO occurring above the threshold of 0.3 µm on the sea surface. Following a bunkering spill, the probability of MGO occurring on the sea surface above the 0.3 µm thickness threshold is between 5 and 10 % at locations a few kilometres from the discharge site, decreasing to less than 5 % further away from the discharge location. These low probabilities are due

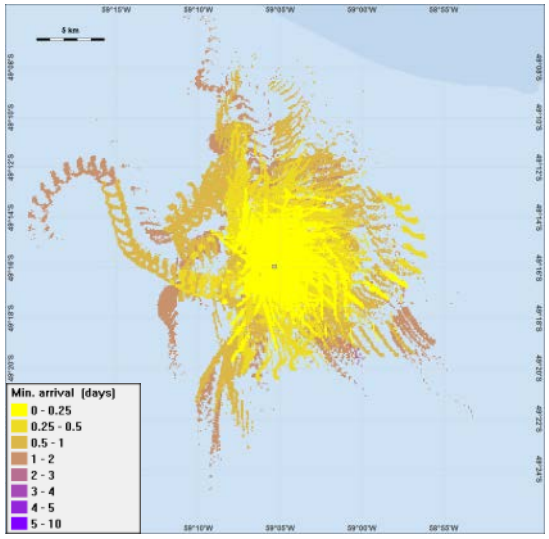
to the small volume of MGO released following a bunkering spill, and the rate at which the MGO evaporates, biodegrades, and becomes dispersed. MGO from a bunkering spill is not predicted to cross the FOCZ as a surface sheen.

Figure 12-40b shows the minimum time taken for MGO above the surface thickness threshold of 0.3 µm to arrive at any location on the sea surface after the bunkering spill. In the most mobile conditions, the MGO can travel up to 20 km within one day, up to 30 km within two days, and up to 55 km within four days. After approximately four days, it is predicted that no MGO will be left on the sea surface, as the majority will have evaporated. No surface location is predicted to be exposed to MGO above the surface thickness threshold of 0.3 µm for more than one day (Figure 12-40c).

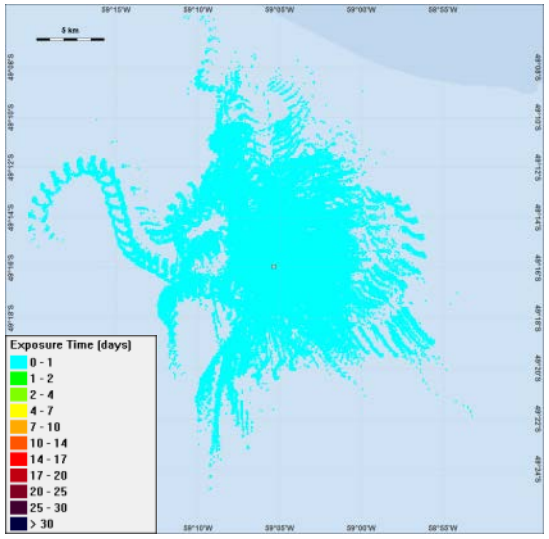
The results in Figure 12-40 are based on an aggregation of results from all the stochastic model runs and therefore do not represent a single spill scenario. To illustrate the impacted surface area for a single, worst-case, spill scenario, a deterministic model run of the MGO bunkering spill was conducted. The total impacted surface area is shown in Figure 12-41. Following a MGO bunkering spill, it is predicted that 'rainbow' sheen could form on the sea surface but would likely only be visible for a short period of time.



a) Probability of surface contamination above threshold of 0.3 µm



b) Minimum arrival times of oil above 0.3 µm on the surface



c) Maximum time surface is exposed to oil above threshold of 0.3 µm

Figure 12-40: Surface results (stochastic) for MGO bunkering spills

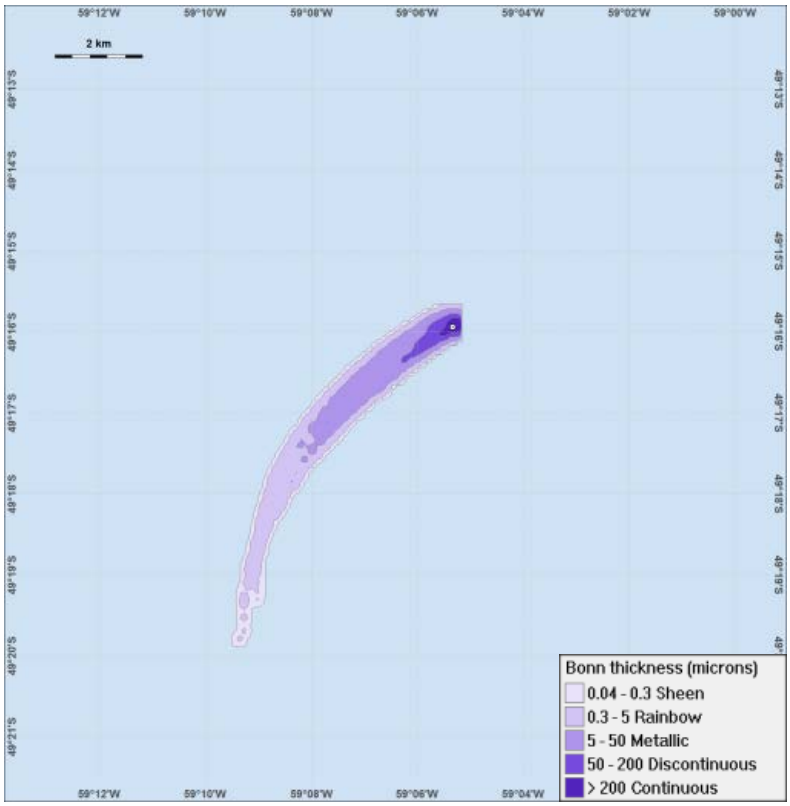


Figure 12-41: Total impacted surface area above threshold of 0.3 µm for the single deterministic model run of the worst-case MGO bunkering spill

12.1.4.8.3 MGO bunkering spill - Water column results

MGO concentrations above the threshold of 25 ppb could occur for up to 5 km downcurrent of the spill in 50 % of cases. The model predictions indicate it is possible for MGO to be found at depths up to 50 metres, but this occurs with low probability. This is primarily related to the rate at which the MGO will evaporate from the sea surface and the depth of the mixing layer caused by surface winds. No water column location is expected to be exposed to MGO above 25 ppb for more than one day. It is expected that for a single spill scenario, the water column threshold of 25 ppb will only be exceeded for short intermittent periods of time, and that the concentration of MGO in the water column will be below this threshold after two days.

12.1.4.8.4 MGO bunkering spill - Shoreline results

No shoreline oiling was predicted in any of the simulations of the MGO bunkering spill scenario. Due to the small volume of MGO involved, and the distance from the discharge location to the Falklands coastline, it is not credible that such a spill would result in any MGO reaching the Falklands shoreline.

12.1.4.8.5 MGO bunkering spill - Effect of oil spill response measures

The rapid dispersion predicted for the MGO inventory release is even more acute in the case of a smaller volume in this case. It is therefore more likely that applying oil spill response measures would be ineffective in altering the environmental impacts of such a scenario.

12.1.4.9 Small scale releases

During the ENVIID workshop (Chapter 9), a number of sources of small spills were identified that, should they occur, could contribute to chronic oil pollution in addition to the low-level contribution made by legally compliant discharges (Section 10.7). Sources of chronic oil pollution from small scale

accidental releases range from small subsea leaks of reservoir hydrocarbon or hydraulic oil to the potential for flare-drop out during emergency blowdowns (Section 5.9.4). These may result from equipment failure or human error and may be very small owing to early detection or discrete volumes of oil, or they may be ongoing e.g., small subsea leaks.

Given that small accidental releases could arise from different sources, it is not possible to estimate the potential volumes of release. However, these will be dealt with appropriately on a case-by-case basis, should they occur. In the event of small spills, the most appropriate response is sometimes for the spill to be monitored and allowed to disperse naturally. All spills, regardless of size, would be reported to FIG *via* the PON 8 (Section 12.1.1.1.5).

As with large accidental spills in the scenarios described above, the behavior, fate and impact of small releases of oil will depend upon the source of leak and the type of the oil. However, it is understood that small spills can result in surface sheens and low-level increases in the background contaminant levels of dispersed and dissolved oils e.g., polyaromatic hydrocarbons (PAHs) etc.

12.1.4.10 Loss of riser contents

If there is a loss of riser contents whilst drilling with NADF, the mud is likely to flow out over the seabed. The volume of drilling fluid lost will be in the region of 60 m^3 as the whole riser volume would always be lost in this situation. The loss of contents would trigger a rapid BOP activation and shutdown of mud pumps to restore the necessary barriers so is unlikely to a be higher volume. It is assumed the drilling fluid would flow out to a thickness of 1 cm, covering an area of approximately 0.006 km^2 around the MODU.

It is not conceivable that a spill from loss of riser contents would reach the shoreline.

12.1.5 Industry-standard mitigation measures

The majority of industry-standard mitigations are built-in to the Phase 1 & 2 Development basis of design and all are factored into the initial risk assessment. These are listed in Table 12.7.

Table 12.7: Industry-standard mitigation measures relevant to each of the oil spill risk scenarios

Scenario	Industry-standard mitigation (and base-case) measures
General	All activities with the potential to result in an oil spill will be carried out by competent personnel in accordance with operational controls, the permit to work system, the requirements of the Navitas OMS (Section 3.2) and Navitas' Drilling Management System, Adherence to the Safety and Environmentally Critical Equipment (SECE) register with appropriate performance standards (Section 3.2.12), Offshore spills, large or small will be reported in compliance with the FIG PON8 using the supplied *pro forma* (Section 12.1.1.1.5), and Offshore spills will be managed in line with the Sea Lion Field OPEP (Section 12.1.1.1.3) which will be submitted to FIG as a separate document for approval prior to the commencement of operations.
1: Subsea well blow-out	The drilling operations will follow established international drilling safety standards to minimise the risk of loss of well control. Well control systems and procedures will be in place as per all Navitas and drilling contractor well control guidelines. Preventative and mitigation controls include: The use of adequately experienced drilling crews, trained in well control techniques and supervised at all times. Training will be continuous with regular emergency drills. Well designs will be reviewed by an independent well examiner. Support contracts will be in place with international well control specialists. Primary well control is achieved by: Development of an appropriate well design for the expected pore pressures with regard to casing etc. (Section 5.4.4.5), Use of appropriately weighted drilling muds to maintain a hydrostatic pressure in the wellbore greater than the pressure of the fluids in the formation being drilled, but less than the formation fracture pressure (Section 5.4.5.3), The use of appropriate mud additives to prevent problems when drilling which can lead to the well becoming underbalanced e.g., lost circulation, fluid loss. The requirement for mud additives e.g., lost circulation material is assessed based on the expected qualities of the reservoir formation. Use of a Blow-Out Preventor (BOP) which will be in place while drilling and will be subject to regular maintenance and testing. BOP equipment / controls and emergency / contingency controls will be tested both prior to and immediately after deployment onto the wellhead. The BOP will be subject to a third-party verification and audit prior to drilling operations commencing. During production a subsea X-mas tree will be in place on each well. Contracts for the supply of a capping device that meets the timescales for deployment described (Table 12.3 above) will be placed to anticipate a sub-sea well blow-out (in the event of failure of both primary and secondary well controls). That is, logistics will be in place to ensure a blow-out can be arrested in an upper estimate of 21 days.
2: FPSO inventory loss	A 1,275 m radius exclusion zone will be established around the FPSO, Cargo and fuel tanks of the FPSO will be double skinned, An ERRV (MRSV) vessel will be on permanent stand-by to intercept any vessel that enters the exclusion zone or assist in the event of emergency situations, and Use of AIS / radar surveillance and radio broadcasts to mariners (advising on the position of the rig and the exclusion zone).
3: Crude transfer spill	Good oilfield practices will be employed to prevent the release of hydrocarbons. Provision of physical barriers, maintenance to minimise leaks and procedures and training to influence human factors will be adopted.

Scenario	Industry-standard mitigation (and base-case) measures
	Navitas working procedures will provide the operational control measures that are designed to minimise the risks. These measures include: Bulk Hose Management in line with procedural control to ensure inspections, and verification of bulk hoses, Use of the 'green line' system to ensure safe crude offload, Hose quick break connectors to prevent spills on disconnection, Reporting of any leaks, or defective equipment, Investigation of any leaks to determine root causes and take action to prevent reoccurrence, and Ensuring that all pipe-work is isolated, drained and purged as required by the permit to work before breaking containment.
4: MGO inventory loss	Working practices will follow industry best practice guidelines designed to prevent the loss of MGO inventory from the drilling rig. Measures such as the use of a 500 m exclusion zone around the MODU, a guard ship, AIS / radar surveillance and radio broadcasts to mariners will further reduce the risk of collisions between vessels and the drilling rig.
5: MGO bunkering spill	Navitas working procedures will provide the operational control measures that are designed to minimise risks associated with MGO bunkering spills. These measures include: Bulk Hose Management in line with procedural control to ensure inspections, and verification of bulk hoses, Hose quick break connectors to prevent spills on disconnection, Reporting of any leaks, or defective equipment, Investigation of any leaks to determine root causes and take action to prevent reoccurrence, and Ensuring that all pipe-work is isolated, drained and purged as required by the permit to work before breaking containment.
Small scale releases	Implementation of the Maintenance Management System (MMS) and inspection protocols, Use of all standard operating procedures and best practice, Following industry bunding guidelines for liquid containing equipment and chemicals, Open deck drains to catch and collect spills to a dedicated slop tank, High level tank filling alarm and emergency shutdown of the process, Reporting of any leaks, or defective equipment, Use of toolbox talks prior to execution of work, and Use of spill kits for deck spills.
Loss of riser contents	Compliance with: ISO 13628-7 - Design and Operation of Subsea Production Systems: Completion / Workover Riser Systems, API 16F - Specification for Marine Drilling Riser Equipment, and DNV RP F204 - Riser Fatigue.

12.1.6 Risk Assessment

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of oil releases should they occur. As any oil release would be an unplanned event, an assessment of the 'Likelihood of Occurrence' is carried out to determine the overall 'Risk' of impacts occurring as a result of oil spills.

A summary of the risk assessment outcomes for this Development is tabulated in Section 12.1.12, which shows the worst-case risk for each activity and receptor, the details of which are provided below.

Owing to the number of receptors which could be impacted by the differing oil spill scenarios, and the number of scenarios, the layout of this chapter is slightly different to the other chapters within this EIS. The *impact* on each receptor is tabulated in each section below, and the *likelihood* of occurrence of the event, which will be consistent within each scenario, is then described as a whole.

The following assessments take account of all industry-standard and base-case mitigations described in Section 12.1.5.

12.1.6.1 Scenario 1: Subsea well blow-out

12.1.6.1.1 Sensitivity of receptor and severity of effect (impact assessment)

A subsea well blow-out is highly unlikely to occur in the lifetime of the proposed Sea Lion Development. The oil dispersion modelling for a subsea blow-out used worst-case conditions to set an upper boundary on potential effects.

In the unlikely event of a well blow-out, prevailing currents and winds in the area will tend to keep oil (wax) at sea where it is subject to dispersion, evaporation and biodegradation. The oil generally travels north as it is transported by dominant currents, or in an arc to the south-south-east, as it is forced by the wind driven surface currents (Section 12.1.4.4.1).

Given its high wax content, extensive surface slicks are not predicted from a Sea Lion crude well blow-out (Section 12.1.4.4.2). Instead, a raft of waxy oil masses is predicted to form and migrate from the area predominantly near the water surface. The oil masses will not coalesce but rather become increasingly dispersed with distance, and their visibility will reduce with increased distance from the release location (Section 12.1.4.4.2). The amount of energy experienced during any release determines the initial size of the oil masses and relatively small droplets are likely to be formed during a blow-out. Some degradation of particle size is expected through prevailing shear forces from waves and turbulence, but very slowly based on laboratory experience. Ultimately, oil may attach to suspended solids and sink (although very little adhesion to suspended solids was observed in the laboratory), or be biodegraded in the water column, involving an element of ingestion, potentially by a range of biota.

Soluble components, which pose a risk to water column ecology, have been shown not to dissolve into the water column in the first seven days after a spill (CEDRE, 2017), and it is assumed that any dissolution will happen slowly. Permeation through the wax is very slow and dissolution relies on new faces being exposed during shearing, and the oil masses appear to be resistant to shearing from typical wave energies in the laboratory. The modelling predicts that toxic water column impacts are not above a widely accepted level of concern, except directly above a blow-out or directly beneath a surface accumulation, and that this occurs for short periods (Section 12.1.4.4.3).

Generally, even in examples where large fractions of the oil transition to sediments, impacts on the benthos show good recovery in the timescale of years and, while effects on lower trophic levels can be observed, little change in higher trophic levels tends to be observed. The area of the western South Atlantic continental shelf is 700,000 km^2. In context, a seabed area of 0.09 % of the continental shelf was shown to contain levels of >10 mg/kg (the most conservative predicted NOEC, Table 12.4 above)

with the maximum predicted concentration of oil in sediment 29.3 mg/kg assuming oil is mixed over a 5 cm layer.

A well-documented example is the Braer incident in 1993 where over 84,000 tonnes of oil was released. Overall, the oil spill caused minimal effect on the ecology of South Shetland (Law and Moffat, 2011). Around 30-35 % of the oil was estimated to have transitioned to sediments, some near the coast and some much further offshore. The nearshore contamination led to a restriction on shellfish fisheries in the area for a period of between 18 months and seven years and the sandeel population, which is a key component in the food chain and a sediment-dweller, exhibited clear increases in hydrocarbon presence but showed only a slight decrease in population level that reversed in one year (Davies and Topping, 1997). In contrast, although the area of sediment contamination further offshore (a better analogue for any Sea Lion impacts) was clearly identified and analysis of fish, including taint testing was undertaken, it did not lead to any closure of fisheries.

Given the above, the potential sediment impacts from a Sea Lion crude release are considered to be low.

The modelling results suggest that there is a possibility that a subsea well blow-out, with the parameters of location and blow-out rate specified, could lead to hydrocarbons reaching the Falklands coastline.

The assessment of the 'Sensitivity of Receptor' and the 'Severity of Effect' for each receptor are provided in Table 12.9 below. The 'Likelihood of Occurrence' of a well blow-out is described below and is also included in Table 12.9 to show how the overall significance ratings of risks associated with a subsea well-blow-out were derived.

12.1.6.1.2 Likelihood of occurrence

Although known in the O&G industry, uncontrolled releases / blow-outs and major losses of containment are extremely rare events. The frequencies of blow-out events in the North Sea are presented in Table 12.8. Here the frequency of blow-out events has been calculated per well drilled, per operation, or per well year in the North Sea (OGP, 2010a). Table 12.8 indicates that the likelihood of a blow-out is generally very low and is higher for High Pressure / High Temperature (HP / HT) gas reservoirs than for normally pressured reservoirs. The Sea Lion reservoir is not an HP / HT reservoir.

Nonetheless, strict regulations governing working practices and lessons learned from previous incidents have helped to further minimise the likelihood of accidental events leading to major losses of containment. Following the Deepwater Horizon incident in the Gulf of Mexico (2010), the Oil Spill Prevention and Response Advisory Group (OSPRAG) was established to review all UK Continental Shelf (UKCS) regulations and pollution response arrangements and to assess the adequacy of financial provisions for that response. This has resulted in significant amendments to the legislation pertaining to oil spill prevention and response.

The International Association of Oil & Gas Producers has issued datasheets (OGP, 2019) on blow-out frequencies for offshore operations of North Sea Standard (NSS). These operations are performed with a Blow-Out Preventer (BOP) installed following the 'two barrier' principle, meaning that there are always two physical barriers preventing the oil from flowing to the seabed, as will be the case with the Sea Lion Development. Taking account of the industry-standard mitigations (Section 12.1.5), the likelihood of occurrence of a subsea blow-out occurring is considered to be '**Unlikely**' (Table 12.9), as it has happened in the industry before, but on extremely rare occasions.

Table 12.8: Blow-out frequencies for offshore operations of North Sea Standard (OGP, 2019)

Operation	Frequency of oil spills	Unit	Proportion Subsea
Development Drilling, Deep (Normal Wells)	3.4×10^{-5} or 0.000034 (1 in every 20,834 wells drilled)	Per well drilled	0.47
Development Drilling (HP/HT)	2.1×10^{-4} or 0.00021 (1 in every 3,333 wells drilled)	Per well drilled	0
Completion	1.4×10^{-4} or 0.00014 (1 in every 18,519 completion operations)	Per operation	0
Producing Wells (Excluding External Causes)	2.1×10^{-5} or 0.000021 (1 in every 384,615 production well year)	Per well year	0.43
Producing Wells (External Causes)	2.7×10^{-5} or 0.000027 (1 in every 25,641 production well year)	Per well year	0

12.1.6.1.3 Overall risk significance

As is shown in Table 12.9 the highest significance of the risk posed by a well blow-out is to the human population (fisheries and tourism), seabirds, marine mammals and coastal areas all of which are considered to be of '**Moderate**' significance and, therefore, project-specific mitigation measures will be required.

Table 12.9: Risk assessment of a subsea well blow-out

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Water quality and plankton	Plankton show high seasonal and spatial variation in abundance and productivity, and it is expected that any effects will be greatest during summer when the area of the shelf-break to the south of the Sea Lion Field supports higher densities of phyto- and zooplankton (Section 12.1.4.2.1). At other times, the area is less significant for zooplankton but is still considered highly productive. Therefore, the sensitivity of plankton is considered to be '**Moderate**'. Although, oil from a blow-out is likely to rise to the upper water column, due to a combination of short generation times, high reproductive rates, known concentration of oil to effect lethal contamination on representative species (Section 12.1.4.1.1.1) and the potential for immigration from outside contaminated areas, the effects on whole plankton communities are expected to be of a short-term and reversible in nature. Due to the temporary impact on plankton in a localised area around the spill site, the severity of the effect of an uncontrolled release / blow-out of Sea Lion crude on plankton has been assessed as '**Moderate**'. Therefore, the significance of the impact on plankton is assessed as '**Moderate (9)**'.	**Unlikely**	**'Low (6)'**
Sediment quality and benthic communities	In the majority of scenarios where the oil remains at sea, <1 % oil is predicted to transition into sediments (Section 12.1.4.4.1). The oil bench tests (Premier, 2016) and lab testing (CEDRE, 2017) have reinforced the finding that the crude is very buoyant. This keeps it away from sediments, and should tar balls form and cause the oil to sink, the majority of oil becomes enclosed in a crust which tends to avoid acute impacts (Section 12.1.6.2.1). Testing of one benthic species indicated that relatively high concentrations of oil in sediments would impact benthic communities (Section 12.1.4.1.1.1). However, these concentrations are not predicted to occur; the maximum level predicted is 29.3 mg/kg (Section 12.1.6.1.1). The sensitivity of the benthic community is considered to be '**Very Low**' due to uniform nature of the benthic community over much of the NFB. The severity of effect is considered to be '**Serious**' due to the potential widespread impact that could take several years to recover. The significance of impact on the benthic community is therefore assessed as '**Moderate (4)**'	**Unlikely**	**'Low (6)'**
Fish and squid	Known fish and squid spawning sites of commercial species are significant distances from the Sea Lion Field (Section 12.1.4.2.3) and it is unlikely that they will be impacted. Investigations of the effects of Sea Lion oil on fish eggs indicates that a spill is unlikely to have an impact (Section 12.1.4.1.1.1). While the adults of many species use the Northern Slope as a feeding ground (Section 7.4.4.2.2) these are likely to be able to avoid areas of contamination. Nonetheless, it is possible that more than 1 % of the Falklands population of fish and squid species using the Northern Slope could be within the zone of influence of a subsea blow-out either directly while foraging or passing through during migration	**Unlikely**	**'Low (6)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	(Section 12.1.4.4) and, therefore, the sensitivity of fish and squid receptors to a blow-out is considered to be '**Moderate**'. The impact of a subsea blow-out will have a temporary and reversible impact on the adult fish and squid exposed to crude oil and therefore the severity of the effect on fish is considered to be '**Moderate**'. Therefore, the significance of the impact of a subsea blow-out on fish and squid is assessed as '**Moderate (9)**'.		
Human population (fisheries)	The main commercial fisheries in the NFB target squid and finfish (Section 12.1.4.2.7). While the squid fishing grounds are not usually near the Sea Lion field, in May and June it is believed that a significant proportion of the *Illex* stock passes through the NFB. A blow-out that happened to coincide with this migration could lead to contamination of the spawning stock with unknown implications for reproduction (Section 12.1.4.2.7). The Patagonian toothfish fishing grounds are to the north and east of the Sea Lion Field and the results of modelling indicate that oil is likely to spread over part of the area fished (Section 12.1.4.4). Given the importance of these fisheries to the Falklands' economy and the uncertainty over the extent of any impacts, a precautionary approach should be taken and it is assumed that a blow-out could result in economic impacts for the fishing industry. Given the low capacity for the fishing industry to absorb the losses in revenue, and that such impacts to fisheries would be unacceptable to a majority of stakeholders, the sensitivity of the human population is considered to be '**Very High**'. An uncontrolled release could result in the closure of the fishing grounds due to potential tainting and contamination and therefore, the severity of the effect of an uncontrolled release on fisheries is considered to be '**Serious**'. Therefore, the significance of the impact on the human population *via* fisheries is assessed as '**High (20)**'.	**Unlikely**	**'Moderate (10)'**
Seabirds	Drilling and production will occur throughout the year and seabird vulnerability varies on a monthly / seasonal basis (Section 12.1.4.2.4.3). Given the waxy nature of the Sea Lion crude, seabirds are generally considered to be less susceptible to fouling compared to other crude oils (Section 12.1.4.2.4). However, testing has shown that at concentrations of 1,000 g/m^2 feathers become stained and microparticles of oil are adsorbed by two of the species tested (Section 12.1.4.1.1.1). Also, there is concern that birds will ingest oil, in much the same way that they ingest plastics. The available data, presented as an oil vulnerability atlas, indicate that at times there are areas of relatively high seabird vulnerability in or close to the Sea Lion Field. Further, the presence of the Development vessels will attract groups of scavenging seabirds, many of which are ACAP species and others that are of global conservation concern (Section 12.1.4.2.4). Therefore, given their susceptibility to the ingestion of oil (and other oil impacts), their presence in the wider NFB, their propensity to associate with vessels, and rigs, and the threatened conservation status of many species, the sensitivity of seabirds to the effects of a blow-out, is considered to be '**Very High**'. While the direct impact of Sea Lion crude by fouling is expected to be less than for more fluid crudes (Section 12.1.4.2.4), testing has indicated that there will be impacts to birds contaminated with higher concentrations (1,000 g/m^2) of oil (Section 12.1.4.1.1.1). Crude from a well blow-out is expected to rise to the upper water column and to	**Unlikely**	**'Moderate (10)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	remain above 1 g/m^2 in the area immediately above the well for up to 30 days (Section 12.1.4.4.2), although it is not predicted to be above levels shown to cause staining and adhesion in laboratory tests. Nonetheless, the behavioural traits of some species increase the likelihood that they will be attracted to the area through their association with vessels, due to the presence of artificial light, discharged wastewater and food, or simply to investigate a novel object in an otherwise uniform environment (Section 12.1.4.2.4.3). This increases the likelihood of contact with and ingestion of oil, potentially resulting in direct mortality or chronic impacts on the survival and reproductive biology of long-lived, late reproducing species (Section 12.1.4.2.4). The severity of the effect of an uncontrolled release on seabirds is therefore considered to be '**Serious**'. Therefore, the significance of the impact on seabirds is assessed as '**High (20)**'.		
Marine mammals	Owing to the presence of the sperm whale (IUCN 'Vulnerable'), the fin whale (IUCN 'Vulnerable') and the sei whale (IUCN 'Endangered') in the NFB (Section 12.1.4.2.5.2), all of which also have priority conservation status under the Falklands biodiversity action plan, the sensitivity of marine mammals is assessed as '**High**'. Away from the immediate release site at which surface oil densities > 1 g/m^2 may persist for up to 30 days, marine mammals may still be at risk from ingestion of the semi-solid waxy crude despite the rapid dispersion of contaminants (Section 12.1.4.1.1 and Section 12.1.4.2.5). While not causing significant immediate impact or mortality, the longer-term effects of sub-lethal exposure or ingestion are not fully understood and may lead to long-term impacts (Section 12.1.4.2.5). Therefore, taking a precautionary approach, the severity of effect of a subsea blow-out on marine mammals has been assessed as '**Moderate**' Therefore, the significance of the impact on marine mammals is assessed as '**Upper Moderate (12)**'.	**Unlikely**	**'Moderate (8)'**
Coastal	There is a slim possibility of oil reaching East Falkland (Section 12.1.4.4.4) which has numerous protected habitats (Section 7.5.2). The likelihood of oil reaching the shore is low (predicted in only approximately 4 % of stochastic model runs and therefore in a very specific and prolonged set of metocean conditions) and the quantity likely to beach is less than 30 tonnes (Section 12.1.4.4.4). However, the areas that are potentially at risk are of national importance. Therefore, the sensitivity of the coastal environment is considered to be '**High**'. Given that there is still some uncertainty regarding the long-term chronic impacts of such a waxy crude on this environment, and the model parameters have a degree of uncertainty, the severity of effect of an uncontrolled blow-out on coastal environment is considered to be '**Moderate**'. Therefore, the significance of the impact of an uncontrolled blow-out is assessed as '**Upper Moderate (12)**'.	**Unlikely**	**'Moderate (8)'**
Human Population (tourism)	The model predicts that some oil could reach the shore following a well blow-out, which will result in a quantity of less than 30 tonnes beaching (Section 12.1.4.4.1). Given the distance offshore and the relatively long travel times of the oil (Section 12.1.4.4.2) it is unlikely that tourists would see oil at-sea arising from a well blow-out. However, media publicity may influence the experience and perceptions of tourists, which may then impact upon their propensity to	**Unlikely**	**'Moderate (10)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	visit. Given that a well blow-out would be unacceptable to the majority of stakeholders, the sensitivity of tourism is considered to be '**High**'. Due to the long-lasting negative impacts of perceived environmental degradation, the severity of effect of an uncontrolled release on tourism has been assessed as '**Serious**'. Therefore, the significance of the impact on the human population (tourism) is assessed as '**High (16)**'.		

12.1.6.2 Scenario 2: Loss of FPSO crude oil inventory

12.1.6.2.1 Sensitivity of receptor and severity of effect (impact assessment)

The results of the oil dispersion modelling indicate that the behaviour of Sea Lion crude following a complete loss of FPSO crude oil inventory are similar to the worst-case well blow-out scenario. There is a low potential in both cases for oil to reach the north Falklands coastline. In the case of the FPSO inventory loss scenario, the shoreline was reached in 5.8 % of the stochastic model runs in specific metocean conditions (Section 12.1.4.5.4), as opposed to 4 % in the case of the well blow-out scenario. Furthermore, when considering the worst-case scenarios, the maximum mass of beached oil predicted by the models was 36 tonnes for the FPSO inventory loss scenario, compared to 29 tonnes in the case of a well blow-out. However, the potential deposition in offshore sediments is much smaller, largely because oil is assumed to remain in larger, more buoyant masses. Deposition above the LC_{50} level of 392 mg/kg (Table 12.1 above) is not predicted; in fact the maximum predicted deposition concentration in either model run over a 5 cm mixed layer in the model grid is 1-2 mg/kg, well below the OSPAR threshold of 50 mg/kg and the NOEC concentration of 10 mg/kg (Table 12.4 above).

Following an FPSO release, the potential for tar ball formation is higher than for the well blow-out scenario. Tests have reinforced the finding that the Sea Lion crude is very buoyant and formed little attachment to suspended solids, attributes that would generally keep it away from sediments (Section 12.1.4.1.1) Should tar balls form and cause the oil to sink, the majority of oil would likely become enclosed in a crust, which tends to reduce acute impacts.

Containment and recovery operations are overall less effective due to the large volume of oil and the dispersion of oil before significant oil spill response resources arrive, but are predicted to be sufficient to prevent oil from reaching some, but not all, areas of the Falkland Islands coastline.

The ‘Sensitivity of Receptor’ and the ‘Severity of Effect’ for each receptor are provided in Table 12.10. The ‘Likelihood of Occurrence’ of losing the crude from the FPSO is described below and is included in Table 12.10 to show how the overall significance ratings of risks associated with the loss of the FPSO crude oil inventory were derived.

12.1.6.2.2 Likelihood of occurrence

There are no recorded examples that match the worst-case scenario modelled here in over 20 years of global FPSO operations. One possible incident that could result in the complete loss of crude inventory from the FPSO however, is the collision with a large vessel. As detailed in Section 11.1, the likelihood of collisions between vessels operating in the south-west Atlantic and the FPSO on station in the Sea Lion Field was assessed using the COLLRISK model (Anatec, 2024b).

Based on vessel activity, the COLLRISK model was used to estimate the collision risks on an annual basis and distributed the predicted frequency of collision according to the level of impact energy based on the sizes and speeds of vessels involved. Specifically, information on shipping movements in the NFB was used to investigate the risk of vessels colliding with an FPSO stationed in the Sea Lion Field (Anatec, 2024b). On average, 216 vessels pass within 15 nautical miles of the Sea Lion Field per year. The majority of these (176) were commercial fishing vessels, 86 % of which were less than 1,500 DWT (Dead Weight Tonnage). Fourteen vessels were cargo vessels, 14 were tankers and 12 were passenger vessels. Given the size of the tankers, 29 % of which were >40,000 DWT, these vessels pose a greater threat in terms of the force of a collision.

Overall, the annual risk of a collision with a passing vessel was calculated as 9.2 x 10-3 per year and the risk, or probability, of a collision with a larger vessel (collision energy >200 MJ) was assessed as 5.1 x 10^{-8} per year (Section 11.1).

The other credible collision risk for vessels located within the Sea Lion Field is that posed by icebergs. An Iceberg Management Strategy was previously produced in consultation with the British Antarctic Survey (BAS) and the results of their assessment are presented in Premier (2015f). Using the available information (satellite and visual observations), it is predicted that an iceberg will pass within 30 nautical miles of the FPSO with a mean return period of 20 years. The strategy indicates that this is a manageable risk but iceberg management zones and protocols will be instigated. Navitas will prepare an updated Iceberg Management Plan prior to the commencement of operations.

With industry-standard mitigation measures in use (Section 12.1.5), the likelihood of occurrence of a full loss of FPSO crude inventory is considered to be '**Very Unlikely'** (Table 12.10).

12.1.6.2.3 Overall risk significance

As is shown in Table 12.10, the highest significance of the risk posed by the loss of crude from the FPSO is to the human population (tourism and fisheries) seabirds, marine mammals and coastal ecology, all of which were assessed as '**Low**'.

Table 12.10: Risk assessment for loss of FPSO crude oil inventory

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Water quality and plankton	Justification for this assessment is the same as that for a blow-out and can be found in Table 12.9. The sensitivity of plankton is considered to be '**Moderate**' and the severity of the effect to be '**Moderate**'. Therefore, the overall significance of the impact is assessed as '**Moderate (9)**'.	**Very Unlikely**	**'Very Low (3)'**
Sediment quality and benthic communities	Due to the buoyancy of the wax and the deep water in which it is released, the deterministic model predicts that a small fraction of oil (<0.5 %) could move into sediments (Section 12.1.4.5.1); this is only predicted when / if the oil approaches shallower water and the cloud of suspended droplets makes contact with the seabed, around 40 days after discharge. Testing of one benthic species indicated that relatively high concentrations (> 392 mg/kg) of oil in sediments would impact benthic communities (Section 12.1.4.1.1.1) although other studies indicate lower thresholds of significance (Table 12.4 above). These concentrations are not predicted to occur; the maximum concentration predicted is 1-2 mg/kg (Section 12.1.6.2.1). The sensitivity of the benthic community is considered to be '**Very Low**' due to the uniform nature of the benthic community over much of the NFB. The severity of effect is considered to be '**Serious**' due to the potential widespread impact that could take several years to recover. Therefore, the significance of impact on the benthic community is therefore assessed as '**Moderate (4)**'	**Very Unlikely**	**'Very Low (3)'**
Fish and squid	Justification for this assessment is the same as that for a blow-out and can be found in Table 12.9. The sensitivity of fish and squid is considered to be '**Moderate**' and the severity of the effect to be '**Moderate**'. Therefore, the overall significance of the impact is assessed as '**Moderate (9)**'.	**Very Unlikely**	**'Very Low (3)'**
Human population (fisheries)	Justification for this assessment is the same as that for a blow-out and can be found in Table 12.9. The sensitivity of fisheries is considered to be '**Very High**' and the severity of the effect to be '**Serious**'. Therefore, the overall significance of the impact is assessed as '**High (20)**'.	**Very Unlikely**	**'Low (5)'**
Seabirds	Justification for this assessment is the same as that for the well blow-out scenario and can be found in Table 12.9, except that there are areas of oil above 100 g/m^2 and above 1,000 g/m^2 near to the release where impacts on plumage are more likely. Additionally, the north Falkland coastline includes the IBAs at Seal Bay, Volunteer Point and Cow Bay (Section 12.1.4.2.6). However, by the time oil reaches the coastline it is predicted to be very degraded and dispersed. Penguins breeding at this and other sites are far more likely to come into contact with oil at sea. The sensitivity of seabirds is considered to be '**Very High**' and the severity of the effect to be '**Serious**'. Therefore, the overall significance of the impact is assessed as '**High (20)**'.	**Very Unlikely**	**'Low (5)'**
Marine mammals	Justification for this assessment is the same as that for a blow-out and can be found in Table 12.9. The sensitivity of marine mammals is considered to be '**High**' and the severity of the effect to be '**Moderate**'. Therefore, the overall significance of the impact is assessed as '**Upper Moderate (12)**'.	**Very Unlikely**	**'Low (4)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Coastal	There is a possibility of oil reaching the coastline of East Falkland (Section 12.1.4.5.4). Parts of this area (Seal Bay; Volunteer Point and Cow Bay) are designated as IBAs (Section 12.1.4.2.6.). Although the likelihood of oil reaching the shore is low (predicted in 5.8 % of stochastic model runs and the quantities involved are barely detectable in the modelled scenario (Section 12.1.4.5.4). However, the areas that are potentially at risk are of national importance. Therefore, the sensitivity of the coastal environment is considered to be '**High**'. Given that there is still some uncertainty regarding the long-term impacts of such a waxy crude on this environment, and the model parameters have a degree of uncertainty, the severity of effect of the FPSO crude inventory loss on coastal environments is considered to be '**Moderate**'. Therefore, the significance of the impact on a complete loss of FPSO inventory is assessed as '**Upper Moderate (12)**'.	**Very Unlikely**	**'Low (4)'**
Human population (tourism)	The potential fouling of iconic tourism destinations would impact greatly on the pristine image of the Falkland Islands and would likely have a negative impact on visitor numbers. While the model predicts that under very specific metocean conditions, oil could reach the shore, the concentrations would be so low (Section 12.1.4.5.4) that it is unlikely that tourists would see oil at sea or along the shore. However, reports, observations and photos of the incident, including affected wildlife that may come ashore will certainly influence the experience and perceptions of tourists. Moreover, international news coverage of the incident (offshore) will potentially influence the perception of the public, whether they see the oil or not. As there is limited capacity to absorb and manage change in visitor numbers in the aftermath of a major incident and given that this will be unacceptable to the majority of stakeholders, the sensitivity of tourism is assessed as '**High**'. Due to the potentially long-lasting negative impacts of perceived environmental degradation the severity of effect of an uncontrolled release on tourism has been assessed as '**Serious**'. Therefore, the significance of the impact on tourism is assessed as '**High (16)**'.	**Very Unlikely**	**'Low (5)'**

12.1.6.3 Scenario 3: Crude oil transfer spill

12.1.6.3.1 Sensitivity of receptor and severity of effect (impact assessment)

The modelling approaches considered a crude oil spill of 70 tonnes that may occur during FPSO crude offload operations. The potential impacts of such a spill on the environmental receptors are similar to that of the larger spill assessed above. The main differences include the volume discharged, the extent of the area affected, the duration of the spill and the number of individuals and proportions of populations of the key environmental receptors exposed to the oil and impacted, which will generally be smaller. Negligible concentrations of oil reached any sediments such that benthic communities are not considered further.

The 'Sensitivity of Receptor' and the 'Severity of Effect' for each receptor are provided in Table 12.11. The 'Likelihood of Occurrence' of a spill during crude oil transfer is described below and is included in Table 12.11 to show how the overall significance ratings of risks associated with crude oil transfer spills were derived.

12.1.6.3.2 Likelihood of occurrence

The likelihood of a crude oil transfer spill associated with the FPSO offload operation can be assessed by investigating the frequency of oil spills associated with such installations in other parts of the world. Figure 12-42 shows the number of all recorded oil spill events associated with offshore O&G installations on the United Kingdom Continental Shelf (UKCS) between 2012 and 2022. This corresponds to 234 installations in 2021 as listed by OSPAR (2023a) with the number declining from 316 in 2012. After accounting for the number of installations, the average number of oil spill events per installation was reasonably consistent over this period although it is important to note that these were not all the result of offloading operations. In 2022, there were 188 unintentional oil releases on the UKCS, involving 33 tonnes of oil released to the marine environment. The average annual reported unintentional oil release size has varied since 2012, between 0.05 and 2.1 tonnes. Infrequent but large releases form a big part of these annual totals, such as was seen in 2020. These data illustrate that spills in the region of 70 tonnes are very infrequent events.

Figure 12-43 illustrates the type of oil involved in unintentional releases from incidents on the UKCS in 2022.

The information presented above suggests that several small spills (from all sources) may occur at an installation each year, although most of these are not necessarily associated with crude oil transfer. The combined impact of these small spills may be more significant than a larger but far less likely spill.

The risk associated with a potential drive-off by a CTT during the offloading operation (i.e., the CTT inadvertently propelling itself off-station during transfer operations) has been mitigated by requiring that the CTT is held by a tug when connecting to the FPSO. The operation will be conducted under a safe system of work such that the CTT is under the control of the tug and is unable to drive-off unintentionally. Taking all the industry-standard mitigation measures into account (Section 12.1.5), the likelihood of occurrence of a 70 tonnes spill is assessed as '**Possible**' (Table 12.11).

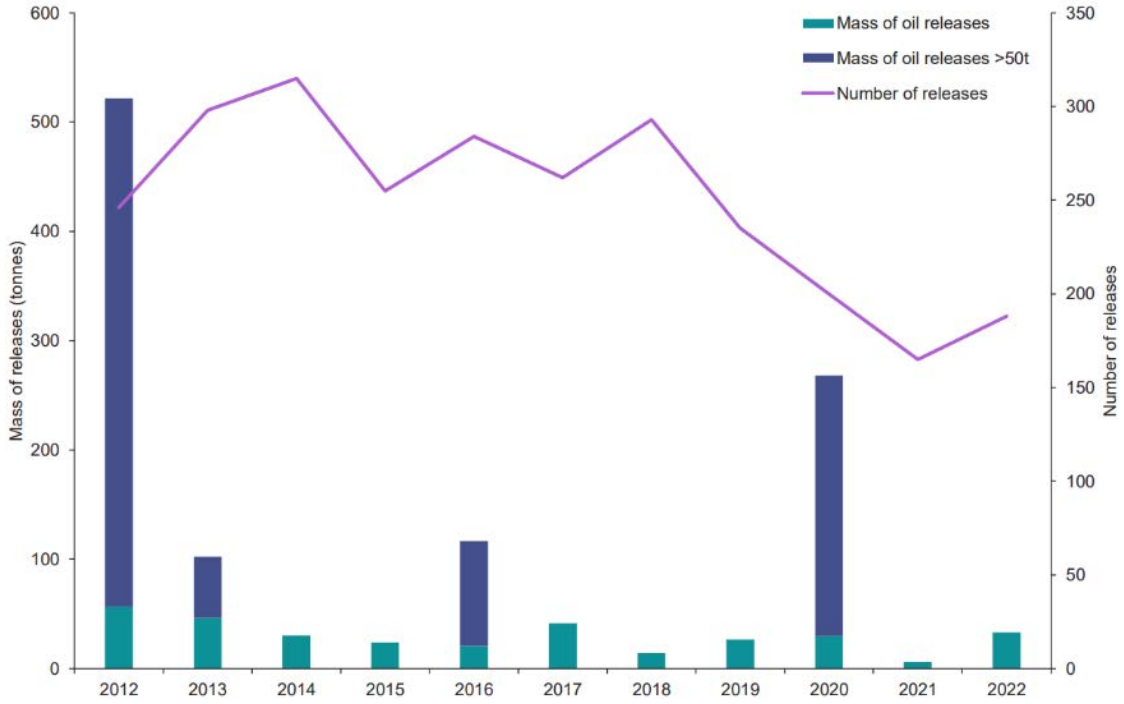

Figure 12-42: Number of oil spills and quantity of oil spilled in UKCS (2012 – 2022) ***(Source: OEUK, 2023)***

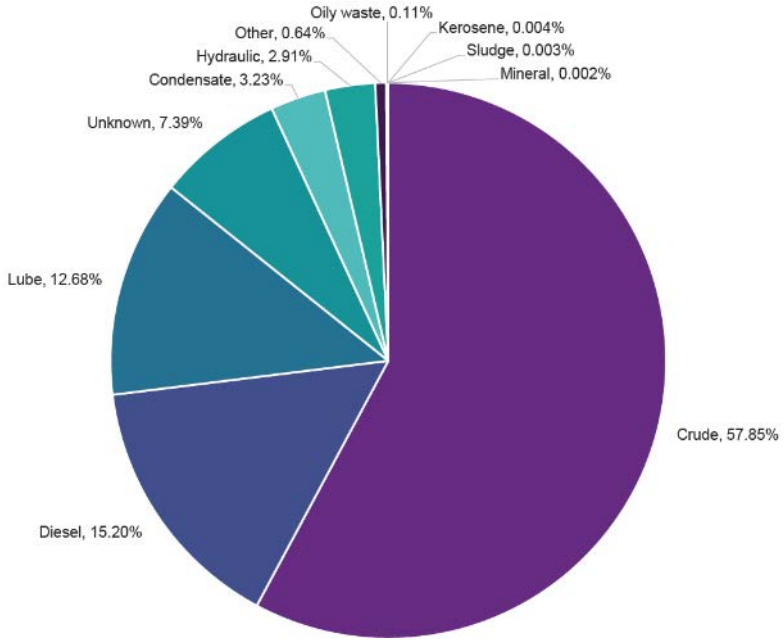

Figure 12-43: UKCS Fraction of releases by oil type, 2022 ***(Source: OEUK, 2023)***

12.1.6.3.3 Overall risk significance

As is shown in Table 12.11, the highest significance of the risk posed by the loss of crude during offloading is to seabirds and the human population (tourism) and is considered to be '**Moderate**' and therefore, project-specific mitigation measures will be required.

Table 12.11: Risk assessment associated with crude oil transfer spills

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Water quality and plankton	The impact of a crude transfer spill will affect a very small area and therefore a small proportion of the local plankton populations. Consequently the sensitivity of plankton is assessed as '**Low**'. A combination of short generation times, high reproductive rates and immigration from outside the affected area would likely see a quick recovery of the affected communities. The severity of the effect of a crude transfer spill on plankton is therefore considered to be '**Slight**'. Therefore, the significance of the impact is assessed as '**Very Low (2)**'.	**Possible**	**Very Low (3)**
Sediment and benthic communities	n/a	**n/a**	**n/a**
Fish and squid	The zone of influence of a crude transfer spill will be small in space and time and will therefore impact a small proportion of the local fish and squid populations. The sensitivity of fish and squid is considered to be '**Low**'. Any effect will be highly localised and short-term and therefore the severity of the effect is considered to be '**Slight**'. Therefore, the overall significance of the impact is assessed as '**Very Low (2)**'.	**Possible**	**Very Low (3)**
Human population (fisheries)	The sensitivity of fisheries is considered to be '**Low**' and given the low volume of oil that is expected to be rapidly dispersed in the water column, the severity of the effect is therefore considered to be '**Minor**'. The overall significance of the impact is therefore assessed as '**Low (4)**'.	**Possible**	**Low (6)**
Seabirds	Although the volume of oil discharged following a crude oil transfer spill is relatively small, the highest density of seabirds in the area will be closely associated with the Development vessels. It is these birds that are at greatest risk of exposure to oil, regardless of the size of the spill (Section 12.1.4.2.4). The sensitivity of seabirds is considered to be '**Very High**'. The impact of a crude oil transfer spill will be short-lived and restricted to the local area. The severity of the effect of a crude oil transfer spill is considered to be '**Minor**'. The overall significance of the impact is consequently assessed as '**Moderate (10)**'.	**Possible**	**Moderate (9)**
Marine mammals	Given the limited extent and duration of an oil spill associated with crude oil transfer operations, and the tendency for marine mammals to associate less with vessels and structures at sea than seabirds, the sensitivity of marine mammals is considered to be '**Moderate**' and the severity of the impact to be '**Slight**'. Therefore, the overall significance of the impact is assessed as '**Very Low (3)**'.	**Possible**	**Very Low (3)**
Coastal	No shoreline oiling was predicted in any of the stochastic simulations of a crude transfer spill.	**n/a**	**n/a**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Human population (tourism)	Given the small volume of oil involved, the distance offshore and the low exposure time (Section 12.1.4.6.2) it is highly unlikely that tourists would see any of the oil discharged following an offshore crude oil transfer spill. While news of an oil spill, even if minor, may influence the perception of the public, whether they see the oil or not, it is very unlikely that smaller spills would come to the attention of tourists. Therefore, the sensitivity of tourism to a crude oil transfer spill, is considered to be '**Moderate**'. Due to the short-term and reversible impacts of a small spill on the perception of tourists regarding environmental degradation, the severity of effect of a crude transfer spill on tourism has been assessed as '**Minor**'. Therefore, the overall significance of the impact is assessed as '**Moderate (6)**'.	**Possible**	**Moderate (9)**

12.1.6.4 Scenario 4: Loss of MODU MGO inventory

12.1.6.4.1 Sensitivity of receptor and severity of effect (impact assessment)

MGO is predicted to remain on the sea surface for a short period of time before it either evaporates or disperses in the water column (Section 12.1.4.7.1). The extent of the sea surface and water column areas likely to be affected by MGO spills is generally more restricted (i.e., close to the release point) than crude oil spills. However, the higher volatility of MGO is such that it is more likely to release toxic substances, such as PAHs into the water column (Section 12.1.4.1.1.2). These chemicals are toxic to marine life and will have localised impacts following exposure. The larger the spill, the greater the area over which the MGO will spread and the longer it will take for the MGO to be reduced to insignificant concentrations.

The 'Sensitivity of Receptor' and the 'Severity of Effect' for each receptor are provided in Table 12.12. The 'Likelihood of Occurrence' of a MGO spill from the MODU is described below and is also included in Table 12.12 to show how the overall significance ratings of risks associated with the loss of MODU's MGO inventory were derived.

12.1.6.4.2 Likelihood of occurrence

One of the most plausible events that could result in a complete loss of the MODUs MGO inventory is a collision with a large vessel. When in the field, during Development Stages 1 and 2, the MODU will be anchored within the vicinity of the FPSO, which will also be anchored. The likelihood of a vessel colliding with the MODU has been assessed by Anatec (2024b) as 1.9×10^{-6} per year, corresponding to a collision return period of approximately 535,000 years, see Section 11.1.

The predicted collision frequency is very low, as for the FPSO, and it is useful to note that only three semi-submersible drilling rigs have ever sunk in the O&G industry. One incident occurred in the Canadian waters of the North Atlantic and was due to a catalogue of errors initiated by a major hurricane (US Coastguard, 1983). The other two incidents occurred in African waters when the MODUs were being towed. No incidents have been recorded on the UKCS, or anywhere since 1995.

With industry-standard mitigation measures in place (12.1.5), the likelihood of occurrence of a vessel colliding with the rig, potentially leading to a loss of containment of the entire MGO inventory, is assessed as '**Unlikely**' (Table 12.12).

12.1.6.4.3 Overall risk significance

As is shown in Table 12.12, the highest significance of the risk posed by the loss of MGO from the MODU is to seabirds and tourism, both of which are considered to be '**Moderate (8)**' and therefore require project-specific mitigation measures.

Table 12.12: Risk assessment of MODU MGO spill

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Water quality and plankton	Following the loss of the MODU MGO inventory, the models predict that the MGO will remain on or close to the surface of the water initially but is rapidly removed by evaporation, biodegradation and dispersion (Section 12.1.4.7.1). MGO concentrations in the water column are only expected to exceed 1,000 ppb in a small area around the discharge site (Section 12.1.4.7.3), but these levels should decrease rapidly and reach negligible levels after 10 days. While deleterious impacts would generally be greatest during periods of increased plankton productivity, the planktonic organisms will be contaminated over a small area of low productivity for a relatively short period of time. Any impacts will affect a small proportion of the local populations and therefore the sensitivity of plankton is considered to be '**Low**'. A combination of short generation times, high reproductive rates and immigration from outside the affected area would likely see a quick recovery of the affected plankton communities. The severity of the effect of MGO spills on plankton is therefore considered to be '**Minor**'. Therefore, the significance of the impact is assessed as '**Low (4)**'.	**Unlikely**	**Very Low (4)**
Sediment and benthic communities	n/a	**n/a**	**n/a**
Fish and squid	Fish and squid could experience lethal effects if they come into contact with high concentrations of MGO; eggs and larvae are particularly vulnerable as they occupy the surface layers of the sea and are immobile (Section 12.1.4.2.3). In the offshore environment, MGO spills will be dispersed and evaporate rapidly and so fish may be more vulnerable to sub-lethal effects and accumulation of toxins (that can taint the flesh of fish) than direct mortality (Section 12.1.4.2.3). However, because no known spawning sites are in the immediate vicinity of the Development area, and adult fish are likely to move away, any impacts of an MGO spill will affect a small proportion of the local fish and squid populations. Therefore, the sensitivity of fish and squid is considered to be '**Low**'. The impacts of the spills modelled here are very localised and short-term in nature and the severity of the effect is assessed as '**Minor**'. Therefore, the significance of the impact is assessed as '**Low (4)**'.	**Unlikely**	**Very Low (4)**
Human population (fisheries)	Although some tainting of fish and squid is possible following the loss of the MODU MGO inventory, fisheries in the NFB are not located near to the Phase 1 & 2 Development area and the MGO is unlikely to extend to the fishing grounds before it has evaporated (Section 12.1.4.7.1). The sensitivity of fisheries is therefore considered to be '**Low**'.	**Unlikely**	**Low (6)**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	Given the rapid rate at which the discharged MGO will evaporate and biodegrade, and thus the limited extent and relatively short duration of a MGO spill associated with the loss of the MODU MGO inventory, the impacts on commercial fisheries are likely to be confined to a relatively small area. The severity of effect of the modelled spill on fisheries is considered to be '**Moderate**', as the effects are expected to be localised and of a short-term nature but could result in localised fisheries closures. The significance of the impact on human population (fisheries) is therefore assessed as '**Moderate (6)**'.		
Seabirds	The MODU will be on location for 44 months in total and seabird vulnerability varies on a monthly / seasonal basis (Section 12.1.4.2.4.3). Further, MGO has greater potential to cause fouling than the Sea Lion crude oil and has greater potential for impacts associated with toxicity (Section 12.1.4.2.4). Following a discharge, MGO rapidly spreads to form a sheen on the surface of the water and the potential impact is proportional to the extent to which seabirds overlap with and encounter the MGO; this is linked to the size of the spill. The presence of the MODU and other vessels associated with the project will attract some seabirds and therefore the density of birds in the immediate vicinity of the vessels, and any spill, will be far higher than the baseline density in surrounding waters (Section 12.1.4.2.4). Due to the potential for the presence of a large number of seabirds, many of which will be ACAP species and / or are of global conservation concern, the sensitivity of seabirds to the effects of a large MGO spill, is considered to be '**Very High**'. Nonetheless, the area affected by the spill is predicted to be relatively small (on the scale of the NFB) and given the relatively rapid rates of evaporation and dispersion, the slick will be short-lived. The severity of effect of a spill resulting from a large MGO spill is therefore considered to be '**Moderate**'. Therefore, the significance of the impact of a loss of MGO inventory from the largest vessel associated with the Development on seabirds is assessed as '**Upper Moderate (15)**'.	**Unlikely**	**Moderate (8)**
Marine mammals	Pinnipeds, and particularly fur seals, that come into contact with a MGO spill may suffer adverse consequences (Section 12.1.4.2.5). However, it is expected that a spill resulting from the loss of the MODU MGO inventory would impact a relatively small area for a short period of time. Cetaceans are more vulnerable to inhaling toxic vapour from MGO spills and are less affected by contact with the skin. They would therefore be most likely to be affected for a short period immediately following a spill before the MGO is dispersed from the release point. Due to seasonal fluctuations in abundance (Section 12.1.4.2.5), the timing of a spill will influence the likely presence, and potential exposure, of different receptor species to a spill of the MODU's MGO inventory. Nonetheless, given that all marine mammals are protected and considered conservation priority species by FIG, the sensitivity of marine mammals to discharged MGO during the Development is assessed as '**High**'.	**Unlikely**	**Low (6)**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	Like seabirds, the potential impacts are related, to some extent, to the size of the spill. MGO spills are predicted to be short-lived and localised. The severity of effect of a large MGO spill on marine mammals is therefore considered to be '**Minor**'. Therefore, the significance of the impact of a loss of the MODU MGO inventory on marine mammals is considered to be '**Moderate (8)**'.		
Coastal	No shoreline oiling was predicted in any of the stochastic simulations of the MODU MGO spill scenario.	**n/a**	**n/a**
Human population (tourism)	The modelling predicts that no MGO would reach the shore and given the rapid rate at which MGO will evaporate and disperse, and the distance offshore, it is highly unlikely that tourists would experience or see MGO at sea. However, observations and photos of oiled wildlife that come ashore will certainly influence the experience and perceptions of tourists. Additionally, media publicity may influence the experience and perceptions of tourists, which may then influence their propensity to visit. Given that there would be moderate capacity to absorb change in the aftermath of a large MGO spill, the sensitivity of tourism is considered to be '**Moderate**'. Due to the long lasting negative impacts of perceived environmental degradation, the severity of effect of an uncontrolled release on tourism is considered to be '**Serious**'. Therefore, the significance of the impact of a loss of the MODU MGO inventory on tourism is considered to be '**Upper Moderate (12)**'.	**Unlikely**	**Moderate (8)**

12.1.6.5 Scenario 5: MGO bunkering spill

12.1.6.5.1 Sensitivity of receptor and severity of effect (impact assessment)

The main difference between a MGO bunkering spill and a spill associated with the loss of the MODU's MGO inventory is the volume of MGO discharged: 3,936 tonnes (4,669 m^3) in the case of the MGO inventory loss scenario as opposed to 20 tonnes in a bunkering spill (Section 12.1.5). In both cases, the MGO is expected to evaporate and disperse rapidly. Especially in the case of the MGO bunkering spill, it is expected that the area and duration of impact will be small and short-lived.

The 'Sensitivity of Receptor' and the 'Severity of Effect' for each receptor are provided in Table 12.13. The 'Likelihood of Occurrence' of a MGO spill during bunkering is described below and is included in Table 12.13 to show how the overall significance ratings of risks associated with a MGO bunkering spill were derived.

12.1.6.5.2 Likelihood of occurrence

Section 12.1.6.6 discusses the likelihood of small spills (from all sources). Assuming the use of industry-standard mitigation measures (Section 12.1.5), the likelihood of small-scale MGO spills during fuel transfer has been assessed as '**Possible**' (Table 12.13).

12.1.6.5.3 Overall risk significance

As is shown in Table 12.13, the highest significance of the risk posed by the loss of MGO during bunkering is to Seabirds and is considered to be '**Moderate (9)**' and therefore, project-specific mitigation measures will be required.

Table 12.13: Risk assessment of MGO bunkering spill

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Water quality and plankton	While any effects will be greater during periods of high plankton productivity, impacts of a MGO bunkering spill will affect a very small proportion of the local populations and therefore the sensitivity of plankton is assessed as '**Low**'. A combination of short generation times, high reproductive rates and immigration from outside the affected area would likely see a quick recovery in the affected communities. The severity of the effect on plankton is therefore considered to be '**Slight**'. Therefore, the significance of the impact associated with a MGO bunkering spill is assessed as '**Very Low (2)**'.	**Possible**	**Very Low (3)**
Sediment and benthic communities	n/a	**n/a**	**n/a**
Fish and squid	The sensitivity assessment is the same as for a MGO inventory spill from the MODU (Table 12.12), and the sensitivity of fish and squid in relation to a MGO bunkering spill is considered to be '**Low**'. Given the small volume of MGO involved the impact of the spills modelled here will be very localised and short-term in nature and so the severity of the effect is considered to be '**Slight**'. Therefore, the significance of the impact associated with a MGO bunkering spill is assessed as '**Very Low (2)**'.	**Possible**	**Very Low (3)**
Human population (fisheries)	The sensitivity assessment is the same as for a MGO spill from the MODU (Table 12.12), and the sensitivity of fisheries in relation to a MGO bunkering spill is considered to be '**Low**'. Given the small volume of MGO involved and the rapid rate at which MGO will evaporate and biodegrade, any impacts on commercially important fish are assessed to be highly localised and short-term in nature. The severity of the effect of a MGO bunkering spill is therefore considered to be '**Slight**'. The significance of the impact on human population (fisheries) is therefore assessed as '**Very Low (2)**'.	**Possible**	**Very Low (3)**
Seabirds	The sensitivity assessment is the same as for a MGO spill from the MODU (Table 12.12), and the sensitivity of seabirds in relation to a MGO bunkering spill is considered to be '**Very High'**. The impact of small MGO spills will be extremely localised and short-term and therefore the severity of the effect of a small transfer MGO spill (20 tonnes) on seabirds is considered to be '**Minor**'. Therefore, the significance of the impact of small MGO bunkering spills on seabirds is assessed as '**Moderate (10)**'.	**Possible**	**'Moderate (9)'**
Marine mammals	The sensitivity assessment is the same as for a MGO spill from the MODU (Table 12.12), and the sensitivity of marine mammals in relation to a MGO bunkering spill is considered to be '**High**'.	**Possible**	**Low (6)**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	Marine mammals could be attracted by potential prey species that may shelter near the rig. The severity of the effect of a small short-term release of MGO on marine mammals is therefore considered to be '**Slight**'. Consequently, the significance of the impact of a small MGO bunkering spill on marine mammals is assessed as '**Low (4)**'.		
Coastal	No shoreline oiling was predicted in any of the stochastic simulations of the MGO bunkering spill.	**n/a**	**n/a**
Human population (tourism)	Tourists are highly unlikely to observe, directly or indirectly, any evidence of a MGO bunkering spill of the volume considered here and the sensitivity of tourism is considered to be '**Low**'. Due to the short-term and reversible impacts of a small spill on the perception of tourists regarding environmental degradation, the severity of the effect of a MGO bunkering spill on Tourism considered to be '**Minor**'. Therefore, the significance of the impact of small MGO spills on tourism is assessed as '**Low (4)**'.	**Possible**	**Low (6)**

12.1.6.6 Small scale releases of oil

12.1.6.6.1 Sensitivity of receptor and severity of effect (impact assessment)

As described in Section 12.1.4.9, it is not possible to predict or quantify the volumes that may be released during small accidental spills. Small spills may create surface sheens which have the potential to cause environmental impacts, primarily upon seabirds (Section 12.1.4.2.4).

It is likely that several seabird species present in close proximity to the Development vessels will be classified as 'Vulnerable' or 'Endangered' by the IUCN (which equates to 'High' sensitivity). Some of the species of seabird that associate with vessels in Falkland Islands waters are also listed under ACAP. These are species that are considered to be under wider threat (largely from fisheries related mortality). Moreover, the use of artificial light (Section 10.1) and the discharge of macerated food waste (Section 10.10) may also attract additional species. Various studies have highlighted the risk and impacts to seabird populations associated with small-scale, but chronic, oil pollution from sources such as shipping. Therefore, overall, the sensitivity of the seabird receptors to chronic oil pollution from discharges is considered to be '**Very High**'.

There are no clear guidelines regarding the degree of impact from sheens of a given thickness and the impact may either be reversible or lethal to the individual depending on the amount of fouling (possibly species specific). A sheen of even 0.1 µm could cause an effect that may reduce fitness (Section 12.1.4.2.4.1). However, given the metocean conditions in the region, any sheen resulting from discharges is likely to be temporary. Therefore, the severity of the effect is considered to be '**Minor**'.

The overall significance of the impact on seabirds associated with chronic oil pollution from the Sea Lion activities is therefore considered to be '**Moderate (10)**'.

12.1.6.6.2 Likelihood of occurrence

Given industry figures for small spills, the need for breach of procedural controls to occur, the likelihood of a sheen forming and seabirds becoming oiled is considered to be '**Possible**'.

12.1.6.6.3 Overall risk significance

The overall significance of the risk of a chronic oiling of seabirds is considered to be '**Moderate (9)**'.

12.1.6.7 Loss of riser contents

12.1.6.7.1 Sensitivity of receptor and severity of effect (impact assessment)

It is anticipated that any loss of riser contents would release approximately 60 m^3 of NADF to sea, which would settle to cover an area of around 0.006 km^2 around the MODU. It is likely to impact benthos and sediments in the vicinity *via* both smothering and toxic effects. According to the surveys already carried out in the area (Section 7.2.2), there are no known vulnerable species recorded within the benthos and the community structure is widespread and typical of the area. However, a data gap exists because the Sea Lion Field environmental baseline survey did not sample the site-specific drilling locations. Therefore, although the sensitivity of the receptor is likely to be '**Very Low**', to take a precautionary approach it is assessed here as '**Low**'.

The area predicted to be impacted by a loss of riser contents would be in close proximity to the drill centre and reversible after a number of years. Therefore, the severity of the effect is considered to be '**Moderate**'.

The overall significance of the impact on the benthos and sediments due to the loss of riser contents is therefore considered to be '**Moderate (6)**'.

12.1.6.7.2 Likelihood of occurrence

Given the need for malfunction to occur, and the incidence of loss of riser contents being known within industry but infrequently, the likelihood of a loss of riser contents is considered to be '**Unlikely**'.

12.1.6.7.3 Overall risk significance

The overall significance of the risk associated with a loss of riser contents is considered to be '**Low (6)**'.

12.1.7 Project-specific mitigation measures

The remoteness, poor transport infrastructure and abundant wildlife in the Falklands pose unique and significant challenges in responding to a major oil pollution incident. Therefore, in addition to the industry-standard mitigation measures (Section 12.1.5) and those that are required by legislation, Navitas, and the former operator (POEPL), have spent considerable time and effort determining what additional oil spill response measures may be appropriate. All oil spill response strategies and equipment will be described in the Sea Lion OPEP (Section 12.1.1.1.3).

While Oil Spill Response (OSR) equipment will be carried on the ERRV / MRSV and AHTS / ERRV offshore, and it may be possible to deploy the containment and recovery equipment under the right conditions, in reality it is unlikely to be effective in the prevailing offshore weather conditions of the Sea Lion Field. The modelling shows that oil spill response can recover a certain amount of oil, and it is possible that this can reduce shoreline (and other) consequences. However, for very large releases, the effect is limited and oil spill response is not considered effective in respect of the largest events.

Therefore, in order to ensure a precautionary approach, these mitigations are not considered applicable to this offshore oil spill assessment. It is likely that oil will eventually be dispersed through natural wave and wind action, evaporate and biodegrade. However, it is currently unknown how long Sea Lion crude will remain in the environment beyond seven days, as indicated in Section 12.1.4.1.1.1.

12.1.8 Residual impacts and risks

In the worst-case scenario, weather conditions offshore will be such that effective recovery of oil spills will not be possible and therefore the residual significance of the risk remains the same as in the initial assessment which takes account of all the legal requirements and the industry-standard mitigations. For ease of reading, the initial (and also residual) worst-case risk outcomes are summarised again in Table 12.14.

Table 12.14: Initial and residual (same) worst-case risks for each oil release scenario

Scenario	Impact assessment	Likelihood	Overall residual risk significance
1: Subsea well blow-out	High for Seabirds and Human Population (Fisheries and Tourism)	Unlikely	**Moderate (10)**
2: FPSO inventory loss	High for Seabirds and Human Population (Fisheries and Tourism)	Very Unlikely	**Low (5)**
3: Crude transfer spill	Moderate for Seabirds and Human Population (Tourism)	Possible	**Moderate (9)**
4: MGO inventory loss	Upper Moderate for Seabirds and Human Population (Tourism)	Unlikely	**Moderate (8)**
5: MGO bunkering spill	Moderate for Seabirds	Possible	**Moderate (9)**
Small scale releases	Moderate for Seabirds	Possible	**Moderate (9)**
Loss of riser contents	Moderate for Benthos	Unlikely	**Low (6)**

12.1.9 Cumulative impact

Not applicable.

12.1.10 Confidence

The Sea Lion Field has now been evaluated by a number of test wells. The properties of Sea Lion crude and probable flow rates are relatively well defined. However, the very waxy nature of the crude means that the behaviour of the oil in the marine environment will be quite different to that of a lighter (fluid) crude. Testing of the Sea Lion crude (CEDRE, 2017), expanding on earlier studies of the properties of Sea Lion crude in the event of a spill, confirms our understanding of:

- Physical state in contact with seawater at ambient temperatures (8 °C),
- Evaporation after 3 - 7 days at sea,
- Dispersion (how the oil would break up at sea),
- Biodegradation of the oil after seven days at sea,
- Interaction of spilled oil with suspended solids at various concentrations,
- Adhesion of the oil to feathers,
- Emulsification of the oil,
- Dissolved fractions of the oil after seven days at sea,
- Ecotoxicity to four marine species,
- Adhesion to three types of seaweed, and
- Adhesion to various shoreline types.

The behaviour and nature of the impact of MGO is relatively well known from several decades of research and also from model validation studies.

With regard to the spill modelling, uncertainties have been identified (Table 12.15) and while their potential to materially alter the outcome of the modelling has been considered, it is acknowledged that improvements in the modelling design could increase accuracy of quantification of the impact. The confidence assessments for each scenario are described in Table 12.16.

The seasonal distribution of potential receptors in the NFB is reasonably well understood but further research is required to improve our knowledge of species distributions, and these are acknowledged as data gaps. The Gap Analysis Programme (GAP) conducted research to fill some of these knowledge gaps. Some receptors, especially seabirds (see Wiese, *et al.,* 2001), are known to congregate around vessels (including O&G installations) at-sea, which places artificially higher numbers of receptors in close proximity to sources of oil spills. Surveys are required to assess the influence of project vessels and activities on seabird abundance within the Sea Lion Field (Chapter 15).

Table 12.15: Oil spill uncertainties

Uncertainty	Description
Release volumes	Well blow-outs are extremely rare events that are often controlled within a matter of days using subsea intervention techniques or by the well 'bridging' over and restricting flow. The assumed total duration for the well blow-out in this EIS is 21 days, which is the time required to mobilise and install a capping device and is considered be the worst-case blow-out duration. The inventory loss scenarios that have been considered in this EIS are also extremely rare events. The crude inventory loss scenario was modelled as being the worst possible case of inventory loss whereby all tanks available on the FPSO for crude storage are discharged to sea, as well as two tanks from the offload tanker. In the extremely rare event of this type of spill, it is very unlikely that the complete inventory would be discharged as has been modelled here.
Oil characterisation and behaviour	The properties of the Sea Lion crude, based on the CEDRE testing (CEDRE, 2017), along with input from oil weathering experts, has been used in the modelling predictions and the risk assessment procedures. The OSCAR model is primarily designed to predict physical behaviour for Newtonian fluids which includes the majority of crude oils. As above, choices have been made within the hydrocarbon characterisation and weathering parameters to allow as close a match as possible between the model algorithms and the expected non-Newtonian behaviour of the wax. The outputs appear to be consistent with expectations based on examining intermediate model steps and the overall outputs.
Metocean conditions	The metocean dataset covers three years. This includes a wide range of weather conditions and the modelling results consistently show a tendency for dispersion to the north-west of the site. However, the currents do move in all directions at different times and deposition is locally variable due to the short nature of each release. During operations a real time offshore hydrodynamic model covering 3-day detailed current and wind forecasts will be run and available in the event of a spill.
Model predictions after the oil has been at sea for a long period of time	It is normal to run scenarios for the entire duration of a blow-out, and for some time following an inventory release, to determine the behaviour and location of oil before taking a view on whether this poses a risk to receptors. There is uncertainty around the fate of oil masses in the long term (several months), given its apparent buoyancy and stability in laboratory tests. Overall, the interpretation of results at long timescales should be done with caution and experience. In general, the model results may exaggerate the apparent impact of dispersed oil.
The performance of containment and recovery equipment	*In situ* performance is uncertain and could affect residual impacts post-response (positively or negatively) particularly for larger spills. This can be further investigated by pursuing industry trials and potentially designing site-specific trials.

Table 12.16: Confidence assessments

Scenario	Description	Confidence
1: Subsea well blow-out	There are many uncertainties and assumptions associated with the modelling of oil spills, both in terms of the properties of the oil and the environmental conditions (currents, wind and wave action) that influence its dispersion. The modelling component of the oil spill risk assessment has used the highest resolution metocean data sets available, as well as direct inputs from oil testing to replicate Sea Lion crude parameters, which provide the best possible basis for predicting oil	Due to the uncertainties associated with major accidental events, the confidence in the significance of the
2: FPSO inventory loss		

Scenario	Description	Confidence
3: Crude transfer spill	behaviour at sea. However, there is always an inherent uncertainty when predicting the fate and behaviour of oils using hindcast winds and currents derived from hydrodynamic models. The sensitivities of many of the environmental receptors to a spill vary due to seasonal changes in their distribution, and a spill could potentially happen at any time of the year. Wherever possible, worst-case scenarios have been used to ensure that the potential impacts are not under-estimated.	risk presented in this assessment is '**Uncertain**'.
4: MGO inventory loss	The modelling component of the oil spill risk assessment has used the highest resolution metocean data sets available, which provide the best possible basis for predicting oil behaviour at sea. However, there is always an inherent uncertainty when predicting the fate and behaviour of oils using hindcast winds and currents derived from hydrodynamic models. The volatile nature of MGO fuel means that spills will evaporate, disperse and biodegrade relatively rapidly, and the impact will be localised and short-lived. The exact nature and extent of the impacts will depend on the concentration of environmental receptors in the immediate vicinity of the MODU / FPSO at the time of a spill, which is not possible to predict with precision. The MODU / FPSO itself will influence the distribution of some seabirds and may also influence the distribution of some marine mammals and their prey.	The confidence in the impact assessment of MGO spills on the marine environment is '**Probable**'.
5: MGO bunkering spill		

12.1.10.1.1 Monitoring required

Seabird and Marine Mammal Observers (SMMOs) will be used on support vessels (most likely the FPSO's support vessels) and the possibility of a collaborative survey with Falkland Islands Fisheries Department (FIFD) will be investigated.

The development of a seabird distribution monitoring programme over several years aimed at improving understanding of species-specific distribution patterns will be established, potentially in collaboration with FIFD.

Once production has commenced, the modelled flow rates will be compared with actual flow rates. If the actual flow rates are higher than predicted, the modelling exercises will be re-run with the revised parameters.

The spill modelling and hydrodynamic data will be used to develop a means of forecasting spill trajectories pre-operation to enable rapid and targeted response in the event of a spill.

Detailed monitoring requirements will be confirmed. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Phase 1 & 2 Environmental Monitoring and Management Plan (EMMP) (Chapter 15).

12.1.11 Offsetting

Neither of the scenarios considered are likely to occur during the duration of project. Offsetting is therefore not considered appropriate for this type of unplanned event. Should a serious event occur, it is expected that remediation will be part of the final stages of the spill response process and subject to discussion with the authorities and stakeholders.

12.1.12 Findings summary

Table 12.17: Summary of the risk assessment for all oil spill scenarios

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
Subsea well blow-out	Scenario 1: Subsea release of oil	Impact to water quality and lethal and sub-lethal toxic effects on Plankton	Accidental	1, 2a, 2b & 3	Moderate	Moderate	Unlikely	**Low (6)**	**n/a**	**Uncertain**	**Industry-standard:** Use of standard operating procedures, Compliance with OMS and Drilling Management System, SECE Register and performance standards, Primary and secondary well control, Development and implementation of the OPEP, and Use of a well capping device. **Project-specific:** None proposed.
		Impact to sediment and lethal and sub-lethal toxic effects on Benthic communities	Accidental	1, 2a, 2b & 3	Very Low	Serious	Unlikely	**Low (6)**	**n/a**	**Uncertain**	
		Lethal and sub-lethal toxic effects on Fish and squid	Accidental	1, 2a, 2b & 3	Moderate	Moderate	Unlikely	**Low (6)**	**n/a**	**Uncertain**	
		Impact on fisheries from tainting of fish and contamination of fishing grounds	Accidental	1, 2a, 2b & 3	Very High	Serious	Unlikely	**Moderate (10)**	**Moderate (10)**	**Uncertain**	
		Plumage contamination and oil ingestion by Seabirds	Accidental	1, 2a, 2b & 3	Very High	Serious	Unlikely	**Moderate (10)**	**Moderate (10)**	**Uncertain**	
		Skin contamination and ingestion of toxins by marine mammals	Accidental	1, 2a, 2b & 3	High	Moderate	Unlikely	**Moderate (8)**	**Moderate (8)**	**Uncertain**	

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
		Impact on coastal ecology	Accidental	1, 2a, 2b & 3	High	Moderate	Unlikely	**Moderate (8)**	**Moderate (8)**	**Uncertain**	
		Negative publicity impacting tourist numbers	Accidental	1, 2a, 2b & 3	High	Serious	Unlikely	**Moderate (10)**	**Moderate (10)**	**Uncertain**	
Catastrophic loss of the FPSO	Scenario 2: Loss of the full FPSO crude oil inventory to surface	Impact to water quality and lethal and sub-lethal toxic effects on Plankton	Accidental	2a, 2b & 3	Moderate	Moderate	Very Unlikely	**Very Low (3)**	**n/a**	**Uncertain**	**Industry-standard:** SECE Register, OMS and performance standards, A 1,275 m radius exclusion zone, An ERRV vessel, AIS and Radar surveillance, Radio broadcasts, and Development and implementation of the OPEP. **Project-specific:** None proposed.
		Impact to sediment and lethal and sub-lethal toxic effects on Benthic communities	Accidental	2a, 2b & 3	Very Low	Serious	Very Unlikely	**Very Low (3)**	**n/a**	**Uncertain**	
		Lethal and sub-lethal toxic effects on Fish and squid	Accidental	2a, 2b & 3	Moderate	Moderate	Very Unlikely	**Very Low (3)**	**n/a**	**Uncertain**	
		Impact of fisheries from tainting of fish and contamination of fishing grounds	Accidental	2a, 2b & 3	Very High	Serious	Very Unlikely	**Low (5)**	**n/a**	**Uncertain**

12.2.1 Introduction

The project activities within Berkeley Sound are limited to the relatively short periods of time when the Sound will be utilised as a sheltered operational area for Large Transport Vessels (LTVs) supporting the offshore installation activities. The main activities during this time will be transit to the location and laying anchor, followed by the transfer (i.e., heavy lift) of subsea structures and materials to installation vessels which will relay them to the Sea Lion location.

As a result, the only credible oil spill scenarios are associated with fuel oil releases.

Note: oil spill waste and the procedure for dealing with oil spill clean-up waste is described in Section 10.10.2.2.3.

12.2.1.1 Relevant legislation

The legislation relevant to inshore oil spills is as described in the offshore oil spill chapter (Section 12.2.1.1), with details provided on the requirements of the project-specific OPEP, the Falklands NOSCP and the PON 8.

12.2.1.1.1 Inshore Oil Spill Strategy

An Inshore Oil Spill Strategy for the Sea Lion Development was developed by the previous operator (Premier, 2017d), which identified the essential components of spill response for the project. Navitas has prepared a preliminary Oil Spill Emergency Plan (OPEP) that will be submitted as a standalone document. The OPEP outlines the organisational responsibilities, actions, reporting requirements and resources available to ensure the effective and timely management of an accidental fuel oil spill and will be compatible with the Falkland Islands' NOSCP. Additional information regarding the NOSCP can be found in Section 12.1.1.1.1. The preliminary OPEP will be updated so that it contains specific operational information such as contact details and detailed action lists for personnel prior to the commencement of operations.

12.2.2 Sources of potential inshore oil spills

During the subsea installation stage of the Sea Lion Development Phase 1 & 2, Berkeley Sound will be utilised as a sheltered operational area for anchored LTVs supporting the offshore installation activities for the storage and transfer (i.e., heavy lift) of subsea structures and materials to installation vessels. Ship to ship diesel bunkering of the installation vessels and LTVs will also be undertaken within Berkeley Sound.

When considering the inshore activities and the sources of spills, it is necessary to consider both:

- Accidental event categories, and
- Differing fuel oil spill scenarios, e.g.:
  - Ship-to-Ship (STS) fuel oil bunkering activities, and
  - Vessel incidents (e.g., collisions, or drift grounding incidents).

A worst-case assumption for LTV fuel inventory was used as the input to inshore oil spill modelling. Table 12.18 gives examples of vessel fuel inventories.

Table 12.18: Potential maximum hydrocarbon inventories

Source	Example Vessel	Inventory	Volume / Type
Large Transport Vessels (LTVs)	Jumbo Jubilee	Marine Gas Oil (MGO)[1]	1, 400 m^3
Offshore Construction Vessels (OCVs)	Severn Arctic	MGO[2]	3,700 m^3
Platform Supply Vessel (PSVs)	Pacific Leader	MGO	820 m^3
Third-party vessels	Jigger	Diesel tanks	600 m^3
	Fuel bunker	Marine Diesel Oil (MDO) / MGO [2]	1,000 m^3
Workboat	n/a	Diesel Tanks	1 m^3

[1] While the LTV may be equipped to carry Intermediate Fuel Oil (IFO) as well as Marine Gas Oil (MGO) (as in this example), Navitas will only store and use MGO fuel on project vessels.
[2] MGO, marine diesel and diesel are available in a number of different forms with similar properties and all represent a light, dispersible and evaporative fuel.

12.2.2.1 Accidental event categories

In this assessment, accidents are defined as unplanned events with the potential to cause a release of MGO.

Spills from the anchored LTVs can result from a number of accidental events, including:

- Fuel bunkering operations, and
- Vessel collision.

12.2.2.1.1 Fuel bunkering operations

While all industry-standard safeguards will be in place (Section 12.2.5), there is the potential for spills of diesel to occur during bunkering operations. Such spills would most likely be small as the bunkering process would cease as soon as any leak or spill was detected.

12.2.2.1.2 Vessel collision

Vessel collisions can occur, for example, between the LTV and installation vessel, or with a third-party vessel (e.g., a jigger). The collision risk is considered to be the same for each type of vessel interaction.

12.2.2.2 MGO spill scenarios

The credible inshore MGO spill scenarios are associated with fuel oil releases from:

- Ship-to-Ship (STS) fuel oil bunkering activities, or
- Vessel incidents (e.g., collisions, or drift grounding incidents).

For vessels going about normal marine activities (including project vessels), spill planning and response are typically matters of Merchant Shipping regulation, and spill planning and response for this situation is addressed in detail in the NOSCP (FIG, 2022b). In choosing the scenarios below for the EIS, consideration was given to situations where spill risk is significantly different to normal harbour operations as a result of the project activities. Inshore, the mooring of LTVs in Berkeley Sound for months at a time presents an unusual risk, and two spill scenarios have been identified to help assess the additional risks presented. The use of other project vessels intermittently tending to the LTVs in Berkeley Sound Harbour or using Stanley Harbour is not significantly different to the normal daily

business of those facilities which are operated for vessel traffic under the Harbour Master[ibid] and which are within the scope of the NOSCP.

The two identified fuel spill scenarios, discussed further below, potentially resulting from Navitas' planned operational activities in Berkeley Sound, include:

- Scenario 1: Loss of fuel during a bunkering incident, and
- Scenario 2: Total inventory loss from an LTV as the result of a collision incident.

12.2.2.2.1 Scenario 1: 10 tonne (12m^3) MGO Bunkering Spill

A review of historic oil spill incidents suggests that the accidental release of MGO during a bunkering operation is the most likely incident to occur as a result of Navitas' planned operations within Berkeley Sound (though still a very unlikely scenario).

A worst-case release of 10 tonnes was selected to determine the consequences of a bunkering incident.

12.2.2.2.2 Scenario 2: 1,200 tonnes (1,400m^3) release of MGO from LTV due to vessel collision

This scenario was identified as the potential worst-case in terms of the volume of hydrocarbon loss into Berkeley Sound. The only credible event that could cause such a release is from a collision with another vessel (e.g., during a period of low visibility). To illustrate the outer envelope, in terms of spill response the modelling assumes that the inventory is lost over a three hour period.

12.2.3 Potential receptors

The ENVironmental Impact IDentification (ENVIID) workshop was used to identify those receptors for which the risks of inshore MGO spills warranted further investigation (Chapter 9). These include:

- Water quality and plankton (Section 7.4.1),
- Marine flora (Section 7.4.2),
- Sediment quality and Berkeley Sound benthic communities (Section 7.4.3.3),
- Fish and squid in Berkeley Sound (Section 7.4.4.3),
- Birds in Berkeley Sound (Section 7.4.5.3),
- Marine mammals in Berkeley Sound (Section 7.4.6.3),
- Coastal communities (Section 7.6),
- Fisheries (Human population) (Section 7.7.3.2.1), and
- Tourism (Human population) (Section 7.7.4.6.1).

These receptors may be impacted upon as they either exist in, or spend time in, the area influenced by fuel oil that might be accidentally released into the marine environment.

12.2.4 Characterising and quantifying the risk and potential impacts of inshore MGO spills

When characterising and quantifying the impacts of MGO spills, it is necessary to consider the following:

- Influencing factors:
  - Summary of MGO properties and its anticipated behaviour at the shoreline, and
  - Interactions with the kelp forests.
- The nature of the impact on each of the receptors,
- The frequency of occurrence of accidents and spills,

- Oil spill modelling methodology:
  - The OSCAR model,
  - The modelling approach inshore,
  - Release parameters,
  - Thresholds of significance, and
  - Understanding the model.
- Spill modelling results for:
  - Scenario 1: 10 tonne MGO bunkering incident, and
  - Scenario 2: 1,200 tonnes of MGO due to LTV collision with non-project vessels.
- Oil fate predictions.

12.2.4.1 Influencing Factors

Over and above the details provided in the offshore oil spill chapter (Section 12.2.4.1), additional factors that may influence the behaviour of MGO spills in *inshore* waters include:

- Inshore vessel MGO properties, and
- The potential for interactions with kelp forests.

12.2.4.1.1 Inshore vessel MGO characteristics

The physical characteristics of MGO are given in Table 12.19. MGO contains relatively light hydrocarbon compounds with a high fraction of aromatics and will readily spread in the marine environment where it will change under the processes of dissolution, evaporation and dispersion (Section 12.1.4.1.1.2). MGO spreads very quickly to a thin film of rainbow and silver sheens and although it disperses quickly, MGO will:

- Adhere to surfaces, fur and feathers,
- Penetrate substrates relatively easily,
- Release an iridescent / silvery sheen on the surface of the water, and
- Will continue to flow readily even at very low temperatures.

Table 12.19: Summary of Typical Fuel Physical and Environmental Properties

Oil type	API (°)	Specific Gravity	Viscosity (cP)	Pour point
MGO (typical)	36.4	0.843-0.86	3.9 cP at 13 ºC	-36 °C
Response	**Surface oil risks**	**Adhesion risk**	**Sediment risks**	**Water column risks**
Limited containment and recovery possible, dispersant ineffective	Significant, short-term sheen	Short-term	More extensive contamination inc. aromatics	Short-term, high

12.2.4.1.2 Fuel oil interactions with kelp forests

It is important to consider the potential for inshore fuel oil spills to interact with kelp for a number of reasons:

- Kelp can promote bio-remediation of certain pollutants, and
- Kelp can impede the spread, and the recovery, of oil.

12.2.4.1.2.1 Kelp as a bioremediation

There is evidence from laboratory studies that kelp may play an important role in the removal of PAHs from the coastal marine environment. Wang and Zhao (2007) found that the brown seaweed *Laminaria japonica* was able to take-up and metabolise two PAHs (phenanthrene and pyrene). This biodegradation appears to be a rapid process and concentration dependent.

At a PAH concentration level of 0.1 mg/l, *Laminaria japonica* tolerated the contamination and survived well with >90 % phenanthrene and pyrene removed, and subsequently degraded, over a two week period. The metabolism of phenanthrene and pyrene in seaweed tissues was carried out mainly by the enzyme-oxidation process converting PAHs to less or non-toxic forms of these compounds. The authors of this study suggest therefore, that, at lower contamination levels, the seaweed could play a role in removing PAHs and possibly other organic pollutants from seawater, thus serving as an 'environmentally-friendly' bioremediation system.

12.2.4.1.2.2 Kelp as a barrier to oil spread and clean-up

Kelp has the potential to impede the spread and the clean-up of fuel oil spills by slowing the progress of fuel oil towards the shoreline, trapping it close to the shoreline, impeding vessels, and dampening swell, thus reducing the break-down and dispersal of oil along the shore through reduced wave-action.

The retention of oil by kelp soon after it is spilled may lead to higher impacts on marine organisms in the immediate vicinity, due to the release of the water-soluble fractions.

12.2.4.2 The nature of the impact on each of the different receptors

The nature of the impact of hydrocarbons (both crude and fuel oils) on the majority of the receptors, which may be affected by an oil spill has already been described in the offshore oil spill chapter (Section 12.1).

However, the potential for inshore fuel oil spills necessitates the additional consideration of:

- Marine flora (kelp),
- Berkeley Sound benthic communities,
- Inshore fisheries,
- Intertidal habitats, and
- Shoreline plants and invertebrates.

12.2.4.2.1 Marine Flora (Kelp)

Notwithstanding the fact that kelp can be a source of bioremediation with regard to the metabolisation of PAH's (Section 12.2.4.1.2.1 above), it should be noted that at higher concentration levels (e.g., >0.2 mg/l), the toxic nature of PAHs to the seaweed was significant, and resulted in serious damage and destruction to the kelp tissue (Wang and Zhao, 2007).

Nonetheless, 'real-life' oil spill incidents of fuel oil spills have not highlighted seaweeds as being particularly sensitive environmental receptors. Worldwide examples of the impact of fuel oils on kelp and other seaweeds are summarised in Table 12.20.

The confidence in the risk assessment for kelp (Section 12.2.6) will be considered 'uncertain' (Section 8.10, Section 12.1.10) as while tests on the impact of sea lion crude were carried out on North Sea analogues, no testing was carried out on Falkland Islands kelp species specifically.

It is recognised that MGO spills will impact upon other marine flora species (e.g., *Ulva pertusa*, Liu, *et al*., 2019), however, Navitas did not assess such other groups as very little is known about the taxonomy and therefore abundance and distribution.

Table 12.20: Case studies on the impact of oil spills on kelp communities

Historical spill	Nature of the impact
World Prodigy Oil Spill 1989 (Peckol, *et al.,* 1990) 922 tonnes of No.2 fuel oil (MGO)	Contamination of subtidal kelps *Laminaria saccharina* and *Laminaria digitata* occurred following this spill. Pre-spill measurements of condition, growth rates and pigment acclimation were compared with post-spill measurements, and there was no evidence that kelps were detrimentally affected by the oiling. Kelp densities were normal and no necrotic or bleached tissue was observed on any kelp in an oiled cove. Background growth rates and other parameters showed wide variation in the absence of oil. Lowest growth rates coincided with an unrelated algal bloom, which also caused high mortality of bivalves. It was concluded that the bay where the spill occurred was spared disaster because little fuel oil mixed into the water column.
Tamano oil spill, Maine, 1975 (USEPA, 1975) 182 tonnes Heavy Fuel Oil (HFO)	Following the spill, 46 miles of varied coastline was contaminated and subsequently cleaned. Of the two seaweed species investigated, *Fucus* sp. accumulated the oil to a much greater extent than *Ascophyllum* sp. Possible reasons put forward were the relative surface area, the lipophylic nature of the mucopolysaccharide substances on the fucoids and simply the degree of exposure related to the location of the seaweed. Oiled seaweed was harvested and was found to be an effective way of removing oil from the intertidal area. When re-surveyed some months following the spill, contaminated *Fucus* was found to have shed much of the oil that had become attached during the oiling incident. Fucoid algae and barnacles were lost from the shoreline and snails, whelks and limpets suffered narcosis.
Evidence from other spills	In Norway, *Laminaria digitata* grown in large concrete basins was continuously exposed to diesel oil for two years. With diesel oil at 130 µg/l, lengthwise growth was reduced by about 50 %. At the lower concentration of 30 µg/l there was no overall inhibition of growth. After two years of continuous exposure, the plants completely recovered during a subsequent oil-free growing season.

12.2.4.2.2 Berkeley Sound benthic communities

Benthic communities consist largely of sessile organisms that are unable to physically move away from areas contaminated by oil or other pollutants and may be affected by MGO releases in inshore waters. Invertebrates such as arthropods and molluscs are known to bioaccumulate hydrocarbons in their tissues (Section 12.1.4.2.3.2). Most of the literature detailing the impacts of hydrocarbon spills on inshore benthic communities refer to inshore crude spills (Glemarec and Hussenot, 1982; Dauvin and Gentil, 1990; Law and Moffat, 1993; Glegg and Rowland, 1996) (Section 12.2.4.2.2). However, the following case-studies illustrate the potential impacts on benthic communities of fuel oils and other pollutants:

- Stark *et al.* (2003) found that experimental contamination of marine sediments with hydrocarbons (diesel and lubrication oils) in Antarctic waters led to changes in recruitment and thus assemblage structure within benthic communities and that hydrocarbon contamination resulted in more severe effects than contamination with metals. This emphasises the potential for ecological switching (changes in community structure) following events that cause significant environmental impact.
- University of California (1971) describes the decimation of a small rocky cove by a 59,000 barrel spill of 'dark diesel oil'. Almost the entire flora and fauna succumbed to the spill, but the elimination of grazers allowed the profusion of giant kelp.

With MGO spills in inshore waters, there is a greater potential for oil to reach the sediments. On a 'balance of evidence' approach, a threshold concentration of 10 mg/kg in sediments for Total Petroleum Hydrocarbons (TPH) is considered a reasonable level below which concentrations would not be considered environmentally significant. For context, North Sea TPH sediment concentrations

have been reported as 10-120 mg/kg (Cefas, 2001) with the PAH component of the TPH concentrations ranging from 0.2 - 2.7 mg/kg.

12.2.4.2.3 Inshore fisheries receptors

The Falkland Islands are important for several commercially harvested fish species including Patagonian toothfish (*Dissostichus eleginoides*) and squid, comprising both Argentine short-finned squid (*Illex argentinus*) and loligo (*Doryteuthis gahi*) (Section 7.7.3.1.1). Loligo is the target species of the largest domestic fishery in the Falklands. Although fishing is not permitted within three nautical miles of the coast, the stock migrate into inshore waters. Loligo have a short lifespan (growing rapidly for one year before breeding and dying) and normally survive in only two cohorts, potentially making populations more vulnerable to short-term impacts e.g., during spawning. For many years their spawning grounds were thought to be associated with kelp beds. However, it is now recognised that there does not appear to be sufficient habitat to support the observed populations. Therefore, it is likely that squid also spawn in other habitat types but the location of their principle spawning grounds currently remain unknown. Squid and other molluscs are known to bioaccumulate hydrocarbons (such as PAH) in their tissues, which has potential human health implications. Section 12.1.4.2.3.2 provides further details regarding the impact of oil on squid.

Although the oil was crude oil rather than MGO, the oil spilled by the Braer in 1993 (Gulfaks) was a heavily biodegraded oil with high PAH levels and this resulted in elevated levels of PAH in both wild fish and farmed fish. However, this spill was considerably larger (84,000 tonnes) than the credible scenarios described here. In the Braer example, concentrations of PAH in wild fish fell rapidly from a maximum of 2,650 mg/kg wet weight to reference concentrations of less than 40 mg/kg over several months, by which time there was also an absence of tainting.

12.2.4.2.4 Intertidal habitats

This section is informed by a review of the impacts of oil spills on shorelines by IPIECA (1995).

The fate of oil that reaches the shoreline is not only determined by the properties of the oil but also the topography of the shore and exposure of the oil to wave and tidal energy. For example, stranded oil that is exposed to heavy wave action is unlikely to remain on the shore for long. However, where oil strands on sheltered coasts with limited water movement it could persist for several years. Penetration of oil in sediments depends on a number of factors such as porosity (sediment type and grain size), the depth of the water table, the viscosity of the oil and the presence of burrowing animals. Once contaminated, oil in the subsurface layer can be persistent.

The characteristics of the shoreline around the Falkland Islands, and the behaviour of oil were used to generate an Environmental Sensitivity Index (ESI) that classifies shores according to the likely persistence of oil. The ESI for Berkeley Sound is presented in Section 7.6.3. (Table 12.21) and summarises the general features of shorelines in relation to the potential impact from oil spills. The greater the ESI number, the greater the potential for oil persistence.

During the 2018 coastal bird surveys carried out in Berkeley Sound, observations of typical Falkland Islands shoreline types were recorded and given a classification index for the purposes of oil spill planning that parallels the IPIECA (2011) system of Environmental Sensitivity Indexing. The ESI data is used in the oil spill modelling and improves understanding of the mitigation measures for oil spill response and will inform the more detailed Oil Pollution Emergency Plan (OPEP) that will follow approval of the project. An example of shoreline type 1A, the most common type in outer Berkeley Sound, is shown in Figure 12-44.

Table 12.21: General features of shorelines that influence their potential susceptibility to oil spill impacts, as classified on the ESI scale

ESI	Shoreline description
1	Exposed rocky shores, steeply sloping. Oil is typically held offshore by reflecting waves. Any oil deposited is rapidly removed by wave action. Impacts on intertidal communities are typically short-term, unless acute exposure of a fresh light oil product causes high mortality.
2	Exposed wave-cut platforms in bedrock. Shelf or platform of variable width and gentle slope. Often backed by steep scarp, sometimes with sediment at base. Pools and crevices are common, possibly with some loose gravel. Oil will not adhere to the platform, but may accumulate among gravel at the high tide line. Persistence is usually short-term.
3	Fine- to medium-grained sand beaches. Flat to moderately sloping and hard packed. Wrack may accumulate along the strandline. Oil may cover large areas but will lift off the lower beach and become concentrated along the upper intertidal zone. Oil may penetrate sand or become buried and there may be a decline in sediment fauna. These beaches are among the easiest to clean.
4	Course-grained sand beaches. Moderate slope of soft sediment. Sediment fauna is limited. Sediment is too soft for vehicles. Oil may cover large areas, but will lift off the lower beach and become concentrated along the upper intertidal zone. Oil may penetrate sand or become buried to depths greater than 1 m and there may be a decline in sediment fauna.
5	Mixed sand and gravel beaches. There may be zones of mobile sand, pebbles or cobbles, and distribution may change. Fauna and flora is generally limited, except on the more stable substrata. Oil may cover the whole beach, but will lift off the lower beach and become concentrated along the upper intertidal zone. Oil may penetrate sediment or become buried. Asphalt pavement may form in sheltered locations.
6	Gravel beaches, ranging from pebbles to boulders. Can be steep with wave-built berms. Fauna and flora is generally limited except on the more stable sub-strata on the lower beach. Stranded oil is likely to penetrate deeply, can be pushed over the high tide line and can be very persistent. Asphalt pavement may form in sheltered locations. Potential for chronic oiling.
7	Exposed tidal flats. Broad, flat areas of sand with some mixed shell or mud. Usually in tidal inlets. Water-saturated except on higher ridges. Can have dense sediment life and be important for wetland birds. Oil does not adhere to wet sediment, but accumulates at the high tide line and may penetrate at the tops of ridges. There may be a severe decline in sediment fauna.
8	Sheltered rocky shores. Variable permeability depending on substrata. Can have high densities of attached fauna and flora. Oil will adhere to rough surfaces along the high tide line, but not on wet lower shore surfaces. Oil will penetrate loosely packed angular rubble with potential for long-term persistence.
9	Sheltered tidal flats. Soft mud, with some sand and shell. Frequently backed by marshes. Can have dense sediment life and be important for wetland birds. Oil does not adhere to wet sediment, but accumulates at the high tide line and may penetrate burrows. Potential for deposition of contaminated sediments. There may be a severe decline in sediment fauna.

ESI	Shoreline description
10	Saltwater and brackish-water marshes. Temperate and subtropical wetlands dominated by marsh plants. Sediments are organic-rich muds, except on the edge of tidal channels where they may be sandy. Abundant flora and fauna. Oil adheres to emergent vegetation. Heavy oil coating restricted to outer fringe of marsh, but lighter oils may penetrate more deeply. Medium and heavy oils do not penetrate wet sediments, but can pool in depressions. Light oils can penetrate the upper few centimetres. There may be a severe decline in flora and fauna.

Figure 12-44: Proposed local shoreline classification 1A, reference location as the north coast of Kidney Island

12.2.4.2.5 Shoreline plants and invertebrates

All intertidal species can potentially be affected directly or indirectly by oil contamination, but some are more susceptible and vulnerable than others. Organisms can interact with shoreline oiling in a number of ways. Direct physical oiling can smother plants and animals, which may interfere with filter feeding appendages. Prolonged exposure to oil may result in direct toxicity. However, tolerance to the toxic effects of oil varies considerably between organisms. For example, filter feeding bivalves can accumulate hydrocarbons in their tissues, which may take weeks or months to purge (e.g., USEPA, 1981). Although bivalves are able to tolerate high concentrations of hydrocarbons, there may be sub-lethal effects, such as reduced growth and reproductive capacity.

Limpets and other marine snails graze on algae and are regarded as one of the most sensitive groups of intertidal invertebrates to the acute toxic effects of oil (e.g., IPIECA, 1995). A small amount of fresh oil on a limpet's foot has a narcotic effect leading to the limpet falling from the rock, where it is then unlikely to survive. Impacts on the populations of these taxa, and the consequent effects on the

abundance of the plants and algae they feed on, have been described following many oil spill incidents. For these reasons, limpets are widely used as the focus of rocky shore monitoring programmes near oil facilities (e.g., SOTEAG).

Oil and diesel spills are known to modify macrobenthic assemblages at the intertidal zone (Zhou, *et. al*., 2019).

12.2.4.3 Oil spill modelling methodology

In order to assess the potential impacts of inshore oil spills on environmental receptors, the two MGO scenarios were modelled by Navitas using the OSCAR model. While there will be an OPEP in place, as is industry standard (Section 12.2.5), it is understood that Oil Spill Response (OSR) efforts are only modestly effective in the event of MGO spills. Therefore the modelling was carried out assuming no OSR effort in order to better understand the behaviour of any such spill and thus to inform the selection of optimal OSR equipment and strategy.

The main aims of the modelling were to understand the:

- Fate of the hydrocarbons in terms of the relative amounts dispersed, evaporated, beached, biodegraded and deposited in sediments,
- Probability of hydrocarbons on the sea surface or reaching the shore,
- Characteristics of hydrocarbons dissolved in the water column, and
- Overall likely transport of MGO at sea in terms of density, direction and time.

The following section summarises the key information to facilitate an appreciation and understanding of the inshore modelling results.

12.2.4.3.1 The OSCAR model

The OSCAR model used for the inshore MGO spill modelling is the same as that carried out for the offshore spill modelling (Section 12.1.4.3). The same approach to modelling using stochastic and deterministic modelling methods was used.

12.2.4.3.2 Release parameters and assumptions

As described in Section 12.2.2.2, two worst-case inshore MGO spill scenarios were modelled using the release parameters summarised in Table 12.22.

Table 12.22: Summary of the release parameters and assumptions used in the model run for each scenario

Scenario	Fluids discharged	Release volume (m^3)	Release duration	Release location	Release temp. (°C)	Release type	Model run duration	Worst-case assumptions
MGO release during bunkering	MGO	12	10 mins[1]	LTV anchorage	10	Bulk release	5 days	Worst-case shoreline oiling illustrated
Total MGO inventory loss - collision	MGO	1,400	3 hours[2]	LTV anchorage	10	Bulk release	5 days	Worst-case shoreline oiling illustrated

[1] A short duration representing a range of possible leak/pumping scenarios during bunkering.
[2] Estimated time for large volume to be displaced from tanks by seawater.

12.2.4.3.3 Understanding the model

The oil spill modelling utilised the two types of modelling approach previously described in Section 12.1.4.3, namely: stochastic modelling - carried out by running individual discharge scenarios multiple

times over different time periods (thereby utilising different wind and current conditions); and deterministic modelling - conducted over a particular time frame which was selected based on the results of the stochastic model results.

12.2.4.4 Modelling results

12.2.4.4.1 Modelling results - Scenario 1: 10 tonne MGO bunkering spill

Figure 12-45 shows the stochastic model for the probability of MGO on the sea surface above the threshold of 0.3 µm (a surface thickness threshold of 0.3 µm thickness corresponds to a rainbow sheen and at thicknesses below this value any sheen is unlikely to be visible) over a five day period. After 12 hours the MGO is typically no longer visible and therefore no longer amenable to response techniques such as enhanced natural dispersion (i.e., where the bow wave, propeller, or firefighting systems of a response vessel are utilised to break up the MGO into smaller fragments which are more susceptible to the effects of natural weathering).

As can be seen in Figure 12-45a generally the oil moves in an eastward direction towards the mouth of Berkeley Sound with a 40 – 70 % probability of impacting the sensitive areas of Cochon and Kidney Islands. Overall, the results show a relatively low probability (10 -20 %) that the oil will migrate in a south-easterly direction impacting the southern coastline of Berkeley Sound. This corresponds with the probable shoreline oiling results shown in Figure 12-45b as it shows the highest probable location of shoreline oiling is the southern coastline of Berkeley Sound, including Cochon and Kidney Islands. Coastline sensitivity mapping of the shoreline shows that the area of shoreline most likely to be impacted is characterised by rocky outcrops (of the kind shown in Figure 12-44 above). Rocky outcrops are recognised as high energy areas where weathering of spilt MGO is increased due to the abrasive action of seawater against the rock face breaking up the oil and increasing the surface area susceptible to natural weathering process. There is a low probability of oil reaching finer-grained sediments associated with the Volunteer Point beaches and with the beaches of inner Berkeley Sound, but the oil will be very dispersed by this point and is predicted to be below surface sheen thresholds.

The modelling suggests that MGO will reach the shoreline within 11 hours on average. In terms of seasonality, the analysis shows that in the months July - December there is a greater likelihood that the relatively small slick will pass straight out of Berkeley Sound without contacting the shore, although if it does reach the shore, the masses beached are consistently around seven tonnes.

It is predicted that 5 % (0.5 tonnes) of the MGO will reach the sediments, mainly near the point at which it first reaches the shoreline. Around 5 % (0.5 tonnes) of MGO will dissolve and present very transient high concentrations of MGO.

12.2.4.4.2 Modelling results - Scenario 2: 1,200 tonnes of MGO due to vessel collision with LTV

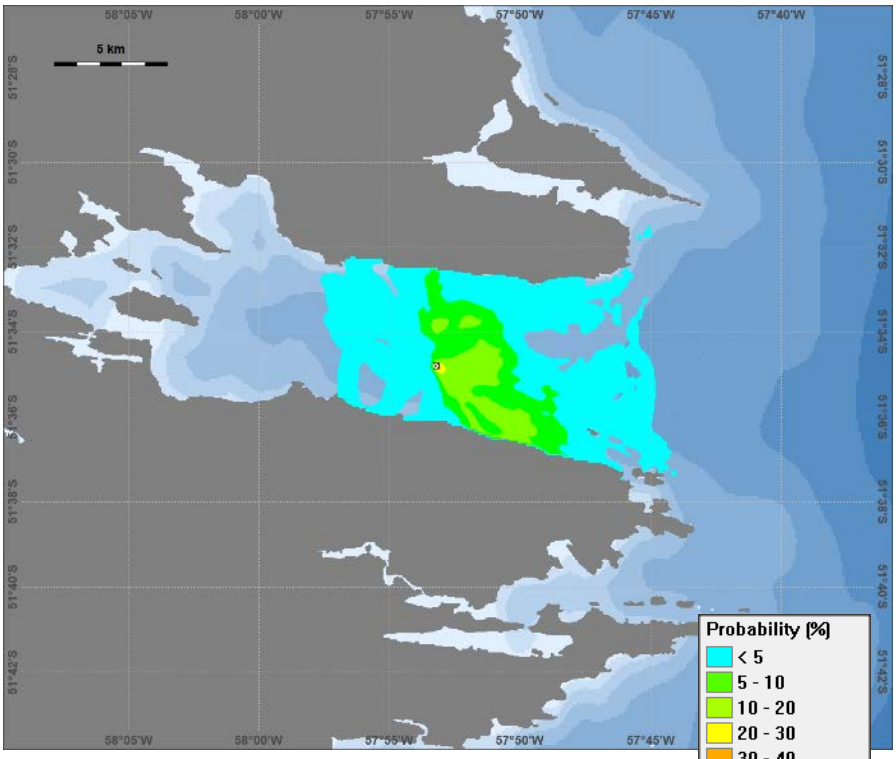
Figure 12-46 shows the stochastic model for the probability of oil on the sea surface above the threshold of 0.3 µm over a five day period.

As can been in Figure 12-46a the movement of the MGO is similar to that in Scenario 1 although, with the higher volumes in the Scenario 2 release, there is a moderate to high (50 – 70 %) probability of impacting the highly sensitive areas of Cochon and Kidney Islands which are known habitats for species of penguins and other vulnerable birds. Although the main shorelines affected there are not amongst the most sensitive types, they still include some areas of gently sloping finer sands that are more sensitive to oil pollution and will tend to retain oil. Similarly, a small amount of MGO could reach Volunteer Point (Section 7.5.2) although the sheen has dissipated after that much time.

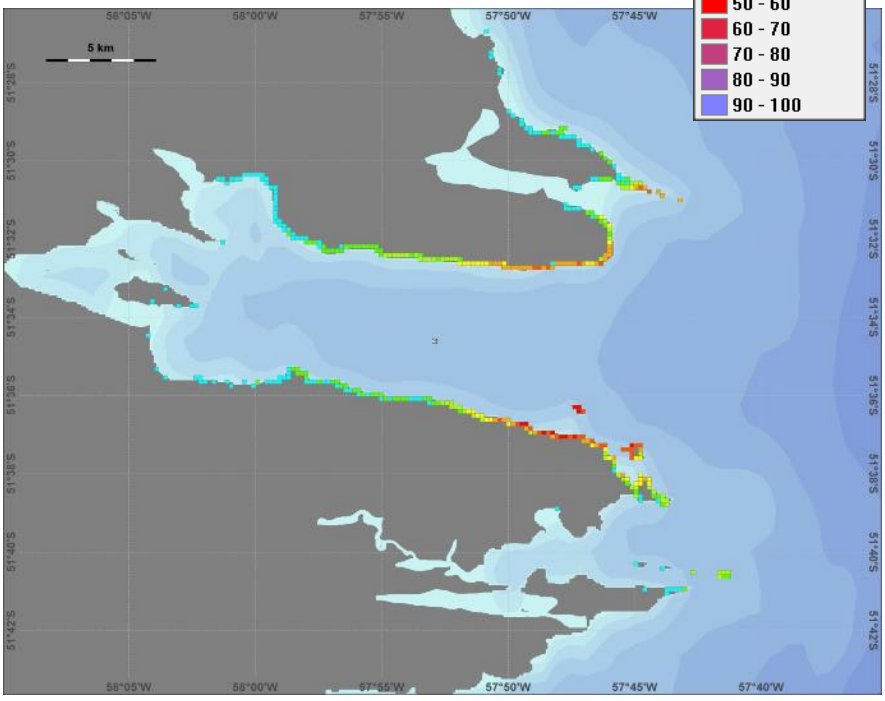
As with Scenario 1, the results also show a relatively high probability that the MGO will migrate in a south-easterly direction thus potentially impacting the southern coastline of the Berkeley Sound, including Cochon and Kidney Islands. This corresponds with the probable shoreline oiling results shown

in Figure 12-46b which shows the highest probable location of shoreline oiling along the southern coastline of Berkeley Sound. There is up to approximately a 40 % probability of oil reaching the finer-grained sediment beaches of Volunteer Point, and up to a 60 % probability of reaching beaches opposite Kidney Island. Should oil reach these beaches, typically after around 24 hours, it will be considerably dispersed although still in the form of a surface sheen and the shoreline and nearshore sediments would be contaminated. It is predicted that 5 % (60 tonnes) of the MGO will reach the sediments. Concentrations are predicted to peak locally in the sediments opposite Kidney Island (0.2 mg/kg), Cochon Island (350 mg/kg), and at Volunteer Point (2 mg/kg). The probability of reaching the beaches of inner Berkeley Sound to the west remains very low. There is a lower probability (20 – 40 %) of the MGO reaching areas on Cape Pembroke.

It is predicted that MGO will impact the shoreline within 11 hours on average, taking at least 6 hours to reach Cochon Island and 12 hours to reach Volunteer Point. An average of nine tonnes of oil is predicted to deposit on the shoreline, with a worst-case of 51 tonnes. In terms of seasonality, seasonal variations have very little effect on the fate of the MGO.

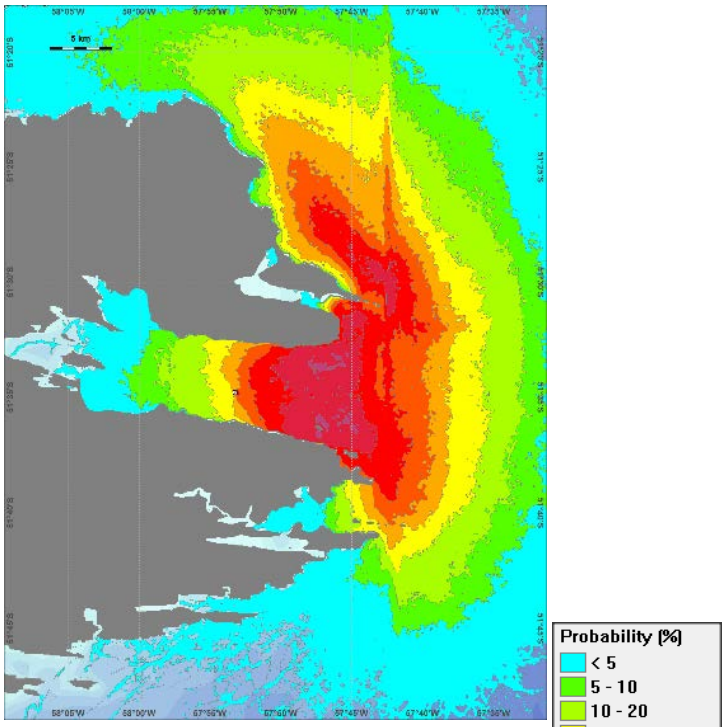


a) Probability of surface oil

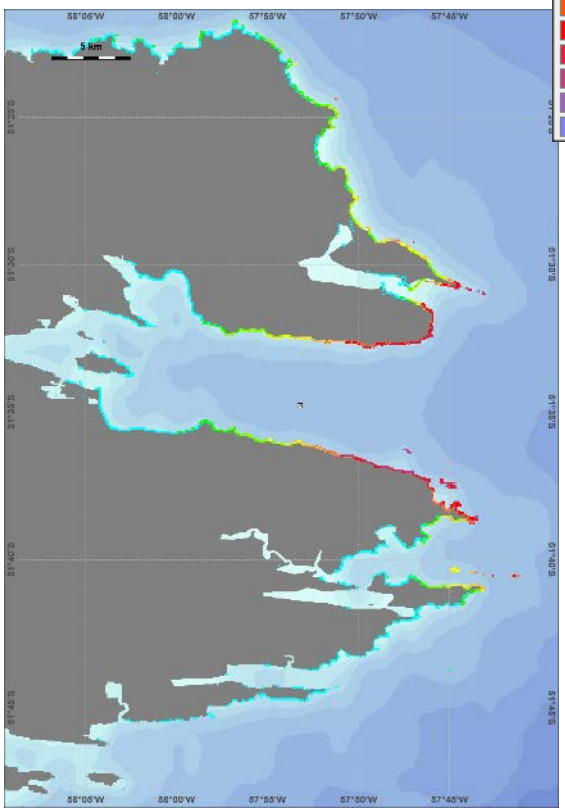


b) Probability of MGO on shoreline

Figure 12-45: Probability of surface contamination and shoreline oiling – Scenario 1



a) Probability of surface oil



(a) Probability of MGO on shoreline

Figure 12-46: Probability of surface contamination and shoreline oiling – Scenario 2

12.2.4.5 Oil fate predictions

The MGO spill modelling predicts that:

- Surface oil remains closely grouped until it is acted on by stronger, more complex currents exiting Berkeley Sound,
- There is up to a 70 % probability of a light sheen reaching Cochon and Kidney Islands (in Scenario 2), and
- MGO leaving Berkeley Sound will tend to continue north-east and out to sea. There is a small likelihood of some MGO returning to the north coast of East Falkland, and very little likelihood of oil reaching the shore south of Cape Pembroke.

With reference to the distribution of kelp beds (Figure 7-37), there is limited risk to kelp beds from the 10 tonnes diesel bunkering scenario. While the main channel of Berkeley Sound contains some kelp beds along the shorelines, these are not the highest density areas, and the 10 tonnes scenario is mainly confined to the main channel and is dispersed before it reaches the mouth of Berkeley Sound. In contrast, the full inventory loss of 1,200 tonnes is likely to lead to exposure of the high densities of kelp beds around Volunteer Point and also Cochon and Kidney Islands (Figure 7-37) to MGO. Much more of the sensitive shoreline types near Cochon Island and Volunteer Point are at risk in this scenario. As noted above in Section 12.2.4.1.2.1, one species of kelp (*Laminaria japonica*) has been shown to have bioremediation properties. It is, as yet, unknown whether Falklands kelp (*Macrocystis pyrifera*) has similar properties but it is possible kelp may play a role in bioremediation in spill events, particularly where contamination levels are lower. However, it should be noted that kelp also has the potential to impede the spread of oil and hamper clean-up operations (Section 12.2.4.1.2.2). This highlights the importance of collision prevention for the LTVs moored in Berkeley Sound and the provision of response equipment that can be mobilised quickly – MGO is predicted to take at least 6 hours to reach Cochon Island and 12 hours to reach Volunteer Point.

12.2.5 Industry-standard mitigation

In addition to the legislative requirements described in Section 12.2.1.1, a number of industry-standard measures exist in order to reduce the likelihood of accidental events occurring during inshore operations. These requirements are factored into the Phase 1 & 2 base-case as follows:

- AIS beacons and other navigation aids and charting / notifications maintained,
- Safety lighting as required,
- Operational limits defined and implemented,
- Development and implementation of bunkering procedures with fuel supplier to ensure corporate standards of operational safety are maintained, and
- Bunkering conducted within the 500 m LTV exclusion zone, or other defined area.

The equipment and strategies for Oil Spill Response (OSR) will be described within the project-specific OPEP (Section 12.2.1.1.1) and will be compatible with the Falkland Islands' NOSCP. However, the majority of the industry-standard mitigation measures defined within OPEPs are aimed at the prevention (avoidance) of spills in line with the hierarchy of risk reduction. As described above, the modelling was carried out assuming no OSR was in place in order to determine the most probable behaviour of any such spill, to inform the project-specific OSR and OPEP strategies that may serve to also lessen the severity of effects, and to take a precautionary approach.

Based upon the modelling outcomes in Section 12.2.4.4, the following section provides detail on the selection of OSR resources.

12.2.5.1 Selection of OSR resources (MGO)

Typically, spills of MGO spread quickly to form a very thin layer that is difficult to recover. For an incident of a small scale such as less than one tonne, recovery attempts are unlikely to be successful. As the volume of a release increases, the size and persistence of a thick oil layer increases and becomes more amenable to containment and recovery in the short-term. Further, in Berkeley Sound, the modelling shows that oil may well move to one or other shoreline and then move slowly along the coast giving some opportunity for a boom to be deployed off the shore to arrest the oil. However, the opportunities for deploying such a boom in Berkeley Sound are limited given the steep rocky sides along much of its length, as shown in Figure 12-44 above.

Navitas will maintain a set of OSR equipment at the supply base / TDF sufficient to respond to Tier 1 and 2 inshore oil spill events (Section 12.2.5.1) such as those described in this chapter. The equipment will be containerised and it will be able to be moved and deployed by a suitable fast response vessel to Berkeley Sound as necessary. This will contain a standard equipment set for dealing with MGO spills such as shore sealing booms, inflation booms and air pumps, mooring lines, water pumps and hoses, two skimmers on each offshore vessel, and an oil pump.

Dispersants are not proposed as marine receptors such as kelp are likely to be more affected by the chemicals and dispersed oil than by the oil remaining on the surface. If seabirds are at risk, then sheen can be minimised by using prop washing techniques to break up and disperse the surface layer, and this can be done more quickly and reliably than the application of dispersants. However, it should be noted that prop washing techniques can be hindered by kelp beds (Section 12.2.4.1.2.2) as found in some of the areas which may be affected e.g., Volunteer Point and Kidney and Cochon Islands (Section 12.2.4.5).

The OPEP will further detail how spill response will be managed within the framework of the NOSCP, as described in Section 12.1.1.1.1 of the offshore oil spill chapter.

12.2.6 Risk assessment

The following section draws on all the data described above to assess the risk of inshore oil spills. As with all risk assessments, it is necessary to consider first the potential impact of the event (i.e., 'Sensitivity of Receptor' x 'Severity of Effect') and then to consider the Likelihood of Occurrence of that event to establish the overall risk. The impact on each receptor is tabulated in each section below, and the likelihood of occurrence, which will be consistent within each scenario, is described as a whole.

The following assessments take account of all legislation and industry-standard and base-case mitigations described in Section 12.2.1.1 and Section 12.2.5 respectively. A summary of all the risk assessment outcomes is tabulated in Section 12.2.12, which shows the worst-case impact / risk for each activity and receptor.

12.2.6.1 Scenario 1: 10 tonne MGO bunkering incident spill

Diesel fuel is most often a light, refined petroleum product. Small diesel spills will usually evaporate and disperse naturally within a day or less, and OSR equipment would not be deployed. This is true for most spills even in cold water. However, 'marine diesel' (MGO) is a slightly heavier fuel oil that will persist longer when spilled. When spilled on water, MGO may form a thicker film of dull or dark colours (Section 12.2.4.1).

MGO spreads rapidly and also evaporates and dissolves or mixes with water, which means that containment and recovery is rarely very successful. MGO forms a significant short-term surface sheen. Birds and other animals may be initially affected *via* contact although the window is confined to a few days and diminishes rapidly. MGO has a relatively high proportion (5 %) of oil that dissolves in the

water column, resulting in a high but short-lived risk (Section 12.2.4.1.1). In the longer-term, sediment toxicity is more likely than with the other oil types modelled in this assessment.

12.2.6.1.1 Likelihood of occurrence

A review of historic oil spill incidents suggests that the accidental release of MGO during a bunkering operation is the most likely incident to occur as a result of Navitas' planned operations within Berkeley Sound. While there is little inshore data on spill size and frequency published to make a direct comparison, it is noted that for UK offshore waters in 2022 there were 188 oil spills reported in total from around 234 installations (OEUK, 2023b), which would each typically receive MGO more than once a month, in much more challenging conditions than Berkeley Sound. MGO formed a minority of the oil spilled and incidents involving more than 1 tonne of MGO are extremely rare.

Bunkering spills have occurred previously in the industry, and while failure of numerous operational controls would be required (e.g., procedural and engineering controls) on balance, the likelihood of occurrence is considered to be '**Unlikely**'.

12.2.6.1.2 Overall significance of the risk

A summary of the risk assessment for a 10 tonne spill of MGO in Berkeley Sound is presented in Table 12.23. While the *impact* of such an event to some of the receptors would be 'High', owing to the likelihood of such an event occurring, the worst-case significance of the *risk* posed by a 10 tonne MGO spill, with the base-case measures in place, is '**Moderate**' for fish and squid, human population (fisheries) ('**Moderate (8)**'), seabirds and marine mammals '**Moderate (10)**'.

Table 12.23: Summary of the impact assessment for a 10 tonne MGO spill at the LTV Mooring location, with base-case mitigation in place

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Water quality and plankton	Plankton show high seasonal and spatial variation in abundance and productivity, and it is expected that any effects will be greatest during summer when productivity is highest (Section 7.4.1.2.2). The planktonic lobster krill is known to be abundant within Berkeley Sound, and elsewhere in the Falklands, which attracts higher predators to feed on this resource. At other times, the area is less significant for zooplankton but is still considered highly productive. Therefore, the sensitivity of plankton is considered to be '**Moderate**'. An MGO spill would rapidly spread to cover a wide area. Although the volatile nature of MGO limits exposure time to receptors, MGO is highly toxic to marine organisms. As the impact would be local, temporary and reversible (due to immigration of planktonic organisms from unaffected areas), the severity of the effect of a 10 tonne spill of MGO on plankton has been assessed as '**Moderate**' Therefore, the significance of the impact on plankton is assessed as '**Moderate (9)**'.	**Unlikely**	**'Low (6)'**
Marine flora	Kelp forest is a widespread habitat around the entire coast of the Falklands archipelago but is relatively sparse within Berkeley Sound (Section 7.4.2). Kelp is a habitat forming species, and although undesignated this habitat is considered to be of national importance and therefore the sensitivity of the receptor is considered to be '**Moderate**'. Kelp is apparently reasonably tolerant of hydrocarbon pollution (Section 12.2.4.1.2). Modelling indicates that there is a low probability of oil reaching large areas of kelp forest. Any impact will be localised, short-term and rapidly reversible leading to a barely detectable impact on kelp taxa such that the severity of effect is considered to be '**Minor**'. Therefore, the significance of the impact is assessed as '**Moderate (6)**'.	**Unlikely**	**'Low (6)'**
Sediment quality and benthic communities	Berkeley Sound supports a diverse benthic fauna (Section 12.2.4.2.2) and includes habitats that could be considered to be biogenic and geogenic reefs congruent with habitats listed in UK Habitats Regulations (Section 12.2.4.2.4). It also forms part of the inshore pMMA. By nature, reef forming organisms are sessile and often filter feeders, and are therefore vulnerable to water borne pollutants. Additionally, recent testing of one benthic species indicated that relatively high concentrations of oil in sediments would impact benthic communities (Section 12.2.4.2.2) Although benthic habitats are undesignated within the Falklands, those found within Berkeley Sound are considered to be of national or local importance. The sensitivity of the benthic community is therefore considered to be '**Moderate**'. Most of the oil reaching the sediment does so in coastal waters. Although buoyant, MGO is more dispersible in water than other oil types. In addition, as it spreads into shallower waters the likelihood of adhering to fine grain particulate matter increases resulting in diesel deposits in the sediment. It is predicted that 5 % (0.5 tonnes) of the MGO will reach the sediments (Section 12.2.4.4.1), a higher proportion than for other oil types. Once in the sediment, MGO will persist as a source of toxic aromatics, such as PAHs. Additionally, about 5 % (0.5 tonnes) of MGO will dissolve, which will pose a	**Unlikely**	**'Low (6)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	locally high risk over the short-term, until the oil disperses. Contamination will be restricted to a local area and is temporary in nature. The severity of effect is considered to be '**Moderate**' due to the potential for localised reversible nature of the impact. The significance of impact on the benthic community is therefore assessed as '**Moderate (9)**'.		
Fish and squid	Loligo squid are known to spawn within Berkeley Sound although large aggregations of squid eggs have not been found to date. Overall, there is a great deal of uncertainty regarding where squid spawn and what areas should be considered as important spawning sites (Section 12.2.4.2.3). However, it is known that eggs and larvae of fish and squid are regarded to be more susceptible to pollution events than adults due to their immobility (Section 12.2.4.2.3). Given the uncertainty regarding the distribution of loligo spawning grounds, it is possible that a regionally important proportion of the population (1 % of biogeographic population) could fall within the zone of influence of the Phase 1 & 2 Development activity. Therefore, the sensitivity of fish and squid receptors to a 10 tonne MGO spill is considered to be '**High**'. Due to the properties of MGO (Section 12.2.4.1.1), the impact of a 10 tonne MGO spill on the water column will be high but very short-lived. Contamination associated with sediments will be more persistent. It is unlikely that adult fish and squid will be impacted directly but they could consume toxins *via* food. Direct toxic effects on fish and squid eggs and larvae could occur but the impact will be locally high, but short-term, and therefore the severity of the effect on fish is considered to be '**Moderate**'. The significance of the impact of a 10 tonne MGO spill on fish and squid is assessed as '**Upper Moderate (12)**'.	**Unlikely**	**'Moderate (8)'**
Human population (fisheries)	The loligo trawl fishery is the second largest (in terms of catch) in the Falklands and is therefore an important part of the Islands economy. The squid are caught off the coast of East Falkland, including waters adjacent to Berkeley Sound and they are known to spawn inshore (Section 12.2.4.2.3). Given the importance of these fisheries to the Falklands' economy, and the uncertainty over the extent of any impacts, a precautionary approach should be taken. Consequently, it is assumed that a 10 tonne spill would result in economic impacts for the fishing industry. Given that there have been spills of hydrocarbons within Berkeley Sound in the past and background levels of contamination are detectable (Section 12.2.4.2.3), the fishery is believed to have a moderate capacity to absorb change on this scale. However, a spill of this size would be unacceptable to a majority of stakeholders and therefore the sensitivity of the human population is considered to be '**High**'. Berkeley Sound has experienced similar sized spills of MGO in the past with no impact on local fishing grounds. Nevertheless, taking the precautionary approach, there is a chance that a 10 tonne MGO spill could result in the localised temporary closure of the fishing grounds due to potential tainting and contamination and therefore, the severity of the effect of an uncontrolled release on fisheries is considered to be '**Moderate**' Therefore, the significance of the impact on the human population *via* fisheries is assessed as '**Upper Moderate (12)**'.	**Unlikely**	**'Moderate (8)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Seabirds	At times, during the summer breeding seasons, more than 1 % of the biogeographic populations of several species (e.g., gentoo penguin and sooty shearwater) and species of IUCN 'Vulnerable' status (e.g., rockhopper penguin, white-chinned petrel) may be present. Species of local conservation concern (Falkland steamer duck) will be present year-round (Section 12.1.4.2.4.3). Therefore, the sensitivity of seabirds to the effects of a 10 tonne MGO spill, is considered to be '**High**'. A spill of 10 tonnes of MGO would rapidly spread to form a sheen throughout Berkeley Sound. Although the sheen will be short-lived due to natural break-down and evaporation, MGO has the potential to contaminate the feathers of any seabirds that come into contact with it. Further, diesel has greater potential than Sea Lion crude for impacts associated with toxicity (Section 12.1.4.2.4). The highest probability is for the MGO to move south-eastwards towards the breeding sites of the species mentioned above. A large proportion of the Falklands populations of sooty shearwaters and white-chinned petrels breed on Kidney Island. During the breeding season, these birds form huge rafts close inshore before returning to nest burrows at dusk. A 10 tonne MGO spill during the breeding season could impact a significant proportion of the regional population, which may have long-term implications for the populations of these species. The severity of the effect of a 10 tonne MGO spill on seabirds is therefore considered to be '**Serious**'. Therefore, the significance of the impact on seabirds is assessed as '**High (16)**'.	**Unlikely**	**'Moderate (10)'**
Marine mammals	Berkeley Sound experiences a seasonal presence of fin and sei whales (classified as IUCN 'Vulnerable' and 'Endangered') (Section 12.1.4.2.5) and the presence of several other species of local conservation concern (Peale's and Commerson's dolphins, South American sea lions and fur seals), as prescribed in the Falklands biodiversity action plan (Section 12.1.4.2.5). Although it is possible that MGO from a spill of this size will not come into direct contact with any marine mammals, this is not certain. Therefore, the sensitivity of marine mammals is assessed as '**High**'. Given the modest volatility of MGO, marine mammals could be susceptible to inhaling hydrocarbons upon surfacing to breath. Further, the coats of fur seals and sea lions that come into contact with oily sheens will become contaminated. This will result in a loss of insulation and direct ingestion while grooming. The potential for exposure is short lived (measured in days). However, as a worst-case the ingestion of MGO could have long-lasting implications for the individuals concerned and potentially the local populations. Therefore, taking a precautionary approach, the severity of effect of a 10 tonne MGO spill within Berkeley Sound on marine mammals is assessed as '**Serious**'. Therefore, the significance of the impact on marine mammals is assessed as '**High (16)**'.	**Unlikely**	**'Moderate (10)'**
Coastal habitats (terrestrial)	The coast of Berkeley Sound contains a wide variety of coastal habitats. The probability plots indicate that the north and south coasts of the outer Sound are more likely to be impacted than elsewhere. These shorelines are steep, rocky and subject to moderate wave action. Of greater concern are the coasts of the inner Sound and Volunteer Lagoon, which have high Environmental Sensitivity Scores due to the fine-grained sediments (Section 7.6), where oil is more likely to	**Unlikely**	**'Low (6)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	persist longest. Probability plots indicate that it is likely that the MGO will drift towards the National Nature Reserve of Cochon and Kidney Island (Section 12.2.4.5). The coastal habitat of these islands is important for all three of the Falklands endemic bird species (Cobb's wren, Tussac bird and Falkland steamer ducks). These are nationally designated sites and therefore the sensitivity of the receptor is considered to be '**High**'. Modelling predicts that under the prevailing environmental conditions MGO will travel towards the coast where it becomes trapped and sedimentation takes place. While a large proportion of the Berkeley Sound coast could be impacted, the nature of the MGO is such that this will be short-term and the severity of effect is therefore assessed as '**Minor**'. Therefore, the significance of the impact is assessed as '**Moderate (8)**'.		
Human Population (tourism)	There are unlikely to be significant impacts on local tourism from an incident at the scale of a 10 tonne MGO spill (see assessments above). However, media publicity may influence the experience and perceptions of tourists, which may then impact upon their propensity to visit. Given that there would be moderate capacity to absorb change in the aftermath of a small inshore MGO spill, the sensitivity of tourism is considered to be '**Moderate**'. Any negative impact from adverse publicity associated with an incident of this size would be short lived but may have a small short-term impact on the number of visitors. The severity of effect of a 10 tonne MGO spill in Berkeley Sound on tourism has been assessed as '**Minor**'. Therefore, the significance of the impact on tourism is assessed as '**Moderate (6)**'.	**Unlikely**	**'Low (6)'**

12.2.6.2 Scenario 2: 1,200 tonnes of MGO due to vessel collision with LTV

This scenario was identified as the potential worst-case in terms of the quantity of hydrocarbon spilled into Berkeley Sound. The only credible event that could cause such a release is from a collision with a vessel during a period of low visibility. To illustrate the outer envelope in terms of spill response, the modelling assumes that the inventory is lost over a three hour period. This is presented as a worst-case scenario.

12.2.6.2.1 Likelihood of occurrence

Of the measures described in Section 12.2.7, the following preventative measures are intended to make such an incident extremely unlikely:

- Clear manoeuvering and approach channel,
- Use of exclusion zones around LTVs, and
- Operational limits defined and implemented.

As a result, on balance, the likelihood of occurrence is considered to be '**Unlikely**'.

12.2.6.2.2 Overall significance of the risk

A summary of the risk assessment for a 1,200 tonne spill of MGO in Berkeley Sound is presented in Table 12.24. While the *impact* of such an event to some of the receptors would be 'High', owing to the likelihood of such an event occurring, the worst-case significance of the *risk* posed by a 1,200 tonne MGO spill, with the base-case measures in place, is '**Moderate**' for fish and squid, human population (fisheries) ('**Moderate (8)**'), seabirds and marine mammals '**Moderate (10)**'.

Table 12.24: Summary of the impact assessment for a 1,200 tonne MGO spill at the LTV Mooring location, with base-case mitigation in place

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
Water quality and plankton	The sensitivity of plankton is as described in Table 12.23 above and is considered to be '**Moderate**'. An MGO spill would rapidly spread to cover a wide area. Although the volatile nature of MGO limits exposure time to receptors, MGO is highly toxic to marine organisms. As the impact would be local, temporary and reversible (due to immigration of planktonic organisms from unaffected areas), the severity of the effect of a 1,200 tonne spill of MGO on plankton has been assessed as '**Moderate**' Therefore, the significance of the impact on plankton is assessed as '**Moderate (9)**'.	**Unlikely**	**'Low (6)'**
Marine flora	The sensitivity of kelp is as described in Table 12.23 above and is considered to be '**Moderate**'. Kelp is apparently reasonably tolerant of hydrocarbon pollution and the exposure timescales are far shorter here than described in Section 12.2.4.2.1. Modelling indicates that there is a moderate probability of oil reaching denser areas of kelp forest. Any impact will be localised, short-term and rapidly reversible leading to a barely detectable impact on kelp taxa. The severity of effect is therefore '**Minor**'. Therefore the significance of the impact is assessed as '**Moderate (6)**'.	**Unlikely**	**'Low (6)'**
Sediment quality and benthic communities	The sensitivity of the benthic community is as described in Table 12.23 and is considered to be '**Moderate**'. Modelling predicts that a relatively high proportion of MGO will reach the sediments (Section 12.2.4.4.2). Most of the MGO reaching the sediment does so in coastal waters. Although buoyant, MGO is more dispersible in water than other oil types. In addition, as it spreads into shallower waters the likelihood of adhering to fine grain particulate matter increases resulting in diesel deposits in the sediment. Without any OSR, it is predicted that 5 % (60 tonnes) of the MGO will reach the sediments, a higher proportion than for other oil types. Concentrations are predicted to peak locally in the sediments opposite Kidney Island (0.2 mg/kg), Cochon Island (350 mg/kg), and at Volunteer Point (2 mg/kg), compared with a potential effects level of 10 mg/kg. Once in the sediment, MGO will persist as a source of toxic aromatics, such as PAHs. Additionally, a significant fraction of MGO will dissolve, which will pose a locally high risk over the short-term, until the oil disperses. Contamination will be restricted to a local area and is temporary in nature. While OSR may reduce the volume of MGO in the water, the severity of effect is considered to be '**Moderate**' due to the potential for localised reversible nature of the impact. The significance of impact on the benthic community is therefore assessed as '**Moderate (9)**'.	**Unlikely**	**'Low (6)'**
Fish and squid	The sensitivity of fish and squid is as described in Table 12.23 above and is considered to be '**High**'. Due to the properties of MGO, the impact of a 1,200 tonne MGO spill on the water column will be high but short-lived. Contamination associated with sediments will be more persistent. It is unlikely that adult fish and squid will be impacted directly but they could consume toxins *via* food. Direct toxic effects on fish and squid eggs and larvae could	**Unlikely**	**'Moderate (8)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	occur but the impact will be locally high, but short-term, and therefore the severity of the effect on fish is considered to be '**Moderate**'. The significance of the impact of a 1,200 tonnes MGO spill on fish and squid is assessed as '**Upper Moderate (12)**'.		
Human population (fisheries)	The sensitivity of the human population is as described in Table 12.23 above and is considered to be considered to be '**High**'. Berkeley Sound has experienced spills of MGO in the past, although not at this scale, with no known impact on local fishing grounds. Therefore, taking the precautionary approach, there is a chance that a 1,200 tonne MGO spill could result in the localised temporary closure of the fishing grounds due to potential tainting and contamination and therefore, the severity of the effect of an uncontrolled release on fisheries is considered to be '**Moderate**' Therefore, the significance of the impact on the human population *via* fisheries is assessed as '**Upper Moderate (12)**'.	**Unlikely**	**'Moderate (8)'**
Seabirds	The sensitivity of the seabird populations is as described in Table 12.23 above and their sensitivity to the effects of a 1,200 tonne MGO spill, is considered to be '**High**'. A spill of 1,200 tonnes of MGO would rapidly spread to form a sheen throughout Berkeley Sound. Although the sheen will be short-lived due to natural break-down, and OSR equipment may reduce the overall volume of MGO in the water, MGO has the potential to contaminate the feathers of any seabirds that come into contact with it. The highest probability is for the MGO to move south-eastwards towards the breeding sites of, for example, sooty shearwaters and white-chinned petrels. A large proportion of the Falklands populations of sooty shearwaters and white-chinned petrels breed on Kidney Island. During the breeding season, these birds form huge rafts close inshore before returning to nest burrows at dusk. Even if strategic booms are deployed as part of the OSR, a 1,200 tonne MGO spill during the breeding season could impact a significant proportion of the regional population, which may have long-term implications for the populations of these species. Similarly, sensitive areas around Volunteer Point could be affected by the spill, although the effects of distance and dispersion will be higher. The severity of the effect of a 1,200 tonne MGO spill on seabirds is therefore considered to be '**Serious**'. Therefore, the significance of the impact on seabirds is assessed as '**High (16)**'.	**Unlikely**	**'Moderate (10)'**
Marine mammals	The sensitivity of marine mammals is as described in Table 12.23 above and is considered to be '**High**'. In addition to the effects of crude oil on marine mammals described in Section 12.1.4.2.5, the volatile nature of MGO is such that marine mammals are susceptible to inhaling hydrocarbons upon surfacing to breath. Further, the coats of fur seals and sea lions that come into contact with oily sheens will become contaminated. This will result in a loss of insulation and direct ingestion while grooming. The potential for exposure is short lived (measured in days). However, as a worst-case the ingestion of MGO could have long-lasting implications for the individuals concerned and potentially the local populations. Therefore, taking a precautionary approach, the severity of effect of a 1,200 tonne MGO spill within Berkeley Sound on marine mammals is assessed as '**Serious**'.	**Unlikely**	**'Moderate (10)'**

Receptor	Sensitivity of Receptor and Severity of Effect (Impact)	Likelihood of occurrence	Overall risk significance
	Therefore the significance of the impact on marine mammals is assessed as '**High (16)**'.		
Coastal habitats (terrestrial)	The sensitivity of the receptor is as described in Table 12.23 and is considered to be '**High**'. Modelling predicts that under the prevailing environmental conditions MGO will travel towards the coast where it becomes trapped and sedimentation takes place. While strategically placed OSR booms may reduce the volume of MGO reaching the coast, modelling (which does not consider OSR) predicts that an average of 9 tonnes of oil is predicted to deposit on the shoreline, with a worst-case of 51 tonnes (Section 12.2.4.4.2). While a large proportion of the Berkeley Sound coast could be impacted, the nature of the MGO is such that this will be short-term and the severity of effect is therefore assessed as '**Minor**'. Therefore, the significance of the impact is assessed as '**Moderate (8)**'.	**Unlikely**	**'Low (6)'**
Human Population (tourism)	Although there would be OSR activity to respond to the spill in areas frequented by tourists, and any tourists in the affected areas would be aware of the issue, there are unlikely to be significant impacts on local tourism from an incident at the scale of a 1,200 tonne MGO spill (see assessments above). However, media publicity may influence the experience and perceptions of tourists, which may then impact upon their propensity to visit. Given that there would be moderate capacity to absorb change in the aftermath of such a spill, the sensitivity of tourism is considered to be '**Moderate**'. Any negative impact from adverse publicity associated with an incident of this size would be short lived but may have a small short-term impact on the number of visitors. The severity of effect of a 1,200 tonne MGO spill in Berkeley Sound on tourism has been assessed as '**Minor**'. Therefore, the significance of the impact on tourism is assessed as '**Moderate (6)**'.	**Unlikely**	**'Low (6)'**

12.2.7 Project-specific mitigation measures

In addition to the industry-standard measures listed in Section 12.2.5, a number of project-specific measures will be implemented to reduce the likelihood of accidental events occurring during inshore operations and to mitigate against any impacts should releases occur. To eliminate the risk of potential collisions due to human error or dynamic positioning control system faults (which could result in a powered collision), both the LTV and installation vessel will be at anchor prior to heavy lifts commencing. Further mitigations to be used include:

- Dialogue with FIG on operating within the Harbour Management Plan, with operational limits defined,
- Speed limitations to minimise collision energies (Sea Lion Development vessels entering Berkeley Sound will be limited to eight knots),
- Watch keeping for errant vessels (in good weather) or radar monitoring (in bad visibility conditions),
- For bunkering operations, good practices as detailed in the Guidelines for Offshore Marine Operations (GOMO, 2013) will be followed to prevent accidental release of bunker fuel at source,
- LTVs vetted for double skinned fuel tanks, and
- Enhanced crew bunkering competency, including but not limited to:
  - Identified by Navitas' Offshore Bunkering Procedure and the Area Specific Operational Guidelines (ASOGs),
  - Achieved by a Hazard Identification and Risk Assessment (HIRA) once the marine contractor for the OSVs has been selected,
  - Verified by Job Safety Assessments and Tool Box Talks prior to each operation, and
  - Regular drills and Navitas' Audit and Assurance Procedure will assure crews achieve and retain the required level of competency.

12.2.8 Residual impacts and risks

While the initial risk assessment for the different oil spill scenarios indicates that the risks to many of the receptors are '**Low**' or '**Very Low**' (Section 12.2.6), this was primarily because the likelihood of the incidents occurring in the first place is '**Unlikely**'. However, as shown in the initial risk assessment sections above, the impacts of the spill, should they actually occur, ranged from '**Moderate**' to '**High**'. Nonetheless, neither the impact nor the likelihood of occurrence are likely to be changed by the project-specific mitigations such the overall risks remain the same as in the initial assessment. For ease of reading, the initial (and also residual) worst-case risk outcomes are summarised again in Table 12.25.

Table 12.25: Summary of the worst-case initial and residual (same) risk assessments for both MGO release scenarios

Scenario	Impact assessment	Likelihood	Overall residual risk significance
1: 10 tonne MGO bunkering spill	High for Seabirds and marine mammals	**Unlikely**	**Moderate (10)**
2: 1,200 tonne MGO spill	High for Seabirds and marine mammals	**Unlikely**	**Moderate (10)**

12.2.9 Cumulative impact

Fuel bunkers are undertaken within Berkeley Sound on a regular basis and all of these operations carry a risk of fuel oil spill. Therefore, there is the potential for cumulative impacts through 'increased concentration' of fuel from oil spills (Section 8.9.1). There are several known spills of MGO in Berkeley Sound, the largest of these are associated with ships that sank or ran aground (Table 12.26), although many of these incidents have not been formally recorded.

Baseline Total Hydrocarbon Concentrations (THC) and PAH in Berkeley Sound sediments have been sampled and reported by Benthic Solutions (BSL, 2015c).

Background levels are interpreted as being a mixture of naturally occurring hydrocarbons and weathered diesel. With regard to THCs, background levels range from 1.03 - 159.89 mg/kg, with typical levels of 10 mg/kg (Section 7.3.7.2.2). It is noted that these baseline levels are already at or above potential levels of concern, starting at 10 mg/kg (Section 12.2.4.2.2).

With regard to PAHs, the baseline levels are reported as <1 µg/kg up to 0.938 mg/kg (Section 7.3.7.2.2.2). Again, these pre-existing levels are already within the range of common levels of concern.

The fuel bunkering operations within Berkeley Sound carry an environmental risk. However, with industry-standard, base-case and project-specific prevention and mitigation measures in place, the risk is reduced to ALARP. Tighter regulation of all activities within Berkeley Sound will help to reduce the risks of accidental events occurring with third-party vessels. Additionally, the availability of vessels with OSR capability and additional OSR equipment should reduce the potential for environmental impacts from any oil spill events that might occur.

Table 12.26: Anecdotal data on incidents that could lead to oil leaks involving vessels in Berkeley Sound[1]

Date	Vessel type	Type of incident	Outcome	Environmental impact
April 2005	Reefer	Grounding in Berkeley Sound (Cochon Island)	Refloated with damage to hull	Fuel oil leak
May 2008	Trawler	Fire in Berkeley Sound	Vessel eventually sank	Fuel oil leaks (*c.*137 Tonnes)
Unknown	Jigger	Struck a rock and sank	Vessel sank	Fuel oil leaks

[1] M. Jamieson, *pers. comm.* and A. Black, *pers. obs*.

12.2.10 Confidence

There are a number of uncertainties regarding:

- The models used to predict the likelihood of oil spill events (Section 12.2.4.3),
- The effectiveness of response measures, and
- The range of environmental effects that could result from a spill.

Overall, confidence in the assessment of the impacts and risks due to oil spills associated with Inshore operations is therefore considered to be '**Uncertain**'.

12.2.10.1 Monitoring required

During operations a real time inshore hydrodynamic model covering 3-day detailed current and wind forecasts will be run and available in the event of a spill.

12.2.11 Offsetting

Neither of the scenarios considered are likely to occur during the duration of project activities in Berkeley Sound which will occur over a maximum period of 13 months. Offsetting is therefore not considered appropriate for this type of unplanned event. Should a serious event occur, it is expected

that remediation will be part of the final stages of the spill response process and subject to discussion with the authorities and stakeholders.

12.2.12 Findings summary

Table 12.27: Summary of the risk assessment for all oil spill scenarios

Activity	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity [1]	Severity [1]	Likelihood [1]	Impact / Risk Significance [1]		Confidence	Mitigation / Prevention / Control

12.3.12 Findings summary 1281

12.3.1 Introduction

The interface between the land-based storage of fuel and chemicals and their offshore use presents a risk in terms of the onshore storage and the 'at-shore' transfer of potentially hazardous liquid products, for example fuel oil and chemicals.

This chapter assesses the impacts and risks associated with:

- The transfer of fuel oil at the Temporary Dock Facility (TDF) and / or Falklands Interim Port And Storage System (FIPASS),
- The movement of chemicals at the TDF, and
- The storage of chemicals at the onshore supply base.

Under the Planning Ordinance 1991, an Environmental Impact Assessment (EIA) was conducted as part of the original planning application for the TDF to cover the construction and operational use of the facility (NEFL, 2013). In addition to the EIA, a TDF Oil Pollution Emergency Plan (OPEP) to cover activities within Stanley Harbour was produced (Premier, 2014b), which is compatible with the Falklands National Oil Spill Contingency Plan (NOSCP). The assessment below draws on the conclusions of the EIA and contents of the project-specific OPEPs.

Note: the other impacts and risks associated with potential oil spills during offshore and inshore operations are described elsewhere in this document (Sections 12.1 and 12.2 respectively).

Note: oil spill waste and the procedure for dealing with oil spill clean-up waste is described in Section 10.10.2.2.3.

12.3.1.1 Relevant legislation

The legislation relevant to all oil spills is described in Section 12.1.1.1.

Additional legislation relevant to at-shore activities or to the selection, use and discharge of chemicals, and / or that which is directly relevant to chemical spills at the TDF and onshore supply base specifically include:

- International legislation:
  - International Convention for the Prevention of Pollution from Ships (MARPOL) 73/78:
    - Annex III- Regulations for the Prevention of Pollution by Harmful Substances Carried by Sea in Packaged Form.
  - OSPAR Decision 2000/2 on a Harmonised Mandatory Control System (HMCS) for the Use and Reduction of the Discharge of Offshore Chemicals.
  - OSPAR Recommendation 2010/3 on a Harmonised Offshore Chemical Notification Format (HOCNF).
  - OSPAR Recommendation 2010/4 on a Harmonised Pre-Screening Scheme for Offshore Chemicals.
  - OSPAR Recommendation 2006/3 on Environmental Goals for the Discharge by the Offshore Industry of Chemicals that are, or which contain Substances Identified as Candidates for Substitution.
  - EC Directive 2012/18/EU on control of major-accident hazards involving dangerous substances.
- UK legislation:
  - Offshore Chemical Regulations (OCR) 2002 (and all amendments).
  - The Control of Major Accident Hazards (COMAH) Regulations 2015.

12.3.1.1.1 Compliance with chemical selection legislation

Details on the compliance requirements relevant to chemical selection are provided in Section 10.7.1.1.2 so are not repeated here.

12.3.1.1.1.1 Compliance with chemical use and discharge legislation

The offshore chemical regulations require that the use and discharge of all chemicals be permitted and reported and that all chemical releases be reported *via* the PON system to FIG.

12.3.1.1.1.2 COMAH regulations compliance

The aim of the COMAH Regulations is to prevent and mitigate the effects on people and the environment of major accidents involving dangerous substances. They are applicable to any establishment storing, or otherwise handling, large quantities of industrial chemicals of a hazardous nature. Types of establishments include chemical warehousing, chemical production facilities and some distributors. Whether or not a site qualifies as a COMAH site will depend upon the type and quantity of chemicals stored:

- Lower tier establishments are required to document a Corporate Major Accident Prevention Policy (CMAPP) which should be signed off by the managing director, and
- Top tier COMAH establishments are required to produce a full safety report which demonstrates that all necessary measures have been taken to minimise risks posed by the site with regard to the environment and local populations.

The proposed storage of up to 400 m^3 of methanol does not qualify the proposed operations base as the equivalent of a lower tier UK COMAH site however, Navitas' internal process will apply a COMAH methodology and require the following activities to be undertaken:

- Reduce risks to ALARP,
- Notify the Competent Authority,
- Prepare a Major Accident Prevention Policy (MAPP),
- Provide information for the public, and
- Consider the possible domino risks.

In addition to the above, Navitas intend to produce a Safety Report covering the transportation and storage of chemicals at the proposed base. Further details are provided in the Major Accident Hazard Assessment completed for POEPL by Risktec (Premier, 2017a).

Full guidance on the COMAH qualification and assessment process is provided by the Health and Safety Executive.

12.3.1.1.2 MARPOL Annex III

In 1973, IMO adopted the International Convention for the Prevention of Pollution from Ships, now known universally as MARPOL. The convention has been repeatedly amended and updated by the Marine Environmental Protection Committee (MEPC).

Annex III sets out regulations for the prevention of pollution by harmful substances in packaged form and includes general requirements for the issuing of detailed standards on packing, marking, labeling, documentation, stowage, quantity limitations, exceptions and notifications for preventing pollution by harmful substances. For the purpose of Annex III, 'harmful substances' are those identified as 'marine pollutants' in the International Maritime Dangerous Goods (IMDG) Code and compliance with Annex III will form part of Navitas' contractor management and audit processes (Section 3.2.15).

12.3.2 Sources of at-shore oil and chemical spills

It is the intention of Navitas to apply to FIG to extend the operational life of the TDF. Further, Navitas shall propose future modifications to improve the Dock's functionality. As described in Section 5.11.1.1.1, proposals to extend the life of the TDF and / or upgrade the facilities will have to go through the process of planning, which may be accompanied by a full separate EIA.

For the purposes of this EIA, it is assumed that proposed upgrades to the TDF will be approved.

Sources of at-shore oil and chemical spills / leaks during the project include:

- The presence and use of pieces of equipment that involve fluid products. Such equipment includes (but may not be limited to):
  - Crane/s,
  - Forklifts,
  - Ballast pumps,
  - Diesel generator,
  - Oil storage tanks and fixed, hard-piped lines, and
  - Heavy goods vehicles and cars.
- Chemical transfer at the TDF (Section 5.11.1.1.1),
- Diesel (Marine Gas Oil, MGO) bunkering at the TDF and / or at FIPASS (Section 5.11.1.1.2),
- Mud and chemical storage at the onshore supply base,
- Major accidents at the supply base, and
- Vessel collisions and groundings on approach to the port facilities

12.3.3 Potential receptors

The ENVironmental Impact and risk IDentification (ENVIID) workshop was used to identify those receptors upon which the impacts and / or risks of oil spills warranted further investigation (Chapter 9). These include:

- Sediment quality and marine benthic flora and fauna in Stanley Harbour and surrounding areas (Section 7.4.3.4),
- Water quality and plankton (Section 7.4.1),
- Fish and squid in Stanley Harbour and surrounding areas (Section 7.4.4.4),
- Seabirds in Stanley Harbour and surrounding areas (Section 7.4.5.4),
- Marine mammals in Stanley Harbour and surrounding areas (Section 7.4.6.4),
- Coastal communities and habitats (Section 7.5.1), and
- Tourism (Human population) (Section 7.7.4.6.1).

These receptors may be impacted upon as they either exist in, or spend time in, the area that might be influenced by fuel oils or chemicals accidentally discharged into the environment.

12.3.4 Characterising and quantifying the risk of at-shore and onshore oil and chemical spills

The influencing factors with regard to oil type and behaviour, and the nature of the impacts of oil spills on receptors have already been described in Section 12.1 above. However, when characterising and quantifying the impacts of at-shore oil and chemical spills specifically, it is also necessary to consider the following:

- Port facility and onshore supply base use and the scenarios which could lead to spills:
  - Day-to-day operations,
  - Bulk transfer of substances,
  - Vessel approaches, and
  - The fate of chemicals in the marine environment.
- Onshore chemical storage, and
- Major accidents at the supply base.

12.3.4.1 Port facility and onshore supply base use

Given the known activities occurring at the TDF, FIPASS and the onshore supply base, a spill scenario identification exercise was conducted in 2014 by POEPL (now Navitas) to identify the credible emergency scenarios that could result in a spill of hydrocarbon and / or chemicals (Premier, 2014b). These scenarios are identified below and will be included within the scope of Navitas' Phase 1 & 2 Development At-shore OPEP.

12.3.4.1.1 Day-to-day operations

Small scale spills and leaks may occur through the presence and / or the day-to-day use of equipment (as listed in Section 12.3.2 above). Specifically, spills and leaks that may result from the presence and / or use of equipment include losses of:

- Fuel oils,
- Hydraulic oils,
- Oily bilges from machinery spaces,
- Oil fouled water from ballast tanks,
- Leaks from propeller shaft or drive-shaft oil seals, and
- Leakage of hydraulic or lubricating oils from various moving parts such as hydraulic ramp and deck moving / lifting mechanisms.

Leaks most commonly occur due to incorrect maintenance or neglect of maintenance schedules and most can be avoided in the first instance through procedural control. However, where leaks do occur, they can be a significant source of discharged fluids, particularly if they go undetected for significant periods of time.

At the TDF, very small leaks or spills of diesel from vehicles or machinery are likely to be contained on the superstructure of the dock where they will rapidly evaporate and are amenable to clean-up. However, larger spills may reach the water which could occur through drains or direct runoff from quayside surfaces.

In water, MGO readily spreads to form a sheen, which evaporates rapidly (Section 12.1.4.1.1.2). Heavier oils, such as hydraulic oil, behave differently and some fractions of these oils will transfer to the bottom and stay there. Eventually, the ingredients of hydraulic fluids are degraded in the environment, but complete degradation may take more than a year (ATSDR, 1997). Little is known about how some of the ingredients in hydraulic fluids break down in the environment, but almost nothing is known about how toxic these breakdown products are. However, there are biodegradable hydraulic oils on the market, the use of which would greatly reduce the risk of environmental impact. Over recent years, the O&G industry has progressively replaced many more harmful fluids that were once oil-based and has transitioned to less harmful oils or non-oil systems. For example, hydraulic fluids planned for the subsea control system on the FPSO, for the operation of the BOP on the MODU

and for the operation of tensioning systems on the MODU are biodegradable products based on the PLONOR chemical Monoethylene Glycol (MEG).

Any unintentional at-shore release which reaches the water, however small, will contribute to chronic pollution of the marine environment.

12.3.4.1.2 Bulk transfer of substances

Bulk transfers involve the use of unbunded flexible bulk hoses which can be considered a weak link in terms of the potential for accidental spills and leaks.

12.3.4.1.2.1 MGO bunkering at the TDF and / or FIPASS

There is a potential risk that during bunkering operations, MGO could be spilled to sea, due to:

- Equipment failure / malfunction e.g., dry-break valve failure, perishing of hoses, failure of level gauge, level alarms, tank failure and / or
- Operator error e.g., poor bulk hose storage, neglect of hose inspections / change-out schedules, neglect of watchman during operations.

In the past ten years there have been several small MGO spills in Stanley Harbour, with the largest amounting to about 100 litres (ITOPF, 2018). However, there have been larger spills recorded within the Islands' territorial waters in the last 20 years, resulting from groundings (see Section 12.2).

The likelihood of unintentional releases of MGO is greatest during transfer operations, when diesel is moved from one secure holding tank to another *via* bulk hoses. Detailed spill statistics are not available for the Falkland Islands, but as dry-break couplings will be used on the bulk hoses alongside shut-down valves and observations, it is assumed that the worst-case maximum volume of any spill would comprise only the volume of diesel contained in the mains pipe before the valve is manually shut down. This is estimated to be approximately one tonne (Table 12.28). This scenario could only occur if the automated emergency shut down valves failed and the quayside watchman was unaware of the incident and pumps remain on for a time before being shut-off.

As detailed in Section 12.1.4.1.1.2, MGO contains a high percentage of low molecular weight hydrocarbon compounds, known as 'light ends' and hence tends to disperse very rapidly upon release to the marine environment (mainly *via* evaporation), usually within a matter of hours on the surface. Further, MGO is biodegraded by naturally occurring microbes in the sediment, under a time frame of months. However, if a large volume of the fuel were to be released in the vicinity of the TDF, it could spread and pose a significant risk of possible impact to wildlife throughout Stanley Harbour, even if only for a brief period of time. Small diesel spills can affect marine birds due to ingestion during preening as well as by hypothermia from matted feathers, though the number of birds affected is usually small because of the short time the diesel is on the water's surface (Section 12.1.4.1.1.2).

When small fuel oil spills do strand on the shoreline, the fuel oil tends to penetrate porous sediments rapidly but also tends to be washed off quickly by waves and tidal flushing. Thus, shoreline clean-up following diesel spills is usually not needed.

12.3.4.1.2.2 Chemical transfer operations

For the purpose of this assessment, it is assumed that all chemical cargo (and other supplies needed to support offshore operations) will be delivered to the TDF and stored at the onshore supply base (Section 5.11.1).

Throughout the project all chemicals will be selected to minimise environmental impacts as much as possible, in compliance with legislation. However, although chemicals may be rated as Posing Little Or NO Risk (PLONOR) when used in-field due to the concentrations and application type, they are transported as undiluted chemicals and in this state, pose a greater environmental risk.

Well chemicals

Details on the specific chemicals that will be used during the drilling operations are not yet known. However, the well chemical function groups required are as described in Section 5.9.1.

Vessels will be loading and offloading a number of chemicals that will be used in the drilling operation. The majority of chemicals required are dry 'bulk' chemicals used in the make-up of drilling fluids. However, Non-Aqueous Drilling Fluid (NADF) may be pumped across the TDF and onto the supply vessels (subject to approval of proposed upgrades to the TDF). Other chemicals that will be transferred at the TDF might include: cementing chemicals, rig cleaning chemicals, and pipe dope (drill pipe connector thread lubricants and sealing compounds). During transfer of chemicals to and from the TDF, there is a potential risk that the chemicals could be spilled to sea. Liquid chemicals will be transported in various sizes of drum, Intermediate Bulk Containers (IBCs) and tote tanks that are sealed for transit, and as such a loss of a load during transfer would not immediately result in a loss of chemical to sea; the container would have to be breached in some way during the incident for this to occur. The most credible spill scenario would be damage to one of the bunkering lines for NADF. These have dry-break couplings and so a release would be limited to the length of one hose section with a likely volume of up to 1 m^3.

Production chemicals

Details on the specific chemicals which will be used during production operations are not yet known. However, the production chemical function groups required are as described in Section 5.9.1.

Of the chemical function groups required, two chemicals which are required to ensure flow assurance (namely wax inhibitor and methanol) are required in significant volumes, while the other chemicals are required in lesser quantities (Section 5.9.1.1). While the quantities of the different production chemicals will change as oil production rates decline, the wax inhibitor and methanol make up 70 % of the total first year production chemical volume requirements. These bulk chemicals will be transported from their place of manufacture (which is likely to be the UK) to the Falklands in 24,000 litre (20') ISO frame tanks.

Once the bulk chemicals are delivered to the Falkland Islands, the tanks will be unloaded at the TDF and moved onshore to be stored in the production chemical laydown yard until they are ready to be taken offshore. When required offshore, the bulk chemicals will be shipped to the field, by transporting the 20' ISO frame containers to the TDF and pumping the contents into the hull tanks of the FPSO's supply vessels. These hull tanks will be used only for these chemicals such that there will be no cross-contamination. The maximum possible spillage that could occur is the full volume of a single tank (Table 12.28). The empty containers will then be returned to the production chemical laydown yard for storage and subsequent back loading (Section 10.10). The FPSO's supply vessel will then transport the chemicals to Sea Lion where they will be offloaded *via* bulk hoses into the storage tanks in the FPSO.

The worst-case scenarios which could lead to the loss of the content of an ISO frame tank to sea during transfer include:

- Offload of the frame tanks from a vessel to a vehicle on the TDF *via* crane-lift, and
- Pumping of the tank content into the FPSO's supply vessel from the TDF.

The smaller volume chemicals will be decanted into tote tanks in the production chemical laydown yard. These will then be transported to the TDF on trucks and lifted by crane onto the back deck space of a supply vessel. They will then be transported out to Sea Lion, where they will be lifted by crane into metal framed bins on the deck of the FPSO.

12.3.4.1.3 Vessel approaches

The increase in the number of vessels utilising Stanley Harbour during the project increases the potential risk of vessel collision, particularly if vessels working on behalf of Navitas are not familiar with the location.

However, by international standards, the Harbour is not regarded as a busy port. Instead it can be described as a relatively quiet port with notable busy periods during cruise ship and fishing seasons such that collisions and groundings should be readily avoidable by following standard navigational procedures (e.g., ColRegs).

Assuming a worst-case-scenario, a fully laden offshore support vessel would contain approximately 800 m^3 of MGO fuel. This would be spread between numerous different tanks and therefore it is extremely unlikely that all of this could be lost in a single event. A more credible worst-case scenario is the loss of fuel from two fuel tanks, which is predicted to be around 320 m^3, based on a typical MRSV. Nevertheless, a breach of a fuel tank could result in a sizable spill in sheltered inshore waters, where dispersal by wind and waves would be limited.

Table 12.28: Summary of the credible worst-case spill quantities for each at-shore scenario

Scenario	Cause	Spill type	Credible worst-case volume (m^3)
Day to Day operations	Leaks, seeps and weeps	Fuel and hydraulic oils to sea	<1 m^3
Diesel bunkering	Equipment failure (e.g., hose rupture) / human error	Diesel to sea	1 m^3
Chemical bunkering	Equipment failure (e.g., hose rupture) / human error	Drilling mud	1 m^3
	Equipment failure (e.g., crane failure) / human error	Wax inhibitor or methanol to sea	24 m^3
Chemical storage	Equipment failure (e.g., failure of forklift truck) / human error	Drilling / production chemical to land	1 m^3
	Major accident with associated spill	Chemical / oil to sea or land	0[1] m^3
Vessel approach	Collision or grounding due to equipment failure / human error	Fuel to sea	320 m^3
		Chemical to sea	10 m^3

[1] No spill is theoretically credible as the bund capacity is 110 % of the total volume of chemicals stored, so any spill on the base will be contained within the bund and double drainage system.

12.3.4.1.3.1 History of collisions in Stanley Harbour

Fishing vessel *Pesca Vaqueiro* ran into the FIPASS dock whilst on approach on 5th September 2019. Otherwise, there are no formal records of collisions in Stanley Harbour although there have been a number of collisions between local vessels, or vessels running aground, in Stanley Harbour and Port William in recent years (A. Black, *pers. obs.*). None of these events involved vessels associated with the Oil and Gas (O&G) industry and none resulted in a major pollution incident.

12.3.4.1.4 Fate of chemicals in the marine environment

The fate of chemicals in the environment will vary enormously depending upon the substances concerned; however, the following properties of each chemical used will be considered:

- Relative biodegradation,
- Persistence and toxicity, and
- Potential to bioaccumulate.

The varying combinations of the above will affect the impact each chemical may have in the event that it is spilled.

For example, the behaviour of a methanol spill would be similar to that of an MGO spill (i.e., relatively rapid evaporation); however, as methanol is soluble in water it would disperse more rapidly to non-toxic levels (<1 %) (dependent on water mixing due to tide or wind) and would biodegrade. Although biodegradation of a large spill in enclosed waters could lead to localised deoxygenation of surface waters, this is unlikely where water is well mixed.

12.3.4.2 Onshore chemical storage

Once offloaded onto the TDF and transported to the yard:

- Drilling chemicals will be stored in a dedicated NADF and bulks facility, and
- Production chemicals will be stored in a dedicated production chemical laydown yard (Section 5.11.1.2).

The worst-case scenarios which could lead to the loss of containment of chemical to ground during transfer include:

- Offload of the frame tanks from the vehicle to the chemical laydown yard, and
- Loading of the frame tanks onto a vehicle at the laydown yard for transportation to the TDF.

12.3.4.2.1 History of onshore chemical spills during exploration campaigns

There were two incidents of chemical spills at the onshore supply base during the 2015 exploration wells campaign. Neither incident resulted in significant release of chemicals or in environmental damage.

The first incident occurred as IBCs, containing approximately 1,000 litres each, were being moved from one laydown yard to another. As the forks of the forklift truck were entered into the lifting pockets of the IBC, the metal plate at the base was caught and scraped by the right-hand fork, resulting in the plate being dented and pushed upwards, thereby puncturing the IBC. When reversing, the forklift operator noticed a puddle of liquid on the ground. The chemical spilled was Halliburton CFS - 476 (Oxygen Scavenger) which is a Cefas Gold chemical (see Section 12.3.1.1.1). The spill was estimated to be in the region of 400 litres. Action was taken to prevent further spillage and the incident was reported to FIG.

The second incident concerned small leaks from several IBCs that had been stored at the laydown yard for over a year. The IBCs had been placed on chipboard boards, which, when lifted, were discovered to be damp, with the screed floor underneath also damp. There was no other obvious source of the dampness other than from the IBCs. The IBCs contain MEG which is an OCNS E rated chemical (see Section 12.3.1.1.1).

It was noticed that some of the caps at the bottom of the IBCs were not fully finger tight, so the decision was made to re-locate all IBCs containing MEG and manually tighten their caps. All IBCs were accessible in the hold of the vessel and in the warehouse, and three were found to have minor leaks from the

cap. They were tightened and spill pads were secured around the cap to prevent any further leakage. It is estimated that 1 litre had leaked over a 12 month period.

12.3.4.3 Major accidents at the supply base

In the event of a major incident at the supply base, such as an explosion, whilst safety of personnel is of greatest concern, there can be the risk of an associated spill to ground or sea. The UK COMAH regulations (Section 12.3.1.1.1.2), which Navitas will adhere to, are designed to prevent any impacts of major accidents, to both the human population through separation distances, and to the surrounding environment *via* the implementation of appropriately designed site bunding and drainage, see Section 12.3.5.2.

The inventories identified as having the potential to cause a major accident are the methanol and explosives, which may be used in drilling to release the drillstring in the event of stuck pipe[99]. The explosives will be stored at a dedicated separate location, such that any explosions instigated by them will not cause an associated spill.

Any fire / explosion in the methanol storage area, which has the potential to cause an associated spill, will be firstly contained within the bund (see Section 12.3.5.2 below), and, due to the highly flammable nature of methanol, is likely to be burnt up in the explosion.

Navitas will apply mitigations to the methanol storage to ensure other flammable material or oils are not stored in proximity to the methanol to prevent event escalation.

12.3.5 Industry standard mitigation

The following sections described the industry standard mitigations relevant to each potential source of spills / leaks and conclude with an overview of the Oil Spill Response (OSR) equipment that will be utilised in accordance with the project-specific OPEP.

12.3.5.1 Day-to-day operations and bulk transfers at the TDF

The industry-standard mitigation measures used by Navitas to prevent and mitigate against leaks and spills at the quayside are as follows:

- Use of Maintenance Management System (MMS) to ensure all equipment remains in good working order and fit for the purpose intended:
  - The MMS will provide alerts for regular Preventative Maintenance Routines (PMR), with priority given to equipment listed in the Safety and Environmentally Critical Elements (SECE) Register (Section 3.2.7),
  - A Locked Open / Locked Closed (LO / LC) Register will be used at the TDF to ensure that all safety and environmentally critical valves will be left in the appropriate position,
  - Critical spares will be identified and in place, and
  - Hose management processes in line with NWEA good practice guidelines (Chamber of Shipping, 2009). Bulk hose and flexible hose management procedures which will ensure that all hoses are stored correctly, inspected and changed-out regularly, colour coded appropriately, listed in hose registers and utilise swivel joints to minimise kinking etc.
- Use of standard operating procedures, for example:
  - Diesel bunkering procedures which will ensure that:
    - Bunkering operations will be monitored throughout by trained personnel under Navitas supervision, and

[99] No explosives will be used to perforate the casing in the proposed basis of design as the wells will be completed using Open Hole Gravel Packs (OHGP) (Section 5.4.5.5).

        - A team utilised to hook up, and following commencement of pumping, to monitor from the quayside.
    - Chemical handling and loading procedures.
- Use of task-specific planning, toolbox talks, risk assessments, job safety analysis and pre-use checks,
- Use of emergency response plans e.g.:
    - Facility Emergency Response Plan (ERP) and OPEP for the TDF will align with the existing OSCP in place for FIPASS,
    - Use of a Hazardous Chemical Management Plan (HCMP) to manage the handling of chemicals, and
    - Sea Lion Field At-shore Development OPEP.
- Use of engineering controls e.g., dry-break coupling on bulk hoses, emergency shut-down valves,
- Training of all personnel in spill prevention and response, and
- Use of spill kits which will be located on the TDF and at FIPASS.

12.3.5.2 Vessel approaches

It is anticipated that Navitas will co-operate in a Harbour Management Plan (HMP), designed and implemented in close collaboration with the Harbour Master[ibid] to include the following:

- Pre-notification protocols associated with the entry of vessels into Stanley Harbour during operation,
- Procedures associated with vessel collision and emergency response,
- Marine night-time lighting requirements, and
- VHF Radio communication protocols.

The system of reporting within the Harbour and Port William will inform all users of vessel movements. The crews of O&G related vessels are highly trained and the vessels (e.g., AHTS/MRSVs) are extremely manoeuverable. All users of Stanley Harbour will continue to be made aware of the position of the TDF and the structure will be lit at night.

Pre-mobilisation audits will be undertaken on all vessels. Vessels will be selected which comply with all IMO codes for the prevention of pollution from both oil and chemicals.

All vessels will have a Shipboard Oil Pollution Emergency plan (SOPEP) in place to enable fast and effective response to any potential pollution incident.

12.3.5.3 Chemical storage at the onshore supply base and major accident prevention

The industry-standard mitigation measures used by Navitas to prevent and mitigate against leaks and spills at the supply base are as follows:

- All onshore storage operations involving the production chemicals will take place in a bunded facility to ensure that any spills can be contained:
    - In line with COMAH (2015), the normal design specifications for bunding require a holding capacity of 110 % of the largest tank contained within the bunding and 25 % of the total capacity of all the tanks within the bund (whichever is the greatest volume).
- A ‘double drainage’ system will be required for surface water in hazardous areas, which will allow the recovery and appropriate disposal of surface water that has become contaminated by any spilt production chemicals,

- Tote tanks will be inspected and maintained within the production chemical laydown yard in compliance with the inspection and certification regime,
- Tote tanks will be returned to the UK for in depth inspections and certification, if it is not possible to complete this within the Islands, and
- All personnel will be adequately trained in spill prevention and response and in the use of spill kits which will be located around the supply base.

Based on the maximum volume of methanol that will be stored at the onshore facility (i.e., up to 400 m^3 at any one time) it is anticipated the location will fall below the definition of a lower tier COMAH site. Nevertheless, Navitas will adopt chemical management standards in line with the COMAH regime in the UK. This will include, amongst other safety precautions, adherence to safe separation distances of flammable chemicals to local houses and roads, which has been calculated to be between 80 - 136 m (Premier, 2017a).

12.3.5.4 Oil Pollution Emergency Plan (OPEP)

Numerous spill response measures will be defined within the OPEP and will therefore be in place to minimise the consequence of a spill should it occur. This equipment will be stored in Stanley and will be available for use, where appropriate, in the event of at-shore incidents.

12.3.5.4.1 Response options available for all at-shore oil and chemical spills

In the unlikely event of a spill in Stanley Harbour, the main response to spilled MGO or chemicals would be to use absorbent materials to contain and collect the spill.

In the event of a larger spill, booms will be deployed to contain the spill to allow recovery and prevent contamination of the shore. Once corralled, sorbents will be used to soak up the hydrocarbons. It may also be possible to use an oil skimmer to recover the spill from the sea's surface. Dispersants are not included here as they would not be considered an appropriate response for chemical or diesel spills in shallow water, such as around Stanley Harbour.

Shorelines may also be boomed, but if the spill impacts the shoreline, personnel may be required to physically remove diesel / chemical deposits from the shoreline using hand tools. However, it should be noted that this is only a viable response option if the safety of personnel is assured and the response will be more effective than allowing the spill to breakdown naturally.

It will always be necessary to monitor the extent of the spill as far as possible from the shore and using boats in the area, and to inform the local authorities of the spill (PON 8) and the planned response.

12.3.5.4.1.1 Equipment List

The following spill response equipment, or similar, will be available in Stanley (see also Section 5.11.1.2.3):

- Oil skimmer[100] with diesel pump and hoses,
- Inshore boom,
- Oil water storage tank with groundsheet and cover,
- Fish totes containing pads and heavy-duty waste bags,
- Chemical sorbent spill kits (stored in wheeled totes),
- Sealed plastic fish tote with spare hand tools, basic Personal Protective Equipment (PPE) and signage,
- Flexible IBCs,

[100] **Note:** oleophilic weir skimmers will only be deployed for response to MGO spills.

- Pressure washer,
- Oil snare and oil snare on rope,
- Steam generator,
- Two trailers,
- A fast response Rigid Inflatable Boat (RIB) which will have oil recovery equipment on board for boom deployment and support will be based in Stanley, and
- FIPASS spill response equipment (mobilised and managed by FIG).

12.3.6 Risk assessment for at-shore oil and chemical spills

The following section draws upon all the information provided above to assess the 'Sensitivity of the Receptor' and the 'Severity of Effect' in order to determine the overall 'Impact' of any spills, followed by an assessment of the 'Likelihood of Occurrence' to determine the overall 'Risk'.

A summary of the risk assessment outcomes for this Development is tabulated in Section 12.3.12, which shows the worst-case risk for each activity and receptor and details are provided below.

12.3.6.1 Day-to-day operations

The nature of the impact of MGO, or chemical spills, on birds and marine mammals is different (see Section 12.2.4.2) and is likely to be greater on birds due to feather fouling and loss of insulation than on marine mammals, which are generally more impacted by ingestion. Therefore, birds are considered to be the more sensitive receptor. As described in Sections 7.4.5.4 and 7.4.6.4, Stanley Harbour supports a population of flightless Falkland steamer ducks, and is utilised by Commerson's and Peale's dolphins and South American sea lions. Although the number of animals present is not significant in terms of the Falklands populations, all of these are included in the list of priority conservation species (Section 7.5.3) and therefore the sensitivity of receptors is considered to be '**High**'.

Although there is some uncertainty regarding the potential impacts of some of the fluids used during operations on the TDF (Section 12.3.4.1.4), the environmental impact of any small leak or spill will be localised, short-term and fully reversible once activity ceases. Considering the range of other activity that could result in leaks or small spills of hydrocarbons that is currently undertaken around the Harbour, the impact from project activity is considered to pose a barely detectable impact on species, habitats or the ecosystem. Small spills or leaks would not warrant the deployment of full OSR equipment although the swift use of localised spill kits may serve to lessen the severity of effect. Nonetheless, this cannot necessarily be relied upon and therefore, on balance, the severity of effect is considered to be '**Minor**'.

Therefore, the overall significance of impact is '**Moderate (8)**'.

Accidental release of small volumes of fluids associated with day-to-day operation of the TDF represents the most likely source of unintentional releases. During the 2015 exploration wells campaign, there were two incidents of small chemical spills and leaks in the laydown yard. There was no risk of the chemicals escaping into the marine environment but it highlights the potential for accidental events and undetected leaks. These events may occur less than once per year but could occur more than once over 10 years in the event that operational controls failed; therefore, the likelihood of small-scale spills or leaks occurring and contaminating the environment is '**Possible**'.

Therefore, the overall risk associated with day-to-day small spills is assessed as '**Moderate (9)**'.

12.3.6.2 Bulk transfer of substances

12.3.6.2.1 MGO fuel transfer spills at TDF and / or FIPASS

The most sensitive potential receptors are the same as those described in Section 12.3.6.1. Therefore, the sensitivity of receptors is considered to be '**High**'.

The environmental effect of small MGO spills (i.e., <1 tonne) would be localised short-term, and fully reversible. The impact would be barely detectable on species, habitats or the ecosystem as a whole and therefore, the severity of effect is considered to be '**Minor**'.

Therefore, the overall significance of impact is '**Moderate (8)**'.

The zone affected by any spill will vary according to weather conditions. In severe weather, for example, any pollution will be moved a greater distance but will be diluted more quickly at the same time by increased turbulence. Although small spills have occurred infrequently during fuel transfer operations at FIPASS in the past, no spills occurred during the 2015 POEPL exploration drilling campaign. The base-case mitigations applied by Navitas vessels represents a higher standard than that applied generally within the shipping industry, such that the likelihood of diesel spills during bunkering operations is considered to be '**Unlikely**'.

Therefore, the overall risk associated with MGO spills during bunkering is '**Low (6)**'.

12.3.6.2.2 Chemical transfer spills at the TDF

The most sensitive potential receptors are the same as those described in Section 12.3.6.1. Therefore, the sensitivity of receptors is considered to be '**High**'.

The nature and severity of the impact of a chemical spill will depend on the chemicals involved. For instance, in terms of volume transferred, methanol will be one of the most significant chemicals used during the project but will rapidly disperse causing only localised deoxygenation (Section 12.3.4.1.4). In contrast, another chemical may be spilled in lower volumes but may, for example, be more toxic. On balance, however, and given that the bulk chemicals intended for use are expected to be Cefas Gold or OCNS E (see Section 12.3.1.1.1), the overall severity of the impact of a chemical spill is considered to be '**Minor**'.

Therefore, the overall significance of the impact is '**Moderate (8)**'.

As above, the zone affected by any spill will vary according to weather conditions. Small chemical spills have occurred previously in the global O&G industry, however, no spills occurred during the POEPL 2015 exploration drilling campaign and failure of numerous operational controls would be required. The likelihood of all mitigation measures described above failing is such that the likelihood of chemical spills is considered to be '**Unlikely**'.

Therefore, the overall risk associated with the transfer of liquid chemicals is '**Low (6)**'.

12.3.6.3 Vessel approaches

The most sensitive potential receptors are the same as those described in Section 12.3.6.1. Therefore, the sensitivity of receptors is considered to be '**High**'.

Small spills such as those that may result from collisions of vessels using Stanley Harbour are likely to have a short-term, rapidly reversible impact on the local ecosystem and species. Nonetheless, the loss of up to 320 m^3 of fuel would warrant an immediate local OSR and therefore the severity of a collision between vessels that resulted in a significant oil spill is considered to be '**Serious**'.

Therefore, the overall significance of impact is '**High (16)**'.

As described in Section 12.3.5, numerous barriers will be in place to prevent collisions between vessels within Stanley Harbour such that the likelihood of collisions involving vessels supporting the project will be minimised as far as reasonably practicable. Failure of nearly all these operational controls would be required for a collision to occur and therefore the likelihood of a collision involving vessels associated with the Phase 1 & 2 Development that resulted in a significant oil spill is considered to be '**Very Unlikely**'.

Therefore, the overall risk associated with the major diesel spills resulting from a collision involving one or more vessels associated with Navitas' operations is '**Low (5)**'.

12.3.6.4 Chemical storage spills at onshore supply base

Given the use of the mitigation measures described in Section 12.3.5.2, it is not considered possible for spills at the supply base to reach any potential receptors. Therefore, as there is 'no potential to transmit contaminants to nearby sensitive receptors' the sensitivity of soil as a receptor is considered to be '**Very Low**'.

With no receptors impacted by any spill which will be contained within the bunds and double drainage system, the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of impact is '**Very Low (1)**'.

Spills and leaks at onshore supply bases have been known to occur within the industry and the majority of operational controls require implementation by humans e.g., correct storage / segregation / local bunding checks etc. rather than reliance on, and maintenance of, engineering controls. Therefore, the likelihood of chemical spills at the onshore is considered to be '**Possible**'.

Therefore, the overall risk associated with storage spills at the supply base is '**Very Low (3)**'.

12.3.6.5 Spills associated with major accidents at the supply base

Given the use of the mitigation measures described in Section 12.3.5.2, it is not considered possible for spills associated with major accidents at the supply base to reach any potential receptors. Therefore, as there is 'no potential to transmit contaminants to nearby sensitive receptors', the sensitivity of soil and sea as receptors is considered to be '**Very Low**'.

With no receptors impacted by any spill, which will be contained within the bunds and double drainage system, the severity of effect is considered to be '**Slight**'.

Therefore, the overall significance of impact is '**Very Low (1)**'.

Major spills at onshore supply bases breaching bunding limits have been known to occur within the industry but are rare. The majority of controls to prevent this happening are appropriate design of the bunding and drainage system, maintenance of bunds and linings and engineering controls. Therefore, the likelihood of chemical spills at the onshore is considered to be '**Unlikely**'.

Therefore, the overall risk of spills associated with major accidents is '**Very Low (2)**'.

12.3.7 Project-specific mitigation measures

With the exception of the presence and use of localised spill kits and the OSR equipment which will be described within the OPEP (Section 12.3.5.4), the majority of industry-standard mitigation measures are based around the prevention of spills occurring. There is not a great deal more which could be put in place to prevent the occurrence of incidents or to reduce the severity of effect.

12.3.8 Residual impacts and risks

With industry-standard mitigations in place, the significance of the risk associated with at-shore and onshore oil and chemical spills is generally '**Low**' or '**Very Low**'. The exception is the risk of small spills

and leaks during day-to-day operations which is considered to be '**Moderate**' as this is the most likely source of oil or chemicals escaping into the environment.

In the absence of additional means of reducing the likelihood of occurrence, or the severity of effect, the overall risk assessment for day-to-day spills and leaks remains '**Moderate (9)**'.

12.3.9 Cumulative impact

Although the TDF is reserved for O&G activities, throughout the lifecycle of the project many other users of the sea will be operating within Stanley Harbour. Many of these vessels will also be taking on fuel at FIPASS and will be required to safely navigate through inshore waters.

The presence of O&G vessels and activity will increase the number of fuel transfers within the Harbour ('increased concentration', Section 8.9.1). Navitas' activity will add to the potential sources of fuel and chemical spills occupying the same 'space' consecutively or soon after each other. This may increase the 'duration' of exposure for the same receptors and / or the 'extent and proportion' (Section 8.9.1) of the local or regional population at risk. However, the O&G industry will also bring many benefits in terms of harbour management and response capability and therefore the cumulative impact of Navitas' activities within Stanley Harbour is likely to be beneficial.

12.3.10 Confidence

Stanley Harbour has been the focus of vessel activity for many years. Records from FIMA (Section 7.6.4) show that from 2000 -2023 there have been 17 spills recorded in Stanley Harbour, indicating these are relatively rare events considering the volume of vessel traffic, and none of these spills have resulted in significant environmental impact. Additionally, the use of the TDF during the 2015 exploration campaign means that procedures have been developed and implemented and will be refined to meet the requirements of the Phase 1 & 2 Development. The history of O&G activity within the Harbour is such that confidence in the assessment of at-shore oil spills is considered to be '**Certain**'.

In contrast, while there have been no chemical spills to sea to date during the O&G activities (as is reflected in the likelihood of chemical spills (Section 12.3.6.2.2)), the current uncertainty over the specific chemicals which will be used is such that the severity of effect of chemical spills is based on assumptions. Therefore, the confidence in the assessment of at-shore chemical spills is considered to be '**Probable**'.

12.3.10.1 Monitoring required

Monitoring will be carried out in the event of any oil or chemical spill. All monitoring requirements agreed by Navitas and FIG will be recorded and managed *via* the project-specific Environmental Monitoring and Management Plan (EMMP) (Chapter 15).

12.3.11 Offsetting

Neither of the scenarios considered are likely to occur during the duration of project. Offsetting is therefore not considered appropriate for this type of unplanned event. Should a serious event occur, it is expected that remediation will be part of the final stages of the spill response process and subject to discussion with the authorities and stakeholders.

12.3.12 Findings summary

Table 12.29: Summary of the risk assessment of leaks and spills at the TDF, FIPASS and the onshore supply base

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity[1]	Severity[1]	Likelihood[1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
At-shore spills of liquid fuel and chemicals	Small leak / spill: day-to-day operations	Pollution of Stanley Harbour through spills and leaks with the potential to impact several species of local conservation concern and human population	Unplanned	1, 2a, 2b & 3	High	Minor	Possible	**Moderate (9)**	**Moderate (9)**	**Certain**	**Industry-standard:** Use of MMS, Use of standard operating procedures, Task specific planning, risk assessments etc., Use of emergency response plans e.g., ERP, OPEP and OSR equipment, NOSCP, HCMP, Use of engineering controls e.g., dry-break couplings, Training and spill kits, Use of HMP, Pre-mobilisation vessel audits, and Use of SOPEPs. **Project-specific:** None proposed
	Spill of diesel fuel during bulk transfer at the TDF and / or FIPASS		Accidental		High	Minor	Unlikely	**Low (6)**	**n/a**	**Certain**	
	Spill of chemical during bulk transfer at the TDF				High	Minor	Unlikely	**Low (6)**	**n/a**	**Probable**	
	Spill of diesel fuel due to collision or grounding during vessel approach				High	Serious	Very unlikely	**Low (5)**	**n/a**	**Certain**	
Spill of chemical at onshore supply base	Spill of chemicals to soil	Potential for impact to soil quality	Accidental		Very Low	Slight	Possible	**Very Low (3)**	**n/a**	**Certain**	**Industry-standard:** Adherence to COMAH (2015), Bunded storage sites,

Activity / Event	Aspect	Potential Impact	Type of Activity	Stage of operation	Sensitivity[1]	Severity[1]	Likelihood[1]	Impact / Risk Significance[1]		Confidence	Mitigation / Prevention / Control
								Initial	Residual		
											Double drainage in hazardous areas, Tank inspection, and Training and use of spill kits. **Project-specific:** None proposed.
Major Accident	Spill of chemical to soil or sea	Potential for impact to soil quality and / or pollution of Stanley Harbour	Accidental		Very Low	Slight	Unlikely	**Very Low (2)**	**n/a**	**Certain**	As above

[1] See Chapter 8 for definitions of sensitivity, severity, likelihood and significance.

13 CUMULATIVE IMPACTS AND IMPACT INTERACTIONS

Table of Contents

13.1 Introduction 1285
13.2 Cumulative impacts 1285
13.3 Indication of impact interactions 1286

13.1 Introduction

The following chapter describes the way that cumulative impacts and impact interactions have been considered within this EIS.

13.2 Cumulative impacts

Within each impact and risk assessment chapter, consideration was given to the potential for the cumulative effects of each aspect of the Phase 1 & 2 Development. Where possible, these qualitative assessments explored the cumulative impacts that may result if a similar activity was to occur at the same time in the same place, nearby, or just before or after the Navitas Development activities, as described in Section 8.9.1. For example, the assessment of the cumulative impact of underwater noise on inshore marine mammals takes account of the noise generated by Navitas vessels along with that generated by other vessels.

The approach taken with regard to assessing cumulative impacts in this EIS was discussed and agreed with FIG on the 25th November 2015. Since this time a review of EIA methodology was carried out as part of the GAP II project with a view to providing a best practice guideline for FIG. This resulted in the following reports:

- GAP II Project: Review of impact and risk assessment methodologies (July 2018) (Spencer, 2019a), and
- Best Practice Guideline for EIA methodology (March 2019) (Spencer, 2019b).

In addition to the cumulative impact of each activity which may overlap with other industries and recognising the potential for impact interactions as shown above, Navitas acknowledge that there is potential for a broader cumulative impact from the project as a whole, in combination with other industries.

The Best Practice Guideline provides extensive guidance on conducting Cumulative Impact Assessments (CIA) and while it lists the best practice approach, the report also states that:

> *'… while the above [best practice] approach is proposed, it is also recognised that it cannot be considered reasonable to expect the proponent of a single project to take responsibility for the full extent of data gathering etc. that is required to achieve the above [a full CIA]. Therefore, the project-level EIA may not be the most appropriate vehicle for conducting the full CIA and arguably, a CIA can only be of real value when connected with the breadth of a Regional Environmental Assessment (REA) and a Strategic Environmental Assessment (SEA) (Sinclair, et al., 2017) which are the responsibility of government rather than individual project proponents.'*

With regard to project-level CIA, the EIS follows the guidance provided in the Best Practice Guideline as follows:

- Narrative on the cumulative impacts associated with each activity is provided in the impact / risk assessment sections in Chapters 10, 11 and 12, consistently using the language described in Section 8.9.1.
- Where possible, and as described in Section 8.9.1, these take account of other operations that immediately precede the proposed operation and / or will occur simultaneously, and other sources of impact e.g., shipping, fisheries etc., and
- Where possible, outputs from the other impact sources are quantified although the majority of the assessments are qualitative.

13.3 Indication of impact interactions

As is detailed in Section 8.9.2 impact interactions can also occur. Impact interactions refer to the potential for one impact upon a given receptor to be 'additive or synergistic' or 'cancelling or ameliorative' to the impact from another activity on the same receptor.

For example, interactions which may exacerbate the impact of separate activities could include the following:

- Where artificial lights on the FPSO / MODU attract plankton, and therefore fish and cephalopods (Section 10.1.6.1.1), these may in turn attract marine mammals to feed. Increased proximity to the FPSO / MODU may then make the marine mammal more vulnerable to the impact of underwater noise (Section 10.4), or
- Where macerated food waste (Section 10.7) and / or artificial light (Section 10.1) attract birds to the MODU / FPSO / vessels, the birds may be more susceptible to collision with the vessel / or to oiling should this coincide with a time when an unplanned process upset means that the Produced Water Re-Injection (PWRI) system is down and produced water is being discharged (Section 10.7) or a small spill has occurred (Section 12.1).

Impact interactions of any kind are very difficult to quantify and assess, particularly when factoring in the potential for unplanned or accidental events. The number of variables, the extent of the unknowns and the inevitable 'what if' element, ultimately make it difficult to carry out a meaningful and representative assessment.

Therefore, this chapter aims only to provide an indication of the potential for impact interactions with a view to informing the Environmental Monitoring and Management Plan (EMMP) (Chapter 15).

Table 13.2 provides a basic indication of the number of impact interactions that may occur throughout the Sea Lion Development, including both planned, and unplanned events. Each receptor to an impact is identified with a 'Y' and is colour-coded, based on the outcome of the impact assessments in Chapters 10, 11 and 12. This aims to give an indication of both the range of receptors affected and the overall worst-case significance of the impact. As per Table 8.4 (Chapter 8), the colours are used to indicate the impact significance level, see Table 13.1 below.

For example, seabirds may be impacted in various ways by six aspects associated with planned activities, and by five aspects associated with unplanned activities, giving a total of eleven ways this receptor could be impacted. This highlights both the number of ways in which the receptor, e.g., seabirds, could be impacted and gives an indication of where impact interactions may occur i.e., by a combination of any of these factors. Table 13.2 illustrates that there is the greatest potential for planned and unplanned impact interactions to fish / cephalopods, seabirds, marine mammals and the seabed.

Table 13.1. Impact significance level colours (after Table 8.4)

High	Upper Moderate	Moderate	Low	Very Low	Beneficial
Unacceptable	ALARP			Broadly acceptable	Beneficial

Table 13.2: The number of ways receptors[1] could be impacted, indicating the worst-case significance[2] of the impact[3]

Receptor	Aspects associated with planned activities													Aspects associated with unplanned and accidental events								Total number of ways receptor could be impacted
	Environmental									Social				Environmental and social								
	Use of artificial light	Onshore disturbance from helicopters	Disturbance to seabed / placement of objects	Underwater noise	Drilling mud and cuttings	Operational discharges to sea	Thermal discharges to sea	Atmospheric emissions (climatic factors)	Management of waste	Increased vessel presence, subsea presence, exclusion	Competition for onshore resources	Nuisance factors to humans	Number of ways receptor could be impacted	Bird-strike	Loss of containment of solid waste	Unplanned emissions	Collision with marine mammals	Non-natives - marine	Non-natives - terrestrial	Loss of containment of crude, fuel oil, chemicals	Number of ways receptor could be impacted	
Human population									Y	Y	Y	Y	4		Y			Y	Y	Y	4	8
Other users of the sea										Y			1							Y	1	2
Commercial fisheries								Y		Y			2		Y			Y		Y	3	5
Plankton	Y		Y		Y	Y	Y	Y					6			Y		Y		Y	3	9
Benthos			Y	Y	Y	Y	Y	Y					6		Y	Y		Y		Y	4	10
Fish / cephalopods	Y		Y	Y	Y	Y	Y	Y					7		Y	Y		Y		Y	4	11
Seabirds	Y	Y		Y		Y	Y	Y					6	Y	Y	Y		Y		Y	5	11
Marine mammals		Y		Y		Y	Y	Y					6		Y	Y	Y	Y		Y	5	11
Terrestrial flora and fauna		Y						Y					2		Y	Y			Y		3	5
Designated sites		Y						Y					2		Y	Y			Y	Y	4	6
Biosecurity													0					Y	Y		2	2

Receptor	Aspects associated with planned activities													Aspects associated with unplanned and accidental events									
	Environmental									Social				Environmental and social									
	Use of artificial light	Onshore disturbance from helicopters	Disturbance to seabed / placement of objects	Underwater noise	Drilling mud and cuttings	Operational discharges to sea	Thermal discharges to sea	Atmospheric emissions (climatic factors)	Management of waste	Increased vessel presence, subsea presence, exclusion	Competition for onshore resources	Nuisance factors to humans	Number of ways receptor could be impacted	Bird-strike	Loss of containment of solid waste	Unplanned emissions	Collision with marine mammals	Non-natives - marine	Non-natives - terrestrial	Loss of containment of crude, fuel oil, chemicals	Number of ways receptor could be impacted	Total number of ways receptor could be impacted
Seabed (including soil)			Y		Y	Y	Y	Y	Y				6		Y	Y		Y	Y	Y	5	11
Water quality			Y		Y	Y	Y	Y	Y				6			Y				Y	2	8
Regional air quality											Y		1								0	1
Global atmosphere								Y	Y				2			Y					1	3
Landscape / seascape													0		Y				Y	Y	3	3
Tangible property, including livestock, landfill		Y							Y		Y	Y	4		Y				Y	Y	3	7

[1] Note: in some chapters, flora and fauna receptors may be grouped and assessed as, for example, 'marine organisms' or may be grouped into 'biodiversity' as a whole. Here these groupings have been separated out to better indicate the interactions e.g., the marine invasive risk assessment chapter assesses the impact to biodiversity as a whole but here each flora / fauna group is itemised.

[2] Where there are multiple impact assessments for a receptor, the higher impact is reflected here. For example, Artificial light impacts to seabirds offshore is assessed as 'Very Low' (green) but inshore the impact is assessed as Low (yellow), so only the higher impact (Low, yellow) is included in the above table.

[3] Please note that this table summarises the worst-case impact / risk assessment outcomes. While some impacts may have been identified as requiring further assessment ('F') in the ENVIID outcome tables (Chapter 9), the further assessment carried out may have concluded that there would be no impact. This is indicated where necessary in the individual assessment chapters (Chapters 10, 11 & 12). Further, while individual receptors may be highlighted within Figure 1-3 above, for some activities the actual impact assessment may refer to biodiversity as a whole to assess the broad and primary impact rather than to itemise each individual receptor, thereby avoiding excessive repetition.

14 SUMMARY OF EIS FINDINGS

14.1 Introduction

Table 14.1 presents a summary of all the impact and risk assessments above. Note that, for summary purposes, the 'residual assessment' column indicates the final outcome for all impacts and risks, whether project-specific mitigations and a residual assessment were required or not.

Table 14.1: Overall summary of EIA findings

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Chapter 10.1: Artificial light									
Presence of all vessels / MODU / FPSO offshore	Deck and accommodation lights, flare pilot light, and flaring during shutdowns.	Planned	The use of blackout blinds in accommodation block.	Attraction of plankton, invertebrates and fish			Reduce light pollution by: Design (where possible and limited by safety) and auditing. Dousing of unrequired lights.	**Very Low (1)**	**Probable**
				Sensitivity	Severity	Significance			
				Very Low	Slight	Very Low (1)			
		Planned		Attraction and disorientation of seabirds				**Very Low (2)**	**Probable**
				Sensitivity	Severity	Significance			
				Low	Slight	Very Low (2)			
		Planned		Attraction of marine mammals				**n/a**	**n/a**
				Sensitivity	Severity	Significance			
				n/a	n/a	n/a			
Presence of all vessels inshore		Planned		Attraction and disorientation of seabirds				**Low (4)**	**Probable**
				Sensitivity	Severity	Significance			
				High	Slight	Low (4)			
		Planned		Attraction of marine mammals				**n/a**	**n/a**
				Sensitivity	Severity	Significance			
				n/a	n/a	n/a			
Small scale bird-strike offshore		Unplanned		Injury or fatality to single / handful of birds				**Low (4)**	**Probable**
				Impact	Likelihood	Significance			
				Very low (2)	Likely	Low (4)			
Large scale bird-strike offshore		Unplanned		Injury or fatality to multiple (dozens) birds				**Moderate (9)**	**Probable**
				Impact	Likelihood	Significance			
				Moderate (6)	Possible	Moderate (9)			
Small scale bird-strike inshore		Unplanned		Injury or fatality to single / handful of birds				**Moderate (8)**	**Probable**
				Impact	Likelihood	Significance			
				Low (4)	Likely	Moderate (8)			
Large scale bird-strike inshore		Unplanned		Injury or fatality to multiple (dozens) birds				**Moderate (9)**	**Probable**
				Impact	Likelihood	Significance			
				Moderate (8)	Possible	Moderate (9)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Chapter 10.2: Onshore disturbance to wildlife from helicopter operations									
Helicopter use	Noise disturbance to wildlife.	Planned	FILFH	Impacts to breeding and moulting seabirds and marine mammals			None proposed.	**Low (4)**	**Certain**
				Sensitivity	Severity	Significance			
				Low	Minor	Low (4)			
Chapter 10.3: Disturbance to the seabed / placement of objects									
Placement of objects on the seabed	Installation of mooring systems, SPS and SURF at Sea Lion Field.	Planned	Good operational practise to minimise anchor scarring, Marine growth removal, Inspection of marine growth during seabed surveys / inspections, and Reporting and retrieval of dropped objects.	Disturbance to the benthos and habitats			None proposed.	**Very Low (1)**	**Probable**
				Sensitivity	Severity	Significance			
				Very Low	Slight	Very Low (1)			
		Planned		Habitat modification and marine growth on artificial substrate				**Low (3)**	**Probable**
				Sensitivity	Severity	Significance			
				Very Low	Moderate	Low (3)			
	Installation of OSR equipment and floating logistics vessel anchors in Berkeley Sound.	Planned		Disturbance to the benthos and habitats				**Very Low (3)**	**Probable**
				Sensitivity	Severity	Significance			
				Moderate	Slight	Very Low (3)			
Dropped objects	Loss of equipment or infrastructure.	Unplanned		Disturbance to the seabed and benthos				**Very Low (2)**	**Probable**
				Impact	Likelihood	Significance			
				Very Low (1)	Unlikely	Very Low (2)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance	Project-specific mitigation	Residual impact / risk	Confidence
Chapter 10.4: Underwater noise offshore							
Underwater vessel noise	Continuous moderate intensity noise.	Planned	No	Injury to invertebrates and fish Sensitivity: Low; Severity: Slight; Significance: Very Low (2)	None proposed.	**Very Low (2)**	**Uncertain**
		Planned		Injury to seabirds Sensitivity: High; Severity: Slight; Significance: Low (4)		**Low (4)**	**Uncertain**
		Planned		Injury to marine mammals Sensitivity: n/a; Severity: n/a; Significance: n/a		**n/a**	**n/a**
		Planned		Behavioural disturbance to marine mammals Sensitivity: High; Severity: Minor; Significance: Moderate (8)		**Moderate (8)**	**Uncertain**
Chapter 10.5: Underwater noise inshore							
Vessel operations within Berkeley Sound	Intermittent moderate intensity noise during LTV operations.	Planned	None	Behavioural disturbance to invertebrates and fish Sensitivity: Low; Severity: Slight; Significance: Very Low (2)	None proposed.	**Very Low (2)**	**Uncertain**
		Planned		Behavioural disturbance to seabirds Sensitivity: High; Severity: Slight; Significance: Low (4)		**Low (4)**	**Uncertain**
		Planned		Behavioural disturbance to marine mammals Sensitivity: High; Severity: Slight; Significance: Low (4)		**Low (4)**	**Uncertain**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance	Project-specific mitigation	Residual impact / risk	Confidence
Chapter 10.6: Discharge of drilling mud and cuttings							
Drilling operations	Discharge of seawater and bentonite sweeps, tophole drill cuttings and thermally treated NADF drill cuttings.	Planned	Compliance with Drilling discharges to be minimised as far as possible in line with BAT, Selection of benign chemicals where possible, NADF cuttings returned to the rig and thermally treated to minimise oil on cuttings (aiming to exceed compliance requirements), and Post-drilling monitoring of seabed recovery.	Water quality: Suspension of particles leading to increased turbidity Sensitivity: Very Low; Severity: Slight; Significance: Very Low (1)	None proposed.	**Very Low (1)**	**Probable**
		Planned		Plankton: Reduction in the ambient light, barite particles may affect zooplankton Sensitivity: Very Low; Severity: Slight; Significance: Very Low (1)		**Very Low (1)**	**Probable**
		Planned		Seabed sediment: Deposition of drill cuttings modifying sediment particle size Sensitivity: Very Low; Severity: Moderate; Significance: Low (3)		**Low (3)**	**Probable**
		Planned		Benthic fauna: Burial of benthic fauna, modification of habitat, toxicity and oxygen depletion Sensitivity: Low; Severity: Moderate; Significance: Moderate (6)	Continual improvement so that oil on cuttings will be minimised, as far as is possible, during drilling campaign to below a 0.5 % average.	**Moderate (6)**	**Probable**
		Planned		Fish and shellfish: Suspended barite particle may affect gill structures Sensitivity: Low; Severity: Minor; Significance: Low (4)	None proposed.	**Low (4)**	**Probable**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance	Project-specific mitigation	Residual impact / risk	Confidence
Chapter 10.7: Operational discharges							
Chemical discharges	Discharge general operational fluids e.g., hydrotest water	Planned	Selection of benign chemicals where possible, OiW target of 10-15 mg/l, RBA of PW, EI (2016) Guidance, Maintenance Management System, OMS, Off spec tank, and OEUK Well Clean-up Guidelines.	Impacts on water quality and marine organisms Sensitivity: Very Low; Severity: Slight; Significance: Very Low (1)	None proposed.	**Very Low (1)**	**Probable**
	PW discharge-commissioning of PWRI units	Planned		Toxic impacts on marine organisms Sensitivity: Very Low; Severity: Moderate; Significance: Low (3)		**Low (3)**	**Probable**
PWRI malfunction / unavailability	Discharge of PW	Unplanned		Acute and chronic impacts on marine fauna Impact: Very Low (2); Likelihood: Unlikely; Significance: Very Low (2)		**Very Low (2)**	**Uncertain**
All MODU, FPSO and vessel activity	Discharge of wastewater / food	Planned		Impacts to water quality and plankton Sensitivity: Very Low; Severity: Slight; Significance: Very Low (1)		**Very Low (1)**	**Certain**
	Discharge of drainage / bilge water	Planned		Impacts to water quality Sensitivity: Very Low; Severity: Slight; Significance: Very Low (1)		**Very Low (1)**	**Certain**
	Discharge of hypersaline water	Planned		Impact to benthos, flora and fauna Sensitivity: Very Low; Severity: Slight; Significance: Very Low (1)		**Very Low (1)**	**Certain**
Off-spec discharges of bilge and drainage	Formation of a sheen	Unplanned		Contamination of seabirds Impact: Upper Moderate (15); Likelihood: Very Unlikely; Significance: Low (4)		**Low (4)**	**Probable**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Chapter 10.8: Thermal discharges									
Heated subsea infrastructure	Radiation of heat	Planned	None.	Potential impact of heat on benthic fauna			None proposed.	**Very Low (1)**	**Probable**
				Sensitivity	Severity	Significance			
				Very Low	Slight	Very Low (1)			
Topside cooling process	Discharge of heated water	Planned		Potential for impacts on flora and fauna				**Very Low (1)**	**Probable**
				Sensitivity	Severity	Significance			
				Very Low	Slight	Very Low (1)			
Production from the FPSO	PW discharge (90°C) - PWRI commissioning	Planned		Potential for impacts on flora and fauna				**Very Low (1)**	**Probable**
				Sensitivity	Severity	Significance			
				Very Low	Slight	Very Low (1)			
PWRI unavailability	Discharge of PW overboard	Unplanned		Potential for impacts on flora and fauna				**Very Low (3)**	**Certain**
				Impact	Likelihood	Significance			
				Very Low (1)	Possible	Very Low (3)			
Chapter 10.9: Atmospheric emissions (climatic factors)									
Fuel combustion throughout Development	Generation of atmospheric emissions (CO_2, CH_4, N_2O, indirect NOx, SO2, CO, VOCs)	Planned	Use of BAT in project design, Monitoring and measuring, Selection and pre-mobilisation audits, Optimisation of operations, Management Maintenance System, SMART objectives and targets, and Ongoing ALARP reviews.	Contribution to global warming			Use of EEOI in developing tanker KPIs, and Investigation of pilot-free flare design using automatic ignition systems.	**Moderate (10)**	**Certain**
				Sensitivity	Severity	Significance			
				Very High	Minor	Moderate (10)			
		Planned		Contribution to ocean acidification				**Moderate (8)**	**Certain**
				Sensitivity	Severity	Significance			
				High	Minor	Moderate (8)			
Emergency blowdown / Venting of full HC gas blanket	Emissions of CO_2, NOx, SO_2, CO, VOCs and/or CH_4	Unplanned		Incremental increase in emissions				**Low (6)**	**Certain**
				Impact	Likelihood	Significance			
				Low (5)	Possible	Low (6)			
		Unplanned		Incremental increase in emissions				**Low (6)**	**Certain**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Malfunction of HVAC and fire-fighting equipment	Venting, flaring, release of F-Gas			Impact	Likelihood	Significance			
				Low (5)	Possible	Low (6)			
Use of sold product	Combustion of product	Planned	Impact is outwith Navitas' ability to influence.	Incremental increase in emissions			Impact is outwith Navitas' ability to influence.	**Upper Moderate (15)**	**Uncertain**
				Sensitivity	Severity	Significance			
				Very High	Moderate	Upper Moderate (15)			
Chapter 10.10: Waste generation and management									
Waste from drilling, installation / production	Use of landfill	Planned	Compliance with the Navitas OMS with regard to contractor management, auditing, performance monitoring and the setting of waste objectives and targets, E-Reps scheme, waste awareness training, segregated bins, signage, netting, dedicated waste laydown areas.	Use of landfill resource			Collaboration with FIG.	**Moderate (8)**	**Probable**
				Sensitivity	Severity	Significance			
				High	Minor	Moderate (8)			
Improper waste containment	Loss of containment of solid and liquid waste	Unplanned		Potential impact to landscape / seascape and human population				**Low (6)**	**Certain**
				Impact	Likelihood	Significance			
				Moderate (8)	Unlikely	Low (6)			
		Unplanned		Potential impact to wildlife				**Low (6)**	**Certain**
				Impact	Likelihood	Significance			
				Moderate (10)	Unlikely	Low (6)			
Improper waste segregation	Cross-contamination of waste	Unplanned		Increased use of landfill			None proposed.	**Low (6)**	**Certain**
				Impact	Likelihood	Significance			
				Low (5)	Possible	Low (6)			
Chapter 10.11: Collisions between vessels and marine mammals									
Presence of project vessels	Collisions during drilling,	Unplanned		Potential for fatal injury			Awareness training for vessel crews,	**Moderate (8)**	**Uncertain**
				Impact	Likelihood	Significance			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
	installation and production		Premise of NOAA (2009) guidelines will be followed. Increased vigilance by officer of the watch in high risk areas, Reduced vessel speed to 10 knots at the MMA boundary.	Upper Moderate (12)	Unlikely	Moderate (8)	Reduced vessel speed to max eight knots in Berkeley Sound Seabird and Marine Mammal Observers on vessels Reporting of collisions.		
	Collisions inshore Berkeley Sound	Unplanned		Potential for fatal injury				**Moderate (8)**	**Uncertain**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Possible	Upper Moderate (12)			
	Collision with small cetaceans	Unplanned		Potential for fatal injury				n/a	**Certain**
				Impact	Likelihood	Significance			
				n/a	n/a	n/a			
	Entanglement with chains	Unplanned		Potential for fatal injury				n/a	**Certain**
				Impact	Likelihood	Significance			
				n/a	n/a	n/a			
Chapter 10.12: Introduction of marine non-native species									
Navitas in-field vessels	Introduction of non-native species by project vessels, *via* ballast water and biofouling Potential to have irreversible impact on biodiversity and designated sites	Unplanned	Pre-selection and pre-mobilisation audits. Compliance with BWMC requirements - Exchange of ballast water *en route* or D2 treatment process. Vessel specific BMP and audit prior to leaving shipyard for to Falkland Islands. Oil Companies International Marine Forum (OCIMF) Ship Inspection Report	Potential impact			LTVs used as floating logistics vessels will have their hulls inspected prior to departure for the Falklands, Non-natives species monitoring programme and ballast sampling.	**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (20)	Unlikely	Moderate (10)			
Navitas *ad hoc* freight vessels		Unplanned		Potential impact				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (20)	Unlikely	Moderate (10)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
			Programme (SIRE) will be applied to audit BWMP and the BFMP and all records.						
Presence of Large Transport Vessels (LTV)		Unplanned		Potential impact				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (20)	Possible	Upper Moderate (15)			
Presence of third-party Conventional Trading Tanker (CTT)		Unplanned		Potential impact				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (20)	Unlikely	Moderate (10)			
Chapter 10.13: Introduction of terrestrial non-native species with cargo imports									
Freight arriving in the Falklands	Introduction of terrestrial non-native species. Potential to have irreversible impact on biodiversity and designated sites	Unplanned	None	Potential impact			Implementation of Project-specific Biosecurity Plan.	**Upper Moderate (12)**	**Probable**
				Impact	Likelihood	Significance			
				Upper moderate (12)	Upper moderate (12)	Upper moderate (12)			
Food products arriving in the Falklands	Introduction of pathogens in Food of Animal Origin (FOAO)	Unplanned		Potential impact			Source food of animal origin from UK / EU certified sources and from within the UK / EU.	**Low (4)**	
				Impact	Likelihood	Significance			
				Upper moderate (15)	Very Unlikely	Low (4)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance	Project-specific mitigation	Residual impact / risk	Confidence
Chapter 11.1: Disturbance to other users of the sea offshore							
Presence of offshore development	Offshore 1,275 m radius exclusion zone	Planned	Exclusion zones added to charts and status issued in 'Notes to Mariners' / on radio.	Exclusion of fishing vessels and loss of catch Sensitivity: Very Low; Severity: Slight; Significance: Very Low (1)	None proposed.	**Very Low (1)**	**Certain**
Interference - fishing gear and subsea infrastructure	Snagging of fishing gear	Unplanned	500 m exclusion zone, Permanent presence of ERRV, Amended Admiralty charts, AIS and radio broadcasts, and Collision risk management procedures.	Loss of fishing gear / subsea damage Impact: Moderate (9); Likelihood: Unlikely; Significance: Low (6)	None proposed.	**Low (6)**	**Probable**
Offshore vessel collision	Third-party vessel collision	Unplanned		Damage to vessel and FPSO / MODU Impact: High (20); Likelihood: Very Unlikely; Significance: Low (5)		**Low (5)**	**Probable**
Chapter 11.2: Disturbance to other users of the sea inshore							
Presence of vessels in Stanley	Use of amenities in Stanley Harbour	Planned	Adherence to the Stanley Harbour Management Plan.	Disruption to other users of Stanley Harbour Sensitivity: Low; Severity: Minor; Significance: Low (4)	None proposed	**Low (4)**	**Certain**
Berkeley Sound exclusion zones	Reduction in the area available to navigating and anchoring vessels	Planned	Use of local pilots for Navitas managed vessels in Berkeley Sound, and Status issued in 'Notes to Mariners' and on radio.	Loss of potential anchorage Sensitivity: Low; Severity: Minor; Significance: Low (4)	Briefing documents issued in the language of the Captain.	**Low (4)**	**Probable**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Collisions due to reduction in sea room in Berkeley Sound	Temporary exclusion zone	Unplanned	Exclusion zones added to charts and status issued in 'Notes to Mariners' / on radio. FI Berthing Master / Pilot will accompany LTVs prior to entering Berkeley Sound. FI information sheets available for Berkeley Sound, Port William and Stanley Harbour	Damage to vessels			In order to help communicate the positions and restrictions associated with the exclusion zones, briefing notes will be issued in the first languages of the vessel Captains.	**Low (4)**	**Probable**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Very Unlikely	Low (4)			
Collision due to addition of Phase 1 & 2 vessels	Collision in Stanley Harbour	Unplanned		Damage to vessels				**Low (6)**	**Probable**
				Impact	Likelihood	Significance			
				Moderate (6)	Unlikely	Low (6)			
Chapter 11.3: Resource competition - Accommodation									
Need to accommodate transitory personnel	Competition with domestic housing needs	Planned	None.	Reduction of available accommodation			None proposed.	**Very Low (2)**	**Probable**
				Sensitivity	Severity	Significance			
				Low	Slight	Very Low (2)			
Need to accommodate permanent personnel	Competition with domestic housing needs	Planned	None.	Reduction of available accommodation			None proposed.	**Low (4)**	**Probable**
				Sensitivity	Severity	Significance			
				Low	Minor	Low (4)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Chapter 11.4: Resource competition - Fresh potable water									
Water use for MODU drilling and vessel top-up and for onshore yards and accomm.	Competition for water resources	Planned	End user prioritisation, Buffer tank capacity and voluntary restrictions, Offshore desalination.	Restriction of water supply and / or quality			Sustainable design, and Offshore planning.	**Upper Moderate (15)**	**Uncertain**
				Sensitivity	Severity	Significance			
				Very High	Serious	High (20)			
Water use for offshore vessel top-up and onshore yards and accomm.		Planned		Restriction of water supply and / or quality				**Upper Moderate (15)**	**Uncertain**
				Sensitivity	Severity	Significance			
				Very High	Moderate	Upper Moderate (15)			
Chapter 11.5: Resource competition - Electricity									
Electricity use by TDF, yards, accomm. and heli ops	Competition with domestic energy needs	Planned	None.	Overloading of current capacity and need for use of stand-by generators			Sustainable design, and Off-peak power utilisation.	**Upper Moderate (12)**	**Uncertain**
				Sensitivity	Severity	Significance			
				High	Serious	High (16)			
Chapter 11.6: Resource competition - Air links									
International movement of personnel to and from the Falkland Islands	Air-link resource competition for seat availability	Planned	None.	Lack of seat availability of seats			The base-case dedicated regular charter flight will be sufficient to meet all personnel travel requirements.	**Low (4)**	**Certain**
				Sensitivity	Severity	Significance			
				High	Slight	Low (4)			
	Additional air-links	Planned		Potential for extra seat availability				**Beneficial**	**Uncertain**
				Sensitivity	Severity	Significance			
				Beneficial					

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Chapter 11.7 Resource competition - Road Network									
Use of existing road network	Increased number of vehicles and use of infrastructure	Planned	Adherence to vehicle and road statutory requirements. Specific applications for abnormal road movements including signage and warning devices. Strict HSE driving policy, risk assessment and local training. All non-critical activities coordinated to avoid peak periods.	Potential for nuisance to human population			Traffic Management Plan. Accommodation with off-street parking will be a preference.	**Moderate (6)**	**Probable**
				Sensitivity	Severity	Significance			
				Moderate	Minor	Moderate (6)			
		Planned		Degradation of road surfaces				**Low (4)**	**Probable**
				Sensitivity	Severity	Significance			
				Low	Minor	Low (4)			
		Planned		Degradation in air quality				**Low (3)**	**Probable**
				Sensitivity	Severity	Significance			
				Moderate	Slight	Low (3)			
Chapter 11.8: Disturbance to the human population - Light									
Operations at the TDF and supply base	Vessel, TDF and yard lighting	Planned	Good working practice and design, and Black-out blinds for the vessel accommodation sections.	Annoyance, sleep disturbance			Deck lights and yard lights will face inwards, Vessel lights to be turned off when not required, particularly deck lighting, TDF offices and yard offices.	**Moderate (6)**	**Probable**
				Sensitivity	Severity	Significance			
				Moderate	Minor	Moderate (6)			
Inshore operations in Berkeley Sound	Deck and accommodation lights	Planned		Annoyance, sleep disturbance, impairment of dark skies				**Moderate (6)**	**Probable**
				Sensitivity	Severity	Significance			
				Moderate	Minor	Moderate (6)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Chapter 11.9: Disturbance to the human population - Noise									
Helicopter use for crew changes and SAR test flights	Disturbance to human population	Planned	Use of specific flight plan in line with the flight avoidance map as the basis for flight planning, following the Falkland Islands Low Flying Handbook Guidance (FILFH, 2024).	Annoyance, sleep disturbance			Optimising design and management to minimise noise, Equipment specific noise mitigations, Activity restrictions.	**Low (4)**	**Probable**
				Sensitivity	Severity	Significance			
				Low	Minor	Low (4)			
	Noise disturbance to livestock	Planned		Stress, reduced lambing success				**Low (4)**	**Certain**
				Sensitivity	Severity	Significance			
				Low	Minor	Low (4)			
Operations at the TDF and supply base	Noise at the TDF, reversing alarms and yard activities	Planned	Compliance with noise guidelines.	Annoyance, sleep disturbance in Stanley				**Very Low (3)**	**Probable**
				Sensitivity	Severity	Significance			
				Moderate	Minor	Moderate (6)			
Inshore operations in Berkeley Sound	Noise from pumps, vessel engines and vessel loading	Planned		Annoyance, sleep disturbance				**Very Low (3)**	**Probable**
				Sensitivity	Severity	Significance			
				Moderate	Minor	Moderate (6)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Chapter 12.1: Offshore accidental and chronic discharges of crude oil and diesel									
Well drilling and production	Scenario 1: Subsea well blow-out	Accidental	Use of standard operating procedures, Compliance with OMS and Drilling Management System, SECE Register and performance standards, Primary and secondary well control, Development and implementation of the OPEP, Use of a well capping device.	Toxic effects on Plankton			Additional oil spill recovery equipment on support vessels.	**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (9)	Unlikely	Low (6)			
		Accidental		Toxic effects on Benthos				**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (4)	Unlikely	Low (6)			
		Accidental		Toxic effects on Fish and squid				**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (9)	Unlikely	Low (6)			
		Accidental		Taint of fish / contamination of grounds				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (20)	Unlikely	Moderate (10)			
		Accidental		Contamination / ingestion by seabirds				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Moderate (10)			
				High (20)	Unlikely	Moderate (10)			
		Accidental		Contamination / ingestion by mammals				**Moderate (8)**	**Uncertain**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Unlikely	Moderate (8)			
		Accidental		Impact on coastal ecology				**Moderate (8)**	**Uncertain**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Unlikely	Moderate (8)			
		Accidental		Negative publicity impacting on tourism				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (16)	Unlikely	Moderate (10)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Catastrophic loss of the FPSO	Scenario 2: loss of the full FPSO crude oil inventory	Accidental	SECE Register, OMS and performance standards, A 500 m radius exclusion zone, A ERRV vessel, AIS and Radar surveillance, Radio broadcasts, and Development and implementation of the OPEP.	Toxic effects on Plankton			Additional oil spill recovery equipment on support vessels.	**Very Low (3)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (9)	Very Unlikely	Very Low (3)			
		Accidental		Toxic effects on Benthos				**Very Low (3)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (4)	Very Unlikely	Very Low (3)			
		Accidental		Toxic effects on Fish and squid				**Very Low (3)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (9)	Very Unlikely	Very Low (3)			
		Accidental		Taint of fish / contamination of grounds				**Low (5)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (20)	Very Unlikely	Low (5)			
		Accidental		Contamination / ingestion by seabirds				**Low (5)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (20)	Very Unlikely	Low (5)			
		Accidental		Contamination / ingestion by mammals				**Low (4)**	**Uncertain**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Very Unlikely	Low (4)			
		Accidental		Impact on coastal ecology				**Low (4)**	**Uncertain**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Very Unlikely	Low (4)			
		Accidental		Negative publicity impacting on tourism				**Low (5)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (16)	Very Unlikely	Low (5)			
Offshore transfer of	Scenario 3: Crude oil transfer spill	Accidental	SECE Register, OMS and performance standards,	Toxic effects on Plankton			Additional oil spill recovery equipment on support vessels.	**Very Low (3)**	**Uncertain**
				Impact	Likelihood	Significance			
				Very Low (2)	Possible	Very Low (3)			

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance	Project-specific mitigation	Residual impact / risk	Confidence
crude from the FPSO to the CTT		Accidental	Pipelines will be protected by pressure alarms, A leak detection system will be fitted, Dry break couplings, Development and implementation of the OPEP.	Toxic effects on Benthos Impact / Likelihood / Significance n/a / n/a / n/a		n/a	n/a
		Accidental		Toxic effects on Fish and squid Impact / Likelihood / Significance Very Low (2) / Possible / Very Low (3)		**Very Low (3)**	**Uncertain**
		Accidental		Taint of fish / contamination of grounds Impact / Likelihood / Significance Low (4) / Possible / Low (6)		**Low (6)**	**Uncertain**
		Accidental		Contamination / ingestion by seabirds Impact / Likelihood / Significance Moderate (10) / Possible / Moderate (9)		**Moderate (9)**	**Uncertain**
		Accidental		Contamination / ingestion by mammals Impact / Likelihood / Significance Very Low (3) / Possible / Very Low (3)		**Very Low (3)**	**Uncertain**
		Accidental		Negative publicity impacting on tourist numbers Impact / Likelihood / Significance Moderate (6) / Possible / Moderate (9)		**Moderate (9)**	**Uncertain**
Catastrophic event leading to the loss of the MODU or FPSO	Scenario 4: Loss of MODU / FPSO full diesel inventory	Accidental	SECE Register, OMS and performance standards, A 500 m radius exclusion zone, A ERRV vessel, AIS and Radar surveillance, Radio broadcasts, and	Toxic effects on Plankton Impact / Likelihood / Significance Low (4) / Unlikely / Very Low (4)	Additional oil spill response equipment on support vessels.	**Very Low (4)**	**Probable**
		Accidental		Toxic effects on Benthos Impact / Likelihood / Significance n/a / n/a / n/a		n/a	n/a
		Accidental		Toxic effects on Fish and squid Impact / Likelihood / Significance		**Very Low (4)**	**Probable**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
			Development and implementation of the OPEP.	Low (4)	Unlikely	Very Low (4)			
		Accidental		Tainting of fish / contamination of fishing grounds				**Low (6)**	**Probable**
				Impact	Likelihood	Significance			
				Moderate (6)	Unlikely	Low (6)			
		Accidental		Contamination / oil ingestion by seabirds				**Moderate (8)**	**Probable**
				Impact	Likelihood	Significance			
				Upper Moderate (15)	Unlikely	Moderate (8)			
		Accidental		Contamination / oil ingestion by marine mammals				**Low (6)**	**Probable**
				Impact	Likelihood	Significance			
				Moderate (8)	Unlikely	Low (6)			
		Accidental		Negative publicity impacting on tourism				**Moderate (8)**	**Probable**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Unlikely	Moderate (8)			
Offshore transfer of diesel fuel	Scenario 5: Diesel bunkering spill	Accidental	SECE Register, OMS and performance standards, Maintenance Management System (MMS), Use of spill kits for spills to deck, Development and implementation of the OPEP.	Toxic effects on Plankton			Additional oil spill response equipment on support vessels.	**Very Low (3)**	**Probable**
				Impact	Likelihood	Significance			
				Very Low (2)	Possible	Very Low (3)			
		Accidental		Toxic effects on Benthos				n/a	n/a
				Impact	Likelihood	Significance			
				n/a	n/a	n/a			
		Accidental		Toxic effects on Fish and squid				**Very Low (3)**	**Probable**
				Impact	Likelihood	Significance			
				Very Low (2)	Possible	Very Low (3)			
		Accidental		Tainting of fish / contamination of fishing grounds				**Very Low (3)**	**Probable**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance	Project-specific mitigation	Residual impact / risk	Confidence
			Bunding of all liquid containing equipment and chemicals, Open deck drains to catch and collect spills to a dedicated slop tank, and High level tank filling alarm and emergency shutdown of the process.	Impact: Very Low (2) / Likelihood: Possible / Significance: Very Low (3)			
		Accidental		Contamination / oil ingestion by seabirds Impact: Moderate (10) / Likelihood: Possible / Significance: Moderate (9)		**Moderate (9)**	**Probable**
		Accidental		Contamination /oil ingestion by marine mammals Impact: Low (4) / Likelihood: Possible / Significance: Low (6)		**Low (6)**	**Probable**
		Accidental		Negative publicity impacting on tourist numbers Impact: Low (4) / Likelihood: Possible / Significance: Low (6)		**Low (6)**	**Probable**
Small scale spills and releases	Development of an oily sheen on the water	Unplanned		Potential for the formation of oily sheens, which can lead to the oiling of seabirds Impact: Moderate (10) / Likelihood: Possible / Significance: Moderate (9)		**Moderate (9)**	**Probable**
Riser disconnect	Loss of riser contents (NADF) to sea	Unplanned	Compliance with OMS and Navitas Drilling Management System.	Smothering and toxic effects on benthos and seabed Impact: Moderate (6) / Likelihood: Unlikely / Significance: Low (6)	Additional oil spill response equipment on support vessels.	**Low (6)**	**Probable**
Chapter 12.2: Inshore oil spill							
MGO Spill during fuel bunkering	Scenario 1: 10 tonne MGO spill	Accidental	Limiting operational criteria, Standard operational procedures,	Toxic effects on Plankton Impact: Moderate (9) / Likelihood: Unlikely / Significance: Low (6)	Clear manoeuvring and approach channel, Operational limits defined and implemented,	**Low (6)**	**Uncertain**
		Accidental		Toxic effects on Marine flora (kelp) Impact: Moderate (6) / Likelihood: Unlikely / Significance: Low (6)		**Low (6)**	**Uncertain**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
		Accidental	Development and implementation of the OPEP. Tug assist during manoeuvering.	Toxic effects on Benthic communities			Development and implementation of bunkering procedures with fuel supplier to ensure corporate standards of operational safety are maintained, Bunkering conducted within the 500 m LTV exclusion zone, or other defined area, Development and implementation of the OPEP, and On-site OSR capability.	**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (9)	Unlikely	Low (6)			
		Accidental		Toxic effects on Fish and squid				**Moderate (8)**	**Uncertain**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Unlikely	Moderate (8)			
		Accidental		Tainting of fish / contamination of fishing grounds				**Moderate (8)**	**Uncertain**
				Impact	Likelihood	Significance			
				Upper Moderate (12)	Unlikely	Moderate (8)			
		Accidental		Contamination / oil ingestion by seabirds				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (16)	Unlikely	Moderate (10)			
		Accidental		Contamination / oil ingestion by marine mammals				**Moderate (10)**	**Uncertain**
				Impact	Likelihood	Significance			
				High (16)	Unlikely	Moderate (10)			
		Accidental		Coastal communities				**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (8)	Unlikely	Low (6)			
		Accidental		Negative publicity impacting tourist numbers				**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (6)	Unlikely	Low (6)			
Vessel collision / grounding leading to MGO	Scenario 2: 1,200 tonne MGO spill	Accidental	Limiting operational criteria, Standard operational procedures,	Toxic effects on Plankton			Clear manoeuvring and approach channel,	**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (9)	Unlikely	Low (6)			
		Accidental		Toxic effects on Marine flora (kelp)				**Low (6)**	**Uncertain**

Activity / Event	Aspect	Type of activity	Industry-standard mitigation	Initial impact / risk and significance			Project-specific mitigation	Residual impact / risk	Confidence
Spill in Berkeley Sound			Development and implementation of the OPEP.	Impact	Likelihood	Significance	Operational limits defined and implemented, Development and implementation of bunkering procedures with fuel supplier to ensure corporate standards of operational safety are maintained, Bunkering conducted within the 500 m LTV exclusion zone, or other defined area, Development and implementation of the OPEP, and On-site OSR capability.		
				Moderate (6)	Unlikely	Low (6)			
		Accidental		Toxic effects on Benthic communities				**Low (6)**	**Uncertain**
				Impact	Likelihood	Significance			
				Moderate (9)	Unlikely	Low (6)			
		Accidental		Toxic effects on Fish and squid				**Moderate (8)**	**Uncertain**
				Impact	Likelihood	Significance

15.7.5 Vessel collisions (disturbance to human population) 1339
15.7.6 Oil spills 1340

15.1 Introduction

The Environmental Management and Monitoring Plan (EMMP), details the actions / plans required to:

- Measure and monitor the predicted and potential impacts of the Development,
- Check the efficacy of the project-specific mitigations in place, and
- Address uncertainties, such as spatial / temporal data gaps, to increase the level of confidence in the impact / risk assessment.

Should the monitoring of impacts indicate that the significance of the impacts and risks predicted in the EIS are not appropriate, and / or that mitigation is not effective, a revised mitigation measure and / or monitoring regime will be required.

The EMMP will identify specific monitoring and management plans for those issues where:

- The impact was assessed as '**Significant**' and / or the confidence in the assessment was assessed as either '**Probable**' or '**Uncertain**', or when
- The sensitivity of a receptor was assessed as '**High**' or '**Very High**' and / or the confidence in the assessment was assessed as either '**Probable**' or '**Uncertain**'.

These monitoring, mitigation, survey and research actions are noted in each assessment chapter (Chapters 10, 11 and 12) and are collated below.

Navitas has developed an EMMP strategy and will collaboratively work with FIG to identify how the EMMP may be jointly best managed. An integral part of the EMMP development process was an EMMP workshop (see below), which was conducted by POEPL in 2019.

Once the FDP has been approved and the project has been sanctioned, the EMMP will become a live document which will provide detail on:

- Specific roles and responsibilities,
- Timelines, deadlines and 'frequency of execution' for actions identified, and
- Progress and completion for use throughout the life of the field.

15.2 EMMP Workshop

A workshop to consider the content of an EMMP to accompany the Phase 1 & 2 Development Environmental Impact Statement (EIS) was held in Stanley, Falkland Islands on 23-25 April 2019. It was attended by 25 interested stakeholders, comprising FIG, POEPL, industry bodies and NGOs. Consideration was given to 11 of the environmental impacts and risks identified in the Environmental Impact Assessment (EIA) where there was potentially a need for further certainty as to the actual impact. Summary EMMP tables were prepared, and reproduced herein, for seven (reduced from 11 as inshore transfer was removed from the project (Section 2.1.1)) of these impacts, namely:

- Seabird attraction to light,
- Effects of underwater noise on marine mammals,
- Effects on offshore benthos,
- Risk of ship collision with cetaceans,
- Invasive species,
- Seabird risk from offshore oil spills, and
- Nuisance effects on humans.

15.3 EMMP Scope

The EMMP covers the activities to be undertaken as part of the construction, drilling and operational phases of the Sea Lion Development and aims to ensure the performance of the mitigations proposed within the EIS on the key project activities are monitored and managed.

Where execution of the proposed actions in the EMMP programme indicates that the mitigations / management actions proposed have not been appropriate, do not deliver the level or value expected, or indeed are considered unnecessary, the EMMP Steering Group may reassess the mitigations in place.

The Monitoring and Management Programme can be split into three types of work:

- Legislative and corporate monitoring activities (Section 15.4),
- Baseline data and survey work (Section 15.6), and /or
- Research and studies (Section 15.7).

The EMMP will also, where possible, identify the thresholds and the associated adaptive management actions.

Legislative and corporate monitoring requirements are determined by FIG or UK legislation and Navitas' corporate requirements, which are themselves driven by:

- Navitas' OMS being certified to ISO14001 or equivalent, and
- Navitas' environmental reporting commitments both to the GRI (Global Reporting Initiative) and in accordance with IOGP (International Association of O&G Producers) guidelines.

15.3.1 Screening

To determine whether actions over and above those stipulated by legislation or corporate governance were required, the EIS assessment results were screened for impacts and risks where:

- The impact was assessed as '**Moderate**' or above and the confidence in the assessment was assessed as either '**Probable**' or '**Uncertain**', and / or
- The sensitivity of a receptor was assessed as '**High**' or above and the confidence in the assessment was assessed as either '**Probable**' or '**Uncertain**'.

A worked example of the screening process is provided below in Table 15.1.

If an action is required it could lead to either further gathering of baseline data and survey effort, a requirement for further research or studies, or a management action.

All 'scoped in' impacts and risks are presented below in Table 15.2 and their corresponding EMMP action referenced.

It should be noted that for some impacts / risks that were scoped out, monitoring will still be required. This is either to comply with Navitas' corporate reporting standards, for example, in the case of the monitoring of day-to-day energy and water usage. There are also some aspects that will be monitored to ensure Navitas is following its social commitments as a responsible operator, such as monitoring for noise nuisance and tracking usage of local accommodation and use of seats on the Airbridge. These monitoring requirements are described in Section 15.4.

Table 15.1: Example: collisions between cetaceans and an inshore vessels

Impact assessment results					
Sensitivity	**Severity**	**Likelihood**	**Impact assessment**	**Residual impact assessment**	**Confidence**
High	Moderate	Unlikely	Moderate (8)	Moderate (8)	Uncertain
Screening					
Is an EMMP action required for this impact /risk?					
Is impact / risk '**Moderate**', '**Upper Moderate**' or '**High**' and is confidence '**Probable**' or '**Uncertain**'?				Yes, therefore EMMP action is required.	
Is sensitivity of receptor '**High**' or '**Very High**' and is confidence '**Probable**' or '**Uncertain**'?				Yes, therefore EMMP action is required.	

Table 15.2: Screened impacts and risks from the assessment that require EMMP action

EIS chapter	Impact / risk	Screening rationale based on impact / risk assessment	EMMP action
10.1 Artificial light	Risk of bird strikes offshore and inshore	Large and small scale bird collisions offshore Impact '**Moderate'**, Confidence '**Probable**' Large and small scale bird collisions inshore: Impact '**Moderate**', Confidence '**Probable**'	See Sections 15.6.2.1.2 and Section 15.7.1
10.4 Underwater noise offshore	Impact of vessel noise on receptors offshore	Injury to seabirds from underwater vessel noise Sensitivity '**High**', Confidence '**Uncertain**' Behavioural disturbance to marine mammals from vessel noise Impact '**Moderate**', Confidence '**Uncertain**'	See Section 15.6.2.1.3 and Section 15.7.3
10.6 Drill muds and cuttings	Impact to benthic fauna	Impact to benthic fauna Impact '**Moderate**', Confidence '**Probable**'	See Table 15.4 and Section 15.6.2.1.1
10.7 Operational discharges	Risk of sheens impacting seabirds offshore	Impact of oil sheens on seabirds Sensitivity '**Very High**', Confidence '**Probable**'	See Table 15.3, Table 15.4, Section 15.6.2.1.2 and Section 15.7.4
10.9 Atmospheric emissions	Combustion of sold product	Emissions from combustion of sold product Sensitivity '**Very High**', Confidence '**Uncertain**'	No action proposed as it is considered beyond the operator's ability to monitor the destination and/or end use of sold product
10.10 Waste	Use of a finite resource	Waste generation for disposal in the UK Impact '**Moderate**', Confidence '**Probable**'	See Table 15.3 and Table 15.4[1]
10.11 Cetacean collisions	Risk of Navitas vessels colliding with marine mammals offshore and inshore	Risk of vessels colliding with marine mammals Sensitivity '**High**', Confidence '**Uncertain**'	See Section 15.6.2.1.4
10.12 Marine invasives	Risk of introducing invasives by vessels associated with the Development	Introduction of invasives by Sea Lion in-field vessels, *ad hoc* freighter and CTT vessels Impact '**Moderate**', Confidence '**Uncertain**' Introduction of invasives by LTVs, in Berkeley Sound Impact '**Upper Moderate**', Confidence '**Uncertain**'	See Table 15.4, Section 15.6.2.1.6 and Section 15.7.2

EIS chapter	Impact / risk	Screening rationale based on impact / risk assessment	EMMP action
10.13 Terrestrial non-natives	Risk of introducing invasives by marine and air freight associated with the Development	Introduction of invasives by air freight Impact '**Upper Moderate**', confidence '**Probable**' Introduction of pathogen species in FOAO (Food of Animal Origin) Sensitivity '**Very High**', confidence '**Probable**'	See Table 15.4[1]
11.1 Other Users of the Sea Offshore	Third-party vessel collision	Damage to FPSO or MODU Sensitivity '**Very High**', Confidence '**Probable**'	See Table 15.5 and 15.7.5 15.6.2.2.1 and Section 15.7.5
11.4 Competition for water resources	Restriction of water supply and / or quality	Risk of restriction of water supply to the community and/or Project Impact '**High**' / '**Upper Moderate**', Confidence '**Uncertain**'	See Table 15.5
11.5 Competition for energy resources	Competition with domestic energy needs	Risk of overloading of current capacity Impact '**High**', Confidence '**Uncertain**'	See Table 15.5
11.7 Competition for roads network	Increased number of vehicles and use of infrastructure	Potential for nuisance to human population, e.g., congestion Impact '**Moderate**', Confidence '**Probable**'	See Table 15.5
11.8 Disturbance to the human population from light	Annoyance, sleep disturbance	Annoyance, sleep disturbance to Stanley residents Impact '**Moderate**', confidence '**Probable**' Annoyance, sleep disturbance and impairment of dark skies Impact '**Moderate**', confidence '**Probable**'	See Table 15.5 and Section 15.6.2.2.1
11.9 Disturbance to the human population from noise	Noise disturbance to residents	Annoyance, sleep disturbance to residents in Stanley and Berkeley Sound Impact '**Moderate**', confidence '**Probable**'	See Table 15.5 and Section 15.6.2.2.1
12.1, 12.2 and 12.3 Oil spills	Risk of oil spills offshore, inshore or at-shore	See Sections 12.1.12, 12.2.12 and 12.3.12	See Table 15.5 and Section 15.6.2.1.5, and Section 15.7.6

[1] Currently there are no additional monitoring measures proposed over and above that already required by legislation and / or Navitas' corporate requirements as there are no other feasible measures expected to be effective in monitoring these impacts / risks.

15.3.2 Periodic review of scope

At least every five years, the scope of the EMMP will be formally reviewed.

If, through acquisition of data outwith the EMMP or through third-party sources or observations, an impact that is initially scoped out appears to have unexpected significance, this will be raised at the Steering Group and a course of action agreed.

Equally, if sufficient evidence is present to demonstrate that the issue no longer reasonably meets the screening criteria, the issue will be removed from scope.

Changes to the EMMP scope may occur within the five-year period if agreed at the EMMP Governance Board.

15.4 Legislative and corporate monitoring

Legislative monitoring requirements cover those that are defined by FIG or, where no local legislation currently exists, the equivalent UK requirement. The EMMP must also cover Navitas' corporate environmental reporting requirements which are defined to meet the company's environmental reporting commitments both as a member of the IOGP and to report to the standards of the GRI.

All Navitas' environmental data systems are included in independent audits as part of Navitas' ISO 14001 certification or its equivalent, and as part of Navitas' annual reporting (Table 15.3) to the standards of the GRI.

Currently understood activities related to legislative and corporate environmental and social monitoring are shown in Table 15.4 and Table 15.5 respectively.

Any additional legislative requirements that may develop as FIG legislation is enacted will be updated in the EMMP as required.

Table 15.3: Navitas' environmental performance data reporting

Area	Sub Area	Data Requirements	Frequency	Units	Comment / Basis
GHG Emissions	Direct Emissions (Scope 1)	Gross Production	Monthly	Tonnes	Collected in Navitas database for HSE statistics
		Flared Gas	Monthly	Tonnes	Collected in Navitas database for HSE statistics
		Fuel Gas Use[1]	Monthly	Tonnes	Collected in Navitas database for HSE statistics
		Diesel Consumption	Monthly	Tonnes	To include diesel used on platforms and in vessels (standby and supply vessels), and to be reported by Business Units (BUs)
		Helicopter Fuel Use	Monthly	Tonnes	Reported to Navitas by helicopter provider
		Vented Gas[1]	Monthly	Tonnes	Estimated from information on point source vents and quantity vented, provided by the BUs.
		Fugitive Emissions	Monthly	Tonnes	Calculated using production figures and information on each facility from BUs
	Indirect Emissions (Scope 2)	Office Energy Consumption	Annually	kW-h	Reported by BUs. Also include the percentage of electricity consumption (if any) from renewable energy
	Indirect Emissions (Scope 3)	Global Business Travel	Annually	Tonnes CO_2e	Collected from corporate travel provider
Pollution Prevention	Planned Discharges	Produced Water	Quarterly	Tonnes	Reported by BUs
		Oil in Produced Water	Quarterly	Tonnes	Reported by BUs
		Drainage Water	Quarterly	Tonnes	Reported by BUs (if available)
		Oil in Drainage Water	Quarterly	Tonnes	Reported by BUs (if available)
		Black Water	Quarterly	Tonnes	Reported by BUs
		Grey Water	Quarterly	Tonnes	Reported by BUs
		Discharges to Air	Annually	Tonnes	Estimated by Navitas, to include NOx, SOx, VOC and CO emissions
	Unplanned releases	Hydrocarbon Spills	Monthly	Tonnes	BU to register cases in Navitas' incident reporting system cases and update as new information becomes available. Corporate to collect number of spills and quantity spilled from Navitas database for HSE statistics
		Chemical Spills	Monthly	Tonnes	BU to register cases in Navitas' incident reporting system and update as new information becomes available. Corporate to collect number of spills and quantity spilled from Navitas database for HSE statistics
	Waste	Hazardous Waste	Quarterly	Tonnes	Reported by BUs, to include quantity of waste recycled

Area	Sub Area	Data Requirements	Frequency	Units	Comment / Basis
		Non Hazardous Waste	Quarterly	Tonnes	Reported by BUs, to include quantity of waste recycled
Natural resources	Energy Use	Fuel Gas and Diesel	Annual	GJ	Calculated by Corporate based on fuel use figures provided by BUs
	Water Use	Drilling water, potable water offshore	Quarterly	Tonnes	Reported by BUs
	Biodiversity impacts	As identified in this EIS	Annual	-	To be covered in annual meeting/phone call for qualitative data collection

[1] Note there is zero planned flaring once into steady state production and zero routine venting.

Table 15.4: Legislative and corporate environmental monitoring requirements

Relevant Chapter	Impact	Relevant legislation	Legal Monitoring & Measurement requirements	Project-specific commitments	Navitas KPI	When monitored	Regularity of monitoring
10.6 Drill muds and cuttings	Discharge of treated NADF cuttings	FIG PON 10: <1 % oil on discharged cuttings	Monitor % oil on discharged cuttings	Navitas targeting 0.5 % oil on cuttings	No	Drilling	Representative (multiple) samples per well section
10.6 Drill muds and cuttings	Discharge of drill muds	UK Offshore Chemical Regulations (OCR) 2002: only approved chemicals may be discharged (application *via* Chemical Permit)	Select OCNS approved chemicals and monitor use and discharge	-	No	Drilling	Daily
10.7 Operational discharges	Discharge of chemicals during commissioning (hydrotest water)	UK OCR 2002: only approved chemicals may be discharged (application *via* Chemical Permit)	Select OCNS approved chemicals and monitor use and discharge	-	No	Commissioning and hook up	Weekly
10.7 Operational discharges	Discharge of chemicals during operations (cooling water, prod water)	UK OCR 2002: only approved chemicals may be discharged (application *via* Chemical Permit)	Select OCNS approved chemicals and monitor use and discharge	-	No	Operations	Monthly
10.7 Operational discharges	Discharge of NADF % in completion fluids	UK Well Cleanup Guidelines: must be visibly clean	Monitor NADF % in completion discharges, only visibly oil-free water discharged	Oily water treatment system installed on MODU, target <30 mg/l	No	Drilling	Representative (multiple) samples during each wellbore clean-up
10.7 Operational discharges	Discharge of drainage water from MODU,	MARPOL (Annex 1): No discharges >15 ppm in transit	Monitor drainage discharges	No discharges > 15 ppm in transit and on station	No	Throughout Field Life	Daily

Relevant Chapter	Impact	Relevant legislation	Legal Monitoring & Measurement requirements	Project-specific commitments	Navitas KPI	When monitored	Regularity of monitoring
	FPSO and vessels						
10.7 Operational discharges	Discharge of produced water (not normal operation)	FIG PON8: 40 mg/l averaged over the month, and that no single discharge exceed 100 mg/l. 30 mg/l monthly average during periods of discharge has been advised by DMR verbally.	Monitor any produced water discharge for oil in water content, Volume injected, Volume discharged, Monitoring of dissolved components	Averaged monthly discharge target 10-15 mg/l. Target 93 % produced water reinjection uptime	Yes (OIW content and PWRI uptime)	Production (if PWRI offline)	Twice daily samples if over-boarding, Volumes taken daily, Dissolved components twice a year
10.9 Atmospheric emissions	Combustion equipment and fuel use	The Climate Change Act 2008 and The Climate Change Act 2008 (2050 Target Amendment) Order 2019.	Meter fuel gas, Monitor all diesel, helifuel and MGO use, Calculate and reports all emissions from MODU and FPSO, Monitor fuel gas composition Monitor NOx and SOx emissions	Injection of surplus gas, Efficient design including turbine selection and waste heat recovery, Use of MGO instead of IFO inshore, Auditing of third-party vessels during pre-mobilisation process	Yes (energy use, GHG intensity and Gas Production / Injection (GPI) uptime)	Throughout Field Life	Monthly. For fuel gas composition, quarterly. For NOx emissions, occasionally during Field Life Annually: Other releases e.g., fugitive emissions, MODU emissions
10.9 Atmospheric emissions	Flaring	UK Petroleum Act 1998 UK Petroleum Licensing (Production) (Seaward Areas) Regulations 2008 World Bank Zero Routine Flaring initiative	Meter all flaring, Monitor flare gas composition	No routine flaring except HP pilot, Flare recovery system on FPSO and gas reinjection, see also studies in Section 15.7.1	Yes (energy use)	Throughout Field Life	Daily. For flare gas composition, quarterly.

Relevant Chapter	Impact	Relevant legislation	Legal Monitoring & Measurement requirements	Project-specific commitments	Navitas KPI	When monitored	Regularity of monitoring
10.9 Atmospheric emissions	Venting	UK Energy Act 1976 UK Petroleum Act 1998 Global Methane Pledge	Monitor all unplanned venting	Vapour recovery package on cargo tanks, Leak detection programme, no routine flaring	Yes	Production	As required
10.9 Atmospheric emissions	F-Gases	The Fluorinated Greenhouse Gases Regulations 2015	Monitor all unplanned F-gas releases	Log all F gas inventories on the facility, maintain *via* specialist contractors	No	Drilling and Production	As required
10.9 Atmospheric emissions	Fugitive emissions	n/a	Minimise all fugitive emissions	Minimisation of releases *via* good practices including STEP Change Hydrocarbon Release Reduction Toolkit	No	Drilling and Production	Ongoing leak detection and repair programme including use of FLIR (Forward looking Infra-Red) Camera
10.10 Waste	Waste production	UK Waste Regulations (various), Falkland Islands Pollution Prevention and Waste Management Policy	Monitor all waste generated on the MODU, FPSO, vessels, TDF and onshore bases	Education of offshore and onshore personnel on waste management and consequences of mis-management. To be included in all personnel inductions, E-Reps[1] programme, Biosecurity Management Plan implemented.	Yes	Throughout Field Life	Monthly

Relevant Chapter	Impact	Relevant legislation	Legal Monitoring & Measurement requirements	Project-specific commitments	Navitas KPI	When monitored	Regularity of monitoring
10.12 Marine non-natives	Introduction of marine non-native species	n/a	Adhere to IMO BWMC[2] (no monitoring actions required)	Adherence to ballast water and biofouling requirements included in pre-selection and pre-mob audits, Sampling of ballast water discharges from LTVs and OCVs in Berkeley Sound. LTVs hull inspection requirement included in vetting, Sampling of shoreline, benthos, settlement plates and structures for presence of non-native species	No	LTVs, OSV and PSV	As required for vessels. Seasonally or less frequently for presence of non-native species in the environment.
10.13 Terrestrial invasives	Introduction of terrestrial non-native species	n/a	Adhere to FIG Biosecurity Guidelines – FIG monitor of incoming cargoes	Biosecurity Management Plan implemented Training and awareness for yard/TDF personnel accepting cargoes, E-Reps[1] programme, Visual inspection of all cargoes on arrival	No	Throughout Field Life	As required
12.1, 12.2 & 12.3 Oil spill offshore, inshore and at-shore	Impact to various flora and fauna	FIG PON8: Reporting spills and sheens FIG OPEP requirements: An OPEP must be submitted to FIG	Monitor all spills and sheens and report to FIG	Regular oil spill response exercises to be conducted. Tests with oil on fur to be completed prior to	Yes	Throughout Field Life	As required

Relevant Chapter	Impact	Relevant legislation	Legal Monitoring & Measurement requirements	Project-specific commitments	Navitas KPI	When monitored	Regularity of monitoring
				drilling commencing and in sufficient time to inform key operational documents including ERPs and OPEPs, subject to import permits (for France).			
Other	n/a	n/a	n/a	Development of an E-Rep[1] role	No	Throughout Field Life	n/a

[1] A voluntary Environmental representative (E-Rep) role on the MODU / FPSO to promote environmental awareness, similar to a Safety Rep.
[2] Ballast Water Management Convention.

Table 15.5: Legislative and corporate social monitoring requirements

Relevant Chapter	Impact	Relevant legislation	Legal Monitoring & Measurement requirements	Project-specific commitments	Navitas KPI	When monitored	Regularity of monitoring
11.3 – 11.7 Competition for Resources	Impact to local residents from competition for accommodation, water, power, air links	n/a	n/a	All complaints will be monitored. All use of local accommodation and Airbridge monitored, Water and power use monitored.	Water use and power use	Throughout Field Life	As required
11.8-11.9 Nuisance to the human population	Impact to local residents from light and noise	n/a	n/a	All complaints will be monitored. Confirm background noise levels.	No	Throughout Field Life	As required
11.1 and 11.2 Disturbance to other users of the sea	Impact to other users of the sea due to additional vessels present and exclusion zones offshore and inshore	n/a	n/a	All complaints will be monitored, reviewed and responded to.	No	Throughout Field Life	Reporting of all vessel incursions into the exclusion zones

15.5 Governance

The following governance framework for the EMMP was discussed at the EMMP Workshop in 2019. A governance board consisting of representatives of FIG and of Navitas was suggested. This would be supported by an advisory forum including both non-technical stakeholders and relevant individuals with expertise in the subjects being monitored and managed (e.g., offshore benthos, seabirds, marine mammals, invasive species). The advisory forum would help draw up the specifications in any scope of work used in contracting particular monitoring work, and would also be able to comment upon the results of the monitoring or performance / success of management actions. This commentary may include giving advice as to whether any threshold has been passed, any further management that might be needed and reviewing whether monitoring efforts should be increased or could be reduced. Decision-taking on the whole EMMP lies ultimately at FIG level, but the above suggestions would provide support to such decisions, while also ensuring that stakeholders would be able to be involved at all relevant stages.

Throughout Field Life, information arising from the EMMP process will be reported to the EMMP Governance Board on a regular basis, likely biannually. The relevant actions will be discussed and the programme of work updated as necessary. Meetings of the Governance Group will include FIG, technical advisors, and invited or statutory stakeholders, with outputs reported publicly.

15.6 Baseline data and survey work

15.6.1 Project timeline

Where uncertainties in the EIS arise from lack of baseline data (Section 7.2.4), Navitas propose to develop a number of key surveys and data collection programmes related to the key phases of the project:

- Pre-sanction,
- Post-sanction and pre-First-Oil, and
- Post-First-Oil and throughout production.

Table 15.6 shows the three main phases of the project timeline. This is included for each EMMP activity to show when it will occur and for how long the programme will continue.

Table 15.6: Project timeline

Pre-sanction			Post-sanction and pre-First-Oil				Post-First-Oil and throughout production		
Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction and Commissioning	First-Oil	Production	End of Field Life

15.6.2 Proposed survey activities

Based on the uncertainties noted in the EIS, the proposed surveys include:

- Offshore seabird monitoring using SMMOs which will be deployed for the first three years of operations initially, followed by a review of the data collected and evaluation of the need for ongoing monitoring,
- Measurements of underwater noise during construction operations at Sea Lion,
- Marine mammal observations prior to and during operations at the Sea Lion location and on transits,

- Pre-drilling seabed surveys of benthos and sediment chemistry at Sea Lion, and ongoing throughout Field Life,
- Invasive species monitoring of shorelines, benthos, settlement plates and structures, and
- Operational monitoring and measurements of potential disturbance to humans ongoing throughout Field Life.

The EMMP activities presented below are an outline only and the final scope of environmental baseline data collection, surveys, monitoring, thresholds and potential management actions will be discussed and agreed with input from technical advisors and the Governance Board.

Table 15.7 below presents an overview of the EMMP survey activities throughout Field Life. They are followed by individual workscope activities (see Section 15.7 below) which provide further details, as guided by the EIS assessment. These proposed activities are set out in each chapter of the EIS but these workscopes describe the proposed scope of the task and any concurrent surveys or monitoring (outwith Navitas activities), which may feed into the Navitas scope of work. Indications of timing and regularity are provided as well as any reporting requirements.

Table 15.7: Overview of proposed EMMP survey activities throughout Sea Lion Field life

Year					1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	...	30	See Section

15.6.2.1 Environmental

15.6.2.1.1 Benthic sediments

Impact Chapter Ref: 10.6 Drill Cuttings										
Reason for inclusion: Pre-drilling environmental surveys to confirm no habitats or species of conservation significance are present within the zone of influence and ongoing surveys every five years thereafter.										
Management Objective: Confirm no habitats or species of conservation significance are present withing the zone of influence of each drill centre										
Scope of work: Seabed grabs for sediment characterisation, benthos, chemistry and heavy metal analysis (e.g., TOM and TOC levels, PAH, metal toxicity etc.) Visual survey with ROV at each monitoring station. Cuttings pile sampling. Analysis of PAH content of treated cuttings.										
Inputs to task	Agree habitats and species of concern prior to ROV survey and ensure competent person on board (or available remotely) during ROV survey who is familiar with these habitats / species									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Notes	Survey repeated every five years.									
Reporting	Results shared with FIG									
Adaptive Management Thresholds	Resample - If habitats of species of significance are found, position will be moved slightly away from habitat or species of conservation significance Review – During production drilling and once drilling complete Investigate - Analysis shows a new or significantly changed species or habitat not previously noted in benthic surveys in the area React – Significant change to species and / or habitats noted during previous benthic surveys at multiple locations Adapt - Presence of habitats or species of conservation significance throughout the area									
Potential Management Actions	Reaction – Move location of penetration to avoid species or habitat of conservation significance									

15.6.2.1.2 Seabirds

<table>
<tr><td colspan="11">Impact Chapter Ref: 10.1 Artificial light, 10.7 Operational discharges and Sections 12.1 and 12.2 on oil spill</td></tr>
<tr><td colspan="11">Reason for inclusion: To support historical seabird at sea Team (SAST) surveys[1]</td></tr>
<tr><td colspan="11">Management Objective: To collect further seabird data from vessels associated with the Sea Lion development.</td></tr>
<tr><td colspan="11">Scope of work: Use of SMMOs for the first three years on vessels in transit between the Falkland Islands and the Field[2]. Offshore SMMO observations will be collated and reviewed every six months and again after the first three years to validate the EIA and determine whether or not ongoing monitoring is required
Investigate – Any multiple bird strikes on single vessel
React – Multiple bird strikes on more than one vessel
Adapt – Occasional but repeated bird strikes</td></tr>
<tr><td>Potential Management Actions</td><td colspan="10">Reaction – Investigate alternative lighting methods (e.g., as new technology emerges)</td></tr>
</table>

[1] The SAST data was a collaboration between FIG and industry in terms of funding and was delivered by the Joint Nature Conservation Council (JNCC) in conjunction with Falklands Conservation (FC). The EMMP workshop agreed that it would be useful to collect further seabird data opportunistically from vessels associated with the Sea Lion Development, but that an area wide data collection effort was considered beyond the scope of an individual operator. It was agreed that this will require a FIG-Pan industry collaboration; an initiative which is considered needs to be coordinated by FIG.

[2] **Post-consultation note (July 2025):** Potential for guidance in the vessel specific ASOGs (Section 5.5.1) regarding northerly passage into Berkeley Sound and adherence to allocated time windows for entry.

15.6.2.1.3 Marine mammals – underwater noise

<table>
<tr><td colspan="11">EIA Chapter Ref: 10.4 Offshore underwater noise</td></tr>

Two SMMOs on vessels transiting between field and Stanley
Systematic programme and protocols to be developed</td></tr>
<tr><td>Reporting</td><td colspan="10">SMMO and noise reports to FIG</td></tr>
<tr><td>Adaptive Management Thresholds</td><td colspan="10">Resample - n/a
Review - SMMO observations will be collated and reviewed every six months and again after the first three years to validate the EIA and determine whether or not ongoing monitoring is required
Investigate - Any adverse noise-related behaviour of marine mammals
React - Any mass noise-related behaviour
Adapt - Chronic noise-related behaviour change</td></tr>
</table>

EIA Chapter Ref: 10.4 Offshore underwater noise	
Potential Management Actions	Reaction - Scale back noisy activity. Adaptation - Adjust timing of operations.

15.6.2.1.4 Marine mammals - Collision

EIA Chapter Ref: 10.11 Cetacean collisions										
Reason for inclusion: Sensitive receptor with potentially significant impact										
Management Objective: Confirm that impacts are within the envelope of predictions in the EIS, and feedback data to review the significance of impacts and the measures to mitigate any significant impacts										
Scope of work: Post-sanction, pre-First-Oil, post-First-Oil: Baseline data collection and ongoing monitoring - Independent SMMOs on OSVs for ongoing monitoring and mitigation										
Inputs to task	Observation protocols to be developed Cetacean Code of Conduct for the Falkland Islands									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Frequency	SMMOs on board vessels periodically covering all seasons over the first three years with particular focus at the time of year when animals are concentrated in the area of ship movements Complete for first three years of the project then review and revise strategy as required (depending on other ongoing work)									
Notes	SMMOs will make observations at site as well as during transits between Sea Lion and the Falkland Islands Align with any concurrent marine mammal monitoring programmes Seabird observers will also contribute to marine mammal survey as well as collecting seabird data Two SMMOs on OSVs transiting between field and Stanley Systematic programme and protocols to be developed									
Reporting	SMMO reports to FIG, real time reports between vessels if aggregations of marine mammals observed.									
Adaptive Management Thresholds	Resample - n/a									

	Review - Inshore SMMO observations will be collated and reviewed once operations in Berkeley Sound cease – these data will be used to validate the EIA. Offshore SMMO observations will be collated and reviewed every six months and again after the first three years to validate the EIA and determine whether or not ongoing monitoring is required Investigate - Any near miss situations with marine mammals React - Any collision or suspected collision Adapt - Occasional but repeated interactions at risk of collision
Potential Management Actions	Reaction - Reduce vessel speed near marine mammals not attracted to the vessel Adaptation - Add marine mammal detection systems (e.g., infra-red camera systems); adjust timing of operations; consider use of deterrents

15.6.2.1.5 Oil Spill

EIA Chapter Ref: 12.1 Offshore oil spill, 12.2 Inshore oil spill and 12.3 At-shore oil spill										
Reason for inclusion: To survey potentially significant impacts resulting from any unplanned oil releases										
Management Objective: Confirm that impacts are within the envelope of predictions in the EIS, and feedback data to review the significance of impacts and the measures to mitigate any significant impacts										
Scope of work: Post-sanction, pre- and post First-Oil: Baseline data collection - Use of Independent SMMOs on Navitas vessels infield and on transit to and from the field and potentially the helicopters to detect oiled birds (and help in wider data collection) Sampling of oil from plumage of oiled birds to determine if it is Sea Lion crude										
Inputs to task	Review GAP modelling work, which may augment the Seabirds At Sea Team data Methods to be agreed Application of project-specific OPEPs									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Frequency	In the event of a spill									
Notes	University of Highlands and Islands are conducting a review of the Oil Vulnerability Indices for oil and gas activities in the sub-Arctic. An Oil Vulnerability Index has been updated to Seabird Oil Sensitivity Index in the UK Continental Shelf The Sea Lion oil spill strategies and statutory reporting of all oil spills are relevant									
Reporting	Data to be reported to FIG									

15.6.2.1.6 Marine Invasive species

Impact Chapter Ref: 10.12 Marine non-natives										
Reason for inclusion: Potentially significant impact resulting from introduction of invasive species										
Management Objective: Confirm that presence of non-native species is not increased beyond levels of background change. Feedback observations into management of the issue.										
Scope of work: Settlement plates will be positioned in Berkeley Sound prior to and during the construction phase of the project. Settlement plates will be positioned at the Temporary Dock Facility / Stanley Harbour for sampling throughout the duration of the project. In the event that a new marine invasive species is discovered, a pathway analysis will be conducted to attempt to determine where / how the species had been brought to the Islands. If appropriate, safe and feasible, efforts will be made to eradicate the invasive species.										
Inputs to task	Discussion with FIG Biosecurity Officer									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Notes	Ballast water management in line with IMO standards will be undertaken regardless of any further actions. Pre-charter inspection of hulls for fouling will also be undertaken									
Reporting	Results shared with FIG									
Adaptive Management Thresholds	Resample - If obvious failure or contamination of a monitoring site or inconclusive tests of settlement plates Review - Annual review of results Investigate - Analysis shows a new or significantly changed species within a list of high-risk species; employ pathway analysis to determine most likely causes React - Obvious infestation or release or gross contamination of equipment / cargo. Adapt - Presence of high risk species or adverse change in species composition outwith background variation									
Potential Management Actions	Reaction - Minimise ballast water discharge inshore, refuse mooring to contaminated vessels, backload contaminated cargo Adaptation - Change vessel logistics, additional treatment or exchange of ballast water									

15.6.2.2 Social

15.6.2.2.1 Disturbance to humans

Impact Chapter Ref: 11.8 and 11.9 Disturbance to the human population from light and noise										
Reason for inclusion: Potentially significant impact from light and noise emissions										
Management Objective: Confirm that impacts are within the envelope of predictions in the EIS and feedback observations into management of the issue										
Scope of work: Post-sanction, pre-First-Oil: Baseline data collection and ongoing monitoring - Light and noise monitoring in Stanley Light and noise monitoring and photographs taken from relevant receptors to establish baseline. Further monitoring and photographs during operations to verify EIS predictions and monitor any changes. Ongoing monitoring and recording of all complaints received										
Inputs to task	Helicopter, FIGAS and onshore baseline noise recordings Any synergistic outcomes from the joint Navitas/FIG Social Effects Monitoring Programme. BS EN 12464-2:2007 for lighting intrusion BS 4142 for industry noise BS 8233 for community noise									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Frequency	Frequency and continued monitoring dependent on impacts recorded and complaints received									
Notes	-									
Reporting	Reports to FIG									
Adaptive Management Thresholds	Resample - If surveys are compromised by weather Review - Review survey findings within 6 months Investigate - If noise levels are >5 dBA above those predicted and there are reasonable grounds to link this to the project activities; any incident of complaint. React - If noise levels are >10 dBA above those predicted and there are reasonable grounds to link this to the project activities; multiple related complaints. Adapt - Continued regular complaints over period of 1 year									
Potential Management Actions	React - Change operational practices e.g., timing of activities; switch off idle equipment Adapt - Replace, muffle or shield equipment; provide additional physical barriers; look at alternative logistics arrangements or equipment									

15.7 Research and studies

15.7.1Seabirds

Impact Chapter Ref: 10.1 Artificial light										
Scope of work: The use of different light spectra (green lighting) and the use of a ballistic flare ignition system to negate the need for a pilot light) will be explored in the FEED process with Reliability, Availability and Maintenance (RAM) studies conducted for viable options, and ongoing monitoring of bird-strikes during the operation will serve to validate the impact assessment and adjust the use of mitigation measures as necessary[1]. Reporting of bird strikes Investigation into the possibility of a collaborative survey with FIFD, potentially using the fisheries patrol vessel as a platform. Investigation of a seabird distribution monitoring programme to be developed over several years with an understanding of ongoing work and in collaboration with FIFD.										
Inputs to task	FEED / Detailed Design contractor studies Bird strike protocol Training for downed seabirds for crew Explore collaboration with FIFD									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Notes	Once activities start in the Falklands, bird strike reporting will commence both offshore and onshore at the base									
Reporting	Results shared with FIG Monthly reporting of bird strikes to FIG									

[1]**Post-consultation note (July 2025):** Potential for guidance in the vessel specific ASOGs (Section 5.5.1) regarding northerly passage into Berkeley Sound and adherence to allocated time windows for entry.

15.7.2 Marine Invasives

Impact Chapter Ref: 10.12 Marine non-natives										
Scope of work: In the event marine invasives are discovered in the course of normal monitoring, pathways analysis will be conducted to determine where / how invasives are being brought into the Islands This will be done in conjunction with genomics whereby water samples are taken at various points and analysed to identify the individual DNA										
Inputs to task	Discussion with FIG Biosecurity Officer (DNR) Investigation into antifouling slick paints Biosecurity Management Plan									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Notes										
Reporting	Results shared with FIG									

15.7.3 Underwater vessel noise

Impact Chapter Ref: 10.4 Underwater noise offshore										
Scope of work: Investigate low noise thrusters and propellers on any Navitas operated and newly constructed / re-fitted vessels, i.e., MRSVs and inshore support vessels, ERRV and AHTS										
Inputs to task	Vessel specifications									
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**		
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life
Notes	Navitas is aware this technology is used by local fishing companies Vessels will be dry docked in accordance with their classification requirements. Hulls and propellers will be cleaned accordingly. Engines shall be maintained similarly and Dynamic Positioning will be used only when necessary									
Reporting	Results shared with FIG and informs EIS impact assessment chapter reviews									

15.7.4 Seawater quality

Impact Chapter Ref: 10.7 Operational discharges											
Scope of work: Risk Based Approach (RBA) to ascertain composition of produced water, and modelling (using a suitable model) of produced water once samples taken and composition known to confirm impact zone, impact assessment in EIS and test the model											
Inputs to task	Produced water samples: Whole Effluent Testing in line with the laboratory analysis requirements of the UK RBA Implementation Programme										
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**			
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life	
Notes	After produced water breakthrough in Sea Lion reservoir										
Reporting	Results shared with FIG										

15.7.5 Vessel collisions (disturbance to human population)

Impact Chapter Ref: 11.1 Disturbance to other users of the sea											
Scope of work: An AIS based study will be carried out at the location of the Sea Lion Development to confirm the shipping traffic pattern in the area once the FPSO exclusion zone is in place											
Inputs to task	AIS data										
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**			
	Now	EIS submission	Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life	
Notes	Once FPSO exclusion zone is established										
Reporting	Results shared with FIG										

15.7.6 Oil spills

Impact Chapter Ref: 12.1, 12.2 & 12.3 Oil spills											
Scope of work: Maintain continuous and live hydrodynamic model for use in the event of any spills. Once into production actual flow rates will be compared with modelled flow rates. If actual flow rates are higher than predicted, modelling will be re-run. Use of the spill modelling and hydrodynamic data to develop a means of forecasting spill trajectories to enable rapid and targeted response in the event of a spill. Complete testing of oil adhesion to seal fur prior to drilling commencing, subject to import permits (for France).											
Inputs to task	Well flowrates. Weather data.										
Timing	**Pre-sanction**			**Post-sanction and pre-First-Oil**				**Post-First-Oil and throughout production**			
	Now		Public consultation	Sanction / FIG approval	Construction of FPSO etc.	Development drilling	Offshore construction	First-Oil	Production	End of Field Life	
Notes	Hydrodynamic data will be collected to develop and improve the model										
Reporting	Results shared with FIG										

16 FINAL REVIEW AND CONCLUSION

Table of Contents

16.1 Introduction 1342
16.2 Significant impacts and risks of planned activities and unplanned events 1342
16.3 Significant risks associated with accidental events 1343
16.4 Overall conclusion 1344

16.1 Introduction

Sea Lion Field Phase 1 & 2 Development is the first proposed oil and gas (O&G) production development in the waters of the Falkland Islands. Therefore, a precautionary approach was taken with respect to all assessments carried out within this EIS. Nonetheless, the majority of the residual impacts and risks associated with the Phase 1 & 2 Development were considered to be of 'Low' or 'Very Low' significance and are not considered to warrant further reduction to meet Navitas' Policy of doing all that is 'reasonably practicable' to minimise environmental impacts. These will, however, be periodically reviewed to ensure that the controls remain in place.

No residual impacts or risks were considered to be '**High**'.

However, while all residual impacts and risks have been reduced to ALARP, some were still considered to be of potentially '**Moderate**' or '**Upper Moderate**' significance and shall be subject to continuous improvement where opportunities exist.

16.2 Significant impacts and risks of planned activities and unplanned events

Significant residual impacts from planned activities and unplanned events associated with planned activities are:

- Artificial light - risk of bird-strikes - **Moderate** (Section 10.1),
- Vessel noise offshore – potential for behavioural disturbance impacts to marine mammals - **Moderate**' (Section 10.4),
- Discharge of drill cuttings – Impacts on benthos including burial of benthic fauna, modification of habitat, toxicity and oxygen depletion – **Moderate** (Section 10.6),
- Emissions - greenhouse gas contribution to global warming and ocean acidification - **Moderate** (Section 10.9),
- Atmospheric emissions associated with the combustion of sold product - **Upper Moderate** (Section 10.9).
- Waste - impact of waste upon unsustainable resources with regards to export and the use of UK landfill – **Moderate** (Section 10.10),
- Collisions between vessels and marine mammals inshore and offshore – **Moderate** (Section 10.11),
- Marine invasive species - risk of introducing marine non-native species from Navitas in field vessels, *ad hoc* freighter vessels, LTVs and the purchaser's CTT- **Moderate** (Section 10.12).
- Terrestrial invasive species - non-native species arriving on marine and air freight – **Upper Moderate** (Section 10.13),
- Competition for freshwater – water use during Development Stages 1 and 2 - **Upper Moderate** (Section 11.4):
- Competition for electrical energy use – **Upper Moderate** (Section 11.5),
- Nuisance to human population from the use of roads – **Moderate** (Section 11.7), and
- Disturbance to the human population from light - Operations at TDF, supply base and LTV operations – **Moderate** (Section 11.8).

These remain significant, despite all mitigations, primarily because:

- A precautionary approach was taken owing to data gaps with regard to the above e.g., data gaps in whale species distribution and the long-term impact of vessel noise on hearing,
- Of the potential consequences with regard to:

- The sensitivity of the receptors e.g., the protected status of whale / bird species or the unsustainability of the resource such as regulated landfill, and / or
- The irreversible nature of some of the impacts e.g., the longevity of GHGs in the atmosphere or the difficulty in detecting whether a species has become invasive and in reversing the potential impacts to biodiversity.

As described in this EIS, technologies to reduce the impacts and risks have been built-in to the Phase 1 & 2 basis of design, where possible, and into the Navitas OMS. These, and the relevant project-specific mitigation measures, include:

- Use of Best Available Technologies,
- Application of all industry-standard safeguards,
- Implementation of the:
  - Bird-strike Management Plan, and
  - Waste Management Plan.
- Awareness of the Navitas Carbon Strategy,
- Application of emissions, discharge and waste ALARP studies carried out during the Execution Phase of the project, and
- The use of SMART environmental targets and Key Performance Indicators (KPIs) throughout the Field Life to ensure continual optimisation of emissions, discharges and waste.

Moreover, monitoring and reporting will be carried out over the lifetime of the Development to ensure verification and comparison with the predictions made in this EIS.

16.3 Significant risks associated with accidental events

Significant residual risks associated with accidental events are:

- The risk of minor or major unplanned releases of hydrocarbon or Marine Gas Oil (MGO) offshore - **Moderate** (Section 12.1),
- The risk of minor or major unplanned releases of hydrocarbon or MGO inshore - **Moderate** (Section 12.2), and
- The risk of day-to-day releases during operations and the TDF – **Moderate** (Section 12.3).

These remain significant, despite all reasonably practicable preventative measures designed to minimise the likelihood of accidental events occurring, primarily because:

- A precautionary approach was used in the assessments, and / or
- Of the potential consequences with regard to:
  - The sensitivity of the receptors to impacts e.g., the fragility of the Falkland Islands ecosystems and tourism industries and the globally important number of protected species (particularly seabirds), and / or
  - The severity of effect e.g., the potentially long-term impacts upon bird populations or public perception and therefore, potentially tourism.

All reasonably practicable efforts will be made to eliminate and prevent accidental events occurring and to Detect, Control, Mitigate, Respond and Remediate any consequences in the event that they do so, such that risks are reduced to ALARP. These measures include:

- Application of all industry-standard safeguards,
- Implementation of the:
  - Oil Pollution Emergency Plans, and

- Wildlife Response Plan.

- ALARP reviews, and
- Preparation of robust operations procedures during the Execution Phase of the project .

16.4 Overall conclusion

In summary thirteen aspects remain of significance:

- Impacts - Planned activities:
  - Artificial light offshore and inshore - **Moderate**,
  - Underwater vessel noise offshore - **Moderate**,
  - Drill cuttings discharges – **Moderate**,
  - Atmospheric emissions directly associated with the Phase 1 & 2 Development (climatic factors) - **Moderate**,
  - Waste management (contingent export to UK with unrecoverable waste going to UK landfill) – **Moderate**,
  - Collisions with marine mammals inshore – **Moderate**,
  - Introduction of marine invasive species - **Moderate**,
  - Introduction of terrestrial invasive species – **Upper Moderate**,
  - Competition for freshwater resources – **Upper Moderate**,
  - Competition for energy resources – **Upper Moderate**,
  - Competition for use of roads – **Moderate**, and
  - Disturbance to the human population from light – **Moderate**.
- Indirect impacts outwith Navitas' control:
  - Atmospheric emissions associated with the combustion of sold product – **Upper Moderate**.
- Risks - Unplanned / accidental events:
  - Oil spill offshore, inshore and at-shore - **Moderate**.

The use of vessels and fossil fuels is necessary to carry out any operation and the generation of some waste which cannot be re-used or recycled is unavoidable. Similarly, the use of third-party vessels from elsewhere in the world will always carry some risk of non-native species introduction and all oil production can carry the risk of oil spill.

Navitas believes that all impacts and risks have been identified, that those of low significance are sufficiently controlled and those that remain significant have been reduced to ALARP. Therefore, Navitas is satisfied that its Policy of doing all that is reasonably practicable to minimise environmental impacts has been met. Navitas will ensure that all impacts and risks are periodically reviewed to ensure that the controls remain in place and that potentially '**Moderate**' and '**Upper Moderate**' impacts and risks are subject to continual improvement where opportunities exist.

17 POST-SUBMISSION CONSULTATION OUTCOMES

Detail on the representations made during the 42-day statutory and public consultation process required under the FIG Offshore Minerals Ordinance (OMO, Section 3.1.7.3.1) are presented below.

Table 17.1 shows the representations made during the public consultation and Table 17.2 shows the requests for information made under section 66 of the OMO. Figure 17-1 below presents the written response from Byron Holdings Ltd. to the Falklands Conservation representation.

Note that some figures, tables and sections have been added to the post-consultation document (Rev 02) in response to the representations made. Therefore, some page numbers and figure / table / section numbers have changed since the statutory consultation version. The references made in the 'Representation' and 'Navitas Response' columns refer to the figure / section numbers (etc.) from the original consultation document and the final column ('Change in Rev 04') refers to the relevant section / figure / table in this current revision (Rev 04).

Also, please note that while not itemised within each response, all additional references have been added to Chapter 20.

Table 17.1: Representations made during the public consultation

Ref.	Representation	Navitas response	Changes in Rev 4
Byron Holdings Limited			
BYR 1	We welcome the recently released Environmental Impact Statement by Navitas Petroleum, and we wish to submit the following statements. We all use oil in our everyday life. It is widely stated that oil will be part of the energy mix during the Energy Transition for at least the next 30 years, or longer. Therefore, oil needs to be produced. It should be produced to high environmental standards. It is hypocritical to use oil but rule out the production of it in the Falklands on environmental grounds, whilst believing it should be produced by other countries, often to lower environmental and other standards. The EIS is a substantial, thorough and very detailed assessment of the impact of the Sea Lion development, impacts and mitigation measures.	Thank you for the comments.	N/A
BYR 2	FIG Policy. The EIS of the Sea Lion development is in accordance with the Islands Plan 2022–2026, that states “This Assembly will… progress extractive industries in an environmentally conscious way.” The EIA recognises other relevant FIG policies including those to protect the environment and biodiversity, and climate change.	Noted and agreed.	N/A
BYR 3	Further work. The EIS recognises further work to be done in legislation & offsetting. This is understandable given that O&G is a new industry to the Falklands. These additional provisions can be pragmatically put in place as the project develops.	Navitas continues to work with FIG and its key contractors to ensure that its arrangements are aligned with industry best practice and FIG's planned changes to legislation. Navitas' offsetting approach is being confirmed with FIG and will be consistent with FIG legislation, policy and guidance. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		a Sea Lion specific carbon and biodiversity offsetting fund.	
BYR 4	The EIS appears to cover all environmental risk areas. The Sea Lion development has Environmental Risks. The EIS does not indicate there are specific, significant, negative environmental impacts. It appears there are environmental risks, if accidental events take place but not definite impacts. Measures to reduce significant adverse effects on the environment. The O&G sector is treated differently to other Falklands business sectors. The Falklands O&G industry has had to undertake an EIA. No other Falklands industry has had to do so. Neither fishing nor tourism (flights) is being asked to do this i.e., the EIS (Chapter 10) assesses the risks of birds landing on ships. The Sea Lion development will only have a handful of modern ships in the EEZ, but including an attending offshore emergency response vessel, and other vessels maintaining modern state of the art features. The fishing industry often has a substantial number >100 vessels, some of which, jiggers and reefer vessels that intentionally utilise a lot of light to conduct fishing operations. There is a real danger of inconsistent standards being applied to the Falklands O&G sector, not applied to other sectors.	Thank you for your comments. In response to the second bullet, Navitas agree that the majority of the impacts and risks identified and assessed throughout the document are not considered significant (i.e., are not Moderate or above). However, the EIS does highlight a number of impacts and risks as potentially significant, e.g., the impact of direct emissions (assessed as Moderate), the risk of impacts from the introduction of terrestrial invasives (assessed as Upper Moderate). Mitigation measures are identified where possible to reduce these significant impacts and risks to ALARP but some remain significant due to the precautionary approach taken in the assessment.	N/A
BYR 5	Oil Pollution Emergency Plans. - Oil Pollution Emergency Plans are based on credible worst-case scenarios (EIS chapters 12.1, 12.2, 12.3). This approach seems appropriate. The likely location of spill, weather, environmental receptors and type of oil are all factors considered. The likelihood of oil beaching in the Falklands is low. - This level of risk is acceptable and compares with existing tanker operations both in Falklands harbours and offshore. Current offshore tanker and bunker operations appear to have fewer mitigating measures being taken and the risk of these appear to be unevaluated by FIG and conservation groups.	Thank you. These comments are noted and are a welcome observation.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
BYR 6	Waste. The use of the planned FIG incinerator to treat and dispose of the majority of project wastes, with non-combustible wastes being returned to the UK for disposal, should mean there is little environmental risk from O&G waste in the Falklands; this compares favourably with the current arrangements for other waste in the Falklands.	Thank you for your comment.	N/A
BYR 7	Offsetting /GHG. - All Green House Gases (GHG) generated from undertaking the development and production should be offset, ideally by offsetting measures within the Falklands. It is recognised that these measures have yet to be fully identified. This is understandable given that O&G is a new industry and little is known about the science and offsetting potential in the Falklands. - The emissions produced by actually using the oil, should be offset by the actual users of the oil that produce the emissions, not the producer i.e.. Navitas. This is consistent with FIG's User Pays Policy. - The EIS proposes that Navitas provides an environmental fund. This is a welcome and positive development and if properly managed will provide an opportunity to address a number of Falkland environmental issues including: biodiversity, habitat reinstatement, land restoration and endangered species protection,	Thank you for the comment. Navitas' Carbon and Biodiversity offsetting fund will be established and intends to pursue the Falkland islands environmental opportunities the comment mentions. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	N/A
BYR 8	No residual impacts or risks in the EIS were considered to be 'High' (Chapter 16). This is highly reassuring for the Falklands and contrasts with the production and developments in other countries. The majority of the residual impacts and risks associated (Chapter 16) with Phases 1 & 2 of the Sea Lion Development were considered to be of 'Low' or 'Very Low' significance. This is acceptable. It is important that these will be periodically reviewed to ensure that proper controls remain in place. Significant impacts & risks of planned activities & unplanned events. There are just thirteen aspects of significance, rated as 'Moderate'. A number of the 'Moderate' risks relate to marine activities: - Artificial light - risk of bird-strikes (Section 10.1); - Vessel noise offshore - impacts to marine mammals (Section 10.4);	See BYR 4 above. There are some impacts and risks that remain significant i.e., (Moderate or above) but no residual impacts and risks remain high owing to the implementation of project specific mitigation measures. Navitas welcome these comments and the context they provide.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	- Emissions – GHG (Section 10.9); - Collisions between vessels and marine mammals inshore and offshore (Section 10.11), - Marine invasive species - risk of introducing marine non-native species (Section 10.12). There is a far greater risk of these impacts and risks from planned and unplanned events in the fishing industry, (or from transiting ocean traffic), which has far more vessels entering and operating within the Falklands EEZ.		
BYR 9	Mitigation. Whilst it is noted that Navitas are planning on using industry standard mitigation measures, it is important that these are effectively monitored by FIG, including using KPIs.	There are extensive statutory monitoring and reporting requirements associated with industry standard mitigation measures. In addition the operations EMMP will detail monitoring and reporting requirements. EMMP outcomes will be reported to the EMMP governance and advisory committee and published. In alignment with Navitas' contracts and procurement procedure, contractors will also be expected to report performance against KPIs.	N/A
BYR 10	The 'Moderate' rating for the onshore activities seems too high: - Waste management (contingent export to UK with unrecoverable waste going to UK landfill) – if the materials come from the UK and can be returned to the UK for disposal in accordance with UK standards, surely this is a high enough environmental standard. The Falklands, with its limited resources and capability cannot expect higher standards than the UK. - Competition for freshwater resources – the freshwater requirement is mainly during the drilling phase. This requirement is not huge in comparison with the overall requirement. FIG should ensure it has the water capacity to be able to deal with this. - Competition for energy resources – the onshore energy use is not that significant to overall grid requirement and FIG already has plans to increase capacity with the increased wind farm and new power station	Thank you for the comment. The EIS deliberately takes a precautionary approach to ensure all impacts and risks are assessed appropriately and with consideration for the human population as receptors. This is particularly true when it comes to onshore activities. Navitas does not propose to make any change to the document in light of the comment.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	- Competition for use of roads – O&G activity will mainly focus on the Gordon Lines area. The increase in traffic is not huge on lightly used roads with lots of capacity. - Disturbance to the human population from light – residents in Stanley already have light pollution from FIPASS and Port William, and Berkeley Sound activities; Oriental jiggers in close proximity to Stanley are the worst light pollution offenders. The development phase is relatively short period and there will not be a major increase in the number of vessels, following First-Oil. We thank you for the opportunity to comment, and wish the project a successful delivery		
BYR2 1	A response to the 57-page Falklands Conservation submission to the Navitas Petroleum EIS.	This is a response from one consultee to another and is included below in Figure 17-1.	N/A
Chamber of Commerce			
CoC 1	The Falkland Islands Chamber of Commerce welcomes the first steps towards potential oil production in the Sea Lion field by Navitas Petroleum Development and Production Limited; and their presentation of the recently released Environmental Impact Statement (EIS) It is encouraging to note that Navitas has considered critical issues of (a) waste management, (b) freshwater supply, (c) energy supply, (d) affected Stanley road networks, (e) air travel and support, and (f) accommodation within the EIS submission. These areas also have an impact on existing businesses, and non-oil and gas vessel berthing operations. Oil exploration has been progressing for about 30 years with the Falkland Islands Government (FIG) having a strategic vision of oil production to secure the economy of the Falkland Islands. Within the next few years there is a strong possibility that this vision will be realised; and oil will start to be produced offshore in the Falkland Islands, reducing the current heavy reliance of revenue from the fishing industry, and enabling the creation of a Patrimony Fund which will secure the Falklands economy for the long term. FIG have set out an agenda to reduce carbon emissions and introduce more	Noted, Navitas welcome the comments and looks forward to continuing to work with the Chamber of Commerce, and in relation to the Socio-Economic Impact Assessment in particular.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	green energy, such as phase 3 of the Sand Bay wind farm. However, as the world transitions to green energy there will still be a reliance on oil for the next few decades. Navitas, during their presentation of the EIS, stated that new methods of oil extraction will be utilised therefore reducing the level of emissions to the atmosphere. It was explained that these emissions, at the worst-case scenario, would be lower than the pro-rata emissions from oil production within the UK. This is an encouraging statement as the Falkland Islands enjoys a unique environment and continues to work towards reducing carbon emissions further. FIG requires Navitas to operate a fund to 'offset' carbon emissions from the Sea Lion development. This fund will be open to all applicants who have investment proposals that they can demonstrate reduce greenhouse gases, contribute to carbon storage, or are otherwise environmentally friendly, including land restoration and bio-diversity protection. FIG and Navitas are seeking to ensure the safest operations, as far as is reasonably practicable, for offshore oil production. These endeavours will ensure the lowest possible risks and impacts, as set out in the EIS, for all areas of our community and the environment. In the view of the Chamber of Commerce, the list of impacts appears comprehensive and the mitigations appropriate to the risk. FIG has an opportunity to shape the future of the Falkland Islands by introducing an industry that will bolster the economy and help deliver sustainable national development. Falkland Islands businesses will have the opportunity to grow to meet the requirements of Navitas and future FIG capital projects. This growth in local businesses will provide further economic stability to the Falkland Islands through more viable business units and sectors, improved opportunities for diversification and generation of corporate taxes to fund social programmes. The Falkland Islands Chamber of Commerce eagerly awaits the Navitas Socio-Economic Impact Statement and looks forward to engaging with aspects of the Field Development Plan. These documents will help to determine how to deliver best possible private sector		

Ref.	Representation	Navitas response	Changes in Rev 4
	support for the project whilst recognising wider national development opportunities and benefits.		
Dragon Fishing and Trading			
DGN 1	We understand that the plan is to anchor LTVs in Berkeley Sound during the construction phase and that there will be a 500m exclusion zone around these. While we haven't had a season comparable to that in 2015 we would seek assurance from Navitas that there won't be any impact on transhipping operations in Berkeley Sound, if we were to have a season with huge catches.	Navitas shall work closely with FIMA throughout the planning and execution stages of the development to ensure that: - final positions for the LTV anchorage sites are agreed and well communicated to mariners and other users of the sea - Activity Specific Operating Guidelines (ASOGs) are developed for the vessels operating in the area - FIMA is advised of all vessels planning to operate in the area - FIMA is advised of the activities and equipment / product transferred between vessels. The LTVs (and 500m radius exclusion zones around both vessels) will take up 1.349% of the area of Berkeley Sound so are not considered to pose a significant impact to other users of the area. This will be referenced in the post-consultation EIS in Section 5.5.1 & Section 11.2	Section 5.5.1 Section 11.2
DGN 2	The *Illex* fishery has changed substantially over the last few years and local companies are more invested in the fishery having built strong relationships with overseas partners. It's no longer a fishery where the financial arrangement is a 'brokers' fee or 'fishing licences are sold' to overseas partners. The potential loss to the local economy if negatively impacted by the oil industry is significant.	FIG requires Navitas to submit a separate 'Financial Liability for Oil Spill Assessment' for review and approval. This assesses the worst-case financial impact arising from an oil spill event and includes an assessment of the financial impact of such a spill on the Falkland Islands fishing industry. Navitas is required to demonstrate that it has insurance arrangements in place to compensate for such impacts in the unlikely event of an oil spill.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
DGN 3	While we appreciate that historically there may not have been a great deal of fishing in the area there is nothing to say that this may not change in the future. Therefore we suggest a stronger commitment to decommissioning and leaving the seabed clear is important.	As stated in the EIS, 'Decommissioning will be carried out in accordance with the legislation in place at the time'. At the time of writing, the project defers to the current UK legislation and its sources. OSPAR Decision 98/3 on the Disposal of Disused Offshore Installations prohibits dumping, and leaving wholly or partly in place, of disused offshore installations within the OSPAR maritime area. While derogation from this prohibition may be sought for qualifying installations, e.g., large steel or concrete footings of fixed platforms, this will not apply to the proposed project which will utilise an FPSO with subsea wellheads and infrastructure. Under OSPAR, all subsea structures must be removed with any associated piles, well conductors etc. cut to a level below the natural seabed which ensures they remain below the seabed in the face of prevailing conditions. Of importance, pipelines and other structures which are listed in a UK Pipeline Works Authorisation are excluded from OSPAR Decision 98/3 and in the UK, decommissioning of these is managed in line with the Petroleum Act 1998 (Part IV) and the Pipeline Safety Regulations 1996. These require a similar assumption of complete removal where reuse of the pipeline and associated structures for further hydrocarbon development is not possible. However, under the UK regulations, there are certain pipelines and/or circumstances in which a pipeline may be wholly or partially left *in situ* e.g., pipelines that are adequately buried or trenched and are not subject to development of spans, and are expected to remain so. However, the decision to do	Section 5.12

Ref.	Representation	Navitas response	Changes in Rev 4
		so would need to be informed by an EIS which is supported by a formal Comparative Assessment of the options which must include a robust assessment of the environmental impact of removal *vs.* that of leaving wholly or partially in situ. Part V of the Offshore Minerals Ordinance 1994 confers obligations for decommissioning. A decommissioning programme has to be approved by FIG in advance. FIG has powers under the Ordinance to develop additional regulations in relation to field decommissioning. As stated in Section 5.12 of the EIS: '…in line with the current legislation, the Phase 1 & 2 Development infrastructure has been designed to enable complete removal of all structures. Equally, the flowlines will be surface laid and will not be trenched or buried thus facilitating complete removal (noting that the seabed is very soft, so flowlines may self-bury which could change the methods required for complete removal).' Also in line with legislation, all relevant 'As Left' surveys will be carried out to ensure that the seabed is left clear. The Sea Lion Phase 1 & 2 offshore installation and subsea infrastructure has been designed so that it can be removed completely and the seabed left clear. Therefore the project has been designed with compliance to current regulation in mind and Navitas will comply with the prevailing legislation at the time of decommissioning.	
DGN 4	The table on Page 1154 does capture the potential severity of blow-out/loss of FPSO to some degree. The EIS goes to some length to show that oil reaching coast of FI is very unlikely however, we believe that the likely	Navitas has submitted a separate 'Financial Liability for Oil Spill Assessment' for review and approval by FIG. This assesses the worst-case financial impact	Section 12.1

Ref.	Representation	Navitas response	Changes in Rev 4
	overlap between a major oil spill and the *Illex* fishery/*Illex* distribution is much greater and that more could be done to model that and define impacts.	arising from an oil spill event and includes an assessment of the financial impact of such a spill on the FI fishing industry. Navitas is required to demonstrate that it has insurance arrangements in place to compensate for such impacts in the unlikely event of an oil spill. Navitas has also analysed AIS data and it is clear that the *Illex* fleet fish on the shelf break and sometimes report either their midday or midnight positions in the relevant grid square XFAK but do not fish in there. The AIS data corroborates the VMS data. The general direction of the oil in a modelled blow out scenario will generally head in a N / NW direction. The oil is also buoyant and will float on the surface away from Ilex biomass generally. Navitas's financial liability assessment recognises that even if there were no, or very a limited or short-lived biological impact on FI fish species, reputational impacts would extend to depress demand and/or prices, even in unaffected areas. These marketing impacts are considered when determining the potential liability and associated insurance arrangement required in order to provide compensation.	
Environmental Department			
ED 1	Page 37: Previous surveys - would be good to state how many previous surveys have been undertaken	A list of surveys will be developed and included as an appendix.	Appendix 4
ED 2	Page 40: Have there been any more unusual influxes of marine mammals reported, or a general change in behaviour since 2017?	2017 was unprecedented compared to previous years and abundances have been similar since. Note that 2017 was also the year that FC and SAERI started	Section 7.4.6.3.1.1

Ref.	Representation	Navitas response	Changes in Rev 4
		surveys and a point in time when empirical data collection started. It is acknowledged that whale populations have increased over time since the cessation of whaling. However, it is not possible to determine whether abundances were similar prior to the commencement of the BEST Sei whale project that commenced in 2017. The post-consultation EIS will be updated for clarity.	
ED 3	Page 45: Titles not complete on table	Noted. This will be amended.	Figure 1-3
ED 4	Page 48: regular monitoring and reporting on performance of offsetting initiatives - what are the timescales?	The governance and timescales for reporting against offsetting initiatives will be agreed with FIG. The establishment, implementation and continued development of the Carbon and Biodiversity Offsetting Fund shall be aligned to key milestones within the Sea Lion development Phase 1 and 2 schedule. Once operations are underway, it is proposed that monitoring will be at 6 month intervals and that performance will be reviewed twice a year with an annual report to be provided to the public. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	N/A
ED 5	Page 52-53: Would discharge of drilling muds at seabed impact on levels of microplastics in the water surrounding the site? No mention of micro-plastics in EIS, drilling chemicals have been found to contain micro-plastics and a be contributor to ocean micro-plastic pollution. This may have cumulative impact on receptors such marine species also. Can this pollution be avoided? Possible to monitor in e.g., discharges?	Drilling muds do not contain plastics/microplastics. There are no plastics in the circulation fluids for gravel packing. The circulation fluid is water-based, which has a gelling agent to increase its viscosity, to improve the ability to transport the proppant into the wellbore. The gelling agent is normally a polysaccharide, such as xanthan, which is a common food additive.	Section 5.4.5.3 Section 5.4.5.5 Section 5.4.6

Ref.	Representation	Navitas response	Changes in Rev 4
		The proppant is not used during the drilling phase of the well. The proppant is placed in the well during the completion phase of the well, which acts as a filter medium during the production of the well. The proppant is inert ceramic with no plastics.	
ED 6	Page 53: Is Marine Flora not disturbed by discharge of drilling mud and cuttings? Table 1.7 mentions Marine Flora is affected by thermal discharge	This section refers to phytoplankton, Navitas are unclear what the query refers to as there is no marine flora (e.g., seaweeds) at the location bar marine growth which will grow on the installation. A footnote will be added to the post-consultation EIS for clarity.	Table 1.8
ED 7	Page 65: At least 9 extra supporting plans area needed, a long list of them appears (incl. oil pollution management plan, bird strike management plan, EMMP). When will all of these be ready?	Navitas are following the regulations and guidance provided by FIG in relation to the timing for submission of supporting plans. Alongside this, Permits, Licences, Notifications and Consents (PLANC) registers are being developed in consultation with FIG DMR, to track the submissions (including the supporting plans mentioned) and the timeframe for their submission in step with the project execution timeline.	N/A
ED 8	Page 118: Are 3m significant wave heights typical for all seasons of weather at Sea Lion? Other studies of the South Atlantic would suggest 3m is average wave height in the South Atlantic with significant waves as 5m.	There will be clear operating limits for connection and offtake. The wave study information gathered for the Sea Lion Project was location specific, the data came from several Metocean data collection exercises conducted to assist in the selection for design and operation of the FPSO. The studies supported the decision that direct offloading to conventional trading tankers was both a viable option and one that could be done safely. Note that connection, offloading and disconnection	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		for direct offloading will only commence, and continue, if the sea state and wind conditions are within the allowable operating parameters, if not then connection will not commence and during operations if conditions reach the operating limits offloading it will be stopped and the operation made safe.	
ED 9	Page 123: How were the financial and environmental costs/considerations for e.g., marine life, seabed, water etc of a drilled disposal well versus processing using thermo-mechanical cuttings (TCC) unit and disposal at site considered against each other?	Without a Thermomechanical Cuttings Cleaner (TCC) the proposed batch drilling strategy would require a disposal well at each drill centre location. The TCC minimises environmental impact and represents the Best Practical Environmental Option and is used internationally.	N/A
ED 10	Page 123: Water injected into wells is seawater- will this be tested prior to injection for e.g., small organisms? What volume of water is considered too much of an unknown impact on the organism?	Seawater is treated with chlorine and also filtered once brought onboard the FPSO. This water then passes into the injection system where it has further filtration and also the oxygen is removed. Water specification is maintained and is monitored automatically and also through laboratory testing. Additionally periodic culture tests will be carried out to check for bacterial / organism growth. The injected water goes into the reservoir not the surrounding environment.	N/A
ED 11	Page 146: Do drilling muds and cuttings contain plastics? Can these be cleaned?	See ED 5.	N/A
ED 12	Page 147: Use of TCU in the table but is not used anywhere else, consistency in abbreviations needs to be used	Noted. This will be amended.	Table 5.8
ED 13	Page 150: Good to see that “chemicals will be selected to minimise environmental impacts as much as possible, in compliance with legislation”. Is this UK legislation? Will the environmental considerations go beyond legislation when choosing chemicals?	Yes. Chemicals will be selected in compliance with all UK legislation and every effort will be made to ensure the selection of those with minimal environmental impact. Text will be added to Section 5.4.6 to refer to Sections 10.6 and 10.7 which provide more detail on	Section 5.4.6

Ref.	Representation	Navitas response	Changes in Rev 4
		the legislation with which the project will comply. All chemicals selected will be listed on the Offshore Chemical Notification Scheme (OCNS) List of Notified and Ranked Product generated by CEFAS (Link).	
ED 14	Page 150: Drilling chemicals being discharged at sea - what are the volumes/frequency?	As stated in Section 5.9.1.1 details on the specific operational chemicals which will be used during the Phase 1 & 2 Development are not yet known, and neither are the actual volumes of individual chemicals over and above the anticipated mud volumes indicated in Section 10.6. Nonetheless, all operational chemicals used during the Development will be selected to minimise environmental impacts as much as possible. Further detail on the UK legislation which will be adhered to is provided in Sections 10.6.1.1 and 10.7.1.1. All chemicals selected will be listed on the Offshore Chemical Notification Scheme (OCNS) List of Notified and Ranked Product generated by CEFAS (Link).	N/A
ED 15	Page 167: Open drains will be routed to marine systems - will meet MARPOL 73/78 annex requirements prior to discharge to sea- how will this be regulated and checked?	The open drains system is not pressurised. It can receive hydrocarbons and it separates out oil from water. However, the open drains system cannot go overboard; t is still contained. What goes in is open, what goes out is enclosed and will either go to the closed drains system or slops tank for further treatment. Any discharges overboard must meet MARPOL requirements.	N/A
ED 16	Page 186: Although well workovers are not planned, and if one is considered an EIA will be carried out and discussion with FIG, this still holds a potential increase for environmental impacts?	If well workovers are required, the requirement for an additional EIA will be discussed with FIG at that time.	N/A
ED 17	Page 195: Number of vessels travelling back and forth is not fully known yet- this will have an effect on emissions data and should be logged and monitored.	The projections included in the emissions chapter are very precautionary - as such it is currently anticipated that the emissions arising for the actual number of	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		vessel movements during operations will be within the emissions envelope that has been estimated. Emissions will be recorded and reported as a matter of course.	
ED 18	Page 201: How will the desalination plant at the FPSO be powered?	All power on the FPSO comes from the electrical distribution system which in turn comes from the main power generated by the Gas Turbine Generators. The desalination system is powered from here. Back up periodic power is supplied by the Essential Diesel Power Generators for the occasions when main power is offline. Power feeds the main electrical board and is distributed accordingly to all electrical users onboard the FPSO.	N/A
ED 19	Page 203: Temporary modular accommodation units initially provided by Navitas, supplemented by local hotels. Transferring to in- transit accommodation as soon as available. Where will this be? Is land for this already designated?	An EOI was issued in the Penguin News in February 2024 for the development's accommodation requirements. Once the project is sanctioned an RFQ can be issued to the respondees which will provide further information on the development's short-, medium- and long-term accommodation needs. This will include a 'hotel'. A number of companies and individuals responded to the February EOI. Navitas has not designated any land for the accommodation requirements this is expected to be covered during the responses to the accommodation RFQ.	N/A
ED 20	Page 209: Will decommissioning involve any species studies prior to removal of all subsea infrastructure to check if there are any potential disturbances to ecosystems that should be carefully managed?	Decommissioning will be covered under a separate and dedicated decommissioning EIS which will be supported by baseline surveys prior to work commencing to ensure that any sensitivities are appropriately managed. 'As left' surveys will be	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		undertaken upon completion of decommissioning activities to ensure the site is left as it is found. Decommissioning activities will be compliant with legislative requirements in place at the time of decommissioning. See also DGN 3.	
ED 21	Page 209: Could be important to know general environmental risks associated with decommissioning - i.e., high risk to decommissioning may influence whether structures should be put in in the first place.	Navitas is required to ensure that all structures are designed to be fully decommissioned in a safe and environmentally responsible manner. The seabed has been extensively surveyed to explore environmental sensitivities. These have not indicated that the structures will cause adverse environmental impact. Location specific site surveys will be undertaken immediately prior to installation to ensure there are no localised environmental sensitivities that suggest installation is inadvisable at that location. Navitas will add this additional commentary to Section 5.12 of the post-consultation EIS. See also DGN 3.	Section 5.12
ED 22	Page 218: Stakeholders: There is reference to the FIG Policy Unit. Please update the names: Directorate of Policy, Economy and Corporate Services, with Environment Department, and Policy Department, as required.	These names were correct at the time of the original scoping exercises. They will be updated to the current names with footnotes to explain.	Section 6.1.3 Table 6.2
ED 23	Page 246: Area wide environmental baseline survey of Sea Lion field in 2012- is there a more recent study?	Rockhopper conducted the area wide survey in 2012. Shortly after, Premier conducted a survey south at Isobel Deep in 2014. In 2015, Premier also carried out investigations at 2 gas well sites adjacent to the Main Drill Centre. These studies examined benthic habitats and sediment and water quality, among other things and will not likely have changed since that time. See Table 7.1, and Figures 7-4 and 7-5.	N/A
ED 24	Page 251: The environmental baseline survey of Berkeley Sound occurred between June and August 2015 - does this survey need to be repeated to	This is not considered necessary due to the small time frame and level of activities taking place in Berkeley	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	capture all the different life cycles, seasons and organisms that may be impacted within that habitat?	Sound (two vessels moored for non-consecutive 13 month period).	
ED 25	Page 252: Four seasonal coastal bird surveys in and around Berkeley Sound were carried out between 2016 to 2019. Do you consider this to be adequate information to form a baseline for birds at that site?	Yes, Navitas does consider this adequate information to form a baseline, not least because of the small time frame and level of activities taking place in Berkeley Sound (two vessels moored for a non-consecutive 13 month period).	N/A
ED 26	Page 253: Were the data gaps of offshore benthic ecosystems, oceanography in relation to oil spill modelling, seabirds with regard to priority species and movements, marine mammals, populations and breeding activities identified before or after the GAP Project?	These gaps were identified after the GAP project.	Section 7.2.4.1
ED 27	Page 253: In regards to the Key Gaps of relevance to the Sea Lion EIA, it is not stated if these have been addressed or are still key gaps; if these are still gaps remaining requiring information, how will this information be obtained, and by whom?	It is important to note that under FIG's guidance the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are addressed in risk assessment. The presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained. The key data gaps will be covered in the EMMP. At the time of project sanction, this will be discussed further with FIG. The EMMP chapter will be updated in the post-consultation EIS to ensure that all of the EMMP workshop conclusions and outline tables are included. Navitas will also update Section 7.2.4 to make it clear which data gaps remain and to more specifically state those which have been filled since the inception of the Sea Lion.	Section 7.2.4

Ref.	Representation	Navitas response	Changes in Rev 4
ED 28	Page general: General concern about lack of references to the data sources, references would allow the data and conclusions derived from data to be checked and assessed by us/ by other stakeholders.	Navitas request further detail on which sections contain unreferenced data. Navitas has committed to preparing a table of primary data sources. This will be added as an appendix to the post-consultation EIS, and reports will be provided on request. Note that during the public consultation Navitas provided any reports and data that were requested.	Appendix 4
ED 29	Page general: Would be good to have a table as an annex with all studies used/ surveys conducted including the dates. As well as an annex of all data gaps identified and if they are going to be further looked into.	Noted. A table will be compiled and appended to the EIS.	Appendix 4
ED 30	Page 262: Water column characteristics were measured for 1 month in March and April 2012. Do you consider that a one-month survey over 10 years ago that doesn't take into consideration seasonality or the changes that may have occurred since then, is acceptable for forming a baseline?	This section is referring to the portion of the survey aimed at characterising the general water column structure e.g., characterisation of layers, presence of thermoclines, and vertical mixing. The respondent is correct that such characteristics may vary seasonally, but seasonal variability will not be so great that it requires special consideration with respect to the potential impacts or mitigations described in relation to the drilling programme. In other words, the water column characterised at the time will be indicative of the present situation, and seasonal variability is not likely to have a strong modifying effect relative to impacts. The measurement is therefore believed to be acceptable for a baseline; however, the text within the EIS will be updated for clarity.	Section 7.3.3.3
ED 31	Page 263: Reference to 1982 study, then references that dynamics of water masses in an area can change over time- is this study still most relevant considering the time elapsed since the study and potential changes in water mass dynamics?	Please see ED 30 above. The text will be modified to say Navitas is referring to variability and not infer that there is a one-way change over time. Although, it is true that there will be long-temporal trends in water mass dynamics, these would be over geologic times scales, although recent climate change is thought to have a modifying effect. Unfortunately there are no	Section 7.3.3.3

Ref.	Representation	Navitas response	Changes in Rev 4
		recent studies aimed at describing water structure and dynamics in the area; recent work focuses primarily on biology and tend to cite the original papers of Bianchi *et al.,* 1982; Peterson and Whitworth, 1989. The text will be updated for clarity.	
ED 32	Page 263: 8 water quality profiles completed within Berkeley Sound survey area over 1-month time period- very short time interval for collecting data or is data still being recorded? Mention of surface temperatures as recent as 2016 and 2017. Where is information kept such as report or data portal?	There is now limited activity planned in Berkeley Sound (13 months [total] of two vessels in non-consecutive activity). Results of profiles indicated relatively well mixed, oxygenated water, which makes sense given the relatively shallow depths, tide, and the persistent wind causing vertical mixing. There is no indication that the water column structure will vary widely from this, but will indeed have some daily and seasonal variation with strengthening and weakening of a shallow thermocline that is reflective of seasonal air temperatures affecting surface water. The water quality profiles (CTD data) is detailed in the Gardline/Benthic Solutions report that is available through the Data Centre or on request. Note that continued Berkeley Sound baseline data collection effort was not considered necessary once inshore transfer in Berkeley Sound was discounted.	N/A
ED 33	Page 277: Organic matter in sediment can influence chemical and biological processes- Survey carried out by Gardline post drilling campaign is in 2013 report but not readily accessible, unable to be found.	All commissioned surveys can be made available upon request.	N/A
ED 34	Page 277: TOM and TOC levels were found to be 5.6% and 0.9% respectively- similar values to pre-drilling survey nearby in 1998, but unable to corroborate data.	All commissioned surveys can be made available upon request.	N/A
ED 35	Page 278: Polycyclic aromatic hydrocarbons from pyrogenic sources due to flare stacks among other reasons- is this going to be monitored as the oil production commences?	Navitas will monitor and report all air emissions in accordance with regulations.	Table 15.4

Ref.	Representation	Navitas response	Changes in Rev 4
ED 36	Page 284: How many recorded oil spills have occurred since this survey was completed in 2012/2013? Is it worth repeating this survey to get a true baseline to be able to determine any impact of production of oil and provide more up-to-date data for point of comparison for the future?	A list of recorded spills in Stanley Harbour, Port William and Berkeley Sound has been provided by FIMA and will be included in the updated, finalised EIS. The baseline environmental survey of Berkeley Sound was completed by Benthic Solutions Limited for Premier Oil in 2015. An SMSG report (2012) noted that there have been numerous fuel oil diesel spills in Berkeley Sound, and section 7.3.7.2.2 references this SMSG report as background context when reporting on the outcomes of the 2015 baseline survey, which indicate that the baseline situation in Berkeley Sound is not a pristine location in terms of hydrocarbons even prior to any oil industry activity in the area. Regarding the suggestion of repeating the survey to get a true baseline for comparison in future, impact from oil production is not considered relevant regarding Berkeley Sound. There is no plan for inventories of crude oil produced at Sea Lion to enter Berkeley Sound. Berkeley Sound is anticipated to be utilised by the Large Transport Vessels (LTVs) for a maximum period of 13 non-consecutive months. There will be bunkering of MGO to these vessels in the Sound, with strict operating guidelines in place. Bunkering in Berkeley Sound is already a common occurrence for numerous (non oil industry vessels). Navitas does not consider that there is any merit in re-examining Berkeley Sound environmental baseline given the limited nature and scale of Sea Lion activity in Berkeley Sound, which is far less than that anticipated by Premier Oil when the 2015 baseline environmental survey was commissioned.	Section 7.6.4 Section 12.3.10

Ref.	Representation	Navitas response	Changes in Rev 4
ED 37	Page 284: Polycyclic aromatic hydrocarbon levels are discussed but it is not mentioned what this means i.e., if these are within acceptable limits? PAH, particularly 2 and 3 ringed aromatics are carcinogens and we should ensure that this is firstly in a suitable level, and secondly is then monitored.	Extensive baseline surveys were conducted in Berkeley Sound ahead of inshore transfer which was subsequently discounted and is no longer part of the project. However, while these data serve as a great legacy for future work, monitoring is not considered necessary due to the small time frame and level of activity taking place in Berkeley Sound (two vessels moored for a non-consecutive 13 month period). PAH levels in Berkeley Sound sediments are mentioned in this section of the EIS which describes the environmental baseline and measured characteristics in Berkeley Sound. The baseline PAH levels encountered have not been caused by oil industry activity, as they were measured prior to any industry use of the Sound. As such whether the PAH levels encountered are within acceptable levels is a matter for FIGs consideration. Furthermore, given the scope and scale of Sea Lion development activity anticipated in Berkeley Sound (up to 13 months' vessel logistics operation and MGO bunkering), ongoing monitoring of PAH levels would not seem a Navitas responsibility.	N/A
ED 38	Page 287: Cd and Ni are above the ERL levels	**Initial Consultation Response:** Noted, see also ED 37. **Post-Consultation Comment:** A footnote will be added to the appropriate sections.	Section 7.3.7.2.2.2 Table 7.2
ED 39	Page 288: V is in low concentrations - a good monitor for the effects of oil production as it is present in most crude oils.	This section of the EIS refers to the environmental baseline survey of Berkeley Sound in 2015. At that time Vanadium was found to be in low concentrations. As oil production activity will not be undertaken in Berkeley Sound, and no crude oil	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		produced will be present in Berkeley Sound at any point Navitas disagrees with the suggestion that Berkeley Sound V levels will be good a monitor for the effects of oil production.	
ED 40	Page 289: Oceanography in summary table - mentions priority to GAP project- It is unclear if this has been addressed by the GAP project or is outstanding to complete	Oceanography was recognised as a gap in the scoping stage, but was not adopted as part of the scope for the GAP project. For the purposes of the EIA, the oceanographic data available is sufficient and valid for the purposes of the modelling. We will clarify the text in the post-consultation EIS.	Table 7.3
ED 41	Page 292: When was the last time data for the NFB and Sealion Field was gathered on the phyto and zooplankton communities?	A small area of like Sea Lion field is highly dynamic and indeed phyto/zooplankton were not identified as a gap.	N/A
ED 42	Page 298: Why was kelp coverage only surveyed in winter? Many species of seaweed have their maximum growth and extent in summer, just showing winter coverage of Berkeley Sound can be misleading and bias the information. Information for other kelp species extent is available however the EIS only includes Giant kelp extent	The commenter is referring to Land-Sat imagery used. This was likely restricted by availability of good quality images. However, a number of sources and analyses were used to fully assess kelp coverage. Kelp was mapped using a variety of sources including analysis by EnvSys (2016) further investigating kelp beds as detected below the water surface, and increased resolution. Sentinel satellite images (10m resolution) under the DPLUS 065 'Mapping the Falklands & South Georgia coastal margins for spatial planning' project. See the same section for further info.	N/A
ED 43	Page 301: While they can be certain none were found in their survey, the EIS says that there is at least a 50% probability of VMEs being present in the production area therefore habitats of high conservation importance cannot be ruled out.	This statement has been revised. Interpretation of both the SAERI (2023) VME study and the Gardline (2013a) survey suggests that even though some VME indicator taxa have at least a 50% probability of being present, the lack of their observation in the Gardline study suggest that they are likely to be sparsely occurring in the focal area. This makes sense, given	Section 7.4.3.2.3

Ref.	Representation	Navitas response	Changes in Rev 4
		that many VME indicator taxa are related to drop-stones (hard substrate) amidst vast areas of silty mud. Additionally, VME indicator taxa are predicted to be widely distributed around the FOCZ, suggesting that VME's potentially impacted within the drilling area will have a high likelihood of recovery.	
ED 44	Page 305: EIS mentions that station 31 is close to the LTV anchorage sites but not what was found in this area. Is that not of more significance than the stations mentioned that may not be close to the LTV anchorage sites?	Thank you for the comment. Navitas will add the findings of Station 31 to the text.	Section 7.4.3.3.1.2
ED 45	Page 323: There is some uncertainty in the data and if habitats appear widespread does not mean that they are not environmentally sensitive or important areas. Could be important source populations for other locations	The commenter is correct. However, please refer to the definition of 'Sensitive' in section '8.5.2.1 Assessment of sensitivity of receptors'. In summary, commonness of the habitat suggests that the probability of recovery after an impact is high, and therefore less sensitive that for example, a habitat that is only found at one particular location. This text will be updated to make this clearer.	Section 7.4.3.3.4
ED 46	Page 328: There is meant to be a summary of the NFB however it is the exact same text that is used in the information for Berkeley sound. This is an error and needs correcting	Noted. This will be amended.	Table 7.8
ED 47	Page 330: What is the significance of skate species spawning in the area? Which species and are these on the IUCN Red List? Is there a data gap that needs to be further surveyed to fully understand potential impacts?	There are data gaps in this area as the commenter points out, due to lack of commercial fishing in this area. Available studies show that the main species is the yellownose skate (*Dipturus chilensis*) and is typically feeding when in the area of interest. IUCN status is given in the text.	N/A
ED 48	Page 330: Coral is mentioned in the Northern Slope area, there is no previous mention of this in previous sections. With the proximity of the site to the NFB there is the potential corals could be present at the site.	It is not quite clear what the commenter is referring to here. However, coral species and distribution is described extensively in Section 7.4.3.	N/A
ED 49	Page 344: EIS should be using up to date IUCN red listings. April 2020 is not considered current. Please update.	This will be reviewed and updated as appropriate.	Section 7.4.5

Ref.	Representation	Navitas response	Changes in Rev 4
ED 50	Page 344: The use of the JNCC SAST data is of concern as it is over 20 years old. Is it still believed to be representative of present-day populations?	Baylis *et al.* (2019) highlights that for nine-species tracked, the probability of occurrence is highest on the Patagonian Shelf, shelf slope and the Burdwood Bank (Fig 7-53, pg. 360). These findings are similar to the at-sea distribution presented for the same species (White *et al.,* 2002). This is likely to reflect productivity on the Patagonian Shelf, being linked to the Patagonian Shelf, slope and Burdwood Bank (static features, associated with predictable areas of enhanced productivity) (e.g., Fig 7-35, pg. 293). Based on the predictive models, and knowledge of local oceanography, the importance of the Patagonian Shelf around the Falkland Islands is unlikely to have changed over the past 24 years, hence animal distribution is still likely to be associated with the Patagonian Shelf. This will be made more explicit in the post-consultation EIS. The EMMP aims to collect further data in the field, specifically using Seabird and Marine Mammal Observers on two vessels for the initial years of the project (post sanction, pre-First-Oil and post-First-Oil).	Section 7.4.5.2.1 Section 15.6.2.1.2
ED 51	Page 382: Species have been given acronyms or codes without any explanation to what those codes mean or reference of where to find them. Please update table caption to explain what the codes mean.	Noted. This will be amended.	Table 7.19
ED 52	Page 481: EIS states that Navitas is currently working on an update to the Sea Lion socio-economic environment of the Falklands - when will this be ready?	The updated socioeconomic impact assessment is currently expected in Q1 2025.	N/A
ED 53	Page 482: Census data is not up to date. Full census now available: The 2021 Census asked people to state their national identity: 42 % of residents considered themselves Falkland Islanders, 18 % British, 7 % St. Helenian, 4 % Filipino and 3 % Chilean (FIG, 2023). However, census data stats 54% identify as FI, 22% British, St Helenian 8%, Filipino 5%, Chilean - 4%	This reflects the census data tables provided prior to the census being published by FIG Policy Dept to calculate these numbers, this reflects the % of ppl present on census night (following Table 1e in the census tables provided). See below but it is	Section 7.7.2.1

Ref.	Representation	Navitas response	Changes in Rev 4
		understood the final census report was adjusted to include those not present on census night where possible. These numbers will be updated to reflect the published census numbers.	
ED 54	Page 482: 433 work permit holders were recorded in Stanley (FIG, 2023 - 456 in census). 663 employed by FIG - 33% as per 2021 census not 487 as per EIS.	Table 8a in the census report notes 433 work permit holders (total), which correlates with the data provided by FIG in the detailed census tables. Although it is noted that in Table 11 in the census report there are 456 WPHs in Stanley. It is understood that while the census data records only the people present on census night a lot of work was done to consider those not present, could this account for the difference in values? We'd be grateful if FIG could confirm. However, the EIS will be amended. to reflect the published census report. Data provided in the census tables notes 487 as FIG employees within Stanley, It is understood the figure in the census report (633) includes UK government and GSGSSI employees as well.	Section 7.7.2.2
ED 55	Page 483: The land surrounding Berkeley Sound is divided between six landowners / farms (Figure 7 115 below) and is primarily used for grazing sheep. However, several farms also run tourism-based businesses, which are described in Section 7.7.4.6.1. What about FIG owned Kidney Island? It is a National Nature reserve	Noted, this will be added.	Section 7.7.2.3
ED 56	Page 484: 'Summary Report of Fishing Activity over the Sea Lion Development Area', conducted by Pale Maiden Consulting (April 2013), and the FIG Fisheries Department Catch Report Database from 2013 to 2022 (FIG, 2023). Some information is also taken from the Fishing and Trawling Risk Study conducted by Jee (2013) on behalf of POEPL. Are there more up to date studies?	2022 data (available in 2023) was the latest available from FIG at the time of writing. Anatec Ltd (2024a and 2024b) were based on 2023 FIG data and will be added to the text.	Section 11.1 Section 12.1
ED 57	Page 485: Argentinian shortfin squid - annual variations but has largest catch 2013-2022 - grid where drill centres taking place are open to fishing vessels	This can be added. Thank you for the comment.	Section 7.7.3.1 Table 7.41

Ref.	Representation	Navitas response	Changes in Rev 4
	to fish for these but have been rarely fished - This grid square has been rarely fished by any licensed vessels in recent years. Total annual fish catch for each year would be good to see in table		
ED 58	Page 485: Catches and fishing effort in the grid square occupied by the Sea Lion Field (XFAK) are relatively low (FIG, 2023). This said, exceptionally high catches of Ilex squid were made in 2014, 2017, and 2022 reflecting high catches throughout the zone during these seasons. Overall however, these data indicate that generally the area of the Sea Lion Field is rarely fished. - but it has been fished and a lot of fish caught very recently too - should not be discounted.	In relative terms, there is a very small fraction of fishing done in this area. The commenter correctly points out years where catch has been reported in XFAK and Navitas has looked into this more closely. Results of this analysis shows that although catch by a few vessels has been attributed to XFAK with either their mid-day or midnight position, in actual fact the vessel did not enter this grid square at all, as evidenced from Marine Satellite -based AIS. These are likely to be rare, accidental mis-reporting's. Navitas will point these out to FIFD for further investigation.	N/A
ED 59	Page 487: Fishery Patrol vessel - inconsistencies in data: • 2014 - 37 visits.; - table says = 37 visits • 2018 - 48 visits. and table says 34 visits • 2022 - 27 visits (Table 7.45). table says 28 visits	Noted, this will be updated.	Section 7.7.4.1.4.2 Table 7.45
ED 60	Page 494: Cargo vessels - Cargo vessels visit Stanley on a regular basis and require a berth at FIPASS to transfer cargo onshore. In 2014, 38 cargo vessels visited FIPASS. In 2018 cargo vessel visits to FIPASS were slightly less at only 32, and less again in 2022, visiting on 27 occasions (Table 7.45). Table clearly says 2014 - 37, 2018 - 32 and 2022 - 25	Noted, this is a typo (table correct, bullets to be updated).	Section 7.7.4.1.4.2 Table 7.44 Table 7.45
ED 61	Page 496: In 2014, 61 yachts came into Stanley Harbour with 71 yachts in 2018. This number had reduced greatly by 2022 with only seven yachts entering the harbour. These vessels usually moor at the Public Jetty, the East Jetty or anchor in the Harbour. - where did this data come from because it only mentions yacht in the table and not pleasure craft?	This section references the Table above as most yachts do not go alongside FIPASS but do enter Stanley harbour, will add ref to Table. Will remove 'pleasure craft' from title.	Section 7.7.4.1.4.7
ED 62	Page 497: The only asphalted roads are those within Stanley, those within the Mount Pleasant Complex (MPC) and most of the main road between Stanley and MPC. - needs updating- all tarmacked now	Will be updated.	Section 7.7.4.2

Ref.	Representation	Navitas response	Changes in Rev 4
ED 63	Page 498: In April 2010, over a 19 day period, 5,484 vehicles (of which 2 % were Heavy Goods Vehicles (HGVs)) used the road between Stanley and Mount Pleasant. This represents a 170 % increase over the previous 10 years for all vehicles (FIG, 2012b) - Use more up to date figures?	Navitas checked with PWD for any updates but there has not been a survey since then.	N/A
ED 64	Page 498: MPC Road usage has generally increased significantly year on year, however exact recent trends are not certain and road usage may have stabilised. - Are these assumptions without up to date data - may have stabilised - may not?	As above there has not been a more recent survey but with the increase in population, SAERI suggest it is a reasonable assumption to make that traffic increases as population increases, particularly with the high vehicle to person ownership in the Falklands.	N/A
ED 65	Page 501: The 2021 Census recorded a total of 1,523 resident households, of which, 1,147 (75 %) are located in Stanley (Table 7.48). - census states 1,600 total and Stanley = 1,148	The census data tables provided by FIG prior to publication of the census report noted 1,523 resident households (1,147 in Stanley), this will be updated to reflect the final census report numbers.	Section 7.7.4.5.1.1 Table 7.48
ED 66	Page 501: In 2021, the majority of houses in Stanley were mortgaged or owned outright (54%) (Table 7.48). Approximately 40 % of Stanley households were held under rental, while a further 5 % were provided rent free as part of an employment package (Table 7.48 - where did this info come from as can't find it in census?)	Noted. This will be amended.	Section 7.7.4.5.1.1
ED 66	Page 509: Household batteries are collected within Stanley and recycled in the UK. Currently they are only collected, but recycling is expected in the future.	Noted, this will be updated.	Section 7.7.4.5.6
ED 68	Page 520: Identified 2 wrecks in close proximity: 1 x 100m away and 1 x 1km away - EIS states they are there but has not said anymore. Has the risk to these wrecks been assessed?	The 100m and 1km distances referred to in this section are the distances that the wrecks have 'moved' from their charted position to the position actually recorded during the survey. Both wrecks are not considered to be close enough to the LTV anchoring locations to be disturbed by the activities proposed.	N/A
ED 69	Page general: If the receptor is deemed low due to IUCN status - will this be an iterative process in that should the IUCN status change during the lifetime of the project would this new status be reflected in the risk assessment?	As the EIS is reviewed every 5 years, changes to IUCN status will be captured then. This will then feed into the EMMP process if there are changes which impact on monitoring and management actions.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 70	Page 550: It is not clear how the fund will be allocated and whether this is for a biodiversity fund being set up by Navitas or using the already set up Environmental Fund. How have offsetting measures have been considered by the operator - where will this be reported?	Navitas has committed to a dedicated carbon and biodiversity offsetting fund that will be financed by contributions from Navitas and governed by a steering group comprising Navitas, FIG, NGO stakeholders and technical advisors. It shall be aligned with FIG's offsetting guidance and policy. Initially the fund will invest in the feasibility of potential local offsetting projects. Navitas will then finance the viable projects that are identified. The Fund will also invite proposals for funding of projects to achieve offsetting objectives which will be considered for approval by the multi-agency steering group. The adopted offsetting projects will be overseen by the governance committee and their performance will be reported upon publicly. In the event that local offsetting cannot be achieved successfully, Navitas will look to invest in international offsetting schemes. The performance of Navitas' offsetting endeavours will be reported. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	N/A
ED 71	Page 561: Has disturbance to the human population through onshore light in Berkeley Sound been considered? Receptors include settlements on the Sound.	Yes, see Section 11.8.	N/A
ED 72	Page 561: Would discharge of chemicals during drilling, or use and discharge of chemicals in produced water, or discharge of hot water from cooling systems, not affect plankton & water quality & marine mammals?	The table will be reviewed against the relevant chapters and both will be updated if considered necessary.	Table 9.1

Ref.	Representation	Navitas response	Changes in Rev 4
ED 73	Page 590: A maximum of two LTVs will be present in Berkeley Sound for only eight months (*c.* August-2022 to end March-2023), should this be 13 months as stated on page 580?	Noted. This will be amended.	Section 10.1.2
ED 74	Page 592: Potential receptors - in bullet points missed off Human populations - identified as needing further investigation in table 9.1	Section 10.1.1 states in a note that impacts to humans are assessed elsewhere (Section 11.8).	N/A
ED 75	Page 619: Helicopters may have a significant impact on penguin behaviour, although degree of habituation to aircraft is believed from South Georgia study- Have any studies been done on the tourist helicopter flights?	Navitas are not aware of any studies on local tourist helicopter flights (which no longer operate), and the South Georgia study is considered the best comparison. It should be noted that tourist flights operated differently to the proposed Sea Lion helicopter flights as, when operating, they landed in close proximity to penguin colonies, while the O&G helicopter flights will be flying overhead, in accordance with the Falkland Islands Low Flying Handbook.	N/A
ED 76	Page 624: Fur seals and sea lions most vulnerable to noise during pupping - between October and January combined	Yes, this is noted in the 5th bullet point.	N/A
ED 77	Page 626: With reference to the Falkland Islands Low Flying Handbook that shows where not to fly - IBA, NNR etc, are these locations up to date and correctly identified in the EIS?	These are replicated as provided by the FILFH, Navitas understand this is a FIG document.	N/A
ED 78	Page 628: There is no monitoring mentioned in terms of the number of flights, or the impact of flights on identified species, this does not appear in Chapter 15 (EMMP) either.	The residual impact from helicopter flights does not trigger an EMMP action as it is neither significant nor has a receptor that is considered 'High' or 'Very High' sensitivity, and confidence is 'Certain'. Although number of helicopter flights will be logged by Navitas.	N/A
ED 79	Page 628: Most vulnerable is King Penguin at Volunteers Point - almost all the population of Falklands' King Penguins are there, and they occupy location year round	Agreed, Navitas feel this is reflected in the text in section 10.2.6.1.	N/A
ED 80	Page 629: Is monitoring the impacts on the IBA and NNR considered as part of the EMMP or offsetting?	See response to comment ED78. As the impact of helicopter use is assessed as 'Low' no offsetting or monitoring measures are proposed.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 81	Page 635: Use of a 1971 study - are there more recent studies which could be used?	The reference is intended to indicate that the way seabed reacts when something lands on it has been verified. It is not expected that this will have changed since 1971.	N/A
ED 82	Page 648: With the data gaps, the numbers of geographical important species are not well know. Given that in section 7.4.3.2.3 there is a 50% probability of VME species present, it cannot be ruled out that habitats of conservation importance are present. This statement should be reviewed.	The text in 7.4.3.2.3 has been revised to indicate that interpretation of the studies in this area suggest that although VME indicator taxa may be present, they are likely to be sparsely occurring in the focal area. Additionally, VME indicator taxa are predicted to be widely distributed around the FOCZ, suggesting that VME's potentially impacted within the drilling area will have a high likelihood of recovery. Therefore, sensitivity is likely to be low. Please refer to '8.5.2.1 Assessment of sensitivity of receptors' for definitions.	Section 7.4.3.2.3
ED 83	Page 657: There is hardly any baseline data on seabird injury thresholds to underwater noise, despite acknowledgment that penguins and diving birds do spend significant time underwater. Info is all about fish and marine mammals. For birds it seems to be entirely based on 'marbled murrelet' - Is this sufficient?	Additional research has been found to support an assessment of underwater noise impacts on seabirds, and the chapter is being revised accordingly. See also FIFD 54.	Section 10.4.4.4.4
ED 84	Page 666: This section presents a risk assessment for offshore underwater noise on seabirds. Given that there is hardly any baseline info going into this assessment, and it focusses only on penguins and ignores other diving seabirds, much of this assessment is based on assumptions rather than facts. There is no info given about the confidence of this assessment (unlike for marine mammals). Whilst we realise this kind of information may be very hard to measure, we do not feel like it has adequately assessed this risk to seabirds.	See comment ED 83 and note that a confidence assessment will be added to the risk assessment for seabirds in the revised chapter.	Section 10.4.10
ED 85	Page 686: Sea bird and Marine mammal observers will be on board vessels to provide ongoing monitoring of birds present. As well as ongoing noise monitoring to understand better the baseline noise levels. Will this will be in the EMMP?	Yes, see Section 15 of the EIS.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 86	Page 690: The EIS notes that the actual locations of the anchoring points for ships in Berkeley Sound are yet to be decided, and will be chosen in conjunction with FIG to be least bother to other vessels that use the area. We would want to make sure that the locations are not too close to Kidney and Cochon NNR so that underwater noise does not disturb wildlife.	The anchorage locations will be chosen in consultation with FIG - criteria for site selection will cover both environmental considerations and disturbance to other users of Berkeley Sound. Anchorages close to the Kidney and Cochon NNRs would not be considered appropriate.	Section 5.5.1 Section 11.2.4.4.1
ED 87	Page 719: It is clear that a baseline is still required for toothfish and other species in this environment. Who will be checking that this baseline is done?	Fisheries in the areas were assessed, and the baseline data comes from the Falkland Islands Fisheries Department. There are gaps however, and these are acknowledged, noting that the assessment has taken a precautionary approach.	N/A
ED 88	Page 744: Sampling and analysis two times per day when discharging and once per month when reinjecting - Who would do the analysis? Where would the analysis take place?	There will be some automatic detection devices on the FPSO that measure oil in water and other discharges and a laboratory technician will be onboard the FPSO to undertake analysis.	N/A
ED 89	Page 746: Discharge giving rise to a visible oil sheen- will others be notified as well as DESNZ?	Thank you for your comment, and yes, Navitas will follow the PON8 requirements as described in Section 10.7.1.1.5. The narrative in 10.7.1.1.3 will be amended for clarity.	Section 10.7.1.1.3
ED 90	Page 746: Will there be an independent representative offshore to ensure compliance with reporting measures for oil sheens?	A PON 8 is required in the unlikely event an oil spill event. Further reporting would then be in accordance with direction from FIMA and DMR. FIG may choose to deploy an independent observer in the event that an oil sheen is reported. Please note that testing of Sea Lion crude by CEDRE has demonstrated that it is unlikely that Sea Lion crude will produce a visible sheen in water.	N/A
ED 91	Page 747: Will macerated food after discharge affect algae levels and attract bird life etc?	As the impact to the water quality and plankton is Very Low, there are unlikely to be impacts up the food chain.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 92	Page 748: How much monoethylene glycol will be used in hydrotesting of the umbilicals? This is a PLONAR chemical; toxic if ingested in large amounts; takes weeks to break down.	MEG is transported in closed containers and is only used in a closed loop processing circuit - i.e., to prevent hydrate formation. Therefore, unless you had a major containment issue there is no risk of MEG ingestion. MEG naturally depletes in a closed system.	N/A
ED 93	Page 748: Discharge of warm seawater discussed in section 10.8- What are the impacts to the local marine environment?	Please refer to section 10.8 for further discussion on the impacts of the discharge of seawater to the local marine environment.	N/A
ED 94	Page 748: PW from oil wells first starts to arrive before the PWRI are commissioned. Volumes of PW that may be discharged are as yet unknown. When will they be confirmed?	There will always be some PW discharge while the PWRI units are commissioned. It is not possible to determine at this point how much PW will need to be discharged prior to the commissioning of the PWRi, as it uncertain how long commissioning of the PWRi will take. However every effort will be made to ensure that discharges will be low-volume and short-lived. In EIS Section 10.7 Navitas states: 'It is anticipated however that there may be discharge of PW when it first starts to appear and the PWRI units are being commissioned. At the time of writing it was not possible to estimate when PW may start to arrive, nor how much may be discharged during the commissioning phase. However, water will start to cut from the production wells at different times and the PWRI commissioning process will commence upon first arrival of water from any one of the production wells. Therefore, all efforts will be made to minimise discharges that follow between the first 'water cut' and full implementation of the PWRI system. Therefore, it is anticipated that PW discharges during the commissioning stage will be low volume and short-lived.'	Section 10.7.2.5 Section 10.7.4.4.2

Ref.	Representation	Navitas response	Changes in Rev 4
ED 95	Page 750: Are there any values that have to be complied with for grey and black water after treatment for discharge? Or any testing that is required before discharge?	As described in Section 10.7.1.1.6: In compliance with MARPOL Annex IV, which applies to vessels > 400 GT or certified to carry > 15 persons on board, untreated black water (sewage) may only be discharged beyond 12 nm from shore whilst the vessel is moving. Between 3-12 nm, sewage must be treated prior to disposal at sea and only if vessels are moving at a speed of greater than or equal to four knots. Depending on the vessel's sewage treatment equipment, some sewage may be discharged within three nm, and again only if it is travelling at a minimum of four knots. For stationary offshore 'vessels' such as the FPSO and MODU, although they are >12 nm from shore, sewage must be treated before discharge to sea. Food waste must be macerated to ensure a maximum solid particle size of 25 mm prior to discharge as required under MARPOL Annex V, to aid its dispersal and decomposition in the water column.	N/A
ED 96	Page 750: Oil separated from drainage water on MODU will be shipped to Stanley prior to incineration- What is the plan if the incinerator in Stanley is not operational by this time? Or is out of action? Has this been included and referenced in emissions data?	See section 10.10.2.2.1 which states that 'occasionally the recovered oil may be sufficiently 'off spec' that it will not be suitable for processing offshore and in these instances it will be collected and stored in drums / transit tanks and will be shipped back to the onshore supply base.' From there it will be transferred into a sludge truck for disposal at the FIG Stanley incinerator. It is understood that the FIG Stanley Incinerator will be operational by end of 2026. This aligns with Navitas' operational schedule. Should the FIG Stanley Incinerator not be available Navitas would: 1. Store the waste in suitable containers onshore until	Section 10.7.2.8 Table 10.72

Ref.	Representation	Navitas response	Changes in Rev 4
		the FIG incinerator is once again available 2. Store the waste in suitable containers onshore until offshore treatment on board either the MODU or FPSO is available 3. Store the waste in suitable containers onshore until a suitable volume is ready for export under the Basel Convention to the UK. Waste oils from this process shall always ben candidates for re-use and incineration is a secondary solution. Section 10.10.2.2.1 will be updated for clarity. Emissions for the FIG incinerator are not included in the assessment but those associated with returning vessels, which would take waste back to the UK, are included, and the incineration emissions volumes are provided in a footnote to Table 10.72. Please refer to comment ED 131	
ED 97	Page 750: Hypersaline water produced from desalination will be discharged to sea- At what concentrations will they be? What are requirements for concentrations? What is the frequency of the discharge?	The minimal amounts of hypersaline water produced will be diluted prior to discharge. As such it is not anticipated that discharge will have any environmental impact. The selected FPSO is currently operating in the UK North Sea and meets all legislative requirements under this regime. The hypersaline concentration is expected to be *c.* three times that of seawater and will be discharged on a continuous basis as the desalinators operate to produce the freshwater. See also ED 104.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 98	Page 750: CW will be dosed with a biocide to prevent marine growth, discharge will contain biocides, CW plume will be buoyant and remain in top 200m of water column, and chemicals selected will minimise potential environmental impact. Detail is lacking on these chemicals - what are these chemicals?	As stated in Section 5.9.1.1 details on the specific operational chemicals which will be used during the Phase 1 & 2 Development are not yet known. Nonetheless, all operational chemicals used during the Development will be selected to minimise environmental impacts as much as possible. Further detail on the UK legislation which will be adhered to is provided in Sections 10.6.1.1 and 10.7.1.1. All chemicals selected will be listed on the Offshore Chemical Notification Scheme (OCNS) List of Notified and Ranked Product generated by CEFAS (Link).	N/A
ED 99	Page 751: Details of biocides discharge to prevent marine growth are not given, what is likely to be used?	See ED 110.	N/A
ED 100	Page 751: Who tests discharge samples?	There will be some automatic detection devices on the FPSO that measure oil in water, and other discharges. A Laboratory technician will also be onboard the FPSO can also undertake analysis. Please also see ED 88.	Section 10.7.5
ED 101	Page 752: If specific composition of Sea Lion PW is not yet known, but estimated, should this be followed up when PW is obtained?	Yes, this is captured in the EMMP. Once PW is produced analysis will be done and the PW sampling confirmed. The EMMP text will be checked and amended. to reflect this as necessary.	Section 10.7.4.1.2
ED 102	Page 752: Although it is clear that the PW concentration of chemicals referenced in this section are small concentrations (Naphthalene, Dibenzothiophene, Dibenzanthracene, Chrysene, Benzofluroanthene, Benzopweylene, Benzofluoranthene, Benzopyrene, Benzanthracene), what is the potential impact of long-term discharge of these chemicals? Concentration of MAH and some Alkyl phenols are also higher than PNEC.	Section 10.7.4.1.2 will be subject to an updated lit review to provide more data where possible.	Section 10.7.4.1.2 Section 10.7.4.2.2
ED 103	Page 756: Will the toxicity of the PW be monitored on a regular basis to check for accumulation of these contaminants in the surrounding area?	Yes. Regular PW testing and 5 yearly seabed surveys. Navitas will include this detail in Section 10.7.5 of the post-consultation EIS.	Section 10.7.5

Ref.	Representation	Navitas response	Changes in Rev 4
ED 104	Page 757: Not much information offered on hypersaline water: Doesn't discuss the impacts of the hypersaline water on the surrounding environment. It mentions the study measured instances of no more than 2mg/l above background salinity - what is the threshold of organisms in the ecosystem?	Noted. The subject matter will be reviewed and the narrative updated where necessary. In a study of the impact potential of hypersaline brines released into the marine environment, Dewar *et al.* (2022) found that dispersion in a hydrodynamically active region like the North Sea acts to dilute disposed brine rapidly such that the potential impact footprint is small, measured in tens of meters. This was found to depend on the release scenario and site specific data, for example the in-situ conditions such as currents and mixing. The method of brine disposal has a significant influence on dispersal, and brines released nearer the sea surface disperse more rapidly, compared with those released at the seabed. All hypersaline discharges at the Sea Lion field will be to the surface. And into such a dynamic environment. Marius Dewar, Jerry Blackford, Tony Espie, Sarah Wilford, Nicolas Bouffin. 2022. Impact potential of hypersaline brines released into the marine environment for CCS reservoir pressure management, International Journal of Greenhouse Gas Control, Volume 114, 103559, ISSN 1750-5836.	Section 10.7.4.1
ED 105	Page 757: Will the effect on marine life due to the low concentrations of produced water be monitored as mesocosm studies show low concentrations of produced water may have subtle effects on marine planktonic communities?	The base case is to re-inject, so discharges are being minimised as far as possible. This is a localised discharge and will be mixed and dilute rapidly. The needs for in situ sampling may be considered should it be justified based upon the results of the RBA modelling. The post-consultation EIS will be updated to reflect this.	Section 10.7.5

Ref.	Representation	Navitas response	Changes in Rev 4
ED 106	Page 758: Increased seabirds at site due to discharged food - will they be exposed to discharges of PW and contaminants within it?	Discussion on indirect impacts such as these are included within the EIS and are more specifically itemised within Chapter 13. Navitas will update Chapter 13 with worst-case impact colours in the post-consultation EIS. See also ED 191	Chapter 13
ED 107	Page 759: Can bilge oil and other discharges that produce oil sheens be minimally discharged on calmer days as dispersal through water less effective in calmer weather?	All discharges will be legally compliant and discharged under permit. Where possible Navitas will endeavour to minimise discharges on calm days.	N/A
ED 108	Page 761: Test on bulk crude oil at 55 degrees released into 18 degree seawater- test not representative or a replication of Falkland Islands waters. Can this be replicated with water conditions mimicking the Falkland Islands?	CEDRE leading facility for this type of testing. The CEDRE test work represents the worst-case (hot oil into warm water). It is not considered necessary or practical to repeat the tests with lower water temperatures. while the outdoor test basin was warmer than NFB, CEDRE drew a firm conclusion from the experiment that sheens were very limited, and the longer-term behaviour in the form of waxy masses was shown in the 9-day flume test at 8 Celsius. Navitas will add this clarification to the post-consultation EIS.	Table 12.1
ED 109	Page 761: Interactions of the birds with oil may affect reproductive success and thermoregulation. Unlikely to occur from a sheen alone. However sheens of thickness of 0.1 micro metres thick could result in measurable oil transfer to feathers. Have interactions of birds with oil contamination been fully investigated or explored here?	There is a good amount in the literature on this. Sea lion crude is waxy and produces a very small sheen when released into water at 18 degrees. However given the metocean conditions, any sheen that might form would be temporary. A precautionary approach has been taken in the assessment to show worst-case impact of sheens on birds from Sea Lion crude.	N/A
ED 110	Page 762: What biocide is likely to be present in discharge water? What impacts are likely?	Biocide is added to the seawater/produced water system for treatment prior to injection into the reservoir to inhibit biological growth in the reservoir and to prevent reservoir souring. Biocide will not be added to discharge water.	Section 5.9.1.1 Table 5.21

Ref.	Representation	Navitas response	Changes in Rev 4
		As stated in Section 5.9.1.1 details on the specific operational chemicals which will be used during the Phase 1 & 2 Development are not yet known. Nonetheless, all operational chemicals used during the Phase 1 & 2 Development will be selected to minimise environmental impacts as much as possible. By nature, biocides are intended to harm marine life, but efforts will be made to ensure selection of a Cefas Gold product with no Sub warnings (there are currently > 40 products on the Ranked listings for production and *c.* 15 for drilling ops).	
ED 111	Page 762: PW that has OIW above limits will be diverted to off-spec tanks - what happens to this?	Off-spec water will be routed back into the separation process and Sections 5.8.5.4.1 and 10.7.2.5 will be amended. for clarity.	Section 10.7.4.4.2 Section 5.8.5.4.1
ED 112	Page 762: Volumes of grey and black water per day per person- how many people will there be? Or likely to be? Actual amounts of grey/black water not currently calculable without this.	The personnel numbers are more explicitly provided in Chapter 10.10 on Waste. However, the estimated personnel numbers will be added as a footnote to Table 10.45.	Section 10.7.4.4.3 Table 10.49
ED 113	Page 763: Volume of water in table 10.46 average is calculated incorrectly	This has been checked and Navitas note the numbers are correct but cannot be exactly replicated in the word document due to rounding in the excel spreadsheet. A note will be added to this effect.	Table 10.49
ED 114	Page 763: Will record be kept of bilge water and drainage water from MODU/FPSO, whether above or below 15mg/l?	Yes. All operational discharge records will be kept in line with the current legislation (Section 10.7.1.1). Reference to reporting requirements will be added to Section 10.7.4.4.4.	Section 10.7.4.4.4 Section 10.7.4.4.5
ED 115	Page 763: W discharges will occur 7% of the time - 25 days per year amounting to 428,294 m3- Is there likely to be more than this, and if so, what will happen?	At all times the outputs to the environment, produced water modelling is based on the realistic worst-case. If this is found to be an underestimate of PWRI down time the impact assessment would need to be revisited. As described in 10.7.4.5.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 116	Page 765: Discharge temperature of the PW is predicted to be around 75 degrees? Salinity is anticipated to be around 6.4mg/l - What impact will this have on the surrounding area?	Section 10.8 describes and assess the impacts of thermal discharges and 10.7 assesses the of PW with the support of modelling.	N/A
ED 117	Page 767: Modelling seems to suggest benthic community will not be affected by PW as it will sit in the top 80-120m of water due to temp and salinity. What about the rest of the water column?	Section 10.7.6.1.2 assesses the impact of PW on water quality and marine fauna that may be exposed but the point of the modelling is to understand and predict the likely dispersion of the plume. As shown in Section 10.7.4.5.2.3 the discharged water does not descend significantly into the water column due to the temperature and salinity of the plume. The PW plume is confined to the top 80 m of the water column in early Field Life, and 120 m in late Field Life such that the deeper water and benthos are unlikely to be exposed.	N/A
ED 118	Page 772: No species or habitats of conservation importance will be affected? Good that chemicals will be chosen to minimise environmental impact, but what are these chemicals?	As stated in Section 5.9.1.1 details on the specific operational chemicals which will be used during the Phase 1 & 2 Development are not yet known. Nonetheless, all operational chemicals used during the Development will be selected to minimise environmental impacts as much as possible. Further detail on the UK legislation which will be adhered to is provided in Sections 10.6.1.1 and 10.7.1.1. All chemicals selected will be listed on the Offshore Chemical Notification Scheme (OCNS) List of Notified and Ranked Product generated by CEFAS (Link).	N/A
ED 119	Page 772: Grey water, black water and food waste causing slight eutrophication. Direct impacts are low- what about for seabirds and marine life?	As the impact to the water quality and plankton is Very Low, there are unlikely to be impacts up the food chain.	N/A
ED 120	Page 774: Will hypersaline water mix in 450m depth water - or will it remain localised and so therefore a problem for local marine life?	Hypersaline water is denser than seawater such that in a static environment it would slowly sink deeper and could affect the deeper water column. However, when discharged into the turbulent waters at the Sea	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		Lion field location it is anticipated that dispersal will be rapid and equilibrium will be reached before any descent to the full water column could occur. See also ED 104.	
ED 121	Page 774: Even though it is unlikely that both PWRI units would malfunction before PW is discharged, the significance of the impact is 'upper moderate ', and given the status of seabirds potentially affected, and potential effects of oiling, is there a contingency in place or considered for this, and for oiling of seabirds?	Navitas assumes the question relates to 10.7.6.2.2 as the assessment in 10.7.6.2.1 is considered to be Very Low. With regard to the potential for oil sheens, this assessment is very precautionary and any off-spec waters would not be discharged such that only water within the compliance limits would be discharged, As yet it is not clear if the Sea Lion oil is able to form significant sheens when discharged in small quantities. The focus here is on preventative mitigation measures such that the likelihood of the series events that could lead to a sheen is very low. Nonetheless, should a sheen occur and should it affect seabirds, the Wildlife Management Plan would be activated. In compliance with the PON8, any sheens will be reported to FIG.	N/A
ED 122	Page 775: No offsetting is determined necessary to reduce impact, e.g., seabirds attracted by discharged food waste?	Offsetting is not designed to reduce an impact. Further, the impact of the discharge of macerated food on seabirds is not significant (moderate or above) so it does not qualify for offsetting. See OMO 1994 as amended (significant impacts to be offset).	N/A
ED 123	Page 784: With little known about the oceanic response to thermal discharge, is the assumption that discharges wouldn't alter temperature in a sustained way valid?	As the discharge is to the open ocean it is not expected that any localised temperature change at the point of discharge will lead to sustained change in the temperature of the ocean.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 124	Page 785: Produced water has a salinity of 6.4 (fresh water). Are the effects of discharging this fresh water accounted for anywhere in the EIS? Will hot fresh water act differently to hot saline water?	Discharge of freshwater is not itemised in the assessment of PW over and above the impacts of the potential content of PW. The impact of freshwater which will disperse quickly is considered as negligible and will be added to Table 9.1 to indicated this impact has been scoped out.	Table 9.1
ED 125	Page 786: With different trajectories of the different thermal discharges and small periods of alignment, do these discharges have a cumulative effect on the area?	The rate of dispersion and the footprint of areas affected are such that the cumulative impact of overlapping trajectories is not considered further in the EIS.	N/A
ED 126	Page 788: Regarding the data gaps, should it not be said that there are indeed populations that are of geographical importance?	No, this concerns the benthos and heated infrastructure. The area is very localised.	N/A
ED 127	Page 788: What are the effects of thermal discharge on algal blooms? The EIS states that there is uncertainty around what continuous discharge will do in regards to algal blooms yet there is no specific monitoring identified for this.	Algal blooms tend to form seasonally when the combination of photoperiod and nutrient mixing is optimal. While sustainable temperature changes may impact upon the proliferation of algal blooms, the thermal discharges associated with the Sea Lion field will disperse rapidly and will not be sustained. Nonetheless, should such impacts occur, these will be recorded and monitored, not least as blooms could impact the seawater intakes. Navitas will review the text in the post-consultation EIS to ensure that this is clear.	Section 10.8.4.2
ED 128	Page 791: We question whether the sensitivity rating of 'very low' is accurate because we do not currently have an adequate baseline for what species are present. Cold water corals, if present, would have a much higher sensitivity to heat radiation and once gone may not be able to recover	Cold water corals are only associated with glacial drop stones in the area; these are patchy. Also note, the area will be surveyed prior to installation of subsea infrastructure or drilling.	N/A
ED 129	Page 798: What energy efficiency measures are being adopted in the vessels being used by Navitas?	Navitas will continue to explore emissions reduction initiatives prior to commencement of operations and throughout the lifecycle of the Sea Lion Field.	Section 10.9.7.1

Ref.	Representation	Navitas response	Changes in Rev 4
		Energy and emissions efficiency will form one of the evaluation criteria within the forthcoming tenders.	
ED 130	Page 799: How will we know f-gases have been accidentally released?	F-gas releases are not identifiable at the time of the release. When the equipment is serviced, releases/leaks are identified by the amount of top-up required. For this reason, all equipment will be serviced in line with legislation. The servicing period is dictated by the GWP of the F-gas and the tonnage of CO_2e that would be released in the event of an F-Gas release. Navitas commit to using low GWP F-gases.	Section 10.9.5.2
ED 131	Page 800: Treatment of waste has not been referenced in emissions activity. Please amend	Navitas does not account for incineration emissions as, in discussion with FIG, it is assumed that the FIG incinerator will have been commissioned and fit for use. Emissions from shipping the waste to the UK are considered the worst-case option and are accounted for in Section 10.9. To include emissions from incineration of waste locally and emissions from shipping the waste for disposal would constitute double counting. Nonetheless, the amount of emissions that would result from incineration of all waste (irrespective of which incinerator) is now itemised in a footnote to Table 10.72.	Section 10.9.2 Table 10.72
ED 132	Page 801: Has the power demand of consumers been cross referenced with PWD?	Navitas assume from the page number (801) that the comment refers to Table 10.55. This table provides detail on the key consumers of electricity generated by the DLE turbines on the FPSO so no consultation with PWD was relevant.	N/A
ED 133	Page 801: What effect will a flare recovery package have on the emissions?	It is not possible to quantify the % reduction that could potentially be achieved at this stage, but it will be evaluated and assessed in FEED and later phases of the project.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 134	Page 802: If CCC have proposed that F gases are replaced by low carbon alternatives by 2030 - should this not be the case here?	Navitas will comply with all relevant FIG/UK legislation regarding the phase out of F-Gases. This will be reiterated in Section 10.9 and specifically in Section 10.9.1.1.4.	Section 10.9.1.1.4
ED 135	Page 810: The values are under the wrong headings. Please amend	The source data will be checked and amended accordingly.	Table 10.62
ED 136	Page 816: No inclusion of car use in the personnel transportation - only refers to air transfer. Please amend this	Fuel consumption data associated with onshore personnel transportation and other vehicle use is included within Table 10.64. The use of cars is included within the category 'supply base' in Table 10.66, so the emissions are included in the calculations. A footnote will be added to Table 10.66 to ensure this is transparent.	Table 10.72
ED 137	Page 820: Table 10.64 Includes car transportation however in table 10.66 it is unclear which category it is included if at all.	Please see response to ED 136.	Table 10.72
ED 138	Page 823: What renewable energy options have been put in place throughout the stage 1 and 2 development to reduce emissions?	Navitas has considered renewable energy options for its onshore infrastructure. Navitas was advised by the PWD Power Station that it is preferred that Navitas does not incorporate individual solar/wind power at its onshore infrastructure facilities as it is difficult for the Stanley grid to absorb any over-production or to accommodate spikes in demand that would arise in incidences in which the renewable energy sources could not supply onshore infrastructure demand (e.g., calm weather, low sunshine). As such, Navitas is exploring how it can support investment in municipal renewable energy generation and battery storage to secure both emissions reduction and offsetting objectives.	N/A
ED 139	Page 824: It would be helpful to separate out the contribution of different vessels to this total for each stage as the data to reach this extends over multiple tables in different sections of the document.	It would be possible to separate out the contribution of different vessels in each Stage of the Development. However, Navitas does not believe this would	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		materially add to the estimation of emissions or to the assessment. In an already complicated Chapter, Navitas opt not to add more tables that do not effectively add to the chapter.	
ED 140	Page 824: What about emissions due to construction of onshore and offshore?	Emissions from offshore construction are related to the vessels used and are included with the 'All vessels' line item in the relevant project Stages. Table 10.66 will be footnoted to indicate this. With regard to onshore construction, these are out of scope of this EIS and will be covered in a dedicated EIS and planning applications as necessary. This is described in Section 2.4 on the 'Scope of the EIS'.	Table 10.72
ED 141	Page 824: Calculation for CO_2e in each stage show possible rounding errors considering GWPs w/o cc feedback. Calculation for CH4 and N2O total project CO_2e incorrect using GWPs w/o cc feedback	An extensive spreadsheet sits behind all the tables presented in the EIS. These spreadsheets calculate the data to many decimal places. Once these are rounded up/down to enable cleaner presentation in the EIS, the totals no longer exactly match the totalled figures. The spreadsheet has been extensively checked as part of the internal QC process. They have been checked again in response to this comment and Navitas are confident that the totals are accurate. A footnote will be added as appropriate to indicate that the data have been rounded up/down from many decimal places.	Table 10.72 Table 10.73
ED 142	Page 826: Calculations of CO_2e for CH4 and N2O are incorrect, also unclear how the average emissions per year (CO_2e) was calculated	See ED 141.	Table 10.72 Table 10.73
ED 143	Page 827: Calculations of CO_2e for direct GHG are incorrect and consequently the total CO_2e is incorrect	See ED 141.	Table 10.72 Table 10.73
ED 144	Page 828: How has the figure of 77.68 tonnes of HC gas that could be released been estimated?	The quantity of HC gas blanket that could be vented is based on the volume of the cargo tanks and works on the worst-case assumption that the VRP malfunctions	Section 10.9.4.4.5

Ref.	Representation	Navitas response	Changes in Rev 4
		when the cargo tanks are empty and remains out of commission for the duration it takes for the tanks to fill. In such a circumstance (albeit unlikely) the full cargo volume of HC gas would be displaced by the crude and vented to the atmosphere. It is very unlikely that this set of circumstances would occur such that this is considered to be a worst-case. The actual figure of 77.68 tonnes was based on the cargo tanks of a larger FPSO than is proposed for use, such that again, this estimates a worst-case. As the development becomes more mature, it can now be confirmed that the cargo tanks will be smaller and the text, and Table 10.69, will be amended. to reflect tanks half the size, such that the quantity of HC released would be 38.84 tonnes.	
ED 145	Page 828: Regarding the emissions resulting from use of municipal electricity generation, has PWD confirmed if this estimate is realistic?	An Emissions Factor was requested from FIG but wasn't available at the time of writing. Navitas judge the EF used to be reasonable and on the conservative side and have referenced the source. Given the amount of emissions for this item is so small in comparison to the overall project, changing this EF will have negligible impact on the overall.	N/A
ED 146	Page 838: Continuation of incorrect values from previous table	**Initial Consultation Response:** Noted. This will be amended. **Post-Consultation Comment:** Relevant tables have been updated with a footnote explaining the potential for differential totals owing to rounding errors. However, Table 10.49 in Section 10.7 has been updated, as has Table 10.85 in Section 10.10.	Table 10.49 Table 10.85

Ref.	Representation	Navitas response	Changes in Rev 4
ED 147	Page 838: Most project specific mitigations have been included - however there could be more opportunities missed to reduce emissions - car transportation could be completed with EV, powered by renewable energy if a suitable wind turbine / battery storage was installed at the Navitas onshore site.	Navitas continues to explore emissions reduction opportunities and will do so throughout field life. Navitas will tender the provision of onshore vehicle transportation in due course. It is anticipated that prospective tenderers will be asked to consider electric transportation opportunities. However, close dialogue will be required with FIG to ensure that the municipal power generation can accommodate an increase in the number of electric vehicles. The situation will also be monitored as technologies advance and capacity increases through the life of field. In the meantime the EIA has assessed the worst-case emissions anticipated, and therefore assumes that vehicles will be powered by traditional combustion engines. In the post-consultation EIS Navitas will add a section under 10.9.7 or 10.9.10.1 on additional measures that may be investigated.	Section 10.9.7.1
ED 148	Page 844: Why have other annexes not been included under 'relevant legislation'? Annex II - control of pollution by noxious liquid, Prevention of pollution by harmful substances carried by sea in packaged form, Annex IV - prevention of pollution by sewage from ships	These will be included.	Section 10.10.1.1
ED 149	Page 844: The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal, the protocols of which apply to the onward processing of waste from the Falkland Islands to the UK. - The FI is not party to the Basel Convention - but has a bilateral agreement in place	Noted, this will be amended.	Section 10.10.1.1 Section 3.1.7.1
ED 150	Page 848: Ash generated from waste incineration (if the FIG incinerator is not operational and a temporary incinerator is required at the onshore base). - Ash will be generated whether from FIG incinerator or Navitas. If generated by Navitas incinerator what will happen to this ash?	As described in 10.10.2.2.2.1 'In the event that the new [FIG] facility is not completed in time, the project will provide a temporary portable incinerator and waste ash will be temporarily securely stored at the supply base and periodically sent back to the UK along with other waste returns.'	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
ED 151	Page 848: However, occasionally the recovered oil may be sufficiently 'off spec' that it will not be suitable for processing offshore and in these instances it will be collected and stored in drums / transit tanks and will be shipped back to the onshore supply base. What happens in this case, will they be taken back to the UK or left in the Falklands?	As described in paragraphs 3 and 4 of section 10.10.2.2.1, this waste stream may be a candidate for re-use, with incineration being another option. Alternatively, if 'off spec' oil is returned to shore due to malfunction on the MODU/FPSO, the waste would be stored onshore and then returned offshore for processing once equipment is fixed.	N/A
ED 152	Page 847: The EIS states that oily water will be treated as sewerage - will this actually go straight to sea as there is no sewerage treatment in the Falklands?	Onshore oily waste water will not go into the Stanley sewerage system unless under consent from FIG. Onshore operations which may result in oily water discharge will be completed in a bunded area which will contain the oily water, this will then be treated, incinerated or dealt with away from the sewerage network and shall align with Navitas' Waste Management Procedure. It is understood that the FIG Stanley Incinerator will be operational by end 2026. This aligns with Navitas' operational schedule. Should the FIG Stanley Incinerator not be available Navitas would: 1. Store the waste in suitable containers onshore until the FIG incinerator is once again available; or 2. Store the waste in suitable containers onshore until offshore treatment on board either the MODU or FPSO is available 3. Store the waste in suitable containers onshore until a suitable volume is ready for export under the Basel Convention to the UK. Waste oils from this process shall always be candidates for re-use, incineration is a secondary solution.	Section 10.10.2.2.1 Table 10.86

Ref.	Representation	Navitas response	Changes in Rev 4
ED 153	Page 848: The EIS states that more details on the oil spill waste clean-up and management will be detailed in Navitas' Waste Management Strategy. When will this strategy be completed?	Navitas has submitted a waste management procedure to FIG for review. The Preliminary OPEPs provide more detail on proposals for oil spill waste management.	N/A
ED 154	Page 858: The Environmental and Emissions Monitoring System (EEMS) is the environmental database of the UK oil and gas industry. The EEMS was updated in Feb 2024. Have the waste figures from 2013 been updated?	The EEMS data is no longer referenced in this chapter - this bullet will be removed.	Section 10.10.4.4.1
ED 155	Page 860: Can the incinerator incinerate hazardous waste, aerosols, pipe dope, oily rags?	Following discussions with FIG it is Navitas' expectation that the incinerator will be able to handle this type of waste. If FIG is no longer able to handle this type of waste Navitas would send these streams back to the UK under the Basel Convention regulations, in accordance with its Waste Management Procedure.	N/A
ED 156	Page 872: Marine Mammals are also protected under the Conservation of Wildlife and Nature Ordinance 1999 - this should be included	This will be added.	Section 10.11.1.1
ED 157	Page 873: There have been collisions reported in the past - Caroline Weir (Falklands Conservation) has the information, and we suggest it should be included in the EIS	This will be added.	Section 10.11.4.1
ED 158	Page 876: Inshore is a ratified KBA for sei whales and 9 seabird species	The KBA is covered in the baseline section (7.5.2.3.4), which is referenced in this section.	N/A
ED 159	Page 880: Falklands guidelines also exist - the cetacean code of conduct - should be included in EIS	This will be added.	Section 10.4.4.1 Section 15.6.2.1.3 Section 15.6.2.1.4
ED 160	Page 881: Says highest number of vessels is during stage 2a/b, however the table shows 13 during this stage but 16 for stage 1. Statement does not add up	Noted, this will be amended.	Section 10.11.4.5 Table 10.83
ED 161	Page 881: There is no definitive data that populations of whales are increasing in the area therefore should be very careful in concluding that the loss of an individual animal would not have a long-term impact on the local population	This sentence will be removed.	Section 10.11.6.1

Ref.	Representation	Navitas response	Changes in Rev 4
ED 162	Page 883: Review of SMMO reports after 5 years. Why such a long wait for the review with the uncertainties over cetaceans interaction? Would a review after 2 years not be more appropriate in the first instance?	This will be revised to regular reviews with an in depth review every 5 years.	Section 10.4.10.1 Section 10.5.10.1 Section 15.6.2.1.2 Section 15.6.2.1.3
ED 163	Page 891: Mentions CBD - but references the old CBD Aichi targets, not the newer Kunming-Montreal targets that superseded them. Please update	This will be updated.	Section 10.12.1.1.2
ED 164	Page 908: This section about biofouling says: In order to specifically mitigate the 'Upper Moderate' risk of species introduction *via* bio-fouling which is posed by the LTVs used as floating logistics barges, these vessels will be required to have a hull inspection prior to transport to Berkeley Sound and consideration will be given to hull cleaning, depending on the results of the survey. If hull cleaning is required, this would not be done in Falklands waters. Questions: will all hulls be cleaned before arriving in the Falklands? There is no information given about whether this will actually happen, who decides when to clean a hull and when not to clean a hull? How will this be decided, managed, monitored and recorded? Given the impacts that bringing invasive species could cause, would not ALL hulls need to be cleaned? These questions are important because the entire mitigation for this risk appears to be at the discretion of someone without any protocols around it.	The standard used will be appropriate and agreed in collaboration with FIG. Navitas will reference the IMO 2023 Biofouling Guidelines and Table 1 - Rating Scale for proposed actions in the post-consultation EIS. Link	Section 10.12.1.1 Section 10.12.7.2
ED 165	Page 918: Mitigations for terrestrial invasive species rely heavily on the biosecurity management plan that exists but needs to be revised (and the EIS says it will be revised for this project). Therefore the EIS is scant on exact information about what mitigations will actually be done to address the risks. Whilst we appreciate that this is a work in progress and has been added to the 'to do list' for Navitas, nonetheless it means that the level of confidence for the risk assessment is not as good as it could have been if those actual mitigations were documented in the EIS. It could also include using the rat detector dogs that operate in the Falklands. Would be good to see this included as part of the mitigations.	The Sea Lion Phase 1 and 2 Biosecurity Management Plan will be developed after project sanction and prior to the commencement of operations. This will build upon the 2015 exploration Biosecurity Management Plan. The EMMP advisory group will be invited to review and input in to the draft Biosecurity Management Plan prior to its finalisation and issue. The intention is to bio-secure cargo at its port of origin. It will be inspected on arrival and any cargo considered deficient will be treated in a dedicated biosecurity area in the supply yard prior to release. Methods of inspection and remediation will be	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		discussed and agreed with the EMMP advisory group and FIG Biosecurity prior to finalisation of the Biosecurity Management Plan.	
ED 166	Page 966: Has there been consideration of impacts if Navitas cannot contract for the building of the transit style accommodation or for new builds that may need to occur for the permanent onshore staff? What would be the impacts if Navitas has to use the limited rental accommodation that exists?	If the local supply chain is unable to respond to the onshore accommodation contract opportunity, then Navitas can seek international contractors to fulfil the construction requirement. Socioeconomic impacts, monitoring and management will be discussed in more detail in the updated Sea Lion Socio-economic Impact Assessment.	N/A
ED 167	Page 974: There has been ongoing policy work surrounding housing. Is there more up to date information available than 2021?	FIG Policy department (FIG Policy, Economy and Corporate Services) was asked and no update was available at the time (Q2 2024).	N/A
ED 168	Page 974: Severity has been categorised as minor; however, more than likely under the current housing climate it will increase to at least moderate.	The EIS can only assess the current situation but it is understood housing is a challenging issue and Navitas will do what they can to minimise impact. As the addition of accommodation required by Navitas is only 2 % change, the assessment looks at the worst-case and is precautionary, Navitas feel the assessment is appropriate. Currently the assessment is sensitivity Low 'The receptor is tolerant of change without detriment to its character, or unacceptable to a handful of stakeholders' and Severity Minor: 'Short-term minor impact on livelihood and/or health, inconvenience of resource use, minor levels of disturbance to local pop, concern to a handful of stakeholders'. Wider aspects of the impact of the development on accommodation are considered in the SIA.	N/A
ED 169	Page 979: Most vessels will have water makers on board however any net deficit will be supplied at the TDF for domestic use- Will the ad hoc nature of demand of water requirements make planning for water difficult?	The trickle-feed buffer tank at TDF will help with this issue as there will be no large drawdowns of water from the FIG system but rather a gradual trickle which	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		will be more manageable. There is also a need for appropriate planning by Navitas in terms of vessels' water requirements e.g., top up times/quantities, which will be managed by the onshore teams.	
ED 170	Page 981: Two receptors by use of Stanley freshwater are human population and tangible property - what about the ecosystem catchment? If more water than is necessary is abstracted, this may impact the health of the catchment, however this is not included in the EIS	This section of the EIS focuses on the competition of a resource (water) for the human population. As such, the natural environment would not be considered a receptor in this case. The volume of water to be extracted from the natural supply is managed by FIG and Navitas will be one of many end users. Navitas are going to be taking water *via* a trickle-feed to minimise significant drawdowns on the system.	N/A
ED 171	Page 981: Impacts to local users may arise from increase in volume and rate of demand- also any significant reduction in rainfall patterns will have impact.	Noted, this will be included.	Section 11.4.4.1.1
ED 172	Page 981: EIS stated that PWD are required to hold two days water supply in storage tanks - is this correct as we believe it is three days water supply?	This has been checked again with PWD who confirm 'there is theoretically enough to supply the town with 2.2 days, and including the water already in the network this could stretch to 2.5 days'. Suggest text is amended. to '2-3 days'	Section 11.4.4.1
ED 173	Page 985: Pumping water to vessels - Has electricity to pump the water been factored into the emissions?	The onshore electricity generation usage has been included in the project's emissions calculations. This includes electricity required to pump water to vessels. Navitas will add a footnote to table 10.66 in the post-consultation EIS to ensure that this is clear.	Table 10.72
ED 174	Page 986: Sustainable design - Will the supply base and accommodation units include rainwater harvesting for grey water use?	Tenderers will be asked to provide detail of their proposed incorporation of sustainable design features in their tender submissions. Environmental considerations and sustainable design will form part of the contract evaluation criteria. This detail will be included in the post-consultation EIS.	Section 5.11.2

Ref.	Representation	Navitas response	Changes in Rev 4
ED 175	Page 986: Alterative to reduce demand of fresh water/ pumping raw water from catchment source rather than the water treatment plant - this needs to be carefully managed with the health of the surrounding ecosystem in mind, especially if average water demand from onshore centres and offshore assets ranges from 99.5-112.5m3 per day, and excess Stanley capacity is 82m3 per day.	FIG Public Works Department has indicated to Navitas that it intends to increase both water catchment and treatment such that the prognosed demand from Sea Lion will easily be accommodated within the prognosed increased capacity. Water demand and pressure on supply will be a matter for continuous monitoring between FIG and Navitas so that if issues are encountered measures to increase capacity/reduce constraints can be implemented.	N/A
ED 176	Page 995: Annual increase in water demand of between 2 to 3 % per annum - we have calculated that there will actually be a 3.5% increase.	Noted, this will be amended. and referenced as (FIG Environment Department, *pers. comm.*)	Section 11.4.9
ED 177	Page 995: Monitoring of onshore water use - Will this be metered?	Yes, water usage will be metered as it was for previous drilling campaigns.	N/A
ED 178	Page 1006: Risk is remaining at 'upper moderate' - Concern that if the energy supply and new power station in Stanley is not significantly upgraded in time that increased demand will not be able to be met for phase 1 & 2.	Risk is assessed as 'Upper Moderate' as it is based on existing capacity - FIGs planned investment in the new power station has not been factored in to the assessment. The Public Works Department has advised that with its planned investment, Sea Lion-associated demands can easily be accommodated. In the event that FIG investment is significantly delayed, and there are capacity constraints, Navitas will rely upon standalone power generation for its onshore facilities until such time as increased municipal power generation is available. As such, it is not anticipated that the Upper Moderate risk will eventuate.	N/A
ED 179	Page 1011: Does this mean at the commencement of the project? If not, can existing flights meet requirements for personnel that will need to arrive in the Islands before drilling begins? Is there a provision for the dedicated charter flight to start earlier if needed?	Navitas acknowledges the limitations of existing air links and is monitoring progress with the provision of additional air links in regular consultation with FIG. Navitas will assess its anticipated seat demand and the capacity on air links prior to commencement of operations. If necessary, in consultation with FIG and MoD, ad hoc dedicated charter flights can be	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		implemented prior to the commencement of drilling to meet Sea Lion development related demand and limit impact on other industry and the general community. This aspect will be discussed further in the socioeconomic impact assessment.	
ED 180	Page 1019: EIS states that waste from the development will be disposed of at the FIG waste management facility at Megabid, and if these are not available then the waste would be incinerated at the supply base or shipped away to be dealt with in another country. Can you please confirm that this is correct?	That is correct. The anticipated wastes arising from Sea Lion was considered in the design and specification of the municipal waste facility. FIG's Public Works Department anticipates that this facility will be available in late 2026 which is prior to the commencement of Sea Lion operations. However, in the event that the municipal facility is significantly delayed, Navitas will temporarily store waste in a dedicated waste area within the onshore supply yards, and if the delay is prolonged has a contingency option to seek planning permission for the situation of a temporary containerised incinerator in the Supply Base facility. There is also the option to export waste for disposal elsewhere, as was undertaken in previous exploration drilling campaigns. This is covered in greater detail in the Waste Management Procedure which was issued to FIG in August 2024 (see ED 153).	N/A
ED 181	Page 1019: Section states that “the Falkland Island municipal waste facilities will become available in time for the project”; section 10.10 expresses confidence that this will be the case for the FIG incinerator; previous sections (such as those following) outline that FIG ‘plan to build’ a ‘facility that is expected to be ready for operation in advance of Sea Lion development campaign’ (5.11.1.2.2) (planned to be available 2024 according to section 10.10.4.2.3). While previous sections acknowledge that this may not be available at time of project (e.g., 5.11.4), and discuss the construction and use of own incinerator at base (e.g., 10.10.1), language and wording for this	Wording will be checked for consistency throughout. It is Navitas' intention to use the FIG incinerator, which is anticipated to be operational by the time Navitas operations begin. In the unlikely case that the FIG incinerator is not available, Navitas will provide a temporary incinerator to deal with their waste until the FIG one is operational. See the response to ED 180 for further information if required.	Section 11.7.2.4

Ref.	Representation	Navitas response	Changes in Rev 4
	particular section is not wholly consistent in conveying that this is a probable scenario (however likely), but implies instead that construction of facility will have happened.		
ED 182	Page 1053: Livestock will be sensitive to helicopter flights, particularly when corralled.	Agreed, this is highlighted in section 11.9.1.1.3, last bullet point and 11.9.4.1.2.	N/A
ED 183	Page 1057: Flight path MPC to Stanley- Does this impact on local settlements (Bluff Cove and Fitzroy)? Could this section be travelled by car? Would this also affect the livestock going to FIMCO?	Yes, it is noted in section 11.9.6.1.1 that helicopter flights will pass over settlements and this is included in the assessment. The base case is to travel the MPN-Stanley section by vehicle (likely minibuses) but an option to move personnel by helicopter is included as a worst-case.	N/A
ED 184	Page 1163: Benthic communities are not included in table 12.11. If there is no affect on it, should it still be included to show that this has been considered and it stated no impact on these?	Noted. Benthos will be included and stated as N/A. Other table will be checked to ensure consistency to indicate those receptors that are not included.	Table 12.11 Table 12.12 Table 12.13 Table 12.17 Chapter 14
ED 185	Page 1084: Tests are planned for pelt and fur adhesion - when are these tests going to happen? Why do tests in water temperature of 18C when the seawater temperature is about 5 degrees C here in the Falklands? Have the same tests been carried out in water 5 degrees C, and if so, does this alter the results? This should be included.	Tests are planned for pelt and fur adhesion and commitment to undertaking these tests is included within the EMMP. These tests haven't yet been undertaken due to difficulties in obtaining the import permits that are required for the tests to be undertaken at the CEDRE laboratory in France. If the project achieves production consent and Final Investment Decision, efforts to secure import permits for the pelt and fur will be reinvigorated. In the event that this is unsuccessful, the contingency option is for the testing to be undertaken within the Falkland Islands. This will require the importation to the Falklands of testing equipment and Sea Lion crude samples. There are limited specialist laboratories for undertaking oil behaviour tests. The water at the specialist testing facility in France was 18 degrees C.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		The results of the testing at that water temperature can be considered worst-case as at 5 degrees water temperature it is anticipated that Sea Lion crude would form a solid even more rapidly and be even less likely to sheen.	
ED 186	Page 1196: This figure, in the first map (a) shows that there is a low probability of surface oil around Cochon and Kidney Island. However, the second map (b) shows a high probability of oil on the shoreline of Cochon and Kidney Island under scenario 1.	Although the scales are the same, the figures represent different model outputs.	N/A
ED 187	Page 1200: Regarding dispersants - would these be used in the Falklands? They can be harmful to the environment, do Navitas have policies for the use of dispersants?	Dispersants are not proposed as marine receptors such as kelp are likely to be more affected by the chemicals and dispersed oil than by the oil remaining on the surface, see section 12.2.4.1. Furthermore, permission to use dispersants would have to be granted by FIG.	N/A
ED 188	Page 1200: Is there a procedure to deal with oil spill clean-up waste, how will this be stored or disposed of? Storage of oiled waste could also lead to contamination if not stored properly.	The preliminary OPEPs, which were issued by Navitas to FIG in August 2024, detail proposals for dealing with oil spill clean-up waste. In the highly unlikely event that a spill incident should occur, Navitas would be supported by international oil spill response contractors who have significant expertise and resources in the appropriate management of oil spill response waste. These response contractors would be deployed to the Islands in the event of a Tier 2 or 3 oil spill event. There will be oil spill response and waste storage capability on the offshore support vessels (OSVs) and at the TDF (Tier 1) and in the onshore supply base facility. An appropriate dedicated bunded area for the storage of oily waste is planned within the supply base yard. Navitas will check section 5.11.4.4.1	Section 5.11.4.4.1 Section 10.10.2.2.3 Section 12.1.1 Section 12.2.1 Section 12.3.1

Ref.	Representation	Navitas response	Changes in Rev 4
		and Sections 12.1 - 12.3 and add additional detail to the post-consultation EIS as necessary.	
ED 189	Page 1201: Why just highlight the south shore? This is slightly misleading as figure 12-46 shows there is a probability between 20-40% of onshore oil around large areas of Cape Pembroke which is known for shorebirds and marine mammals. All of Cape Pembroke is also a designated nature reserve.	Text will be amended.	Section 12.2.4.4.2
ED 190	Page 1201: During calm weather, the oil would be amenable to recovery given the buoyant nature of the wax masses. What about other weather states - not very often it is calm in FI?	In the highly unlikely event of a spill to sea, every effort will be made to effect the recovery operations. However, as noted in the EIS, there are operating limitations in the deployment and recovery efficiency of the oil spill response equipment identified as suitable for the characteristics of Sea Lion crude (as there is with any oil spill response). The optimum oil spill response approach would need to be determined in real-time during the incident and the approach would be dependent on: - the short, medium and long-term metocean conditions and their forecast - the spill modelling and tracking data - the consideration of the nature and size of spill As detailed both in the EIS and the Preliminary OPEPs, laboratory tests (by CEDRE) indicate that, given the nature of the Sea Lion crude, allowing for weathering and natural dispersion (which would occur faster in worse metocean conditions, when response equipment could not be deployed) may often represent the optimal response approach. In summary, Navitas has: - Modelled numerous oil spill event scenarios - Committed to recover as much spilled oil as possible - Submitted its Preliminary OPEPs to FIG	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		Most importantly, Navitas will operate within a regime and structure that should prevent the occurrence of such an incident happening in the first place.	
ED 191	Page 1235: Cumulative impacts (or impact interactions) are not covered in depth in chapter 13. Two pages for cumulative impacts does not seem enough detail, it is paying lip service at best, especially when some receptors such as seabirds and marine mammals could be impacted in multiple different ways. We expect the cumulative risks to be considered in more detail.	It is acknowledged that meaningful assessment of cumulative impacts is difficult. However, a colour-coded matrix in Section 13 has been included to give an idea of residual risk for each receptor. While this may overstate the impacts for some receptors, this is felt to be in line with the precautionary approach of the EIS. Thought will be given on the most effective way to summarise the non-project activities which contribute to cumulative impacts on each receptor. This presentation will be included within Chapter 13 of the post-consultation EIS and the title will be changed to 'Cumulative impacts and impact interactions'.	Chapter 13
ED 192	General: Continuous environmental monitoring hasn't been mentioned, which would allow for an understanding of any changes within the local environment potentially due to O&G activity. Will this be included?	Environmental monitoring to be conducted is detailed in the EMMP. Daily monitoring will be done offshore on any discharges (e.g., chemicals, produced water, if being discharged at the time, exhaust emissions etc) and these are reported regularly to the Regulatory authority (if the UK regime is to be followed). Monthly, quarterly and annual reporting is also conducted.	N/A
ED 193	General: Multiple variables from chapter 7.3 that are mentioned such as Tom and TOC levels, PAH, metal toxicity should be routinely monitored during the life of the project	These metrics are included in the benthic sediment surveys, which are proposed every 5 years throughout field life. Navitas will update the text to	Section 10.6.10.1 Section 15.6.2.1.1

Ref.	Representation	Navitas response	Changes in Rev 4
		ensure that this is clear in the relevant sections of the post-consultation EIS.	
ED 194	General: This may not come under environmental monitoring - however if IUCN status of species changes within the lifetime of the project - how would additional risk assessments address this?	This would be addressed in the 5 yearly revisions of the EIS.	N/A
ED 195	General: chapter 10.2 mentions disturbance of local populations due to helicopter flights. Will the number of flights be monitored - and surveys conducted to ensure the local bird populations are not affected?	Number of flights will be recorded. Baseline data and ongoing monitoring of noise will be conducted and all complaints monitored, see section 15.6.2.2.1. Surveys of local bird populations are not proposed as the assessed impact does not trigger the need for a monitoring action.	N/A
ED 196	General: What baseline data would be needed to be collected to be able to identify impacts of the project when it started? E.g., temperature, salinity, conductivity, presence of metals, suspended solids, etc. this needs to cover all seasons for multiple years to account for natural variability. Would also be useful to know the baseline composition of the communities at the drill locations to be able to identify the impact and regeneration of the community to look at impact but also inform the EIA for decommissioning of the oil field	Please see Chapter 7 of the EIS for baseline data at the field. Also there will be Remotely Operated Vehicle (ROV) surveys at each drill centre prior to the commencement of drilling.	N/A
Falklands Conservation			
FC 1	The International Energy Agency has stated that no new oil and gas fields should be opened if we are to achieve net zero emissions by 2050. This would be necessary to keep temperature rises under the safe 2°C limit, avoiding far more severe climate change effects on wildlife, ecosystems and people, including for the Falkland Islands. Opening a new oil field in the Falkland Islands would not align with this, therefore Falklands Conservation (FC) cannot support the proposal laid out in the Environmental Impact Statement (EIS).	Please refer to RSPB 7.	N/A
FC 2	The presented EIS is not fit for purpose FC believes the EIS sets out an avoidable and clearly environmentally damaging development proposal that is inconsistent with the Government's	Navitas refutes the assertion that the EIS has cut corners - it represents 14 years of investment in data acquisition, analysis, stakeholder engagement etc., in	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	objective to 'reduce our carbon emissions, in order to ensure we act as a responsible global citizen' (Islands Plan 2022). The EIS is an incomplete update to previous submissions. It remains inadequate in meeting key requirements of EIA process. It provides an incomplete picture of the risks to the Falklands environment. A major shortcoming is the failure to provide a firm commitment to offsetting all carbon emissions: the 9 million tonnes produced during the development and the more than 100 million tonnes from burning of Falklands oil. EIS statements regarding local offsetting guarantee nothing, are likely unachievable, and could easily be viewed as climate-washing. The EIS contains significant data omissions and errors. Key data, highlighted as required 10 years previous have still failed to be collected, existing data have not been included. Two sections looked at in detail, though not exhaustively, contain over 100 errors, omissions or uncertainties. These put Falklands and other globally significant wildlife at risk. FC believes the current EIS confirms a corner-cutting approach, which unnecessarily results in environmental and reputational impacts for the Falklands community, and one which has limited meaningful commitment to mitigating key environmental harms.	order to assess environmental risk and impact and shape the Phase 1 and 2 development so that residual risks and impacts are ALARP. Navitas notes that independent assessment of the EIS by leading UK industry bodies compliments the structure and content of the EIS, use of data and approach to data gaps. The JV [POEPL (now NPDP) and Rockhopper Exploration] has invested significant sums in data acquisition to inform this EIS and *via* FIPLA has contributed to the GAP project. It has also committed to additional data acquisition in advance of commencement of operations in order to validate the risk assessment. The FIG EIA Guidance states that 'data gaps do not make an EIS unfit for purpose as long as these are acknowledged and explained'; it is how they are treated in the risk assessment that is important (see sections 3.13 and 3.18 of the guidance for reference). Navitas believes that where data gaps remain the EIA has been considerably precautionary, and residual risk reduced to ALARP. Some of the identified data gaps are beyond the capability of an individual operator to fill. With regard to seabird data, for example, the EMMP workshop report (April 2019) notes that 'Challenges to the adequacy of data were raised during the EIS public consultation and were reiterated in the EMMP workshop. The workshop agreed that it would be	

Ref.	Representation	Navitas response	Changes in Rev 4
		useful to collect further data opportunistically from vessels associated with the Sea Lion development, but that a wider data collection effort to update seabird information was beyond the scope of the EMMP. It was also decided not to monitor seabird populations ashore due to the difficulty of attributing any change to activities in the Sea Lion field.' Globally there is no precedent that a developer will offset emissions from sold product (please refer to response to DMR 288). **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	
FC 3	The current legal framework is incomplete for good environmental governance In conjunction with the above concerns, FC believes that Falkland Islands Government (FIG) has not made the promised progress in three key areas of environmental legislation that would help ensure that environmental impacts are minimised and would therefore help guide any Environmental Impact Statements to best practice standards. These were 'polluter pays', updated wildlife ordinance and 'environmental case' legislation. The lack of any identified key marine features such as Marine Protected Areas and Vulnerable Marine Ecosystems, and associated protective policy is a significant weakness for risk assessment, decision-making and protection of the marine environment. There is risk that many new oil projects could become uneconomical before the intended project end-date. The lack of an early commitment to how decommissioning would happen in an environmentally sustainable manner is therefore a critical omission.	Navitas has submitted the Field Development Plan (FDP) and Environmental Impact Statement (EIS) in accordance with FIG's current legislative framework. Navitas continues to work with FIG and its key contractors to ensure that its arrangements are aligned with industry best practice and FIG's planned changes to legislation. On decommissioning, please see response to DGN 3. Navitas expects that FIG will comment separately on the EIS public consultation representations which cover FIG's Oil Readiness and planned legislation.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	If FIG gives a green light to this Environmental Impact Statement that does not meet best practice standards and before legislation is put in place, it makes the legal reliability of the agreement uncertain in case of any infringements and puts the government at risk of being sued if trying to impose standards later.		
FC 4	Recommendation FIG should not sanction unnecessary environmental impacts caused by a corner-cutting development proposal, under high-risk and inadequately legislated circumstances. Determining an EIS of this quality would be to endorse low standards and commitment that delivers a poor outcome for the environment and the community. The EIS should be re-submitted only once key gaps have been filled, errors addressed, and standards met.	Navitas notes the comment and opinion. Navitas continues to work within the legislative framework provided by FIG and has delivered amongst one of the industry's most comprehensive FDP and EIS. These have resulted in many environmental impact reductions including a reduced carbon intensity per barrel from the previously accepted EIS. Post FID / sanction, further environmental research / data collection will continue and validate the EIA's precautionary assessment and inform the EMMP. Navitas expects FIG to comment separately on the EIS Public consultation representations which cover FIG's oil preparedness and legislation.	N/A
FC 5	1. Carbon emissions and lack of commitment to offsetting The EIS lists CO_2 emissions from oil production at approximately 9 million tonnes (p.825). Emissions from the burning of Falklands Sea Lion field oil (a legitimate inclusion in the Statement1) are listed as more than 150 million tonnes if production were to be maximised. The developers have also indicated that further development phases could more than double production of Phases I and II. These are very large amounts of CO_2 that would launch a major increase in national carbon pollution and would make the Falkland Islands the highest per capita carbon emitting country in the world – but could be avoided as offsetting is a viable option right now. Comments regarding local offsetting guarantee nothing and are likely unachievable. FIG Guidance2 requires that mitigation and off-setting measures 'should not be hypothetical or unrealistic'. The EIS currently fails to	Navitas' issued the Carbon and Biodiversity Fund strategy to FIG in August 2024. In this paper the company's offsetting strategy has been detailed; this will be further discussed with FIG should the development be sanctioned. Local carbon and biodiversity offsetting opportunities require further evaluation and research to define the level of offsetting that can be achieved. This too is discussed at length within the strategy paper. Navitas is committed to follow FIG legislation, policy and guidance. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	provide a realistic and firm commitment to offsetting all carbon emissions and is inconsistent with FIG guidance. There needs to be a solid commitment in the EIS to offset all emissions. The EIS does not set out how the development will increase emissions in comparison to other local sectors, or the Falkland Islands national figures, as stated as required in FIG Guidance3. A comparison with UK budgets and emissions is neither in line with this guidance or consistent with use of UK comparisons in the rest of the EIS. At over approximately 60% of Falkland Island's recent annual emissions, the proposed development has an enormous and significant national impact. FC is concerned that the current approaches contradict FIG guidelines, good environmental assessment principles and global commitments, while also having negative reputational impacts for the Islands. Given that the amount of carbon emissions is presented as small in global terms, it is even more important that FIG ensure a real and viable commitment to offsetting all emissions within the EIS.	contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund. Emissions are compared to Falkland Island's emissions in the EIS, see section in 10.9.	
FC 6	2. Impacts on our wildlife and data gaps There still remain many gaps in information in the EIS – a number of these are acknowledged within the EIS itself. For such a major proposal and for a robust assessment these should be filled prior to the determination of any EIS, as is consistent with good practice, and to avoid significant risks to environmental features and processes. These are critical, given the Falklands economy is underpinned by a healthy environment. Data gaps include those on invasive species risk, bird strike, waxy oil implications for pinniped fur and cetaceans, impacts on benthos, as well as seabirds and cetaceans:	As noted in the April 2019 EMMP workshop: 'The workshop agreed that it would be useful to collect further [seabird] data opportunistically from vessels associated with the Sea Lion development, but that a wider data collection effort to update seabird information was beyond the scope of the EMMP.' Monitoring is included in the EMMP and this aims to fill gaps and confirm (precautionary) EIS Assessments once the project is sanctioned. In addition to the above response, please also refer to the response to FC 7 below.	N/A
FC 7	Seabirds The Falklands supports globally important breeding populations of penguins, albatross and prions during the breeding season. However, a much larger diversity of seabirds has been recorded in Falklands waters than simply	Navitas has aligned its EIS with the FIG EIA Guidance, which states: data gaps are to be acknowledged in the assessment and the risk assessment should be	Section 10.1.10.1 Section 15.6.2.1.2 Section 15.7.1

Ref.	Representation	Navitas response	Changes in Rev 4
	breeds. Seabirds can be extremely wide-ranging, particularly during winter migrations and consequently, birds from colonies hundreds or thousands of kilometres away occur in Falklands waters and could be at risk from the development proposals. These can include those of conservation concern such as the 'Vulnerable' wandering albatross including those from South Georgia, the 'Endangered' Atlantic petrel from St Helena, Ascension and Tristan, and the 'Vulnerable' southern royal albatross from NZ which have all been sighted in the Falklands even close inshore - however, the potential range of species at risk is much larger. The EIS identifies that seabirds are at risk from a number of impacts, including oil spills and bird-strike. In order to determine which seabirds could be at risk and how to avoid or mitigate such risk, up-to-date baseline data on the total range of seabirds that utilise potentially impacted areas are required. Species-focussed approaches, such as tracking studies, are no substitute for this all-inclusive baseline data4 as they inform on only those species, life-history stages and locations tracked. Neither are they an effective way to track changes in the use of the site by a changing seabird assemblage over time. The approach to delivering useful seabird data therefore needs to be area-based boat or aerial surveys, with a survey method that will provide appropriate representation of the diversity and abundance of all seabirds using the risk area. The only presented seabird data of a broadly appropriate type in the EIS is more than 20 years old. It is well-known that climate change is rapidly changing the distribution of seabirds and their prey at sea. Good practice in places such as the North Sea would expect data to be collected within five years. Projects are expected to provide comprehensive data on bird distributions and movements over a two-year period at considerable cost, before submitting consent applications. This is done ahead of projects being approved, and with all the associated risks of having to change the development. We would consider that this Environmental Impact Statement has cut corners in this potentially expensive but essential aspect of data collection.	precautionary where there are data gaps. The EMMP commits to Seabird and Marine Mammal Observation in the Sea Lion area for an initial 3 years to validate the impact assessment. Attendees at the EMMP workshop (April 2019) agreed that 'A wider data collection effort to update seabird information was beyond the scope of the EMMP.' It is not reasonable to expect an individual operator to fund and undertake a seabird data survey on the area wide scale and for the duration that would be required. However, as is specified in Section 10.1.10.1, 'Offshore, Navitas will use independent Seabird and Marine Mammal Observers (SMMOs) on support vessels and investigate the possibility of a collaborative survey with FIFD, potentially using the fisheries patrol vessel as a platform. A seabird distribution monitoring programme will be developed over several years with an understanding of ongoing work and in collaboration with FIFD, if possible. This will cover the offshore area, transit zones and targeted onshore colonies. Dedicated seabird observers will be deployed offshore during any initial well test and commissioning flaring to quantify any impacts.' As indicated in the EMMP workshop report 2019, the summary tables will be further developed post-sanction in consultation with an appointed advisory group.	

Ref.	Representation	Navitas response	Changes in Rev 4
	The consequences of a lack of appropriate data are strongly evident in the assessment of risk to seabirds in the EIS, these include: • Superfluous referencing to data that are not subsequently used, or analyses that could occur, but do not; • Acknowledgement of data weaknesses and data gaps that could have been addressed, but have not; • Inconsistent and inaccurate representation of data and analyses that are included; and • Unjustified and contradictory argument for use of data sets that are too old and do not follow good practice. Further detailed comments on these points are included in Appendix 1.		
FC 8a	Cetaceans The Berkeley Sound development area is proposed to operate within critical sensitive whale habitat. The extent of the global importance of these areas for whales has not been recognised through the omission of large whale datasets in the EIS. Important Marine Mammal Areas (IMMAs) have been designated for endangered sei whales and for wintering southern right whales. Such non-statutory designations of sites should be a standard part of any EIS that wishes to determine adequate risk categories and suitable mitigation e.g., how to adapt operations for animals engaged in sensitive behaviours including feeding and mating within Berkeley Sound. Information on whale distribution, movements, seasonality, behaviour, habitat, site fidelity, conservation status and population trends are provided in the supporting evidence for these IMMAs, almost none of which has been used to recognise the extent of whale sensitivities in the EIS which should be changed to Very High sensitivity. The EIS risk assessment relies on the identification of 'Key Environmental Sensitivities', and the sensitivity assessment is based on criteria including conservation status, critical habitat, seasonality, vulnerable parts of a species lifecycle etc. Consequently, it is essential to correctly identify and consider the latest available information on those Sensitivities. Eight years of data, primarily for sei whales and southern right whales in Berkeley Sound, has not	Chapter 7 is based upon the peer-reviewed papers that are in the public domain. Published papers related to the FC work in Berkeley Sound over the last eight years have been referenced, except for those from 2023/24 which will be added. Navitas recognises that there are metadata records in the data portal based on the work that is referred to here, however Navitas does not have access to the primary data so that it can't effectively be used for analysis. The IMMA detail will be updated in the document and Navitas will amend the text with new data where appropriate. Please note: the respondent was specifically invited to a dedicated scoping session (see Navitas emails 17th and 27th November 2023) with a view to discussing sensitivities and to explore available data to inform the assessment, but the invitation was declined. Please note: Given the limited extent of project	Section 7.5.2.3.5 Section 15.6.2.1.3 Section 15.6.2.1.4

Ref.	Representation	Navitas response	Changes in Rev 4
	been appropriately represented in the EIS. In addition, erroneous findings from early studies are perpetuated (e.g., that Berkeley Sound is a fin whale hotspot). The importance of nearshore Falklands waters for wintering southern right whale aggregations has been almost completely omitted from the EIS. Offshore: information on the offshore occurrence of cetaceans that would facilitate a robust assessment of the Key Environmental Sensitivities at the Sea Lion field is largely lacking. Efforts have not been made to implement offshore cetacean surveys as an environmental baseline assessment ahead of production commencing. However, a potentially useful year-round dataset was collected. Only 5% of this appears to have been fully analysed and used to inform the EIS.	activity in Berkeley Sound (the elimination of inshore ship-to-ship crude oil transfers from the Field Development Plan (FDP)), it was previously agreed that 'four impacts (oil spill effects on inshore seabirds, effects of underwater noise on marine mammals inshore, effects on squid spawning grounds and effects on intertidal/nearshore benthic habitats) were considered by the workshop to be now outside the scope of the EMMP. ' (EMMP Workshop Report 2019). Please note: It is not practicable for a single operator to implement offshore cetacean surveys pre-sanction of the development. Please refer also to RSPB 3. Efforts have been made to acquire data to inform the assessment. The comment itself acknowledges that a year round dataset that was specifically commissioned to inform the environmental baseline assessment for the project. Furthermore please note that ahead of production Navitas has committed to employ SMMOs on vessels operating between the Falkland Islands and the Sea lion Field for three years pre First-Oil. In addition, further acoustic work will be conducted. Regarding the comment on 5% of the year round dataset being used, please refer to Comment FC 129.	
FC 8b	Whale entanglement risk: there has been little recognition of the risks of cetacean entanglement in mooring equipment in the EIS. Foraging sei whales, that use subsurface lunge feeding, and breeding southern right	Thank you for the comment. Of note, Berkeley Sound is not a development area. It will only be used as an anchorage area for two LTVs over a cumulative (and	Figure 1-3 Section 10.11.2.2 Table 1.8

Ref.	Representation	Navitas response	Changes in Rev 4
	whales in Berkeley Sound are vulnerable to entanglement, potentially leading to mortality by drowning, unrecoverable injuries, or subsequent infections. Offshore cetaceans can also become entangled.	non-consecutive) period of 13 months. These are expected to take up 0.004% (excluding the exclusion zones) of the area in Berkely Sound. The LTV and FPSO anchor chains are large gauge (> 2 inches) and will be taut and therefore unlikely to lead to entanglement. Based upon a literature search, most cetacean entanglement is in relation to static fishing gear. Nonetheless, a risk assessment for entanglement inshore and offshore will be added to Chapter 10.11.	Chapter 14
FC 8c	Vessel collisions: the sections on vessel collisions make no acknowledgement of the existing Code of Conduct (endorsed by FIG) for the Falklands which provides guidance on suitable speeds, wide berths etc for avoiding injurious/fatal collision with cetaceans. Small cetaceans have been omitted despite local documented mortalities of dolphins from vessel strike. With regard to nearshore wintering southern right whale aggregations, reducing the risk of vessel collision would benefit from an expanded 'reduce vessel speed' (10 knots) zone between 1 June and 31 August to 10 km from the coast to match the IMMA and telemetry data showing highest-use habitats. This would greatly improve confidence that the vulnerable surface groups of mating southern right whales - which occur out from the coast - would be at lower risk of a fatal collision, and would be a better all round mitigation approach than only the use of visual observers (given there are 16 hours of darkness in winter).	Navitas fully commit to the Code of Conduct and this will be stated in the text. Small cetaceans will be added to the risk assessment. Navitas agree that speed restrictions are the most effective mitigation against vessel collisions with marine mammals and in the EIS propose reducing speed to 10 knots at the pMMA boundary (as industry standard mitigation (Section 10.11.5)) and then 8 knots within Berkeley Sound (as project-specific mitigation (Section 10.11.7)). Navitas will also commit to reducing speed to ≤10 knots in Port William. Please also refer to FC 188 and FC 162. The IMMA boundary has not been proposed as the limit for the speed restrictions as it is not a statutory boundary and the boundary may change over time.	Section 1.8.4.2.6.1 Section 1.8.4.2.6.2 Table 1.8 Section 10.4.1.1 Section 10.11.1.1 Section 10.11.2.2 Section 10.11.3 Chapter 14

Ref.	Representation	Navitas response	Changes in Rev 4
FC 8d	Information provided in the EIS indicates that the risk of injury/mortality to cetaceans from noise is negligible in both the offshore and Berkeley Sound environments. However, concerns remain about behavioural impacts, given the lack of data on cetacean residency (exposure time) in the Sea Lion field and the non-conservative approaches used in the EIS. The semi-enclosed waters, seasonally-high existing noise levels, and known importance of Berkeley Sound for feeding sei and mating right whales, raises concerns over the cumulative impacts of noise from moored vessels on whale behaviour and use of the Sound.	The EMMP workshop determined that effects of underwater noise on marine mammals inshore 'were considered by the [EMMP] workshop to be now outside the scope of the EMMP' due to the elimination of inshore ship-to ship crude oil transfers from the development plan. Nonetheless Chapter 10.5 is being revised. Please see also FIFD 54. In addition Navitas will employ SMMOs on vessels operating between the Falkland Islands and the Sea lion Field for three years pre First-Oil. In addition further acoustic work will be conducted.	N/A
FC 9	3. Environmental commitments and Falkland Islands legislation Commitments The Environmental Impact Statement presents a set of very significant environmental impacts, and it is therefore necessary for MLAs to compare policies and commitments that have been undertaken. We believe that the impacts are inconsistent with several key commitments: The Islands Plan 2022-2026: • "We will carry out work to measure and reduce our carbon emissions, in order to ensure we act as a responsible global citizen." (p. 8) 5 Falkland Islands Environment Strategy: • "Vision 2040: Renewable energy has been embraced, we play our role in tackling the climate emergency, and are able to understand and adapt to global change at a local level." (p.18)6 • "Our Strategic objectives: to reduce our carbon emissions through transitioning to using renewable (low carbon) energy sources for power generation" (p. 7)6 • "Our Strategic objectives: to conduct the extraction of non-renewable resources, including any hydrocarbon development, in a way that values and conserves our unique biodiversity and ecology, supported by effective regulation" (p.8)6	Thank you for your comment. Navitas continues to work within the legislative framework provided by FIG. Navitas expects FIG to comment separately on the EIS Public consultation representations which cover FIG's oil preparedness, policy and legislation.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
FC 10	Falkland Islands laws and policies are not 'oil-ready' FIG should have put in place rules before an Environmental Impact Statement. For good environmental protection and for Environmental Impact Assessments to work to the best standards, it is important to have a consolidated set of policies and laws to identify what elements of the environment should be protected strictly or to lesser degrees, and how projects can operate within the law. It is also important, so that if rules are infringed, reliable court challenges are possible. This is important for MLAs to know that they are making safe decisions when consenting projects – but also for potential investors in projects in order to see if their investments are safe. Before 2020, FIG recognised this and committed to updating standards in: • the Conservation of Wildlife and Nature Ordinance 1999 7 • establishing clear liability rules for polluters • introducing a form of technical environmental protection rules called 'environmental case'. Regrettably, none of these standards were completed before the Sea Lion Environmental Impact Statement was submitted. If MLAs give a green light to the Environmental Impact Statement before legislation is put in place, it makes the legal reliability of the agreement uncertain in case of any infringements and puts the government at risk of being sued if trying to impose standards later. The lack of this environmental framework means that international standards, as would be found in jurisdictions such as the North Sea, would be unable to be adopted. For example, there is a lack of national habitat categorisation and prioritisation in Falkland Island waters (equivalent to EU Habitats Directive, OSPAR and other UK categorisations). This makes it difficult to attribute value and risk to different sites and therefore suitable mitigation proposed.	Navitas expects FIG to comment separately on the EIS Public consultation representations which cover FIG's oil preparedness, policy and legislation.	N/A
FC 11	4. Decommissioning and spill risks Several studies have called into question how long certain oil developments can continue if the world is to meet international climate change goals which	Navitas is committed and legally obliged to fund and conduct decommissioning under Falkland Islands legislation. Navitas will have arrangements in place to	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	restrict warming to below 2°C. If these studies are correct, then there is a risk that many new oil projects will become uneconomical after a period of time. It is therefore important that the Sea Lion Environmental Impact Statement include decommissioning commitments up front with consent for the project. Commitment to clean and environmentally friendly decommissioning of the Sea Lion project is essential to avoid the 'cheapest option' being chosen once the economics have been agreed upon. This would avoid potential problems like those which have been seen with the decommissioning of Stanley's existing polluted barge port (FIPASS). Spills are a key risk to the environment. Whilst there is commitment to an Oil Pollution Emergency Plan (OPEP) there is insufficient information presented within the EIS on the nature of oil impacts and the wildlife likely to be impacted. Furthermore, any OPEP should be properly financed by the developer and that liability should not be passed to Falkland Islanders as part of the National Oil Spill Contingency Plan, which by its very nature is limited by local resource.	secure funding for any early or end of field life decommissioning and these arrangements need to be agreed with FIG prior to field development approval being granted. Navitas has prepared and submitted its preliminary (Pre-FID) OPEPs to FIG for their review and approval. These shall be finalised prior to the commencement of operations. Navitas is committed to mitigating the risks of such an event from occurring. Navitas is committed and legally obliged to demonstrate that it has adequate arrangements funding / insurance in place to fund any oil spill response activities and any environmental remediation and to compensate for adverse impact on the Falklands economy (including fishing and tourism) that would arise in the event of a worst-case spill event. In August 2024 Navitas submitted the 'Financial Liability Assessment for Oil Spill' to FIG for their review / approval. NPDP (formerly PEOPL) has invested significant resources in understanding Sea Lion crude behaviour and the metocean environment in order to predict the potential impacts on wildlife and inform optimum spill response equipment. Spill Response will be supported by specialist oil spill and wildlife response agencies with resources (equipment and manpower) available to respond at very short notice. The oil spill response arrangements are not reliant on	

Ref.	Representation	Navitas response	Changes in Rev 4
		the NOSCP and associated resources. The preliminary OPEPs have been prepared in order to interface appropriately with the NOSCP (as required and stipulated in the NOSCP) and Navitas has committed to regular engagement, training and joint spill response exercises with FIG to ensure that a spill response can be effected appropriately.	
FC 12	The risk analysis for seabirds is confusing and superficial, and the type of data ultimately considered and analysed for the purpose of this risk assessment is inappropriate for several reasons: (1) The EIS refers to several data that are not actually considered any further or are referred to as "additional analyses could be undertaken". This is misleading and makes it difficult to assess what information was actually used and how for the purpose of informing this EIS. (E.g., SAST data collected between Falklands and South Georgia 2003-2005, data from DPLUS139, data from Global Procellariiform Tracking Database and "its recent extension to penguins and other seabirds"). A similar approach is seen elsewhere in the EIS, e.g., in regard to zooplankton work which is yet to be conducted. (2) The EIS refers to the 3-year data collected in 1998-2001. However, the vulnerability index taken from Webb *et al.* (2001) is actually based on only 2 years of these data. This detail is, misleadingly, not highlighted in the EIS. Best practice advice for oil & gas developments asks for a minimum of three years of data (Webb *et al.,* 2014). (3) Data gaps are acknowledged but are not addressed (e.g., lack of seasonal and age-specific information from tracking data). (4) The EIS and previous responses to public concerns argue the suitability of the old ESAS data by referencing the independent review undertaken by Genesis (2017). However, a quick read of this report reveals a series of poorly supported and biased arguments with contradicting, distorted or incomplete information, and with key literature altogether missing. This superficial review process severely undermines the integrity of this EIS. a. Genesis (2017) did not conduct a power analysis to assess the suitability of	1) These data were collected through GAP and used in the EIS. They were used to compare tracking data with the White *et al.* (2001) vulnerability maps. Note that the availability of tracking data is continuously evolving with regards to local projects. 2) There were three years and some of the latter year's data were used to inform more inshore areas. 3) Data gaps are acceptable as long as they are treated appropriately in the assessment. In other words, the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they address the gaps in the assessment. Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained. When carrying out the risk assessment data gaps have been taken into account. The EMMP workshop agreed that it would be useful to collect further [seabird] data opportunistically from vessels associated with the Sea Lion development, but that a wider data collection effort to update seabird information was beyond the scope of the EMMP. It was also decided not to monitor seabird populations ashore due to the difficulty of attributing any change to activities in the Sea Lion field.	Section 15.6.2.1.2

Ref.	Representation	Navitas response	Changes in Rev 4
	the data to determine whether sufficient data exist to enable adequate baseline characterisation and robust assessment of changes that could arise should the project be approved. b. In regard to the suitability of the age of the data, the review compares the situation with UK examples, which are actually based on larger and more recent temporal extent and of more complete coverage. For example, Kober *et al.* (2010) used data from 24 years, and as recent as 6 years prior to analysis, compared to Falklands with 2-3 years of data, as recent as 23 years ago; "other projects" in the Atlantic Frontier (projects not specified in review of EIS) using data from 1979 – 1997. Modern developments actually use (boat-based) data from between 1980 – 2018 (see e.g., Rosebank EIS). c. Genesis (2017) distorts the information provided in Webb *et al.* (2014) with regards to data suitability. Webb *et al.* (2014) clearly state that surveys of less than 15 years old and certainly no more than 20 years be used to assess the sensitivity of seabird concentrations to oil pollution. d. Webb *et al.* (2016) was not considered in the review or the EIS. (Webb *et al.,* 2016, Sensitivity of offshore seabird concentrations to oil pollution around the United Kingdom: Report to Oil & Gas UK). This report refers to data suitability in terms of age and highlights why tracking data cannot act as a substitute for at-sea data. (5) Important information provided by Genesis (2017) in relation to data suitability and data gaps was ignored in the EIS and in responses to public concerns. Cherry-picking of information by the authors of the review further undermines the integrity of this EIS. E.g., Genesis (2017) states: "Pollock & Barton (2006) recommended that data over 20 years old should not be used for assessment purposes." The review also hints at Webb *et al.* (2014) recommendation, albeit in an incomplete and distorted fashion. Neither reference can be found in this EIS. b. Genesis 2017 expresses the need for updated boat data in particular for information on risk areas in case of an oil spill. This recommendation has not been considered in the EIS. c. Genesis 2017 states, "The seabird data collected in the Falkland Islands is	4) The SAST data are dated and are acknowledged as such. Data collection from SMMO observations is planned for three years prior to First-Oil. a) All acknowledge that this data set is old but it does inform the base line and the UD from tracking work overlaps well with SAST data. The available data is considered sufficient for the purposes of the risk assessment. The SAST data was a collaboration between FIG and industry in terms of funding and delivered by JNCC in conjunction with FC. Navitas would refer to the EMMP with regards to further data collection in the area pre First-Oil. It is not possible, practical or appropriate for a single operator to undertake this work pre-sanction. 5) Navitas has acknowledged the age of the dataset consistently and has agreed to collect more vessel based data as the field is developed, 3 years prior to First-Oil. This is referenced in the EMMP, but the point will be strengthened in the post-consultation EIS. Navitas has considered the age of the data in the EIS narrative. As a consequence of the age of the data, additional data acquisition was funded by FIG and industry under the GAP project and these additional data that has shown similar distributions for the species that were tracked to the SAST data suggesting that these data are complementary and the distributions still valid. The EIS discusses the static features that produce oceanographic patterns. Specifically this relates to the importance of the Patagonian Shelf around the Falkland Islands as foraging habitat for seabirds and marine mammals and static ocean features that are associated with	

Ref.	Representation	Navitas response	Changes in Rev 4
	less than 20 years old and therefore considered suitable for EIA and oil spill sensitivity purposes. However, it is noted that the data obtained from boat-based surveys in the Falkland Islands is becoming older and its suitability for assessment purposes may become less reliable in future years." This information has not been considered in the EIS. (6) This EIS has made no attempt at an updated, integrated analytical approach for refined seabird vulnerability assessments. Instead, the EIS simply reproduces the vulnerability maps produced by White *et al.* (2001) (which are based on 2 years of data and using an outdated method (see Webb *et al.,* 2016) and reproduces figures from Baylis *et al.* (2019) and (2021) which portray the results of predicted habitat use, which is different to a vulnerability assessment. Since 2001, there has been significant progress in the statistical approaches available for seabird vulnerability assessments, with more powerful methods now in use (see e.g., Webb *et al.,* 2016; Waggitt *et al.,* 2020).	enhanced primary productivity. On 6) To update the seabird vulnerability maps would require further area wide at sea data collection. This would have to be at the least to the scale of the northern FICZ/FOCZ to ensure that the coverage captured communities' structure and their dynamics at appropriate scale. The appropriate spatial/temporal scales would need to be informed by statistical analyses. What we can see from the GAP project is that the seabirds that were tracked show similar distributions and utilisation as the SAST data, so the vulnerability maps are considered appropriate. However it is acknowledged that the dataset is old. Navitas will be collecting additional data in the vicinity of the Sea Lion field. As stated previously, area wide data collection was considered beyond the scope of an individual operator and will require a FIG-Pan industry collaboration; an initiative which is considered needs to be coordinated by FIG. The EIS states 'Offshore Navitas will use independent Seabird and Marine Mammal Observers(SMMOs) on support vessels and investigate the possibility of a collaborative survey with FIFD, potentially using the fisheries patrol vessel as a platform. A seabird distribution monitoring programme will be developed over several years with an understanding of ongoing work and in collaboration with FIFD, if possible. This will cover the offshore area, transit zones and targeted onshore colonies. Dedicated seabird observers will be deployed offshore during any initial well test and commissioning flaring to quantify any impacts.' (Section 10.1.10.1).	

Ref.	Representation	Navitas response	Changes in Rev 4
FC 13	EIS: "the level of confidence in the assessment was used to inform the monitoring requirements for each potential impact / risk". FC: We understand that this informs monitoring requirements. However, it's less clear as to whether confidence level impacts the risk level provided. How can a risk be assessed with no data?	In the absence of site-specific data, where data gaps exist, the sensitivity of receptors and the severity of effect can be generically estimated using published and grey literature as well as prior personnel and industry experience. However, the fact that there is no site-specific data needs to be taken into consideration and is reflected in the confidence assessment which then alerts the need for further monitoring and data collection. Similarly, with regard to risk, the likelihood of an unplanned event occurring can be estimated using industry statistics but where there is any uncertainty in the fine details of the development, this is also reflected in the confidence assessment. Therefore, while the data gaps are considered and acknowledged when determining the sensitivity and severity, they are also reflected in the level of confidence thus ensuring appropriate monitoring is in place to ground-truth the EIA and inform additional mitigation/restorative efforts where necessary. The approach is intended to be precautionary.	N/A
FC 14	EIS: "POEPL commissioned SAERI to conduct a series of four seasonal coastal bird surveys in and around Berkeley Sound, which were carried out between February 2016 to May 2019. In the course of these surveys, the opportunity was taken to develop an initial shoreline classification index specific to the Falkland Islands for use in oil spill planning." FC: Tides and time of day, which significantly impact species number and types, were not considered. A baseline survey should be repeatable and allow detectability of change. However, this survey design fails in this aspect, due to the varying temporal and tidal conditions likely to be encountered at any particular season. At the very least, 3 years of seasonal data should be collected, as is the recommended period for seabird data.	Please note that this work was conducted when POEPL was considering inshore transfer which is no longer proposed. Navitas consider this data sufficient for the much smaller operations now proposed in Berkeley Sound (two vessels moored for a non-consecutive period of 13 months).	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
FC 15	EIS: "the baseline here was generated from extant literature" FC: Extant literature is practically non-existent, and this area is extremely data poor, as highlighted also by Van der Grient (2022). Also, up-to date references should be included, such as to highlight the importance of lobster krill to higher predators (incl. Baylis *et al.,* 2014; Kuepfer *et al.,* 2022; Kuepfer *et al.,* 2023).	Regarding extant literature, 7.4.1.3.1 includes the following references: (Harrison-Matthews, 1932; Arkhipkin *et al.,* 2001; Arata and Xavier, 2003; Laptikhovsky and Arkhipkin, 2003; Laptikhovsky, 2004; Clausen *et al.,* 2005; Brickle *et al.,* 2009; Michalik *et al.,* 2010; Quillfeldt *et al.,* 2011 and P. Brickle, pers. obs.). (Mouat *et al.,* 2001; Agnew, 2002; Brickle *et al.,* 2009) (Arkhipkin and Laptikhovsky, 2013). Padovani *et al.* (2012) (Tarling *et al.,* 1995; Boltovskoy, 2000) (Agnew, 2002). Navitas will modify the sentence 'Similarly, lobster krill can be found in dense shoals on the shelf where they constitute prey for seabirds, fish and baleen whales' to reflect krill constitute 'important' prey for higher predators.	Section 7.4.1.3.1
FC 16	EIS: "There is a PhD studentship (SAERI and the University of Aberdeen) currently working on inshore zooplankton dynamics in Berkeley Sound. However, the results of this study will not be available for another year (i.e., mid-2025)." FC: Again, the EIS lists superfluous information that is not actually considered for the assessment. This adds unnecessary bulk to this lengthy document and is misleading.	The intention here was to note the ongoing work which will be available once the PhD is complete.	N/A
FC 17	Section 7.4.5.2.1 EIS: "Although the JNCC Seabirds At Sea Team (SAST) surveys are 24 years old, it is unlikely that broad-scale animal distribution and movement patterns have changed significantly. Hence, the SAST data remains useful to characterise occurrence of species, particularly where no tracking data exists." FC: This statement is completely unfounded. Seabird assemblages are known to change, particularly in a changing climate. For example, in the UK, Webb *et al.* (2014) concluded that the abundance of some seabird species had changed significantly, and other species had shown an increase and	Regarding occurrence and distribution: The statement that the 'general distribution and animal movement patterns' are unlikely to have substantially changed, is supported by tracking data and modelling work. It specifically relates to the importance of the Patagonian Shelf around the Falkland Islands, as foraging habitat for seabirds and marine mammals and static ocean features that are associated with enhanced primary productivity. Specifically, Baylis *et al.* (2019) highlights that for nine-species tracked, the	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	subsequent decrease, compared to previous vulnerability assessments. (This was also highlighted in the Genesis 2017 review.) Also see e.g., Peron *et al.* (2010) which specifically refer to the effect of climate change on sub-Antarctic seabird distribution and abundance at sea. Webb *et al.* (2014) therefore recommended that data under 15 years old would be the most appropriate (with no data older than 20 years) when assessing sensitive seabird concentrations to oil pollution.	probability of occurrence is highest on the Patagonian Shelf, shelf slope and the Burdwood Bank (Fig 7-53, pg. 360). These findings are similar to the at-sea distribution presented for the same species (White *et al.,* 2002). This is likely to reflect productivity on the Patagonian Shelf, being linked to the Patagonian Shelf, slope and Burdwood Bank (static features, associated with predictable areas of enhanced productivity) (e.g., Fig 7-35, pg. 293). Based on the predictive models, and knowledge of local oceanography, the importance of the Patagonian Shelf around the Falkland Islands is unlikely to have changed over the past 24 years, hence animal distribution is still likely to be associated with the Patagonian Shelf. Peron (2010) is an interesting study, but is associated with oceanic fronts, rather than shelf-break fronts (i.e., static vs dynamic features). Regarding abundance: The statement specifically relates to the distribution and movements of animals. Data gaps remain for both Falkland Islands breeding species, and migratory visitors. Filling data gaps will improve our understanding of occurrence and distribution.	
FC 18	EIS: "Surveys commenced in 1998 and continued for three years" FC: Nowhere within this EIS is it highlighted that the OVI presented is actually based on just 2 years of data (see White *et al.,* 2002: "The results of the first two years of surveys were published as an atlas depicting vulnerability of seabird concentrations to surface pollution Vulnerable concentrations of seabirds in Falkland Islands waters (White *et al.,* 2001)".) As highlighted by Genesis (2017): Webb *et al.* (2014) recommend at least three years of data for assessment purposes. In addition, nowhere is it explicitly shown what the	This work was conducted by FC in collaboration with the JNCC. Note that further surveys will target the region for three years pre-First-Oil by deploying SMMOs.	Section 7.4.5.6.1 Section 15.6.2.1.2 Section 15.7.1

Ref.	Representation	Navitas response	Changes in Rev 4
	actual survey effort was, relative to area of interest, not just the drilling site, but also the risk area in the event of a spill.		
FC 19	EIS: "Over a two-year period between 2003 and 2005, additional data was collected by one of the original SAST observers using the same methodology *en route* between the Falkland Islands and South Georgia (Black, 2005b)." FC: These data are not actually considered further anywhere. Merely mentioning (potentially) useful data for informing this EIS is misleading and adds unnecessary bulk.	These data were included updating inshore observations; the data sets were re-analysed for this by one of the original SAST team.	N/A
FC 20	EIS: "There remain gaps in the SAST coverage but it is possible to infer the species assemblages that are likely to be found in these areas with the data available, therefore, White *et al.* (2002) has been used as a reference in the EIS." FC: Please elaborate on the methodology used for such inferences and provide results of such analyses.	Please refer to section 7.4.5.2.1.1 JNCC Seabirds At Sea Team (SAST) surveys for context. As stated 'The SAST distribution atlas (White *et al.,* 2002) and associated database remain the most useful description of seabird distributions within Falkland Islands waters, in terms of broad scale spatial and temporal patterns of distribution of breeding and non-breeding birds.' Hence, species assemblages, (the sentence following from this statement), refers to those species reported by White *et al.* (2002).	N/A
FC 21	EIS: "The [Genesis 2017] review concluded that the survey methods used, the coverage and the age of the data are comparable with existing datasets used to inform similar impact assessments undertaken in the UK" FC: This statement is deceptive and cherry-picks information provided within a highly biased and superficial review. FC make the following points: The Genesis 2017 report is not available online, reducing procedural transparency. FC appreciate that the report was provided to FC by Navitas for consideration upon request. • Even if data were comparable (which they are not), this does not mean that the approach is adequate. • Genesis 2017 did not conduct a power analysis to assess the suitability of the Falklands data to determine whether sufficient data exist to enable adequate baseline characterisation and robust assessment of changes that could arise should the project be approved. The review merely discusses the	Thank you for the comment. It is acknowledged that the data set is old. As mentioned above, the tracking work complements the SAST data (see response to FC 17). Navitas are committed to deploying SMMOs on vessels developing the field 3 years prior to First-Oil.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	results of a power analysis conducted on UK data. • The Genesis 2017 report misinterprets information that it uses for its arguments in relation to data suitability. For example, Kober *et al.* (2010) actually used data from 24 years ago, and as recent as 6 years prior to analysis, compared to Falklands with 2-3 years of data, as recent as 23 years ago. Other similar and more recent analyses to Kober *et al.* (2010) (e.g., Wilson *et al.,* 2014) used data from 2009 – 2011 (i.e., <7 years old), yet this very comparable example was not used as would be expected in a non-biased review. The review further states that "The data obtained in the Atlantic Frontier is widely used as the baseline information used to assess potential impacts and vulnerability of seabirds from oil and gas developments within waters to the north and west of Scotland." The specific projects are not actually referenced. Also, the data referred to spans from 1979 – 1997, and as highlighted in the review, "the survey effort is greater than that from waters around the Falkland Islands, particularly in the main areas of interest". • An example of an up-to-date O&G EIS in the UK is the Rosebank EIS, which uses the JNCC SOSI (data from 1995 - 2015), and analyses by Waggitt *et al.,* 2020 (data from 1980 – 2018). • Genesis 2017: "In their review of the ESAS data, Pollock & Barton (2006) recommended that data over 20 years old should not be used for assessment purposes." This information / reference is not considered in the EIS. • Genesis 2017: "Similarly, Webb *et al.* (2016) [should be Webb *et al.,* 2014] advised that data in excess of 20 years may be 'too old' for all species but as a 'compromise' data from 1995 could be used as this was when the quality of data improved through standardised survey techniques." This interpretation of the information is false and misleading. Webb *et al.,* 2014 recommended that surveys of less than 15 years old and certainly no more than 20 years be used to assess the sensitivity of seabird concentrations to oil pollution. Webb *et al.* (2014) further stated the recommendation "Revise and update maps of seabird distribution and of the sensitivity of seabird		

Ref.	Representation	Navitas response	Changes in Rev 4
	concentrations to oil pollution using only data in ESAS collected since the start of 1995". This statement does not negate the recommendation that surveys of less than 15 years old and certainly no more than 20 years be used. •Genesis (2017): "Additional surveys focussed on areas where survey coverage is relatively low would improve the information used in the baseline." This indirect suggestion was ignored in the EIS •Genesis (2017): "Oil spill modelling indicates that there is a risk of oil arising from a blow-out to occur in areas to the north of 47°S for which there are no published survey data. Consequently, there is a risk that seabirds that were infrequently recorded by White *et al.* (2002) may occur more frequently in the largely un-surveyed areas to the north, e.g., Atlantic petrel" This concern is not mentioned in the EIS. •Genesis (2017): "There are gaps in the data obtained from boat-based surveys undertaken between 1998 and 2001. Of most relevance and importance is the lack of data within the area which, in the event of a blow-out, would be at very high risk of sea surface contamination. … The collection of additional survey data using boat-based methods to reduce the gaps in the existing data may provide a more robust understanding of the temporal and spatial distribution of seabirds within the region. This, may help inform the risk to seabirds from either sea surface contamination or light attractions which, in turn, would help in the undertaking of EIAs." These indirect suggestions have not been considered. •Genesis (2017) states that, "The seabird data collected in the Falkland Islands is less than 20 years old and therefore considered suitable for EIA and oil spill sensitivity purposes. However, it is noted that the data obtained from boat-based surveys in the Falkland Islands is becoming older and its suitability for assessment purposes may become less reliable in future years." The data is now over 20 years old, and thus any inference of its suitability by Genesis 2017 is no longer a valid argument. •JNCC are currently looking to update their SOSI (which is based on data		

Ref.	Representation	Navitas response	Changes in Rev 4
	from 1995 – 2015), as these data are now considered too old (J. Black *pers. comm.*, Senior Marine Industries Ornithologist at JNCC).		
FC 22	EIS: "However, the survey effort is not dissimilar to the level of effort from the Atlantic Frontier waters located off the north and west coast of Scotland, where O&G exploration is also relatively new and developing" FC: Can this be substantiated by references to any specific projects or impact assessment? The Genesis report states: "The data obtained in the Atlantic Frontier is widely used as the baseline information used to assess potential impacts and vulnerability of seabirds from oil and gas developments within waters to the north and west of Scotland." However, no particular projects or impact statements are referenced. The Genesis report further states: "Although the survey effort is greater than that from waters around the Falkland Islands, particularly in the main areas of interest, the overall coverage is also not complete." An example of an up-to-date O&G EIS is the UK is the Rosebank EIS, which uses the JNCC SOSI (which uses data from 1995 - 2015), and analyses by Waggitt *et al.* (2020) (which uses data from 1980 – 2018).	It is acknowledged that the data set is old. Please refer to FC 17 with regards to tracking data and SAST derived distributions. Navitas are committed to collecting further data with SMMOs on vessels operating in the field for three years prior to First-Oil.	N/A
FC 23	EIS: "in addition to the SAST data, a significant amount of recent tracking data was collected and synthesised through the GAP process, which is also utilised in the impact assessment" EIS: "Preliminary results [from GAP tracking data] showing the range of each species, as derived from probability of occurrence data, support the known distributions of the species concerned. However, while vulnerability maps were produced, there is scope for additional work to interpret this data." (Also, in section 7.4.5.2.1.3) EIS: "The initial results of the GAP project are presented in Blockley and Tierney (2016) and Baylis *et al.* (2019). However, further work could potentially be undertaken to interpret this data with the aim of producing vulnerability maps." FC: It is unclear what work has actually been conducted with the GAP data specifically for the purpose of this EIS. It appears to be limited to reproducing the maps from Baylis *et al.* (2019) in the EIS with the location of the drilling site superimposed on them. The maps show predicted habitat use. They are	Vulnerability maps were not produced with the tracking data - the vulnerability maps were based on the at-sea data and White *et al.* (2001) (Fig. 7-73). The EIS compared tracking data with vulnerability maps produced by White *et al.* (2001) and these are therefore considered complementary. Note that the availability of tracking data is continually evolving with regard to local projects. To ensure clarity, Navitas will edit the statement 'However, while vulnerability maps were produced, there is scope for additional work to interpret this data." (pg. 348) in the post-consultation EIS.	Section 7.4.5.2.1.1

Ref.	Representation	Navitas response	Changes in Rev 4
	not vulnerability maps. Tracking data can provide useful complementary data, but they unfortunately do not compensate for the lack of up-to date at-sea data.		
FC 24	EIS "During the three years of the project major inter-annual variations in species distribution were not identified, perhaps because the study covered a relatively short time frame. Recent studies suggest that there may be significant inter-annual and spatial variation in foraging and migration patterns, for individuals of the same species breeding on the same island (Masello *et al.,* 2010) and on island breeding sites that are in close proximity (Granadeiro *et al.,* 2011; Catry *et al.,* 2013). This is likely to be the case for individual birds but whether this is reflected in the foraging ranges of populations as a whole remains to be seen." FC: This directly contradicts a statement the EIS made in section 7.4.5.2.1 and supports the need for further data. See also Peron *et al.* (2010) and Webb *et al.* (2014) for evidence of changes in seabird assemblages over time, including within the sub-Antarctic.	The at-sea seabird surveys highlighted that for the majority of species, spatial distribution was broadly consistent between years (White *et al.,* 2001 pg. 86). [While the majority of species were consistent, White *et al.* (2021) also highlight for some species - particularly migratory visitors - inter-annual variation existed. See FC 25)]. The reference to Masello *et al.* (2010) will be clarified. The statement draws attention to the spatial segregation and individual variability both within and between species, at a colony and individual level - which may impact distribution, but is generally not well understood. The EIS does state that 'whether this is reflected in the foraging ranges of populations as a whole remains to be seen'.	Section 7.4.5.2.1.1
FC 25	EIS: "The three years of SAST surveys did detect some inter-annual variation but most of these concerned non-breeding visitors to Falkland Islands waters." FC: This directly contradicts a statement the EIS made in section 7.4.5.2.1 and supports the need for updated at-sea data and integration of data from Procellariiformes tracking database.	Regarding occurrence and distribution: The statement that the 'general distribution and animal movement patterns' are unlikely to have substantially changed, is supported by tracking data and modelling work. It specifically relates to the importance of the Patagonian Shelf around the Falkland Islands, as foraging habitat for seabirds and marine mammals and static ocean features that are associated with enhanced primary productivity. Specifically, Baylis *et al.* (2019) highlights that for nine-species tracked, the probability of occurrence is highest on the Patagonian Shelf, shelf slope and the Burdwood Bank (Fig 7-53, pg. 360). These findings are similar to the at-sea distribution presented for the same species (White *et*	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		al., 2002). This is likely to reflect productivity on the Patagonian Shelf, being linked to the Patagonian Shelf, slope and Burdwood Bank (static features, associated with predictable areas of enhanced productivity) (e.g., Fig 7-35, pg. 293). Based on the predictive models, and knowledge of local oceanography, the importance of the Patagonian Shelf around the Falkland Islands is unlikely to have changed over the past 24 years, hence animal distribution is still likely to be associated with Patagonian Shelf. To reiterate, the general pattern will not have changed and this is supported by tracking data from the GAP programme and for the reasons outlined above. Individual variability will be inherent even over very small timescales. Navitas states that "major inter-annual variations in species distribution were not identified" but acknowledge that some variation occurred, specifically with some non-breeding visitors. Therefore, we do not consider this a contradiction.	
FC 26	EIS: "A total of 242 seabird surveys were conducted from January until May 2011 during a 3D seismic survey in the licence area PL001, which is adjacent to the block containing the Sea Lion Field (Geomotive and MRAG, 2011). In addition, 226 individual seabird surveys were conducted over a larger area covering many of the [North Falklands Basin] NFB licence blocks from the end of November 2010 to May 2011 (Polarcus, 2011) … Additionally, a mixture of line transect and point surveys were conducted in March and April 2012 as part of the Sea Lion Field environmental baseline survey (Gardline, 2013a)." FC: The numerous surveys listed sounds substantial, but this information is meaningless in the absence of effort details. For example, according to information on the MRAG website (https://mrag.co.uk/experience/marine-	Navitas are happy to provide these reports. Note that this was conducted by a variety of observers not just MRAG and Gardline. These data and many other data sets (survey and telemetry) were used to the develop the baseline.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	mammal-and-seabirds-observation-survey-north-falkland-basin) the effort of the 242 seabird surveys by Geomotive & MRAG 2011 totalled 308 hours and 1350 km, which equates to approx. 1.25 hours and 5.5 km per survey. No effort details are provided for Gardline 2013a.		
FC 27	EIS: Table 7.13 Number of seabird sightings during the PL001 and NFB Surveys FC: Table 7.13 lists the species for which tracking data are available within the FCZ. However, for several species (e.g., southern giant petrel, northern giant petrel, great shearwater, soft-plumaged petrel, white-chinned petrel, wandering albatross, northern royal albatross), most of which are Endangered, Threatened or Protected (ETP) species, these data are not further considered within this EIS. Again, the report is misleading by referring to data which are ultimately not considered further in the EIS.	Noted, however the assessments are precautionary. The assessment on seabirds considers all of the assemblage.	N/A
FC 28	EIS: "The initial results of the GAP project are presented in Blockley and Tierney (2016) and Baylis *et al.* (2019). However, further work could potentially be undertaken to interpret this data with the aim of producing vulnerability maps." FC: Why has this work not been undertaken, given data have been available for > 5 years? Also, see Webb *et al.* (2016), who explain why the use of tracking data is not suitable for producing vulnerability maps: "These [tracking] studies have contributed greatly to our understanding of individual movements of seabirds but fall short when attempting to describe seabird populations and seabird concentrations as is required for this project. The main shortcomings of these data are their focus on the movements of adult birds and their focus on the breeding season. This means that there are relatively little data available covering the non-breeding season and non-breeding full-grown or immature seabirds. Furthermore, data for some species is limited by their suitability for carrying tags (e.g., on account of their size, their foraging behaviour or their behaviour in response to the tags). In order to include tracking data to determine the sensitivity of seabird concentrations to oil pollution, data would be needed for all species and all age classes in reasonable sample sizes within and out of the study area."	Please see section 7.4.5.2.1. The ES draws attention to the fact more recent tracking data is complementary to the SAST data. Specifically, 'Hence, the SAST data are considered to be complementary to more recent occurrence data when undertaking the assessments in this ES. Limitations of the SAST data are described in the section below.' There are numerous peer reviewed publications that highlight the value of combining tracking data with at-sea surveys to improve occurrence and distribution estimates. Many of the gaps outlined in the comment, cannot be addressed through at-sea surveys - particularly gaps related to sex, breeding status and age. The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
FC 29	EIS: "Tracking data for different age-classes, breeding stages and breeding colonies are limited for most species. This is particularly the case for immature / juvenile birds, periods outside of the breeding season and species that breed elsewhere (noting that most of the IUCN Endangered, Vulnerable and Near Threatened species encountered within Falklands waters do not breed on the Islands). So, although there has been a considerable research effort on tracking seabirds in recent years, there remain substantial data gaps." FC: Whilst the EIS recognises the limitations of available tracking data, particularly in terms of cryptic life stages and non-Falklands breeding birds, including ETP species, it fails to acknowledge that the best way to address the data gap is through at-sea surveys, as also highlighted in Webb *et al.* (2016).	Please see section 7.4.5.2.1. The ES draws attention to the fact more recent tracking data is complementary to SAST data. Specifically, 'Hence, the SAST data are considered to be complementary to more recent occurrence data when undertaking the assessments in this ES. Limitations of the SAST data are described in the section below.' There are numerous peer reviewed publications that highlight the value of combining tracking data with at-sea surveys to improve occurrence and distribution estimates. Many of the gaps outlined in the comment, cannot be addressed through at-sea surveys - particularly gaps related to sex, breeding status and age. The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil.	N/A
FC 30	In the previous EIS, it is stated: "Generally, small sample sizes and data gaps limit the ability to obtain statistically significant and biologically relevant results. Work is currently underway to address priority tracking data gaps in the Falklands (section 7.2.4.2), so that these data can be used in future assessments." The current EIS state "Generally, small sample sizes and data gaps limit the ability to assess vulnerability for all age-classes, breeding stages and in some instances, species. Further work is required to address priority tracking data gaps in the Falklands (Section 7.2.4.2), so that these data can be used in future assessments." FC: When will this additional work actually be undertaken? Also, see Webb *et al.* (2016), who state why use of tracking data is not suitable for producing vulnerability maps. Tracking data are not a substitute for the all-inclusive data that can be delivered by boat surveys. Instead, the data gap should be addressed using at-sea surveys.	At-sea observer data has limitations. For example, for many species it is not possible to identify sex, age and breeding status during at-sea observations. Hence, the EIS highlights tracking and at-sea observer data complements one another, and ultimately strengthens our understanding of species distributions. The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil. See also FC 7.	N/A
FC 31	EIS: "Notable additions to seabird tracking data since the GAP project, include a recent SAERI led tracking project (DPLUS139) that included six	At-sea observer data has limitations. For example, for many species it is not possible to identify sex, age and	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	species and 5 breeding colonies (Table 7.14). Combined with the GAP project data, this yields over 360,000 at-sea locations from 10 species (Figure 7-48). This data is yet to be formally analysed but could be integrated into future assessments. FC: This merely states the availability of more tracking data that have not actually been further analysed for the purpose of this EIS. Again, we highlight that tracking data are not suitable for producing vulnerability maps in the absence of much more all-inclusive at-sea data.	breeding status during at-sea observations. Hence, the EIS highlights tracking and at-sea observer data complements one another, and ultimately strengthens our understanding of species distributions. The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil.	
FC 32	EIS: "In addition, the Falkland Islands provides important foraging habitat for seabird species that breed elsewhere, particularly at South Georgia (e.g., Berrow *et al.,* 2000; Phillips *et al.,* 2006; Ratcliffe *et al.,* 2014). BirdLife International manages the Global Procellariiform Tracking Database (BirdLife International, 2004), which serves as a central repository for albatross and petrel tracking data from all over the world. The model has recently been extended to penguins (and other seabirds). Work is currently underway in the Falklands to collate, and determine how best to use, the tracking data available for seabirds breeding and visiting the Falkland Islands" FC: Again, the EIS refers to available data which could potentially provide useful complementary information without actually using the information. This is misleading and adds unnecessary bulk. The previous EIS already stated that data from the Global Procellariiform Tracking Database would be used to include more info from non-Falklands breeding birds. This has not happened. Instead, the current EIS merely repeats that this work will be conducted. Similarly, it was already mentioned in the previous EIS that "Work is currently underway in the Falklands to collate, and determine how best to use, the tracking data available for seabirds breeding and visiting the Falkland Islands". Although some additional raw data figures have been reproduced in the new EIS of Falklands breeding birds, no additional analyses have been undertaken, nor have any additional data for non-breeding birds been considered.	Figure 7-53 does indeed reflect global population for individual species. The prior EIS and associated development was not continued. Hence, no further work was carried out. The current EIS relates to Navitas and an updated development plan. The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil. Note: Baylis *et al.,* 2020 will be corrected to 2021.	Figure 7-53

Ref.	Representation	Navitas response	Changes in Rev 4
FC 33	EIS: "The EMMP (Chapter 15) will collect further data in the field, specifically using SMMOs on two vessels for the first three years of the project (post sanction, pre-First-Oil and post-First-Oil). Data collected here will allow of a comparison of the SAST data going forward'." FC: Such data should be collected and appropriately analysed pre-sanctioning to adequately inform the EIS of this development. This section identifies the issue of annual variation in foraging patterns, and limited temporal extent of tracking and boat-based data. Why has additional data not been collected to fill this gap?	Please refer to the response to FC 12.	N/A
FC 34	EIS: Table 7.14 Summary of deployments from a recent multi-colony tracking project. FC: Good to see additional tracking data from NW/SW Falklands which can serve as complementary information, although information continues to be scarce from north/northeast Falklands colonies. Importantly, we again stress the point that tracking data can only serve as complementary information to adequate at-sea data. The previous EIS version said that these additional data would be included in vulnerability analyses. As we understand the data presented, this work has not been conducted.	The EMMP aims to collect further data in the field, specifically using Seabird and Marine Mammal Observers on two vessels for the initial years of the project (post sanction, pre-First-Oil and post-First-Oil).	N/A
FC 35	EIS: Figure 7-48 Combined data, from both satellite (PTT) and GPS tags EIS: Table 7.16 Data derived from tags other than GLS tags FC: It would be useful to have a table showing how much data originates from individual colonies and years given the issue of inter-colony and inter-annual variation. Also, the original source of these data should be referenced.	Table 7.16 includes season and colonies from which tracking data was derived. Baylis *et al.* (2019) will be included as the data reference.	Table 7.16
FC 36	EIS: Figure 7-53 An overview of the GAP data from Baylis *et al.,* 2019 and Baylis *et al.,* 2020 FC: The reference should be Baylis *et al.,* 2021 not Baylis *et al.,* 2020. The percentage of global population plot is misleading, as this table is about the importance of the site to Falklands birds. Whilst this additional plot has been included, the previous EIS stated that these data would be considered as part of a vulnerability analysis. This work has not been conducted. Simply	Figure 7-53 does indeed reflect global population for individual species. The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil. The development outlined in the previous EIS (related to Premier Oil), was not continued. Hence, no further work was carried out. The current EIS relates to	Figure 7-53

Ref.	Representation	Navitas response	Changes in Rev 4
	superimposing the drilling area on a map is not a vulnerability assessment, particularly as a much wider area can potentially be at risk in case of a spill.	Navitas and an updated development plan. Note: Baylis *et al.,* 2020 will be corrected to 2021.	
FC 37	EIS: "the resources required to undertake simultaneous tag deployments on multiple predator species from multiple colonies is typically not feasible." FC: Resources should be made available to collect the necessary data prior to sanctioning a large project like this and though expensive, in relative terms to the development, is small. However, importantly, the focus should be on at-sea data collection, rather than tracking, for all the reasons highlighted previously.	Please refer to the response to FC 12.	N/A
FC 38	EIS: Figure 7-59 The locations of 30 gentoo penguins tracked during the winter and early summer from five locations FC: It would be helpful to see the drilling area superimposed on these maps, as well as the risk areas in case of a spill. In any case, it's not clear as to where these additional data fit in. Baylis *et al.* (2019) uses data from 25 + 45 individuals. Baylis *et al.* (2021) do not show these maps. Where do these 30 birds fit in? Is this additional data or is this the same data as shown elsewhere but presented in a different way? If this is additional data, this could be added within an updated analysis.	The comment is noted, thank you. This reference should be '25 gentoo penguins tracked'. This will be corrected and the drilling area superimposed in the finalised version of the EIS. Data are the same as Baylis *et al.,* 2019.	Figure 7-59
FC 39	EIS: "The best known and probably largest colony of sooty shearwaters (Ardenna griseus) is found on Kidney Island, in the mouth of Berkeley Sound, which is estimated to comprise 139,000 pairs (Wakefield *et al.,* 2017)." FC: Clark 2019 is a peer-reviewed publication of Wakefield *et al.,* 2017 report. Also see latest survey of WCP and SSW on Kidney and Top Islands (Kuepfer *et al.,* 2024 – appreciated this report was not available at the time of the EIS preparation).	Reference to Clarke *et al.,* 2019 will be included.	Section 7.4.5.2.2 (Sooty Shearwater)
FC 40	EIS: "There is a very small breeding population of white-chinned petrels (*Procellaria aequinoctialis*) in the Falkland Islands, estimated at 55-100 pairs (Reid *et al.,* 2007)." FC: See Kuepfer *et al.* (2024) for updated estimates at two of Falklands breeding sites – appreciate this info was not available at the time that the EIS was prepared.	This information was not available when the EIS was published. Wherever possible, Navitas will include a reference to reports published after the EIS was produced.	Section 7.4.5.2.2 White-chinned petrel

Ref.	Representation	Navitas response	Changes in Rev 4
FC 41	EIS: Table 7.17 FC: BBA dive to at least 19 m, not 10 m (see Guilford *et al.,* 2022). IUCN Red List needs correcting. MAG is Least Concern, not NT (See BirdLife International 2020). For BBA population estimate in FI, reference Crofts (2020), which lists data from the 2017 census.	Table 7.17 will be amended. to include IUCN status, and references.	Section 7.4.5.2.3
FC 42	EIS: Table 7.20 FC: This is a bit confusing. How can we know the long-term trend without knowing the short-term trend for certain species? KS Eagle Hill 2010 counts – where are these data from? The EIS states that 2022 data are from Stanworth 2014.	Table 7.20 has 'unknown' to reflect data gaps for some species/locations. Kuepfer and Stanworth (2023) will be included as a reference for Berkley Sound counts in 2022.	Table 7.20
FC 43	EIS: "all colonies are counted during the island-wide census, which takes place approximately every five years." FC: This is incorrect. The last census was 14 years ago.	The comment is acknowledged and the finalised version of the EIS shall be re-worded to reflect the island wide-census being undertaken 5-yearly until 2010, and no subsequent island-wide census since 2010.	Section 7.4.5.3.1.2
FC 44	EIS: "For example, on the basis of the most recent archipelago-wide census, the population trend for the black-browed albatross population in the Falklands is positive (Wolfaardt, 2012)" FC: Reference Crofts (2020) which lists information from the latest census in 2017.	Include reference to Crofts (2020).	Section 7.4.5.5
FC 45	EIS: "To assess the relative risk to different species, the JNCC developed an index to assess the vulnerability of bird species to the threat of oil pollution (Williams *et al.,* 1994). One of the main outputs of the SAST surveys in the Falkland Islands was the production of an Oil Vulnerability Atlas (White *et al.,* 2001)." FC: These Vulnerability maps do not consider the full dataset collected, and only include 2 years of data. This important detail is not highlighted to readers (see White *et al.,* 2002: "The results of the first two years of surveys were published as an atlas depicting vulnerability of seabird concentrations to surface pollution Vulnerable concentrations of seabirds in Falkland Islands waters (White *et al.,* 2001)"). As highlighted also in the Genesis (2017)	The maps were produced by SAST, an FC and JNCC collaboration, funded by industry and FIG. Navitas has acknowledged that whilst the data set is old; complimentary, additional surveys and tracking work have augmented and improved the baseline. Please also note that Navitas has committed to deploying SMMOs on the offshore support vessels (OSVs) for the first three years of operations.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	report, Webb *et al.* (2014) recommend at least three years of data for assessment purposes.		
FC 46	EIS: "Recently, JNCC have updated the OVI to include recent survey data and using a new method, which has been named the Seabird Oil Sensitivity Index (SOSI)" Page 20 of 57 FC: It's not clear why an OVI is used as opposed to the newer method of SOSI, which is highlighted by JNCC as an improved measure of seabirds' sensitivity to oil pollution.	The SAST used the OVI and therefore this was used as part of the risk assessment. Navitas are aware of the SOSI and this could be used with new data gathered in the future. Note that Navitas will deploy SMMOs on vessels developing the field for three years pre First-Oil.	N/A
FC 47	EIS: Figure 7-73 Seabird Vulnerability Maps for summer months FC: The OVI by White *et al.,* 2001 only used data from 2 out of 3 years of survey. So not only is the OVI based on very old data, but it also fails to consider all data available. According to Webb *et al.,* 2014, vulnerability maps for oil and gas should be based on at least 3 years of data. Additional tracking data have been collected and presented in current EIS, but this has not actually been included as part of an updated integrated vulnerability assessment analysis. The Falkland Islands waters are recognised as one of the most important seabird areas globally, and the EIS of such a large undertaking should produce a comprehensive and up-to-date seabird vulnerability index.	Noted - please see responses to previous comments above. Also note that the scale of a SAST like programme pre-sanction is not appropriate for a single operator (see FC 12). This would need to be an industry / government collaboration. Note that Navitas will deploy SMMOs on vessels developing the field for three years pre First-Oil.	N/A
FC 48	EIS: "Data collection and analyses are now complete as set out by GAPII objectives. However, it will take further analysis to determine how the results of this work can best be used to quantitatively assess the potential impact of the O&G industry in the Falkland Islands." FC: Although additional data have been collected, the EIS itself states that further analyses are required to adequately make use of these data to assess the potential impact of this project. GAP collected tracking data on 9 Falklands breeding birds, which does not provide information on all other species/ age groups/ colonies that utilise the area, many of which do not breed in the Falklands. The EIS itself states: "The SAST data set is also useful in that it includes species that do breed in the Falkland Islands but use its waters for foraging or as migrations corridors."	The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil. This will include reviewing data gaps. The additional analysis of the data collected by the GAP project, and indeed other projects associated with a wide-range of groups, is ongoing. Outcomes from this ongoing work which are relevant to the project will be used to inform the EMMP and project-specific data collection and monitoring requirements.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
FC 49	EIS: "Existing data will be collated and used to perform assessments through expert-led processes." FC: Can you clarify what is meant by "expert-led processes"? Any further analyses that can help inform this impact statement should be conducted and presented prior to the project being sanctioned.	An expert-led process in the analysis of telemetry data i.e., individual/s with expertise in animal telemetry and data analysis. The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil.	N/A
FC 50	EIS: "At the time of compiling this Environmental Baseline Description, initial analysis of data collected by the GAP project has been published by Baylis *et al.* (2019), Baylis *et al.* (2021) and by the seal by-catch project through SAERI (Riaz *et al.,* 2023). The results from this work are included and referenced in the relevant sections below." FC: Results from Riaz *et al.* (2023) are not referred to in any further sections. Hence, this is not relevant to the EIS.	The comment is noted, Navitas shall delete the sentence: 'The results from this work are included and referenced in the relevant sections below.' in the updated version of the EIS.	Section 7.2.4.2.1
FC 51	EIS: Gap results FC: This whole section simply regurgitates the results from Baylis *et al.* (2019, 2021). The EIS does not attempt to make the results relevant to the Sea Lion area, or the area at risk in case of a spill. As the EIS acknowledges, this tracking data can lead to misleading conclusions being drawn and important areas missed (annual variation / seasonal variation / age-specific variation).	The EMMP aims to undertake further analysis of the satellite tracking data post sanction, pre-First-Oil and post-First-Oil. This will include reviewing data gaps.	N/A
FC 52	EIS: "Vulnerable areas within Berkeley Sound, for seabirds, are linked to the location of colonies and aggregations associated with these colonies" FC: Are the many designations (KBA/IBA/NNR/ACAP breeding sites) assigned to colonies within Berkeley Sound being considered at all?	Please refer to sections 7.5.2.3.1.1 IBAs in Berkeley Sound and 7.5.2.3.4 Key Biodiversity Areas	N/A
FC 53	EIS: Table 7.34 FC: New Island – Landowner should be FC.	Noted, this will be updated.	Section 7.5.2.1 Table 7.34
FC 54	EIS: "The Kidney Island Group are designated as an Important Bird Area (Falklands Conservation, 2006). The most significant species contributing to the IBA status are shown in Table 7.36." FC: Kidney and Cochon Islands have National Nature Reserve (NNR) and Important Bird Area (IBA) designations. Kidney Island also has Key Biodiversity Area (KBA) designation. Kidney, Top & Bottom Islands represent ACAP breeding sites No. 80 and 81 for white-chinned petrels. The vicinity of Top & Bottom Islands is not considered in this EIS.	Noted, this will be updated.	Section 7.5.2.3.1.1

Ref.	Representation	Navitas response	Changes in Rev 4
FC 55	EIS: "Although there is some seasonal movement of birds between the Falklands and South America, the location of the Sea Lion Field and Berkeley Sound are not regarded to be on the route of migrating land …" FC: Please provide supporting references.	White *et al.* (2002) will be added. Note the sentence reads 'not regarded to be on the route of migrating land birds and therefore the potential risk to seabirds is of greatest concern'	Section 10.1.4.3.1
FC 56	EIS: "the impact of lighting has been estimated to extend to 3-5 km around offshore installations" FC: Please provide a reference for distance at which birds are affected by light sources.	The reference already provided for 3-5km was Marquenie (2007) - report is freely available online. Nevertheless, Navitas will update this clarify light pollution could impact birds differently (age/stage) and at different distances, and Navitas cannot rule out birds are attracted at a much greater distance.	Section 10.1.4.3.1
FC 57	EIS: "Data compiled from at-sea surveys, annual monitoring programs, coastal surveys and tracking data were used to indicate the seasonal abundance of the most susceptible species near the Sea Lion Field (Knipe and Pendoley, 2019)." FC: It would be helpful to make the work conducted in reports such as Genesis (2017) and Knipe & Pendoley (2019) publicly accessible for improved transparency. See above our comments why the seabird data used is inadequate / insufficient for the purpose of this risk assessment.	Noted. These are available upon request. The Genesis 2017 report has already been requested and provided.	N/A
FC 58	EIS: Table 10.3 FC: Southern rockhopper penguins are listed as Vulnerable, which does not appear to be considered in this table.	Noted. This will be amended.	Table 10.3
FC 59	EIS: "The available survey data indicate that there will be a low number of individuals of all of the potentially susceptible species present within the zone of influence of the Development (Section 10.1.4.3.1.4). Although accurate population estimates are not available for all species, the biogeographical populations are known to be very large. Therefore, it is anticipated that the assemblage of birds within the zone of influence of the Development, at any given time, will not be of geographical importance (i.e., <1 % of the local population). FC: "The biogeographical populations are known to be very large." - Please reference. This section makes assumptions based on inadequate data of bird	Biogeography is geographic distribution. Hence, the statement that there is no information on geographic distribution of species listed in Table 10.4, to which the statement pertains (petrels, prions, shearwaters) is incorrect. Reference to BirdLife International (2024) will be included.	Table 7.17 Table 7.23 (referred to in Section 10.1.6.1.2)

Ref.	Representation	Navitas response	Changes in Rev 4
	assemblages, insufficient data on bird-strikes, and non-existing data on biogeographical populations. Low fecundity rates and a relatively protracted time to reach maturity of procellariiformes means seemingly small impacts on survival rates can have large impacts on population viability, making them particularly vulnerable to lethal impacts. Cumulative threats will have additive impacts.		
FC 60	EIS: "While seabirds may be distracted from natural feeding behaviour or may expend energy flying in circles around the vessel which has the potential to affect the body condition of the birds, the impact will be short-lived (a matter of hours) and should not have long-term consequences provided there is no contact between the birds and the vessel." FC: Please provide supporting references for this statement. The distance from which birds may be attracted has not been considered here. This information may not be available; however, if birds are potentially attracted from several kilometres away, the adverse effects could greatly increase, as the number of birds impacted increases.	Thank you for the comment. This shall be taken into consideration. Navitas will provide a supporting reference in the post-consultation EIS.	Section 10.1
FC 61	EIS: "the LTV anchorage location is situated approximately 10 km inshore of the breeding colony, so birds will not routinely pass the site en route to the colony" FC: Please provide a reference. Particularly fledglings may become disorientated by lights up to 15 km, see e.g., https://www.dcceew.gov.au/campaign/light-pollution/seabirds.)	Bonnet-Lebrun *et al.,* 2020 will be included as a reference, and sentence clarified to refer to breeding SSW. While appealing, the 15 km stated in multiple Australian Government pamphlets on light pollution, it is derived from Rodriguez *et al.,* 2014.The authors simply state that 'This factory is located on mainland Australia about 15 km from the closest shearwater breeding colony (Cape Woolamai) and produced light pollution levels around 27 nW/sr*cm^2 during the construction phase, which is 5 times higher than the most light-polluted area on Phillip Island (Figure 1). In 2012, 237 fledglings were grounded at this site, which constituted the equivalent to one-quarter of all grounded birds on Phillip Island in the same year and supports the hypothesis that fledglings can be attracted to lights after reaching the ocean.' There is	Section 10.1.4.3.1 Section 10.1.4.3.1.4

Ref.	Representation	Navitas response	Changes in Rev 4
		no information on the distance from which birds were attracted to light, just a straight-line distance from the breeding colony to the grounding location.	
FC 62	EIS: "Significant as multiple seabird strikes are closely linked to weather conditions (Section 10.1.4.3.1.3) and are more likely to occur when visibility is reduced due to fog or snow. However, under these conditions, the deck lights of vessels may not be visible at a range of 10 km such that the zone of influence is effectively reduced." FC: Please reference what is visible to birds under various conditions. The literature suggests that collisions generally increase in conditions of poor visibility.	The context of the statement is in relation to the LTV being located 10 km inshore from the breeding colony, and the fact that tracking data shows that birds don't routinely travel inshore during foraging trips. Specifically, the EIS states 'However, the situation in Berkeley Sound is unusual in that the LTV anchorage location is situated approximately 10 km inshore of the breeding colony, so birds will not routinely pass the site en route to the colony. This is significant as multiple seabird strikes are closely linked to weather conditions (Section 10.1.4.3.1.3) and are more likely to occur when visibility is reduced due to fog or snow. However, under these conditions, the deck lights of vessels may not be visible at a range of 10 km such that the zone of influence is effectively reduced.' The sight-distance of birds at night in poor visibility is not something that features readily in scientific literature. The point being made is the LTVs will be 10km from the colony, and lighting will be minimised as far as practicable. Consequently it is thought unlikely that the vessel lights will be visible to birds some 10km away in weather conditions that result in poor visibility. Note also that the birds will be in burrows at night-time rather than in-flight.	N/A
FC 63	EIS: "Penguins are known to use contact calls to communicate when on the surface, however, there is little evidence to suggest that they vocalise underwater (O'Brian, 2002)." EIS: "EIS: "An SEL threshold of injury of 202 dB re 1µPa2 s was agreed on by the panel (SAIC, 2011). The threshold found for the marbled murrelet was	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	applied here to estimate the underwater noise impacts to diving seabirds." FC: This EIS is missing some key up-to-date literature. The EIS suggests that there is no clear evidence that penguins are disturbed by noise, or that they use sound for communication underwater. However, see e.g., Sørensen *et al.,* 2020, Thiebault *et al.,* 2019, Pichegru *et al.,* 2022. - Sørensen *et al.* (2020) state: "The fact that penguins can detect and react to underwater stimuli may indicate that they make use of sound stimuli for orientation and prey detection during dives. Further, it suggests that penguins may be sensitive to anthropogenic noise, like many species of marine mammals." "strong reactions in more than 60% of the playbacks at 120 dB re 1 µPa" "The fact that penguins react strongly towards these rather weak sounds,…", "Another surprise was that the 20 dB increment in received level was sufficient to change the reaction of the birds from no observable response to a strong aversive response." - Thiebault *et al.* (2019) on use of vocalisation in hunting penguins (King, Gentoo, Macaroni) state: "All vocalisations were emitted during feeding dives and more than 50% of them were directly associated with hunting behaviour"	with consideration for the comments received. See also FIFD 54.	
FC 64	EIS: "Although anecdotal, these observations indicate that penguins do not strongly avoid areas where vessel noise is prevalent." Page 23 of 57 FC : See Pichegru *et al.* (2017, 2022): "African penguins likely relocated away from their traditional feeding zone to avoid the disturbance generated by the noise of the seismic vessels, rather than to follow their prey"	No seismic operations are planned as part of the proposed development and please also note that the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also FIFD 54.	Section 10.4 Section 10.5
FC 65	EIS: Table 10.31 Summary of the impact assessment for underwater noise offshore FC: Behavioural disturbance to seabirds should be included given evidence from elsewhere (see comments above)	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also FIFD 54.	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
FC 66	EIS: "Disturbance and behavioural response thresholds: § Fish (Popper *et al.,* 2014), and § Marine mammals (Southall *et al.,* 2007)." FC: In light of information from up-to-date references, seabirds should also be considered here in terms of peak pressure level results.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also FIFD 54.	Section 10.4 Section 10.5
FC 67	Section 10.4.4.4.4.2 EIS: "For seabirds, there are no guidelines to determine what constitutes a behavioural disturbance or threshold sound level." FC: See e.g., Sørensen *et al.* (2020) who recorded strong reactions by Gentoo penguins in more than 60% of the playbacks at 120 dB re 1 µPa.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also FIFD 54.	Section 10.4 Section 10.5
FC 68	EIS: "levels of sound during inshore operations will be similar to the noise levels currently occurring within the Sound and therefore, there will be little or no additional impact from underwater noise on seabirds present in the area" FC: What about the additive effects of more noise?	This is considered in cumulative impacts, see section 10.5.9, noting that there will be only two additional vessels at any one time (and will they will mostly have their engines off and weather vaning for the duration of their stay in the sound).	N/A
FC 69	EIS: "Where artificial light, poor visibility and high seabird numbers coincide, 1,000's of birds may collide with a vessel on a single night. While there are no published records, light induced bird collisions with vessels, with varying numbers of birds affected, are a regular occurrence around the Falkland Islands (A. Black pers. obs.)," EIS: "Multiple bird strike events can result in hundreds of bird mortalities in a single night, however, these events usually occur close to land (i.e., breeding sites) where some birds congregate at dusk" FC: It is unfortunate that no efforts have been made to improve the bird-strike data. If you speak to captains from fishing vessels, it appears that larger-scale bird strikes away from shores are not uncommon. As the EIS states – "However, in conditions of poor visibility (due to fog, snow or rain) the problem is	In line with the BSMP, bird-strike data will be reported on all vessels. With regard to existing data from cargo/cruise /fisheries vessels etc. in the Falkland Islands, Navitas would welcome receipt of such reported data. Navitas believe the approach to be precautionary however papers suggested, such as, Coleman *et al.,* 2022 will be reviewed and changes made to the chapter if it is deemed appropriate. See also FC 78.	Section 10.1.4.3.1.2

Ref.	Representation	Navitas response	Changes in Rev 4
	exacerbated, and more individuals are likely to interact with vessels emitting light".		
FC 70	EIS: "Therefore, there is a need to identify opportunities for improvement through mitigation and controls, and to consult with project stakeholders" FC: When will this be done? This should be done pre project sanctioning. It is disappointing that no efforts have been made to try and fill this data gap.	The EMMP Summary table regarding EIS Artificial light was discussed with key stakeholders during the EMMP workshop (April 2019). This detailed proposed monitoring and management actions. The EMMP workshop also discussed governance and suggested that the EMMP board 'would be supported by an advisory committee including both non-technical stakeholders and relevant individuals with expertise in the subjects being monitored. The advisory committee would help draw up the specifications to be used in contracting particular monitoring work, and would be able to comment on the results of the monitoring - this would include giving advice as to whether any threshold had been passed, any further management that might be needed and reviewing whether monitoring efforts should be increased or could be reduced.'	N/A
FC 71	EIS: "With regard to the likelihood of a multiple bird-strike event occurring, such a strike is likely to occur less than once per year but more than once in 10 years." The assumption that this will happen less than once in a year is unfounded. It is very likely that multiple bird strikes are not uncommon (based on communications with fishing captains), but simply under-reported. See e.g., Coleman *et al.,* 2022.	Thank you for the comment. See FC 69 and 78.	N/A
FC 72	EIS: "The Falklands population has shown a long-term decline in numbers and is the subject of a dedicated management plan." FC: Please reference FISMP report (Kuepfer & Stanworth 2023): Breeding population (Falkland Islands): 1991–2022, stable; last 10 years, decreasing Breeding success (Falkland Islands): 1993–2022, decreasing; last 10 years: stable-decreasing	Noted, this will be updated. See also FIFD 54.	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
FC 73	EIS: "Although anecdotal, these observations indicate that penguins do not strongly avoid areas where vessel noise is prevalent." FC: Please provide supporting references for such statements. Penguins are known to be sensitive to vessel noise and other marine noise pollution. See e.g., Pichegru *et al.,* 2022 who assessed vessel-derived underwater noise levels on a penguin population.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also FIFD 54.	Section 10.4 Section 10.5
FC 74	EIS: "Local feathers from nine species of Falkland birds were tested in dispersed oil at a concentration of 100 mg/l, and oil droplets of *c.* 100 microns were produced into the water column." FC: Would be useful to refer to the table here where the species are listed. It is unfortunate that this important report is not readily accessible to the public for independent assessment of the methods used.	Noted. The reference to the table will be added. All reports are available upon request.	Section 10.7.4.3.2
FC 75	EIS: "This species has a high potential for natural dispersion and is known to be established in Port William and may have reached Berkeley Sound already (P. Brickle *pers. comm.*)." FC: We feel that the use of *pers. comm.* for statements like these is inappropriate. Please provide an adequate reference or remove.	Thank you for the comment. Navitas believe this is valid as there is a great deal of expertise and many years of observation from those that imparted knowledge.	N/A
FC 76	EIS: "Feathers were dipped into a concentration of 100g/m2 oil in seawater: No oil was adsorbed by feathers" FC: how was it determined whether or not oil had been absorbed by feathers? Visual assessments under normal light conditions can be insufficient to detect sub-lethal oil concentration on feathers which may nonetheless have impacts on individual's performance and survival (See e.g., Fallon *et al.,* 2020)	The work was done by CEDRE. Based in France this company is considered internationally to be expert in accidental water pollution. CEDRE has five main activities: response support, contingency planning, training, analysis and testing and research. It conducts this research to a standard. It should be noted that Sea Lion crude is very waxy and at ambient temperatures does not stick to feathers. Under experimental conditions the oil had to be heated up for it to stick to feathers. The report can be shared for more information. The Fallon (2020) paper refers to crude from Macondo. This is very light and non-viscous in nature and therefore not a good comparison.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
FC 77	EIS: "A preliminary assessment of seasonal vulnerability of seabirds to oil contamination within Falkland Islands waters was performed on data collected by the Joint Nature Conservation Committee (JNCC) to produce an Oil Vulnerability Atlas, (White *et al.,* 2001)." FC: For reasons explained earlier, these data and analyses are inadequate for the purpose of a risk assessment. There is no evidence to suggest that bird assemblages and distributions have remained the same as documented 20+ years ago. The data are too old (see best practice advice by JNCC, Webb *et al.,* 2016). In addition, the vulnerability maps are based on 2 years of data, which is less than the recommended number of years of data (see Webb *et al.,* 2014, 2016).	The EMMP aims to collect further data in the field, specifically using Seabird and Marine Mammal Observers on two vessels for the initial years of the project (post sanction, pre-First-Oil and post-First-Oil).	N/A
FC 78	EIS: Table 14.1: Overall summary of EIA findings FC: Large scale bird strike with vessels is not "possible", it's at best "probable" ("Likely"). Efforts to collect appropriate data should be made pre-sanction. Cumulative bird strikes over the years and with other anthropogenic sources should also be considered. Small scale bird collision is not "likely", it is "certain". An effort to collect appropriate data should be made pre-sanction. Behavioural disturbance to seabirds from underwater noise is not considered, despite evidence that this can be an issue.	See also FC 69. Navitas understand that this data is not routinely collected on vessels. The likelihoods are based upon the data available. If data can be provided to better inform the likelihood of small and large-scale bird strikes, these will be considered within the impact and risk assessment. The underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also FIFD 54.	N/A
FC 79	EIS: "where uncertainties in the EIS arise from lack of baseline data" FC: Baseline data need to be available prior to project sanctioning. Also, previous EIS have promised certain work that has not been completed. Given this history, what assurance do we have that any further information will be provided in a timely manner?	FIG EIA guidance (2016) acknowledges that the presence of justifiable data gaps 'does not make an EIS unfit for purpose' (Section 3.13) and that where there are data gaps a risk may be increased to reflect a higher level of uncertainty.' (Section 3.18) . Previous commitments undertaken during the 2020 EIS were made to collect additional data and undertake	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		additional work following project sanction. The project has not yet been sanctioned; however, Navitas has restated its commitment to gather this data and undertake additional work post FID and regulatory approval. FIG can condition project approvals on this further work being undertaken and has powers to sanction the Operator if these commitments not met.	
FC 80	Omission of relevant spatial areas identified as having global importance for marine mammals. Although the following areas are non-statutory, they have been identified and accepted by the IUCN. Section 7.5.2.3 (P475) of the EIS acknowledges that such areas should be considered during planning and risk assessment. However, Important Marine Mammal Areas (IMMAs) have not been mentioned in the EIS (despite both Important Plant Areas and Important Bird Areas being acknowledged as relevant and shown in Figures). While the FI IMMAs are relatively recent (2023 to 2024), the process has been ongoing since 2022 and been publicised locally. The areas relevant to marine mammals in the Falklands include: i. Key Biodiversity Area (KBA) for endangered sei whales (and more recently also for seabird species): www.keybiodiversityareas.org/site/factsheet/49174 The KBA is shown in Figure 7-96 and mentioned in Section 7.5.2.3.4 and briefly on P858, 1058 and 858. The KBA was accepted by the IUCN following independent review and its existence for sei whales warrants improved recognition in the EIS considering that Berkeley Sound falls within it; ii. Important Marine Mammal Area (IMMA) for endangered sei whales (and for marine mammal aggregations): https://www.marinemammalhabitat.org/factsheets/falkland-islands-malvinas-inner-shelf-waters-imma/ iii. Important Marine Mammal Area (IMMA) for wintering southern right whales: https://www.marinemammalhabitat.org/factsheets/north-east-falklands-malvinas-right-whale-wintering-area-imma/	Thank you for comments. They shall be taken into consideration.	Section 7.5

Ref.	Representation	Navitas response	Changes in Rev 4
	iv. Important Marine Mammal Area (IMMA) for foraging elephant seals: https://www.marinemammalhabitat.org/factsheets/south-western-patagonian-continental-shelf-imma/ v. Important Marine Mammal Area (IMMA) for breeding/moulting elephant seals and for killer whales: https://www.marinemammalhabitat.org/factsheets/sea-lion-islands-group-imma/ The latter two IMMAs do not overlap with either the Sea Lion field or Berkeley Sound, but are included here for information. The boundary of one additional IMMA (https://www.marinemammalhabitat.org/portfolio-item/slope-front-of-the-argentine-shelf-imma) is located approx. 100 km north-west of the Sea Lion oil fields and supports a high diversity of marine mammal species. This should be recognised and discussed in relation to the oil spill modelling results. The boundaries of the KBA, Inner Shelf Waters IMMA and North-east Falklands IMMA include the waters of Berkeley Sound and Port William, and their existence should be incorporated throughout the EIS in relation to their recognised high marine mammal sensitivity, especially in sections where other spatial sites (e.g., NNR, IBA) are discussed. A wealth of information on whale distribution, movements, seasonality, behaviour, habitat, site fidelity, conservation status and population trends are provided in the supporting evidence for the sites (see IMMA links and Weir, 2021), almost none of which has been used to recognise the extent of whale sensitivities in the EIS. • Identification of Key Environmental Sensitivities (KES). The risk assessment relies on the identification of 'Key Environmental Sensitivities (KES - also 'Environmental Receptors')', and the sensitivity assessment is based on criteria including conservation status, critical habitat, seasonality, vulnerable parts of a species lifecycle etc (Section 8.5.2.1 and Table 8.1). Consequently, it is essential to correctly identify and consider the latest available information on those KES. With regard to cetaceans, the eight years of work on baleen whales (primarily sei whales and southern right whales, SRWs) in the		

Ref.	Representation	Navitas response	Changes in Rev 4
	Berkeley Sound area has not been appropriately represented in the EIS. Erroneous findings from early studies are listed throughout the EIS (for example, that Berkeley Sound is a fin whale hotspot, and that 2017 was a 'one-off' year for Southern Right Whales). Key concerns regarding the cetacean sensitivity assessments are: i. Information on the offshore occurrence of cetaceans that would facilitate a robust assessment of the KES at the Sea Lion field is largely lacking, and the limited information presented has been over-interpreted and over-described in the EIS, risking making it appear to be a more reliable indicator of offshore cetacean occurrence than evidence suggests. For example: • the seismic MMO data is approximately a decade old (the last survey in FI waters was 2013). The total amount of data is small; • the White *et al.* (2002) report is two decades old (data collection from Feb 1998 to Jan 2001) and primarily used ESAS methods aimed at recording seabirds in a strip transect (rather than methods that optimise for cetaceans); • the Hipsey *et al.* (2013) report analysed only 5% of the data from a 1-year period (Jul 2012 to Aug 2013) of continuous acoustic monitoring, and the remaining 95% has not been assessed. Notwithstanding caveats (like animals might be present but not vocalising), this latter dataset could have potentially provided the best information on year-round occurrence of cetaceans at the Sea Lion field. Additionally, some conclusions reached in the Hipsey *et al.* (2013) report have since been shown to be erroneous (specifically they stated that they did not record Sei Whales, whereas Cerchio and Weir (2022) show that the vocalisations they attributed to Leopard Seals were Sei Whale song). The latter finding is significant in terms of confirming reproductive behaviour (singing) of sei whales at the Sea Lion field, but has not been mentioned in the EIS. While we accept that robust information for cetaceans at the Sea Lion field simply isn't available at this time, it's unfortunate that: (1) efforts haven't been made to implement such surveys as an environmental baseline ahead of production commencing; and (2) the existing year-round acoustic dataset hasn't been fully analysed and		

Ref.	Representation	Navitas response	Changes in Rev 4
	used to inform the EIS as would have been good practice. ii. Nearshore: Sei whales. Seven seasons of fieldwork on Endangered sei whales in the Berkeley Sound area have been conducted (each year except 2018). Despite this, it is repeatedly stated in the EIS that information on cetaceans in that area is scant (see detailed comments below). Only Weir (2017) is expanded upon in Section 7.4.6, with subsequent data either omitted or briefly mentioned. Consequently, there is significant under-representation of the importance of Berkeley Sound for sei whales. With regard to the criteria for determining sensitivity provided in Section 8.5.2.1: o The species is of high global conservation concern (IUCN: Endangered); o The numbers using nearshore FI waters are globally significant according to IUCN thresholds (see Weir, 2021 – KBA assessment) and the 1% thresholds applied in the EIS (Table 8.1); o The numbers using Berkeley Sound specifically are almost certainly also of global significance – over 400 individuals have been photo-identified in Berkeley Sound between 2017 and 2021 (excluding 2018, see Weir, 2022) which is 0.5% of the estimated global all-age population in the IUCN Red List assessment. (It is realistic that this value may double to 1% once the 2022–2024 data are analysed); o Mother-calf pairs of sei whales inside Berkeley Sound have been documented (Weir 2022), indicating that lactating adults and newly weaned juveniles also forage at the site. Moreover, Berkeley Sound is the only location globally where sei whale singing are not recognised within the EIS in the context of threats such as noise, entanglement, vessel strike or disruption of prey species. o There are important conservation habitats (KBA and IMMA) for the species in the FI, including Berkeley Sound, which should warrant a 'Very High' sensitivity (Table 8.1); o Their seasonality has been well documented from a 2-yr acoustic programme and effort-related visual datasets collected from 2017-2024 (see Cerchio *et al.,* 2022; Weir *et al.,* 2019; Weir, 2022). However, the EIS has focussed on presenting anecdotal and unconfirmed interview data as the		

Ref.	Representation	Navitas response	Changes in Rev 4
	supporting temporal information; o Their occurrence in the FI represents critical periods of the species lifecycle, specifically feeding (Weir, 2017; Weir *et al.,* 2019; Weir, 2022) and reproductive behaviour (singing: Cerchio and Weir, 2022). The fact that sei whales use Berkeley Sound as a foraging ground has not been appropriately recognised in this EIS (apart from brief mentions on p.444/454/697, but it isn't considered in the context of sensitivity to noise etc). Potential impacts on prey species (especially *Munida*, but also Themisto and other species – see Jackson *et al.,* 2022a for a full list of documented prey species) should therefore be expected to have indirect impacts on sei whales too, because the occurrence of those species inside Berkeley Sound is the primary reason why sei whales are present. This link hasn't been considered. o Nearshore & offshore: Southern right whales (SRWs). The importance of nearshore FI waters for wintering SRW aggregations has been largely omitted from the EIS, despite five years of research widely known within the local community. It is repeatedly stated within the EIS that the winter of 2017 saw an 'unprecedented influx' of SRWs. However, it is widely understood that coastal right whale aggregations have formed every year since. The evidence-base is extensive (boat surveys, aerial surveys, telemetry work), such that the nearshore waters in the north-east of the Falklands have been recently recognised as an IMMA for wintering southern right whales. The EIS fails to distinguish between the different uses of the FI by SRWs (which means that their occurrence at the Sea Lion field and in Berkeley Sound is in different seasons and for different behaviours), comprising: (1) a winter breeding/socialising area in coastal waters; (2) occurrence in pelagic waters perhaps year-round for foraging (and probably used also by SRWs from the South African breeding area: Vermeulen *et al.,* 2023); and (3) seasonal use in spring and autumn while making movements between wintering and foraging areas. Much of this is explained in the literature (Weir and Stanworth, 2019) and updated more recently in International Whaling Commission papers (Weir, 2021, 2024), yet these sources are not used. SRW has been treated as a species that just		

Ref.	Representation	Navitas response	Changes in Rev 4
	occasionally passes through the Berkeley Sound area (e.g., lumped with minke whales in Table 1.3 on P63), rather than as a KES for which nearshore FI waters (including Port William and Berkeley Sound) comprise a globally significant wintering area. The following details are relevant with regard to the criteria for determining sensitivity provided in Section 8.5.2.1: o The species has an IUCN conservation status of Least Concern; however, the south-west Atlantic population of SRWs is of regional conservation concern and there is an International Whaling Commission Conservation Management Plan (IWC-CMP) in place which is not mentioned in the EIS. Moreover, >1% of the global population occurring in FI waters would warrant a 'Very High' sensitivity category (P539/540) – this is the case for SRWs in the FI; o The numbers using nearshore FI waters are globally significant according to IUCN thresholds (results from 2023-2024 aerial surveys, available by Dec 2024) and will form the basis for a forthcoming KBA application; o There is an important conservation habitat (IMMA – see below) recognised for the species that includes Berkeley Sound which should warrant a 'Very High' sensitivity (Table 8.1); The annual (winter) and seasonal (mid-May to early September) aggregations in nearshore FI waters (including Port William and Berkeley Sound) has been well documented using a 2-yr acoustic programme (Cerchio *et al.,* 2022), satellite tracking (Falklands Conservation website), and effort-related visual datasets collected from 2017-2024 (Weir, 2021, 2022, 2024), yet the EIS repeatedly refers to an 'unprecedented' influx of SRWs in 2017 and does not acknowledge them as being an important KES in Berkeley Sound; o Their occurrence in the FI represents critical periods of the species lifecycle, specifically reproductive (mating and singing) behaviour (Cerchio *et al.,* 2022; Weir, 2021, 2022, 2024) which are sensitive to underwater noise (see Cerhio *et al.,* 2022 for example) and other disturbances.		
FC 81	Whale Omission of relevant data. The use of 'pers. comms.' and 'pers. obs.' has been widely applied within the EIS for cetaceans. While these are	Noted. References will be updated but please note that Navitas also consider pers. com. from experts to	Section 7.4.6

Ref.	Representation	Navitas response	Changes in Rev 4
	legitimate data sources, they should not be used as substitutes for available peer-reviewed and published information where available. Little or none of the published data or accessible telemetry data for SRWs and omission of the single most robust available report on whale occurrence in the Islands (distribution and seasonality during boat surveys; photo-identification (movements, fidelity); diet (faecal analysis and stable isotopes); genetics, suction cup tagging, and passive acoustic monitoring (seasonality, singing, behaviour) which has been available since 2022 (Weir, 2022) and none of the distribution or effort-related seasonal data are represented appropriately. Recognition of publicly accessible satellite telemetry data for whales is included on P444, yet no reference to the movements or maps is made elsewhere in the EIS, and although the telemetry data reveal extensive use of Berkeley Sound over weeks by individual sei whales then they are described elsewhere in the EIS as only using the area in transit (P453). The identification of KES is critical to the EIS and should use the evidence base available.	be valid. Please also note: Navitas invited the respondent to a dedicated scoping consultation session (see emails on November 17th and 27th 2023) and specifically asked for any data that may be considered relevant to the EIA process. The invitation to participate in scoping was declined.	
FC 82	Whale entanglement risk. There has been little or no recognition of the risks of cetacean entanglement in mooring equipment in the EIS. It should be recognised that anything in the water column (cables, ropes, lines, chains), particularly anything with slack around tides, has the potential to entangle whales. This includes gear that is looped off the seabed. There are numerous documented examples of whale entanglements, including in deep habitats (where sperm whales can become stuck in underwater cables) and in shallow habitats (most commonly vessel and aquaculture mooring gear, and fixed fishing gear such as pots and gillnets). While entanglement should be considered for all aspects of the project, it is especially pertinent to the Berkeley Sound area which is used by foraging sei whales (with vulnerable subsurface lunge feeding) and breeding southern right whales (*Eubalaena* spp. are highly vulnerable to entanglements, see published literature). Entanglement is both a welfare issue (when whales swim off carrying equipment) and likely to lead to mortality (by drowning or subsequent injury infections). It wasn't possible from the EIA to properly understand how the	The lines that will be placed in the water for the Sea Lion project include flowlines, risers and anchor chains. All of these are substantial and solid pieces of equipment, which Navitas believe pose a very low risk of entanglement to marine mammals. However, the requirement for such a Whale Collision and Entanglement Plan will be considered upon completion of the entanglement risk assessment which will be included in Section 10.11.	Entanglement risk has been added to all NTS summary tables, the ENVIID output tables and Section 10.11.2.2

Ref.	Representation	Navitas response	Changes in Rev 4
	moorings would work for various vessels, but entanglement consideration should be made in the planning of these. We would also recommend that a clear and transparent reporting system for large whale entanglements is introduced, such that expert advice can be sought for handing live entangled animals and the corpses of dead animals can be recovered for sampling/analysis.		
FC 83	Vessel collisions. The sections on vessel collisions make no acknowledgement of the fact that a Code of Conduct (endorsed by FIG) already exists for the FI and provides guidance on suitable speeds, wide berths etc for avoiding injurious/fatal collision with whales. The EIS has omitted small cetaceans from the vessel collision risk assessment, which is inappropriate considering there are documented mortalities of dolphins from vessel strike in the FI (see detailed comments below). With regard to nearshore wintering SRW aggregations, reducing the risk of vessel collision (considering there are 16 hrs of darkness in winter during which visual observation will not be valid) would benefit from an expanded 'reduce vessel speed' (10 knots) zone between 1 June and 31 August to 10 km from the coast to match the IMMA and telemetry data showing highest-use habitats. This would greatly improve confidence that the vulnerable surface groups of mating SRWs which occur out from the coast would be at lower risk of a fatal collision, and would be a better all round mitigation approach than the use of SMMOs (especially at night).	The Falkland Islands Code of Conduct will be added and referenced here. An assessment of vessel collisions with small cetaceans will be undertaken and added to the next revision of the EIS. Navitas agree that speed restrictions are the most effective mitigation against vessel collisions with marine mammals and propose reducing speed to 10 knots at the pMMA boundary (as industry standard mitigation (Section 10.11.5)) and then 8 knots within Berkeley Sound (as project-specific mitigation (Section 10.11.7)). The IMMA boundary has not been proposed as the limit for the speed restrictions as it is not a statutory boundary and the boundary may change over time.	Section 10.4.1.1 Section 10.11.1 Section 15.6.2.1.3 Section 15.6.2.1.4
FC 84	As a general comment, there is a heavy reliance on SMMOs for all of the mitigation listed for vessel collision, but there are obvious limitations with this: (1) SMMOs cannot see in the dark, and especially in winter then it is dark for two-thirds of the time; (2) SMMOs are engaged in simultaneous seabird observations (in a strip transect on one side of the boat if ESAS methods are being used) which means that they are not looking in a concentrated manner ahead of the boat on both sides as would be optimal for cetacean detection; (3) the weather is likely to be unsuitable most of the time in offshore areas for reliably detecting whales; and (4) whales are submerged for most of the time and may surface unpredictably close to a	Navitas agree that the best mitigation for collisions is speed reductions and propose reducing speed to 10 knots at the pMMA boundary (as industry standard mitigation (Section 10.11.5)) and then 8 knots within Berkeley Sound (as project-specific mitigation (Section 10.11.7)).	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	ship when it is too late to respond. The use of SMMOs is definitely preferable to no-one looking, but these limitations do need to be factored in. Mitigating vessel strike is not an easy thing to achieve.		
FC 85	Cumulative Impacts. Section 13 (3 pages) is inadequate. See detailed comments for examples.	Noted, see below for detailed response.	N/A
FC 86	The blue whale is recorded within the Falklands and has an IUCN status of Endangered, so there are actually two Endangered species of cetacean known in the Islands. The southern right whale is also of regional conservation concern (IWC-CMP) and, given their documented abundance in the FI, should also be listed here as a key marine mammal sensitivity in the FI. Given the lack of knowledge of the seasonality of almost all of the cetaceans in offshore waters, it is not clear why the monthly sensitivity (low, medium high) has been assigned. Certainly, key sensitive species such as sperm whale (Vulnerable) are present year-round (as is recognised on P429) and therefore the marine mammal sensitivity would better be considered high year-round. It is difficult to understand the shading for low/medium/high on Table 7.57, because the colours of the key at the top does not match the actual shading provided for the species.	Thank you for the comments. Navitas consider the assessment to be precautionary based on the activity, and risks. The text on blue whales, and the colours in Table 1.2 and Table 7.57 will be amended. In addition, SMMOs will be deployed on vessels developing the field for three years pre First-Oil in order to collect further data.	Section 7.4.6
FC 87	Marine mammals: There is very good information available on the seasonality of sensitive marine mammals in Berkeley Sound, which is not reflected here. The months from December through June should all be marked as high sensitivity for sei whales which are an endangered species which forage in this area throughout those months. The southern right whale aggregates in nearshore waters including Port William and Berkeley Sound from mid-May through to early September. The SRW uses this area for breeding purposes, and the SW Atlantic population is of regional conservation concern (IWC-CMP) - this species should be recognised as a KES within Berkeley Sound. Therefore, the entire period from December through to early September is of high sensitivity for baleen whales in Berkeley Sound (and adjacent waters), and these Tables should be revised accordingly.	Noted, tables will be revised.	Table 1.4 Table 7.58

Ref.	Representation	Navitas response	Changes in Rev 4
	• Commerson's and Peale's dolphins do breed in Berkeley Sound (i.e., this is a 'definite' not a 'likely'). • The influx of SRW in 2017 was not 'unprecedented' as stated in the Table – it has been repeated every year since. • Conservation sites: this table does not recognise that Berkeley Sound is part of three internationally-important sites for marine mammals – one KBA and two IMMAs.		
FC 88	Entanglement of cetaceans in mooring apparatus should be added to 'Environmental aspects' and considered in relevant Tables (e.g., 1.5, 1.6, 1.9, 2.2 etc.). The locations shown in Figure 5.5.2 (Section 5.5.1) are within high-use habitats for both sei whales and southern right whales (indicated by FC vessel data, aerial surveys, acoustic monitoring and satellite-tracking). Since the mooring locations seem to have some flexibility, it would be useful if consultation regarding anchorage locations also included whale experts in addition to FIMA/Fisheries in order to minimise disruption to both humans and whales. Same comment for P684 and P697.	This will be added to the ENVIID chapter (Chapter 9) tables, and the NTS with an assessment included in Chapter 10.11. Such consultations will be considered in discussion with FIG. See also FC 82.	Entanglement risk has been added to all NTS summary tables, the ENVIID output tables and Section 10.11.2.2 Section 5.5.1
FC 89	We suggest that the production of a Whale Collision and Entanglement Management Plan would be appropriate in order to raise awareness of these topics and of the sensitivity of local whale populations and to communicate commitments clearly to all key personnel.	Navitas will consider any additional credible measures and the requirement for such a report upon completion of the entanglement risk assessment (see FC 82, FC 88). Navitas is committed to following the Falkland Islands cetacean code of conduct.	Section 10.11.2.2
FC 90	Discussion "on the EIA requirements for the construction of any new facilities will be held with FIG prior to the submission of the relevant planning applications / requests for extension of existing planning permission." We take the opportunity here to highlight that pile-driving and other loud impulsive noise sources associated with construction has the potential to injure and disturb dolphins and other marine mammals within Stanley Harbour, and FC would seek reassurance that appropriate mitigation (i.e., the JNCC piling guidelines) would be followed during activities associated with Temporary Dock Facility (TDF) construction/expansion.	No pile driving will be required for the TDF causeway upgrade works. The previous EIS which is referred to is that of the one developed by Noble Energy Falklands Ltd for the original siting of the TDF.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	Especially since on P248 it states that "the full environmental baseline of Stanley Harbour is provided in the EIS previously submitted to support the construction of the Temporary Dock Facility (NEFL, 2013)" and so possibly an EIA/EIS has already been submitted for this? FC and SAERI have collected considerable data on dolphin sensitivity within Stanley Harbour in recent years that should be used to inform mitigation.		
FC 91	It is stated that the FI Data Portal has been consulted for the literature review. Metadata for the whale projects has been submitted to the Data Portal, yet whale information since 2017 is hardly represented in the EIS and FC has not been approached to discuss whale sensitivities.	Thank you from the comment. Metadata, such as that on the data portal, is information about data and does not contain raw data in a usable format. The baseline was constructed on published papers and data collected *via* research commissioned by Navitas. Please note: Navitas invited the respondent to a dedicated scoping consultation session (see emails on November 17th and 27th 2023) and specifically asked for any data that may be considered relevant to the EIA process. The invitation to participate in scoping was declined.	N/A
FC 92	"It is believed that many of the baleen whales recorded offshore within Falkland Islands waters are on passage …" As an important deduction this statement needs a reference. It may in fact be likely that sei whales and right whales forage routinely in offshore FI waters (i.e., it's a destination rather than just passing through) as shown by e.g., whaling catch data, Zerbini satellite data papers, etc. "It is thought that the productive inshore waters around the Falkland Islands (including Berkeley Sound) are of importance as feeding areas". Again, a reference would be needed. There are eight years of data demonstrating the importance of Berkeley Sound (and other areas) as a feeding area for sei whales. Additionally, the KBA and IMMA designated for sei whales both recognise the global importance of inshore FI waters as a feeding ground for this species.	Noted. The suggested references will be included. Navitas note that not all of the data to which the respondent refers is readily available. As noted elsewhere, the respondent was invited to a dedicated scoping session for this EIS and was also asked whether it had data relevant to the EIA (see emails sent on 17th and 27th November 2023) but the invitation was declined.	Section 7.4.6

Ref.	Representation	Navitas response	Changes in Rev 4
FC 93	This subheading should be 'relative abundance' not abundance as it does not describe actual abundance. • "However, the age of the dataset, and inherent limitations associated with at-sea surveys, raise uncertainty as to how representative it is of present day populations." While the reliance on White *et al.* (2002) is understandable (given the total absence of other effort-related data from offshore areas) it is clear that it does not represent contemporary populations (as highlighted at the July FIOHEF meeting) and this should be given greater acknowledgement in the EIS. For example, the White *et al.* (2002) report includes only 31 sightings of sei whales and 5 sightings of southern right whales from three years of year-round survey effort (both coastal and offshore). Currently, those numbers can be exceeded in a single day in Berkeley Sound area. There has obviously been substantial changes in whale populations over the 20 years since that report, and those sensitivities are simply not reflected in this EIS. • The Hipsey *et al.* (2013) report analysed only 5% of the one year of acoustic data collected at Sea Lion. It isn't clear why only 5% of that potentially very informative dataset has been analysed, especially when the EIS acknowledges (P422) that recent improvements in knowledge of species calls may mean that the Sea Lion acoustic dataset contains records of species hitherto overlooked. Since this dataset potentially comprises the best available source of information on the temporal occurrence of cetaceans at the exact location of the oil field, it is a pity that the other 95% has never been analysed and especially in light of recent findings (such as sei whale song – Cerchio and Weir 2022). • Figure 7-78: Using percentage to allocate months of importance for species for which there are few sightings is inappropriate and misleading. And also, this must be number of individuals not number of sightings as stated in the legend. Because White *et al.* (2002) reported only five sightings of southern right whales in total.	Thank you for the comments. Relative Abundance will be added. See previous responses on the age the SAST dataset (FC 7, FC 28). This is acknowledged. Also see previous comments on the AMAR data (FC 129). Note that SMMOs will be deployed for three years prior to First-Oil. Metadata, such as that on the data portal, is information about data and does not contain raw data in a usable format. The baseline was constructed on published papers and data collected *via* research commissioned by Navitas. Figure 7-78 will be reviewed.	Section 7.4.6.2.1 Figure 7-78
FC 94	"Additionally, there is limited knowledge regarding the range of vocalisations produced by each species. For example, Hipsey *et al.* (2013) did not record	The sei whale / leopard seal vocalisations are a matter for debate. The Cerchio and Weir (2022)	Section 7.4.6.2.1.2

Ref.	Representation	Navitas response	Changes in Rev 4
	any sei whales, although they are known to be regularly sighted during visual surveys". The study did record sei whales at the Sea Lion field, they just incorrectly assigned those vocalisations to leopard seals (this should be corrected in Table 7.27). See Cerchio and Weir (2022). As there have not been regular visual surveys in the areas of the acoustic deployments the source of the 'regularly sighted' statement is unclear. The presence of sei whale song at the Sea Lion field needs to be acknowledged in the EIS, as it implies higher acoustic sensitivity and sensitive behaviour of an Endangered species in the vicinity of a drilling operation and FPSO.	paper acknowledge that leopard seals can't be ruled out they but they 'consider that their spectrograms illustrate portions of sei whale song rather than aberrant leopard seal calls.' The paper suggest that leopard seals are not common in the Falklands based on surveys in Berkeley Sound. Leopard seals are very regular visitors to the Islands and are regularly seen around our coasts and at sea. Nonetheless, the text will be reviewed with respect to recent work conducted in Berkeley Sound. Based on the information that is available Navitas is confident in the marine mammal assessment. Note that SMMOs will be deployed prior to First-Oil in addition Navitas has committed to using hydrophones on the field.	
FC 95	It would be good to have the summary table (sightings and individuals) of species recorded during the MMO seismic datasets, since the same has been provided for White *et al.* (2002) and Hipsey *et al.* (2013). Which species were recorded by MMOs would be relevant.	Navitas consider that these data are summarised in an adequate way. These data are summarised in the text and considered in the assessments. These reports are available on request.	N/A
FC 96	The information presented here on southern right whales (SRWs) is very out of date. SRWs in the SW Atlantic were increasing, but in recent years that increase has levelled off (see papers by Crespo et al.) due to high calf mortalities and some mortalities also of adults. Consequently, since 2012 the SW Atlantic population of SRWs has been the subject of an International Whaling Commission (IWC) Conservation Management Plan (CMP) – see https://iwc.int/south-atlantic-southern-right-whale The regional conservation status of this population is therefore of higher concern (translating to higher sensitivity) than the species as a whole (globally Least Concern) which has not been acknowledged in the EIS. • "The migratory behaviour of southern right whales suggests that animals may travel through Falklands waters on passage between their Patagonian spring breeding grounds and summer feeding grounds near South Georgia	Thank you for the comment. The text will be updated with references accordingly. Please note that the SRW tracking data is not readily available, specifically for work conducted in the Falkland Islands.	Section 7.4.6.2.1.4

Ref.	Representation	Navitas response	Changes in Rev 4
	and Antarctica." This over-simplification is unhelpful for determining how any development should proceed sensitively. Whaling catches and satellite tracking show that SRWs utilise the entire SW Atlantic region – they aren't only breeding in Patagonia and they don't only feed in SG/Antarctica. They probably forage in pelagic FI waters year-round as well as using the area during migrations and, especially, as a wintering destination (for breeding and socialising) in nearshore waters around the FI. • "During the winter of 2017, an unusually high number of southern right whales was recorded in coastal waters around East Falkland (Section 7.4.6.3.1.1). This adds to the evidence of significant inter-annual variation in the number of these animals present within Falklands waters." Again, this is over-simplified. The winter of 2017 was the first year that a wintering aggregation was documented. However, it can no longer be considered 'unusual' but in fact occurs persistently every year – one of the reasons that an IMMA was identified for the species.		
FC 97	"Conversely, analysis of the acoustic data from the Sea Lion area did not contain any confirmed sei whale calls. … Acoustic detection of sei whales is further hampered by the absence of sei whale call descriptions for the South Atlantic." This information is two years out of date. Sei whale song was shown in spectrograms in the Hipsey *et al.* (2013) report but unfortunately, they reported them as leopard seal vocalisations. The repertoire of acoustic signals produced by SW Atlantic sei whales was published in 2022 and actually relates specifically to Berkeley Sound. The sei whale is now the best acoustically characterised species in the Falklands. See Cerchio and Weir (2022) and also the acoustic chapter by Cerchio *et al.,* in Weir *et al.* (2022). The full one-year acoustic dataset from Sea Lion could (and should) be re-analysed in this context, because the presence of sei whale song (linked to reproductive behaviour) in the Sea Lion oil field is a significant finding with regard to mitigation and sensitivity. "Three recent projects have surveyed the distribution of sei whales, and other cetaceans, in inshore waters (Thomson and Munro, 2014, Weir, 2017;	See responses to FC 94 for detail on sei / leopard seal calls. The text will be reviewed with respect to recent work conducted on Berkeley Sound.	Section 7.4.6.2.1.4

Ref.	Representation	Navitas response	Changes in Rev 4
	Costa and Cazzola, 2018). The preliminary results and anecdotal observations….” This statement is out of date. Eight years of boat-based surveys, aerial surveys, three years of 24/7 acoustic monitoring, diet analysis, genetic analysis, satellite-tracking and stranding attendance has been conducted. Much of this is available online.		
FC 98	Two species of minke whale occur around the Falklands, and it isn’t clear why this section focuses only on one of them. Same comment for Table 7.28, and for the summary on P454. At least one stranding in the FI has been genetically confirmed as *B. acutorostrata* not *B. bonaerensis* (C. Weir, *pers. comm.*). Humpback whales are not rare around the Falklands anymore – this information is out of date and does not represent what is currently known of species occurrence. Same comment for P455.	Noted. The text will be updated accordingly. See also FIFD 28.	Section 7.4.6.2.1.4 Table 7.28
FC 99	“Pilot whales were recorded on approximately 35 days throughout the year-long monitoring period (Hipsey *et al.,* 2013)” This is a meaningless/misleading statement considering that only 5% of the dataset was analysed. Southern bottlenose whales (and beaked whales in general) are almost certainly in the NFB year-round, given what we know of the site fidelity of beaked whale species globally. The fact they were not recorded in winter doubtlessly reflects weather conditions or is just a chance result (as the sighting rate of this species is anyway very low). Describing Long Finned pilot whales as ‘shallow divers’ is incorrect. Pilot whales are very capable divers reaching 1000 m – there are numerous published papers to support this.	See responses to FC 129 on the AMAR methodology. Currently there are no data to support Southern bottlenose whales (and beaked whales in general) abundance / distribution in the NFB. The pilot whale diving detail will be updated.	Section 7.4.6.2.1.4
FC 100	“This was subsequently supported by satellite tagging efforts by Falklands Conservation, which although preliminary (see https://falklandsconservation.com/sei-whale-tracking/), revealed long-distance movements of sei whales, both around the Falkland Islands and	This will be checked and updated where necessary. However, Weir *et al.* (2019) report on migratory movement of a single sei whale between Brazil and	Section 7.4.6.3

Ref.	Representation	Navitas response	Changes in Rev 4
	between the Falkland Islands and South America." This is incorrect, none of the tagged sei whales went to South America.	the Falkland Islands based on photo identification. The text will be updated accordingly.	
FC 101	The figure legend refers to section 1.5.2.3.4 but that section does not actually seem to exist in the report.	This reference will be removed.	Removed in course of QA process
FC 102	"Notably, of the species that are regularly observed within Berkeley Sound, sei whales are listed as 'Endangered' on the IUCN Red List…and all other cetaceans, are listed as species of conservation priority and are the subject of a Falkland Islands Cetacean Management Plan (FIG, 2008c)". They are not the focus of a FI CMP – cetaceans did have a Species Action Plan but it expired in 2018 and has not been renewed. This information also fails to acknowledge the SRW and the IWC-CMP that exists for the population. "For many years large numbers of sei whales (*B. borealis*) have been observed in inshore waters around the Falkland Islands (White *et al.,* 2002; Frans and Augé, 2016)". White *et al.* (2002) reported only 31 sightings in three years. "However, photo-identification within Berkeley Sound indicates that the animals are transitory with most animals spending a short period of time within Berkeley Sound (Weir, 2017)." This does not reflect current knowledge. Publicly available satellite-tracking for sei whales show sei whales remaining within Berkeley Sound continuously for periods of several weeks. This has to supersede the one-season of photo-ID data assessed in Weir (2017). More recent photo-ID data shows some individuals remaining a longer too (see photo-ID chapter in Weir, 2022).	Noted. Navitas will clarify and update references to reflect recent tracking work where it is possible. Note that these data are not readily available.	Section 7.4.6.3.1.6
FC 103	Sightings of fin whales in inshore waters are not supported (Weir, 2017). The report is that there aren't any confirmed (i.e., supplemented with photographs, video or genetic data) sightings of fin whales in inshore waters. Moreover, two years of acoustic monitoring in Berkeley Sound did not yield fin whale detection. Continuing to suggest that fin whales are common in Berkeley Sound is misleading. Given fin whales are an IUCN Vulnerable species, it isn't helpful for the industry if they are reported in the EIS as being	Fin whale - Weir (2017), while a valuable study, is not the only, nor definitive, cetacean sighting information available for the Falkland Islands. Indeed, Weir (2022) states that 'Fin whales (*Balaenoptera physalus*) have been anecdotally reported in coastal areas around the Falkland Islands, in some areas frequently enough to suggest that their occurrence might support a Key	Section 7.4.6 Section 10.11

Ref.	Representation	Navitas response	Changes in Rev 4
	present. "Once they arrive on their feeding grounds, southern right whales (*Eubalanus australis*) tend to be found in coastal or inshore waters (*c.f.* Black, 2005b)". This is likely incorrect. The feeding grounds of SRWs mostly comprise pelagic mid-latitude regions, including the outer Patagonian Shelf, the Argentine Basin, the subantarctic Islands etc. Not that many feeding grounds are located close to shore – this is the premise for most of the current satellite-tracking work going on for SRWs globally, aimed at locating their pelagic foraging areas. The whole section on SRWs under-represents what we know about the species in the FI currently and requires a major overhaul to properly reflect that species' occurrence and sensitivity. There is no recognition that SRWs aggregate in nearshore FI waters every year in winter for breeding and socialising, that satellite-tracking has revealed the durations that they stay on the FI coast, that they are part of the SW Atlantic population for which the IWC CMP exists, that their occurrence has warranted an IMMA, that the same animals return in different years, that Berkeley Sound is an important breeding habitat, etc.	Biodiversity Area (e.g., Frans and Augé, 2016; Taylor *et al.,* 2016). However, there is some debate over whether they actually occur on a regular basis in nearshore waters or if reported sightings are in fact misidentified sei whales (see Weir, 2017).' Given this debate is ongoing, it is both prudent and precautionary to include fin whales. Southern Right Whale - noted, Navitas will clarify and update references.	
FC 104	"Although there are no known records from Berkeley Sound, killer whales may visit the area". Killer whales were confirmed during the DOKE project around Kidney Island and FC has seen them inside Berkeley Sound and around Volunteer Point (see social media posts), local landowners (e.g., Adrian Lowe) have reported them anecdotally, etc. The Peale's dolphin section for some reason focuses on the 20-year-old JNCC surveys, while not citing at all recent information in Weir (2017, 2018) or Baines & Weir (2020). The same is true of the Commerson's dolphin section on P456.	Noted. Navitas Will update references.	Section 7.4.6.3.1.7
FC 105	The behaviour column contains a high number of inaccuracies. • SRW seasonality should be updated to reflect work done since 2019. See earlier points. • Fin whales: see previous comment.	Noted. Will update where relevant.	Table 7.28 Table 7.32

Ref.	Representation	Navitas response	Changes in Rev 4
	• Minke whales are not 'regularly sighted', occasional at best. • Humpback whales – They have been reported in Berkeley Sound. See Weir *et al.* (2022) report. • Killer whales - See comment above.		
FC 106	SRWs, fur seals and elephant seals have also been seen inside Stanley Harbour on occasion. Commerson's dolphins are significantly more common inside Stanley Harbour than Peale's dolphins – the distribution of the latter normally ends at The Narrows and we have seen them only very occasionally inside the Harbour itself. This section could be improved to make it clear that Commerson's dolphins and sea lions are the main sensitivities within the Harbour, with the other species far less common.	Noted. Will update where relevant.	Section 7.4.6.4
FC 107	This section (and subsequently Sections 7.5.2.3 and 7.6.2.1) fails to mention the IMMAs that are in existence for whales in the Falklands. Plus two additional IMMAs for elephant seals. As IMMAs are equivalent processes to IPAs and IBAs and are relevant to Berkeley Sound then they should be considered.	Noted. Reference to IMMA will be included in the section. Navitas note that the IMMA overlaps with the KBA, so there is multiple non-statutory designations overlapping one another, in the context of whales, based on the same data. IMMA and KBA boundaries are subject to change, as more data becomes available, and methods are improved.	Section 7.5.2.3.5
FC 108	It is not clear why some have ticks for an Action Plan (AP) plan required and others don't. If they are identified as conservation concern, then logically all might need an AP. There is no AP currently adopted by FIG solely for dolphins, and the globally Endangered sei whale should certainly be a priority species requiring an AP. APs in the past have been for all cetacean species grouped together, and currently none are valid beyond 2018.	Comment for FIG in terms of the status of Species Action Plans identified in the 2008 State of the Environment report. Navitas can update the table with the most recent cetacean action plan.	Section 7.4.6.3.1.7
FC 109	"While a range of taxa may be impacted by an oil spill, the assessment was predominantly based upon colonial seabirds for which census data are available." This seems inadequate with regard to sei whales and southern right whales for which extensive data are now available and which are species of global and regional conservation concern respectively. The potential impacts of oil spills (in all areas but especially in coastal high-use habitats) on baleen whales is not appropriately considered in this EIS.	Navitas would contest that there is extensive data available. Metadata, such as that on the data portal, is information about data and does not contain raw data in a usable format. The baseline was constructed on published papers and data collected *via* research commissioned by Navitas. Please note: Navitas invited the respondent to a dedicated scoping consultation session (see emails on November 17th	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		and 27th 2023) and specifically asked for any data that may be considered relevant to the EIA process. The invitation to participate in scoping was declined. Please note: only MGO will be used inshore by project vessels and project activities are small in scale and duration when considered alongside all other existing activity within Berkeley Sound.	
FC 110	Cumulative impacts are very difficult to measure and are likely to be complex. It should be acknowledged that Berkeley Sound is already an intermittently busy (with vessel traffic) and noisy environment for baleen whales, and that additional noise and traffic would need to be interpreted in a cumulative and additive context with that already present. Chapter 13 essentially consists of 2 pages in which both seabirds and marine mammals are evidenced as having the highest potential exposure to cumulative impacts but are not considered further.	Cumulative impacts are challenging to appropriately assess - following suggestion from SAMS, Navitas has qualitatively colour-coded the cumulative impacts to help present the impacts and risks, whist acknowledging this is a difficult thing to assess accurately.	Chapter 13
FC 111	In the list of 'environmental aspects' for the routes that activities might interact with the environment, no mention was made about the placement of objects in the water column – such as mooring lines, ropes, chains etc. Yet these have the potential to entangle whales. This risk has not been identified in this risk assessment.	The lines that will be placed in the water for the Sea Lion project include flowlines, risers and anchor chains. All of these are substantial and solid pieces of equipment, which Navitas believe pose a very low risk of entanglement to marine mammals. However, it is recognised that whale entanglement in anchor chains does occur, so a Whale Entanglement Management Plan will be put in place. Further detail on entanglement will be included in section 10.11.	Entanglement risk has been added to all NTS summary tables, the ENVIID output tables and Section 10.11.2.2
FC 112	Under 'large dropped objects', marine mammals have not been identified as a potential receptor. It should be noted that in other sensitive areas (e.g., the Beatrice field in the Moray Firth) then MMOs and PAM have been used during anchor-handling operations to limit impacts on cetaceans. As unlikely a risk as this might seem, it is acknowledged elsewhere and cetaceans were present in the pre-watches around the Beatrice anchor-handling tugs. Consequently, this risk could be recognised here, especially when	Suction Anchors will be lowered in a controlled manner from a dedicated Offshore Construction Vessel (OCV) as will the MODU's pre-layed moorings (which will be paid out by the AHTS.) Both operations are standard offshore practice. MMOs will be aboard the vessels and shall monitor the area prior to the operation commencing. The highly unlikely risk is	Table 9.1 Section 10.1.4.2.3

Ref.	Representation	Navitas response	Changes in Rev 4
	Endangered species (sei and blue whales) might occur in the offshore oil field. It could be mitigated simply by having a dedicated crew member on the tug look for whales before deploying any large mooring anchors (or other large objects). Although that would not help if performed during the dark. Chemicals and drill cuttings and oil spills offshore – Section 10.6 and 10.7. If these affect plankton, fish and squid, then they should be considered to affect the species that predate those prey groups. Artificial lighting offshore – Marine mammals are flagged here as requiring further assessment in relation to artificial light, but then no assessment is provided in Section 10.1 beyond two sentences on P597 and one sentence in P607. It is not clear if that is the extent of the assessment.	therefore mitigated to as low as reasonably practical. The assessment results in 'Low' and 'Very low' impacts to plankton, fish and squid from chemicals, drill cuttings and oil spills offshore. As the impacts are Low/Very low, impacts up the food chain are not considered further. Additionally, the area impacted is very small relative to the whole foraging area of species up the food chain. This is a typo, marine mammals will be removed from the table in Section 9.1.	
FC 113	Inshore physical presence is relevant to whales too – it excludes them from that area. The LTVs are around 160 m long (P172) which is large, and there will be two of them at a time. It's probably a relatively small effect alone, but in the context of all the other traffic already using Berkeley Sound then it should be acknowledged, especially if the LTVs anchor in a preferred whale foraging hotspot within Berkeley Sound. Artificial Light is considered to require further assessment for marine mammals in Offshore but is not flagged here for Inshore. Even though on P592 Inshore is flagged. The potential for attracting marine mammals may be higher inshore because of the specific case of foraging sei whales inside Berkeley Sound. If Munida is attracted to light (P596) and that sei whales use Berkeley Sound as a foraging area with Munida as a key prey species (Buss *et al.,* 2019; Jackson *et al.,* 2022 in Weir, 2022), then it should be considered likely that sei whales may also be indirectly attracted to vessel lights in Berkeley Sound at night. Thus inadvertently increasing their potential exposure to noise (briefly acknowledged on P607) and vessel strike. This	Navitas calculate that the LTVs physical presence in Berkeley Sound will take up 0.004% of the area available, which Navitas does not consider to be significant. The literature will be reviewed and Section 10.1 will be updated as necessary. Of note: marine mammal occurrence will be monitored and recorded by SMMO's as stated in the EMMP.	Section 10.1.4.2.3

Ref.	Representation	Navitas response	Changes in Rev 4
	likelihood isn't highlighted anywhere in the EIS with specificity to the clear case of the sei whale–Munida situation within Berkeley Sound.		
FC 114	There is no mention of Underwater Noise or Vessel Collision associated with the FIPASS/TDF facility, even though the Table considers physical presence of vessels at those facilities and there is acceptance that vessel traffic within the port will increase in association with OGP operations. Commerson's dolphins (and pinnipeds) are very common around FIPASS and the TDF, and there is already a documented instance of a launch striking and killing a Commerson's dolphin while coming alongside at FIPASS (S. Cartwright, pers. comm). The FI Code of Conduct for Cetaceans (adopted by FIG) highlights vessel manoeuvres within ports as a clear risk for dolphin strikes. It is not clear why increase in noise and vessel strike has not been included as a risk for marine mammals here.	Noted, this will be included.	Table 9.3
FC 115	"The current schedule expects that, during Stage 1, a maximum of two LTVs will be present in Berkeley Sound for only eight months (c. August-2022 to end March-2023), which supports the target of avoiding competition for sea room during the peak fishing period" These dates have expired, and so it isn't clear what months/years the LTVs are expected to be present as part of Stage 1 now. No indicative dates are provided here for Stage 2. The stated priority for planning is to avoid the peak fishing period (P591), even though the spatial overlap with the anchoring areas used by other vessels in Berkeley Sound is minimal (Fig 11-6, P930) and March is one of the busiest months for vessel traffic in Berkeley Sound (Figure 7-118). The single best approach with regard to mitigating potential impacts on baleen whales in Berkeley Sound would be to avoid them in time (since there is clear overlap in space). The documented seasonal peaks for whales in Berkeley Sound includes Feb–Apr for sei whales and Jun–Aug for SRWs. There hasn't been any consideration presented in the EIS for timing operations around those periods to minimise impacts on two important KES species.	The dates (months and year) noted here were included in error. Timings for periods of LTV operations are not yet fixed and consideration will be given to avoiding peak periods, but operational flexibility is required. The vessel traffic associated with the LTV operation represents a very small increase on the general vessel traffic in Berkeley Sound.	Section 5.5.1
FC 116	Not clear why lighting at the TDF/FIPASS included here, when vessels used throughout the operation will visit those port facilities. Presumably lighting	**Initial consultation response:** Noted. The TDF/FIPASS will be added to the list of receptors in Section 10.1.3 [This was the consultation response].	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	at those sites (at least at the TDR) will be expected to increase significantly in association with vessel visits and onshore safety requirements.	**Post-consultation comment:** Upon further review, Navitas determined not to add these to the list of receptors as Section 10.1 assesses the impacts of light to wildlife and all ecological receptors are listed as being offshore and inshore, therefore inherently including individual sites such as the TDF etc. Human populations living near sources of light onshore are included and assessed in Section 11.8.	
FC 117	"However, despite the growing volume of research this remains an area with many uncertainties, largely due to the difficulties of observing and measuring the impact of noise on animals in the marine environment." This is correct. Yet on P1235 the EMMP indicates that 'any adverse noise-related behaviour of marine mammals' will be investigated. No information is provided on how that will be achieved in practice, given that the limitations of doing so are highlighted here on P650. See below comment for text on P1235 too.	Agreed, this is a challenge. Underwater noise measurements will be undertaken during construction (see section 15.6.2) and SMMOs will be on board vessels to observe behaviour.	N/A
FC 118	TTS is also an injury to a marine mammal. From Nowacek *et al.* (2007): "Both PTS and TTS represent actual changes in the ability of an animal to hear, usually at a particular frequency, whereby it is less sensitive at one or more frequencies as a result of exposure to sound." I.e., TTS can still compromise a cetacean's ability to navigate and find prey, so it should be included here as a potential injury. Same comment for Table 10.18 with regard to defining 'injury threshold.' "it is an offence to intentionally or deliberately disturb any marine mammal in a way which is likely to…Impair its ability to…Survive, reproduce or rear / nurture their young, and / or Migrate… [or] Significantly affect the local distribution or abundance of the species to which it belongs" With regard to noise impacts within Berkeley Sound, it will be difficult to demonstrate that noise impacts from the vessels are not affecting reproductive behaviour	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also FIFD 54.	Section 10.4 Table 10.27 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	(singing activity) by both whale species, potentially affecting the feeding ability of sei whales, and potentially affecting local distribution by displacing whales from important habitats. Especially considering the cumulative impacts of the LTVs anchoring in a different area to all the other vessels within BS, thus causing cumulative disturbance over a wider area.		
FC 119	"In general, sound from drilling has been found to be predominantly low frequency (<1,000 Hz) with relatively low source levels. This appears to be a somewhat best-case and old (1987) example – 'in general' would imply the need for multiple examples to support the statement. There must be more recent studies published on sound levels produced by underwater drilling? A study by Greene (1987) quoted in Genesis (2016) found that the sound generated by drilling activities from a semi-submersible did not exceed local ambient levels beyond 1 km". Kyhn *et al.* (2014) report a drillship working in similar water depths to Sea Lion producing source levels of up to 190 dB re 1 µPa (rms) during maintenance and 184 dB re 1 µPa (rms) during drilling, with noise above ambient levels to a 38 km radius around the source. This section simply does not provide enough detail on the source and sound levels relevant to this specific project in order to assess likely impacts on marine mammals.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation. See also FIFD 54.	Section 10.4 Section 10.5
FC 120	"Recoverable injury, refers to injuries, including hair cell damage, minor internal or external bleeding. None of these injuries are likely to cause direct mortality" No, but this is a little disingenuous because a deaf cetacean (at least odontocetes) cannot catch food or navigate, so indirect mortality is a possibility if TTS extends over days/weeks. This could be more objectively presented.	Noted, this will be considered as the underwater noise sections are revised. See also FIFD 54.	Section 10.4.4.5.3.2 Table 10.27
FC 121	This is the first mention of 'received noise levels' which is not defined in Table on P654. Received sound levels is a fundamental concept in discussing impacts of noise on marine mammals and should be properly defined. "Note however, that the audiograms for most marine species remain	This will be added to the definitions. Text will be added regarding the baleen whales.	Section 10.4.4.3 Table 10.18

Ref.	Representation	Navitas response	Changes in Rev 4
	unknown and those that have been published are often derived from a few individuals under artificial conditions." While it is good that this important caveat has been mentioned, more needs to be said. In particular, in the context of baleen whale sensitivities at the NBF.		
FC 122	The cetacean groups represented here comprise three odontocetes and one baleen whale. So, two cetacean hearing groups. It would be relevant to also include audiograms of beaked whales (as a marine mammal group found in the NFB and with particular sensitivities to human noise) and of NBHF species (audiograms are available for harbour porpoises for example, as a proxy for Peale's/hourglass). Erbe 2002 given in this Figure is not cited in the EIS reference list. Assuming it is this one (https://cradpdf.drdc-rddc.gc.ca/PDFS/unc09/p519661.pdf), it should be noted that this is not a measured audiogram for the humpback whale – it is a predicted one by Houser *et al.* (2001). Another important point is that some other baleen whale species (including blue, fin and SRWs – all found in the NBHF) may be more specialised for the use of very low frequencies than the humpback whale (see P134 of Southall *et al.,* 2019), and consequently the example of the humpback whale provided in Fig 1-11 may not adequately reflect the sensitivities of those species. It would be better to use Fig 9/10 from Southall *et al.* (2019) as the best available information on hearing sensitivity in the baleen whale group. No audiograms have been measured for baleen whale species and this is a significant and widely-acknowledged data gap in understanding and modelling noise impacts on baleen whale species (see P134 of Southall *et al.,* 2019 for example). This should be mentioned at the bottom of P662 when discussing baleen whales too. It would be appropriate to label the audiograms in this Figure according to whether they are measured or estimated, to give a better indication of uncertainty. Given that baleen whale sensitivities in the NFB may be high (singing	Noted. This will be amended.	Section 10.4.4.3 Figure 10-11

Ref.	Representation	Navitas response	Changes in Rev 4
	behaviour, conservation status etc), the data available on other baleen whale species should be included here, albeit estimated/modelled. This includes right whales, which is relevant to the NFB. See references on P130 of Southall *et al.* (2019).		
FC 123	"The auditory range of species can only be determined through field observations, which are extremely difficult for free-ranging animals in the marine environment". It can be determined through field experiments but also by experiments in captivity (for porpoises, dolphins and pinnipeds). It is not possible to 'observe' an auditory range.	Noted, experiments in captivity will be added as examples as the underwater noise sections are revised. See also FIFD 54.	Section 10.4.4.4.5.1
FC 124	Blue whale should be added. Beaked whales (as a group) should be added too – its not just bottlenose whales found in the NFB but also Mesoplodon species etc, which are of concern with regard to noise impacts (recognised in Table 10.23).	Noted, this will be amended where appropriate.	Section 10.4.4.4.5 Table 10.21
FC 125	"For cetaceans, published TTS data are limited to the bottlenose dolphin and beluga whale" Incorrect, Southall *et al.* (2019) state two additional NBHF species (i.e., porpoises) which should be included here as proxies for NBHF species found in the NFB (e.g., hourglass dolphins).	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. FIFD 54.	Section 10.4 Section 10.5
FC 126	The disturbance thresholds presented in Southall *et al.* (2019) weren't evident.	These are noted in section 10.4.4.3.4.5. Please note the noise chapters are being revised and updated, see FIFD 54.	Section 10.4 Section 10.5
FC 127	"This is a realistic snapshot of the proposed project, but this could be exceeded at times if a second installation vessel or supply vessel is present" Does two installation vessels mean two simultaneous drilling operations? If so then the cumulative noise impacts for this scenario should also be modelled as a precautionary approach?	An installation vessel refers to a ship which is involved in the construction of the field, there will only be one drilling operation at any one time.	N/A
FC 128	"The sound source levels for the Phase 1 & 2 activities were estimated using published data as shown in Figure 10-12 and described in Table 10.26." The drilling operation is not actually shown in Figure 10-12 or in Table 10.26?	This section is being revised to include drilling noise in the model. See FIFD 54.	Section 10.4 Section 10.5 Section 15.6.2.1.3

Ref.	Representation	Navitas response	Changes in Rev 4
	"The anchored drilling rig when operating has a low noise output, typically some 30 dB lower than the other marine sources present (vessels on dynamic positioning or using propulsion frequently) (DECC, 2011) and will not contribute significantly to noise in the presence of the other vessels noted." It is not clear where is this information presented in the EIS along with the Genesis (2016) report. Relevant information should be provided in the EIS if the report is not public. It would be beneficial for calibrated sound measurements to be made in the field during drilling to verify this information.	Monitoring of noise offshore will be done, see section 15.6.2.1.1, which will be used to verify this information.	
FC 129	"Although there are sightings from various surveys and recordings from an acoustic monitoring study, there are currently no population estimates for any cetacean species in Falkland Islands waters. However, the available data do not indicate that the area surrounding the Sea Lion Field is home to resident populations of marine mammals or is a feeding area of overriding importance for any species." As discussed earlier, the sightings surveys are very out of date and the acoustic monitoring report presents only 5% of available data and missed singing sei whales. The "available data" are therefore inappropriate for determining the importance of the Sea Lion field for cetaceans. Independent baseline surveys should be carried out prior to making statements such as this. "Given the lack of population estimates, the proportion of the available habitat within the area of disturbance and avoidance / displacement could be used as a proxy to assess the potential impact on marine mammals. However, the habitat is not uniform throughout Falkland Islands waters and the available information indicates that many species show clear distribution patterns (Section 7.4.6.2)." These sentences lack clarity. The Sea Lion field is on the upper continental slope, an area where water depths increase – slope habitats are usually associated with upwelling, currents and topography that make them some of the most important for marine mammals globally. Indeed, an IMMA is located just north-west of the Sea Lion field. It is likely	The comment on 5% is misleading: Five percent of the AMAR data from each recorder were analysed manually by two trained analysts visually examining spectrograms and listening to audio playbacks. For Phase 1, the first 90 seconds of each 30 minute file per AMAR each day were sampled for manual analysis. For Phase 2, the middle 45 seconds of each 13 minute 45 second file was analysed. For Phase 3, the middle 45 seconds of each 12 minute file was analysed. The analysts annotated one call per species per sample for all files and AMARs to record each species in the dataset. This is a considerable amount of work. Navitas believes it has taken a precautionary approach. Also note that SMMOs will be deployed on vessels for three years pre-First-Oil and will collect data on marine mammals in the area.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	that beaked whales and some other species such as sperm whales use those slope habitats year-round, and a precautionary approach (in the absence of the necessary field research data) would consider that likely. Thus we may expect behavioural disturbance in a ~20 km radius of the field. The importance of this simply cannot be ascertained, considering the absence of targeted cetacean field studies in that area and information on exact species present, their site fidelity etc (especially with regard to beaked and sperm whales, which often exhibit quite high fidelity to regions of slope).		
FC 130	"This is not, as yet, an established part of marine vessel hire, but may form part of future environmental considerations." As part of the contracting process these mitigations could clearly be requested/implemented in order to minimise noise. Same comment for the relevant text on P680. "At present, it is not clear whether vessels operating offshore will be equipped with fixed or variable pitch propellors." As above along with same comment for the relevant text on P680. "Although speed restrictions are not proposed offshore, vessels operating in the vicinity of the Sea Lion Field are likely to be operating at low speed" With regard to sperm whales and other sensitive species, speed vessels should be considered offshore as part of collision risk mitigation. Especially at night.	All of the offshore support vessels, the FPSO and the MODU (if a DP MODU selected) will have variable pitch propellors. This will be clarified in the post-consultation EIS.	Section 10.4.5.1
FC 131	In the absence of information on the noise of the drilling being provided in the EIS, best practice mitigation could be used to check that no marine mammals are close to the source prior to its use. E.g., JNCC Guidelines, requiring a visual/acoustic monitoring period before the drilling commences. This would increase confidence that injury would not occur due to animals present close to the source prior to its initiation.	The JNCC guidelines are more for impulsive noise such as pile driving, or wells using Vertical Seismic Profiling, rather than drilling noise. It is not felt that SMMOs would be an appropriate mitigation here as drilling noise is constant rather than intermittent and impulsive.	N/A
FC 132	"It is assumed that animals would move away from the source of noise before being subject to a sound exposure level that would cause injury and therefore the impact of vessel noise is assessed as disturbance (below) rather than the potential for injury." This assumption is one often debated! For example, humans regularly undertake activities known to be dangerous,	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and	Section 10.4.4.5.3.2 Section 10.5.4.4.3.2

Ref.	Representation	Navitas response	Changes in Rev 4
	including exposure to injurious sound levels (e.g., at concerts). It is recognised elsewhere in this EIS that whales might not move away from areas where their food is concentrated (for example) even if noise is high. On that basis it would be more precautionary to also consider vessel noise in the context of potential for injury.	with consideration for the comments received. See FIFD 54.	
FC 133	"Although it is unlikely that the area under the influence of vessel noise around the Development site supports resident populations of cetaceans" We simply cannot determine if this is correct based on the paucity of targeted cetacean surveys in the NFB (and total lack of surveys that might determine residency, such as satellite tracking or photo-identification at the Sea Lion field). In terms of likelihood, objectively one could expect beaked whale or sperm whales in particular to be resident to that region of slope, based on what we know of them elsewhere. But it is unknown and this statement is unsubstantiated. A precautionary approach would assume that resident populations might be present, and work to assess that risk.	**Initial consultation response:** Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See FIFD 54. **Post-consultation comment:** The underwater noise modelling was reworked using a more recent model. The conclusions are that injury to marine mammals is not considered to be a credible possibility. Two situations were considered both inshore and offshore: a) marine mammals remaining stationary in the presence of the introduced noise, and b) the case where they flee in response to the noise. For the stationary marine mammal situation, only the VHF cetaceans (for Scenarios 1 and 3) are predicted to exceed the cumulative SEL TTS threshold. However, this would only occur if the animal remained stationary for 24 hours within (worst-case) a 0.2 km^2 area of the sound source. For all other marine mammal hearing groups (LF and HF cetaceans, and PW and OW pinnipeds), the cumulative SEL thresholds for PTS and TTS were not	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
		predicted to be exceeded over 24 hours in Scenarios 1, 2 or 3. If marine mammals are assumed to flee from the noise source then marine mammal PTS and TTS thresholds will not be exceeded for any marine mammal hearing group, in any offshore scenario, provided that they swim away at a speed of at least 1.5 m/s from the vessel location. Please see the revised noise chapters for further information.	
FC 134	"In terms of species sensitivity, the low-frequency cetaceans, such as fin and sei whales (both in the LF (7 – 3,500 Hz) hearing group), are considered the most sensitive receptors." SRWs should be added here, for reasons already explained.	Noted, this will be added. Please note the noise chapters are being revised and updated, see FIFD 54.	Section 10.5.4.3
FC 135	"However, if the source was located in an area that was regarded as an important feeding or breeding ground (not believed to be the case here) the impact would be more significant" There is no data to determine that this is not the case. Or that it is the case! The data needed to support this statement simply don't exist. But what data do exist suggest is that this topic needs more attention – for example, the presence of sei whale song at the Sea Lion field in the Hipsey *et al.* (2013) report (see Cerchio and Weir, 2022) indicate that the region may be more sensitive than is being portrayed here. This is just one example, but the true importance of that area for marine mammals has not been properly investigated – another reason why baseline targeted marine mammal surveys at the site should have been undertaken.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See FIFD 54.	Section 10.4
FC 136	A major omission here is the total lack of measured hearing range data for baleen whale species. Yet it is not mentioned? In contrast, Southall *et al.* (2019) repeatedly mention this, along with many other caveats in the extrapolations of TTS and PTS thresholds to LF species. These inherent uncertainties need to be highlighted. "With regard to the uncertainty over marine mammal distribution, previous observational and acoustic surveys give a reasonable indication of the	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See FIFD 54.	Section 10.4 Table 10.21 Section 10.5 Section 15.6.2.1.3

Ref.	Representation	Navitas response	Changes in Rev 4
	species present but further surveys would help to determine the inter-annual variation in marine mammal abundance in the area and help to resolve the status of rare species" Actually, with regard to understanding the impacts of noise on cetaceans, one of the key relevant data gaps is the residency/site fidelity of cetacean individuals/populations in the NFB, and thus their exposure time? Potentially the acoustic data could inform on that for sperm whales (for the population as a whole). But otherwise, that kind of data requires telemetry or photo-identification datasets rather than SMMOs or other visual approaches. Same comment in Section 10.4.10.1. A programme of real-time calibrated sound measurements during drilling/production/decommissioning etc would help to validate the modelling results of this EIS.	Also see section 15.6.2.1.1: noise monitoring will be undertaken at the field of day-to-day operational noise and during various vessel scenarios.	
FC 137	The introduction focuses on the anchored LTVs but there will be additional vessel traffic introduced to the Berkeley Sound and Port William areas in relation to the offshore operations which should be considered too such as launches.	There will be minimal vessels attending the LTVs once they are moored in Berkeley Sound but text will be added to describe this.	Section 5.5.1 Section 11.2.2.2
FC 138	As indicated earlier in these comments, the information provided for sei whales and southern right whales in Berkeley Sound in 7.4.6.3 is outdated, non-inclusive and does not take into account the wealth of information that has been collected during 8 years of targeted whale research. In particular, it fails to recognise that: o Endangered sei whales use Berkeley Sound as a foraging ground, with individuals remaining for several weeks continuously and returning in different years; o Southern right whale aggregations utilise Berkeley Sound for breeding and socialising between mid-May and early September; o Berkeley Sound is the only location in the world where sei whale singing (indicative of reproductive activity) has been documented to occur (Cerchio and Weir, 2022); o There is already evidence for acoustic disturbance of SRWs from vessel noise inside Berkeley Sound (Cerchio *et al.,* 2022 in Weir, 2022);	Noted, Section 7.4.6.3 will be updated accordingly.	Section 7.4.6

Ref.	Representation	Navitas response	Changes in Rev 4
	o Berkeley Sound is included as a KBA for sei whales and as IMMAs for sei whales and southern right whales. • The available data need to be thoroughly represented in Section 7.4.6.3 if that section is then going to be referred to here as the basis for understanding the 'receptors' for noise assessment.		
FC 139	Cerchio *et al.* (2022, in Weir, 2022) provide some actual measurements of vessel noise inside Berkeley Sound and in relation to some specific vessel types (although it wasn't known how far away the vessels were from the hydrophone at the time). This information is relevant to include here. They also show a decrease in SRW calls in relation to the increase in noise, which is certainly relevant to the EIS because SRWs use Berkeley Sound to breed requiring that their contact calls (upsweeps) and song (gunshots) can be heard. "Greatest sound levels occur at low frequencies typically between 10 – 300 Hz with broadband sounds predominantly below 150 Hz and in some cases below 40 Hz (Ross, 1993; McKenna *et al.,* 2012)" Its widely documented that vessel noise swamps all of the low frequencies that baleen whales use (primarily <1000 Hz) and is loud across that range. An example of this over the 0–1000 Hz range can clearly be seen in the spectrograms in Cerchio *et al.* (2002).	Noted. This will be amended. Please note the noise chapters are being revised and updated, see FIFD 54.	Section 10.5.4.4.1
FC 140	Interesting. Cerchio *et al.* (2022, in Weir, 2022) recorded actual received sound levels at a hydrophone inside Berkeley Sound peak of 130 dB RMS re: 1µPa in relation to either a reefer or a tanker and without knowing how far away from the hydrophone the vessel was. This, and lower, were sufficient to apparently impact on SRW vocal behaviour within the Sound.	Thank you for this information. Please note the noise chapters are being revised and updated, see FIFD 54.	Section 10.5.4.4.1
FC 141	These figures don't seem to represent the actual anchoring locations shown in Figure 5-5. It would be more useful to show the sound levels around the LTS at the actual mooring locations proposed rather than in the middle of the Sound? Does the 120 dB zone then extend to the south coast? This is relevant to understanding impacts on SRWs in particular, which often travel along the coasts quite close to shore.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and	Section 10.5 Section 10.5.9

Ref.	Representation	Navitas response	Changes in Rev 4
	"As can be seen from Scenario 3 below, these noise levels are within those already experienced in Berkeley Sound." While that may be true, Figure 11-6 shows quite clearly that large portions of inner Berkeley Sound are already heavily used by anchored vessels which cumulatively probably produce noise levels that exceed the disturbance threshold (appreciating that a high-use year was shown in the Figure, but a similar pattern will be evident in other years too). The LTVs will be anchored further east, thus extending this noisy area across even more of Berkeley Sound and introducing noise into a currently less noisy area. As can be seen from the acoustic results in Cerchio *et al.* (2022, in Weir 2022), sei whale vocal behaviour is highest at the mouth of Berkeley Sound, medium in the central area and lowest in the innermost Berkeley Sound. This perhaps represents responses to vessel anchoring or differences in how the lobster krill are distributed, but either way then adding LTVs to that part of Berkeley Sound is not an impact that should be considered alone but rather cumulatively with all the other noise. Especially as this section clearly indicates that noise levels sufficient to exceed the disturbance threshold extend in a 0.5 km radius around the anchorage. There will be two LTVs, leading to a 2 km area of noise that exceeds the stated disturbance threshold in addition to all the existing noise from other vessels further west. Since foraging and breeding are key life cycle activities for the two LF-sensitive whale species then these noise levels have the potential to impact their behaviour inside Berkeley Sound in tandem with the noise already there, and this should be fully acknowledged.	with consideration for the comments received. See FIFD 54.	
FC 142	"An example, based on the worst-case scenario (Scenario 1), of received SEL(cum) for marine mammals and fish moving away from the sound source at 1 m/s over a 14 hour period is presented in Figure 10-22" A more realistic 'worst-case' scenario modelling exercise might be a sei whale that remains inside Berkeley Sound for several weeks continuously and doesn't move away at all, as has been shown by satellite tracking data (links to tracking data are in Annex 1). It would be desirable to see this modelled and presented in the EIS for transparency. Another very plausible worst-case	**Initial consultation response:** Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See also, FIFD 54	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	scenario that should be investigated would be that whales are already feeding west of the mooring area when the LTV arrives, and so they cannot move out to sea for 14 hr in response to the sound levels but rather, given the semi-enclosed nature of Berkeley Sound, would actually have to travel towards it first (increasing their exposure) before they can get past and move away. The fact that whale calls from the same animals were heard simultaneously on FC hydrophones (placed 7 km apart) indicates that LF noise within Berkeley Sound does carry over considerable distance despite the properties of inshore coastal environments. This scenario should also be modelled with regard to SEL(cum), as it is something highly likely to happen in practice.	**Post-consultation comment:** The underwater noise modelling has been reworked using a more recent model. Noise modelling undertaken indicates that the displacement thresholds are not exceeded in Scenarios 1 or 2. However, the lower disturbance threshold is exceeded such that marine mammals of all hearing groups may exhibit altered behaviour within an area of 2 km^2 around the vessels. Noise generated by the transiting vessels could lead to disturbance *via* reduced communication and reduced feeding, swim speeds and dive intervals. Berkeley Sound is known to be a feeding site for sei whales and other marine mammals. Importantly however, noise from transiting vessels will be intermittent, of very short duration and the affected area accounts for only 1.1 % of the available area in Berkeley Sound. Once the vessels have stopped, noise levels will reduce to background levels. In consequence, any additional disturbance impacts will quickly return to existing background levels. Navitas calculate that the LTVs physical presence in Berkeley Sound will take up 0.004 % of the area available, which Navitas does not consider to be significant and as such believe there is sufficient space for whales to move from the inner to outer sound without impact.	
FC 143	The legend says a 14-hr period but the x-axis only goes to 1000 m. Over 14 hr a sei whale could be 50 km away. This figure legend needs a bit of clarification as it appears to relate to distance rather than time.	Noted this will be reviewed and amended.	Figure 10-22
FC 144	See comment above. These are not the realistic worst-case scenarios for whales, and this section should be revised accordingly.	**Initial consultation response:** Noted, the underwater noise modelling is currently being re-run to more	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
		accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See FIFD 54. **Post-consultation comment:** Please also see response to FC 142 above	
FC 145	Same comment here as provided above to Figures 10-19 and 10-20 (P690-691). The concern is the cumulative impact and the location of the LTVs in a more sensitive part of Berkeley Sound for sei whales. Presumably Table 10.34 is for one LTV (the figure legend should be amended. to make this clear). It would be relevant to have data added to this Table to show the realistic scenario of two LTVs at the same time – what is the cumulative area disturbance impact.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See FIFD 54.	Section 10.5.9
FC 146	"This is similar in extent to the current level of disturbance, (estimated to be 594 m for a mid-size tanker), caused by existing shipping in the area" It's actually 65% higher.	Noted, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation and with consideration for the comments received. See FIFD 54.	Section 10.5.9
FC 147	"Importantly however, noise from transiting vessels will be intermittent and very short duration (Section 10.5.2) and once the vessels have stopped, noise levels will reduce to background levels such that any additional disturbance impacts will quickly return to existing background levels." Here, and throughout this Section of the EIS, the noise introduced into Berkeley Sound by the LTVs has been repeatedly justified using the fact that other vessels in Berkeley Sound are also noisy. There is little acknowledgement that this is two more noisy vessels in an area of Berkeley Sound that other vessels haven't been using much (but whales do). Stating that the LTV noise levels are similar to other vessels misses the point that the introduction of	When at anchor and not offloading their cargo, the LTVs will maintain one generator to keep the ship's facilities running but otherwise they will be on the anchor, weather vaning, minimising the noise they produce. When offloading they will be fully powered to enable safe operations etc. This will be acknowledged in the revised underwater noise section. Please also see FIFD 54.	Section 10.5.2.1

Ref.	Representation	Navitas response	Changes in Rev 4
	the one or two LTVs is cumulative – its additional noise, it lasts continuously for consecutive months, and it extends the existing area of noise in Berkeley Sound over an increased area. There isn't a lot that can be done to mitigate that, but not to fully acknowledge it when Berkeley Sound is a high-use habitat for two acoustically sensitive whales that have both been regularly recorded singing and calling in the area seems inappropriate. And also the fact that the LTVs will (presumably) also be present in months that have historically been quieter with regard to vessels within Berkeley Sound such as the winter months when SRWs sing and call within the Sound as part of their mating behaviour. The final sentence in 10.5.9. is the only real acknowledgement of the bigger picture in this whole section, but is not expanded upon regarding the IMMA/KBA/acoustic data/behaviour for the two whale species that emphasise the importance of Berkeley Sound as habitat for them.		
FC 148	"The status of the potential receptors in Berkeley Sound is relatively well understood, although the influx of southern right whales in the winter of 2017 (Section 7.4.6.3.1.1) highlights that unusual years do occur and long-term trends can change" As per earlier comments, the importance of Berkeley Sound for whales has not been fully represented by Section 7. The influx of SRWs in 2017 was not unusual – it only appeared so in 2017, but has since been shown to be a predictable and repeated annual occurrence that is very well-documented by both FC research and the local community. "The inter-annual distribution and abundance of marine mammals are acknowledged as a data gap" This neglects seven seasons of whale work inside Berkeley Sound (every year since 2017 except 2018) which has also routinely recorded dolphins – the inter-annual distribution of cetaceans inside Berkeley Sound is better known than anywhere else in the Falklands and is very well-documented. That information wasn't represented in Section 7.	Noted, will amend text and update references accordingly.	Section 7.4.6 Section 10.5
FC 149	"Navitas will deploy hydrophones in the Sound to record marine mammal vocalisations for 1-2 years to establish the baseline." FC has already collected three years of acoustic data inside Berkeley Sound and published initial	Regarding the analysis of only 5% of one years acoustic data, please refer to FC 129.	Section 7.4.6 Section 15.6.2.1.3

Ref.	Representation	Navitas response	Changes in Rev 4
	results (Cerchio *et al.,* 2022, in Weir 2022; Cerchio and Weir 2022). The baseline is well documented but not represented in the EIS. Additionally, only 5% of the one year of acoustic data collected as a baseline at Sea Lion (Hipsey *et al.,* 2013) has been analysed and actually used to inform this EIS. This doesn't provide high confidence in an additional Berkeley Sound dataset being used to its full potential. "Marine Mammal Observers (MMOs) will be placed on the OCVs … a review of the MMO reports will be conducted after five years and used to improve knowledge of locations and behaviour of marine mammals." The data from MMOs on OCVs occasionally visiting Berkeley Sound will be used, but the 7 years of targeted research (including satellite-tracking, acoustics, photo-ID etc) inside Berkeley Sound is largely omitted from Section 7. "Two projects studying the inshore cetaceans of the Falklands, with a focus on Berkeley Sound, have recently concluded (Weir, 2020 and 2021)." The extensive work published in Weir (2022) would be the most relevant and substantial information on whales in Berkeley Sound available to date but has been omitted from this EIS.	The EMMP workshop determined that effects of underwater noise on marine mammals inshore 'were considered by the [EMMP] workshop to be now outside the scope of the EMMP' due to the elimination of inshore ship-to ship crude oil transfers from the development plan. Nonetheless, Chapter 10.5 is being revised (Please see also FIFD 54) and SMMOs will be deployed on vessels for three years pre-First-Oil. The suggested papers will be included in Section 7.4.6.	
FC 150	In 'Impacts on wildlife' pinnipeds are given as the only marine mammal example. It should be added that cetaceans are also vulnerable to entanglement in, and ingestion of, waste materials, including the whole range of species from small porpoises/dolphins to large baleen whales. From Weir and Prieto (In Press, available on request) – "From 2013 to 2020, three instances of live entangled sei whales were reported off the eastern USA seaboard, including one animal with plastic strapping around its rostrum … In cases where entanglements limit the mouth opening to feed, or are sufficiently severe to limit mobility, they are highly likely to cause mortality. Sei whale feeding methods are non-selective, and lunge-feeding in particular can result in the accidental ingestion of non-target items including plastics and other debris. Additionally, microplastics may occur within sei whale prey species, particularly when they are feeding coastally on shoaling fish (e.g.,	Noted. This will be amended.	Section 10.10.4.1.2.1

Ref.	Representation	Navitas response	Changes in Rev 4
	Scombridae, Clupeidae and Engraulidae) which have high potential for ingesting microplastics *via* their own prey (Burkhardt-Holm and N'Guyen 2019). Plastic ingestion may be an increasing threat, with plastic debris being recently identified in a sei whale faecal sample in Chile (Buchan *et al.,* 2021). Stranded sei whales have been found with plastic in their stomachs in the UK (Baulch and Perry 2014) and in the USA (Henry *et al.,* 2020), with the ingestion directly contributing to mortality in the latter case. Additionally, microplastics are readily trapped within baleen plates and where they are a fouling risk that prevents whales feeding efficiently (Werth *et al.,* 2019)." While this text refers specifically to sei whales, literature searches will reveal extensive documentation of cetaceans with plastic ingestion – offshore species including beaked whales and sperm whales also appear particularly prone to this.		
FC 151	"Most publication however focus in the larger whales. Schoeman *et al.* (2020) found that smaller animals are also affected and recommend the establishment of a species-specific necropsy protocol and a database for smaller species as well as the larger animals." This isn't correct there is a lot of information on smaller cetaceans too (a literature search reveals many papers). A key reference that should be included here would be Van Waerebeek *et al.* (2007) who completed a review of vessel collisions on small cetaceans worldwide, as well on baleen whales in the Southern Hemisphere. "Few vessels will visit other inshore waters e.g., Berkeley Sound" This is likely over-simplistic because no doubt there will at least be tankers, and likely regular launches attending the LTVs from Stanley for a variety of reasons (supplies, customs, maintenance, crew changes, medical visits etc) as do the other vessels in Berkeley Sound. For example, project use of launches hasn't been mentioned in this EIS.	Noted, this reference will be added. Vessel visits to the LTVs while they are in Berkeley Sound will be minimal. The LTVs will likely require one crew change, one bunkering top up and one resupply each during their time in Berkeley Sound meaning a couple of PSV trips for each LTV during their stay.	Section 1.8.4.2.6.1 Section 10.11.1 Section 10.11.3 Section 10.4.1.1 Section 15.6.2.1.3 Section 15.6.2.1.4
FC 152	While there isn't legislation, there are guidelines. A Code of Conduct for Cetaceans has existed in the Falkland Islands since 2020 and has been adopted by FIG. This should be included in the EIS.	Noted. This will be amended.	Section 10.11.1.1

Ref.	Representation	Navitas response	Changes in Rev 4
FC 153	"The receptors that may be subject to the risk of collision during the Phase 1 & 2 Development include a wide range of large cetacean species that are known to occur within Falkland Islands waters (Section 7.4.6). Small cetaceans (dolphins) are fast moving and agile enough to avoid vessels travelling at moderate speed and are likely to be at greater risk from small fast-moving craft rather than those associated with the Development…For these reasons, small cetaceans are not considered further in this assessment, which explores only the risk of collisions between Phase 1 & 2 vessels and large cetaceans (whales)." We strongly disagree with these sentiments. There is a large amount of published information worldwide showing small cetaceans being injured and/or killed by vessels, including very large vessels such as ferries. We would be happy to provide a list of applicable information on request. Small cetaceans are not agile enough to avoid vessels moving at moderate speed – this is a very misleading statement, and fails to account for the fact that calves or compromised animals may not be as responsive, or that much depends on the behaviour/responsiveness of individual animals and on what the platform is doing – erratic changes in direction or speed are especially an issue, given that dolphins in the Falklands are interested in propellers and often in close proximity to them. Indeed, as an example, a Commerson's dolphin was struck and killed by a launch coming alongside at FIPASS (see below), and we are also aware of an incident with Concordia Bay. Porpoises, dolphins and whales should all be included in a Vessel Collision assessment for the Falklands, especially since all of the offshore vessels will be coming into Stanley/Port William for crew changes and supplies and so it's not only offshore waters that need to be considered. Vessel strike was in fact identified in the draft cetacean Species Action Plan (SAP) by SAERI/DOKE as a likely threat to Commerson's dolphins. "Indeed, some species, such as Peale's dolphin (*Lagenorhynchus australis*), are attracted to large vessels to bow-ride. For these reasons, small cetaceans are not considered further." Most experts agree that this behaviour increases their risk, not eliminates it. See Van Waerebeek *et al.* (2007).	Noted, an assessment of vessel collisions with small marine mammals will be included in section 10.11.	Section 10.11.1

Ref.	Representation	Navitas response	Changes in Rev 4
FC 154	There is no "current Falkland Islands Species Action Plan for Cetaceans (FIG, 2008c)" - it expired in 2018. "…identifies a number of potential threats to cetaceans but does not regard ship-strike to be a problem in the Falklands." The 2008-2018 SAP expired and not including vessel strike was an oversight by those authors and does not reflect best available evidence. Any SAP proposed now would include vessel strike – see the draft SAP for all cetaceans by SAERI/DOKE, and the sei whale SAP that is currently in preparation by FC (to be completed before December 2024, but current draft available on request). "Indeed, there are no known records of collisions between vessels and cetaceans in the Falkland Islands." And similar on P864 and P867. This is incorrect and demonstrates a lack of familiarity with available information which includes: o A launch reporting a 'bang' as it made physical contact with a sei whale in 2017 in Berkeley Sound (Weir, 2017; draft cetacean SAP, SAERI); o A near-miss between Concordia Bay and a sei whale in Falkland Sound in 2017 (Weir, 2017; draft cetacean SAP, SAERI); o A 'bang' on the hull of Golden Fleece from an interaction with a sei whale on the west coast of the Falklands in 2018 (Weir, 2018; draft cetacean SAP, SAERI); o A Commerson's dolphin killed by a launch manoeuvring at FIPASS in the mid-1990s (S. Cartwright, pers.comm.; draft cetacean SAP, SAERI); o An anecdotal account of a Commerson's dolphin being fatally injured by Concordia Bay while manoeuvring at the jetty at Port Howard; o An anecdotal account of a launch hitting a right whale on the south coast of Berkeley Sound (no damage to the launch, no certainty on injury to the whale); and o Propeller wounds on the bodies of southern right whales photographed in the Falklands (available from FC), which could have occurred anywhere in the SW Atlantic but clearly demonstrate risk. In most of these cases, vessels were actually going slow <10 knots or	Noted. Reference to the Falkland Islands Species Action Plan for Cetaceans (FIG, 2008c) will be removed. Navitas would be grateful for sight of the FC draft of the SAP and will include these records in this section.	Section 7.4.6.3.1.7 Section 10.11.4.1

Ref.	Representation	Navitas response	Changes in Rev 4
	manoeuvring at the time of the incident. Regardless of the above evidence, it is clear from the published literature that all of the cetacean species occurring in coastal waters around the FI (and many of the offshore ones) have documented injuries or mortalities from vessel strikes (see Van Waerebeek *et al.,* 2007), and that local cetacean experts (Costa, Weir) that have worked in the FI understand the risk to be real for all species not just whales.		
FC 155	"Therefore, when assessing the impact and the likelihood of cetacean collisions it is important to consider…The known behaviour of different species which can make individuals of a particular species more likely to be involved in a collision". This has not happened in the EIS. There is little recognition that: (1) both coastal dolphin species are attracted to propellers and mill around boats while they are manoeuvring alongside at jetties; (2) sei whales are feeding in the Falklands during which they can become oblivious to boats; and (3) SRWs engaged in socialising and mating are largely oblivious to boats, and Eubalaena whales are anyway particularly vulnerable to vessel strike due to their buoyancy.	Noted, an assessment of vessel collisions with small marine mammals will be included in section 10.11.	Section 1.8.4.2.6.1 Section 10.11.1 Section 10.11.3 Section 10.4.1.1
FC 156	"The size of the southern right whale population that breeds off the Argentine coast is well studied and tripled since 1999 to 2006." The most relevant information is related to the Falklands to assess collision risk. Again, there is a failure to cite appropriate sources here (e.g., Weir and Stanworth, 2019). Once more, the misleading statement about the 2017 'influx' appears. The list is ambiguous. SRWs do not "tend toward a coastal distribution" – they occur in 5000 m water depth offshore in the Argentine Basin and all over the SW Atlantic (see many satellite telemetry papers). Their coastal occurrence is linked with wintering grounds, for the remainder of the year they are pelagic. A better representation of SRW vulnerability to collision would be: o Are particularly buoyant and slow moving, so can be slower to react to approaching vessels than many other whales; o Aggregate in nearshore waters around the Falklands coast during winter (but occur offshore year-round), where high densities overlap with vessel	Noted. This will be amended.	Section 10.11.4.3.1

Ref.	Representation	Navitas response	Changes in Rev 4
	traffic (especially Berkeley Sound and Port William); o When engaged in some behaviours (especially mating and socialising winter aggregations) can become oblivious to boats; Spend prolonged periods at, or near, the surface when engaged in social/breeding behaviour, or when resting between foraging dives.		
FC 157	"While the results of photo-identification are emerging (Weir, 2022) there is not sufficient survey data to determine an accurate population estimate, although there is anecdotal evidence that the number within Falklands' waters, and more generally within the south-west Atlantic, is increasing (Iñíguez *et al.,* 2010)." There is an abundance estimate published for sei whales in one part of the Falklands (Weir *et al.,* 2020), and also minimum population sizes (from photo-ID) provided for Berkeley Sound and other areas in published reports (Weir, 2017, 2018, 2022). These have been assessed in a global context (Weir, 2021) to support the fact that FI waters support a globally significant sei whale population. In lieu of all the targeted whale work carried out on sei whales in the Islands, a paper (Iñíguez et al) has been cited that refers to only 3 sightings in the FI between 2004 and 2008 as evidence that the species is increasing here. • "With regard to their behaviour, while there are records from around the world of collisions between sei whales and vessels (IWC database, 2014) they are considered to be at lower risk than most other large whale species (Vanderlaan and Taggart, 2007). This is primarily because they: Appear to respond to approaching vessels, Are relatively fast swimmers, and Tend to swim just below the surface leaving a clear trail of 'fluke prints' in their wake (Sea Watch Foundation, 2012). It should be noted that elsewhere in the world sei whales are considered to be an offshore species; however, in the Falklands this species is associated with relatively shallow inshore waters." We strongly disagree with most of these statements, which are outdated and relate to sei whales in other regions rather than in the Falklands. It should be realised that the work in the Falklands (and a couple of other geographic locations) is some of the first extensive field research carried out on sei whales anywhere globally, and lots of these misconceptions will be	Noted. This will be amended.	Section 10.11.4.3.2

Ref.	Representation	Navitas response	Changes in Rev 4
	rectified in the coming years. Reviews of sei whale collisions can be found in Prieto and Weir (2022) and Weir and Prieto (In Press, available on request). The fact that there are documented vessel strikes both globally and in the FI means that they don't always respond to vessels. While they can be fast swimmers, they can also be very slow. See Segre *et al.* (2021) for examples of slow skim-feeding in the FI. It is not clear what relevance the 'fluke prints' have, but they often appear at the surface 100s of metres away from where the animal actually is. There is little point in comparing sei whale behaviour in the North Atlantic and North Pacific (where many of these perceptions come from) with that in the FI, because sei whales in those areas generally use pelagic offshore habitats. Whereas sei whales in the FI also intensively use nearshore areas, where overlap with human activities is far higher. A better representation of sei whale vulnerability to collision would be: o Occur in high densities in nearshore waters during summer and autumn, including in Berkeley Sound; o Use nearshore waters as a foraging habitat, where their focus on feeding may make them less responsive to vessels; o Are especially vulnerable when surface skim- and lunge-feeding (Segre *et al.,* 2021) when they spend prolonged periods moving slowly near the surface; o Often behave unpredictably, making them difficult to spot and avoid by vessel crews.		
FC 158	"While there are limited data regarding cetacean distributions around the Falkland Islands, there is some very detailed information regarding shipping movements, although this has only been recorded since June 2014." Limited information offshore, but there is now a wealth of information in the nearshore waters…including in the shipping routes. See published literature.	Noted. This will be amended.	Section 10.11.4.4.2
FC 159	"With regard to the overlap in vessel activity and cetacean distribution, the distribution of right and sei whales in particular is not well understood (Section 10.11.4.3). However, the fact that both are sighted within the NFB, Berkeley Sound and near Stanley Harbour year-round suggests that these species have spatial and temporal patterns of distribution, which overlap	Noted. This will be amended.	Section 10.11.4.5

Ref.	Representation	Navitas response	Changes in Rev 4
	with shipping activity." Those are two species for which the distributions (at least coastally, but also some offshore data from telemetry) are actually particularly well understood. Their overlap with shipping is a fact, not a suggestion. See published literature.		
FC 160	This again overlooks support/supply vessels such as launches used during this project for moving supplies etc between Stanley Harbour and the LTVs.	Vessel visits to the LTVs while they are in Berkeley Sound will be minimal. The LTVs will likely require one crew change, one bunkering top up and one resupply each during their time in Berkeley Sound meaning a couple of PSV trips for each LTV during their stay.	N/A
FC 161	The existence of Falkland Islands-specific guidelines (adopted by FIG) since 2020 has been omitted here.	Noted, this will be added.	Section 10.4.1.1 Section 10.11.3 Section 15.6.2.1.3 Section 15.6.2.1.4
FC 162	"As part of Navitas' operating procedures, speed restrictions will be applied to vessels entering the boundary of the inshore proposed Marine Managed Area (pMMA); as vessels approach the inshore pMMA boundary line the maximum speed permitted will be ≤10 knots. Additionally, vessels generally will only transit the Sound during daylight hours, with daylight-only berthing and night-time departure by exception only." 10 knots is fine to reduce collision risk, but the EIS also refers to 8 knots in places e.g., P865. For clarity please can you confirm – is it ≤10 knots at the pMMA line but then further reduced to ≤8 knots in Berkeley Sound (defined as west of the Vol Pt-Mengeary Pt line). Ideally, it would be desirable to maintain speeds of ≤10 knots in Port William too between (at least) 1 June to the end of August in order to reduce the likelihood of injurious SRW strike (sei whales are uncommon inside Port William) – perhaps this is already covered in the areas above?	That is correct, vessels will reduce speed to 10 knots at the pMMA boundary, and then down to 8 knots in Berkeley Sound (west of the Volunteer point - Mengeary Pt line). Navitas will amend the text in the EIS to clarify that vessel speeds will also reduce to ≤10 knots within Port William.	Section 10.11.5 Section 10.11.7
FC 163	"With regard to the sensitivity of each receptor, southern right whales are considered to be susceptible due to their behaviour (Section 10.11.4.3.1)." Both species are susceptible due to their behaviour – surface feeding sei whales are just as susceptible as SRWs. •"This species is listed as 'Least Concern' by IUCN." Yes but the SW Atlantic	Noted. This will be amended.	Section 10.11.4.3.2 Section 10.11.6.1

Ref.	Representation	Navitas response	Changes in Rev 4
	population is of regional conservation concern (see earlier comments re. IWC-CMP). •"However, vessel speed will decrease and watch-keeper vigilance will be heightened as vessels approach land in response to the increased risks of navigating in coastal waters, which increases the likelihood of detecting and avoiding cetaceans" Even the most vigilant of watch-keepers cannot see at night. It should be noted that inshore SRW aggregations form in winter when daylight hours are the least and it will be too dark to detect whales visually for 16 hrs in each day. The reduction in vessel speed is the main thing. •This section omits any consideration of sperm whales. Sperm whales are regular in offshore waters of the FI, are an IUCN Vulnerable species, and are another species whose behaviour (long periods of logging at the surface between deep foraging dives) makes them particularly vulnerable to ship strike. See for example https://journal.iwc.int/index.php/jcrm/article/view/446		
FC 164	"In addition to the lookouts posted on the forecastle of the vessels as already referred to in Section 10.11.5" There is no mention of this in Section 10.11.5? Was it deleted? Is it still happening?	Lookouts are noted in 10.11.7, this will be re-worded and refer to the correct section.	Section 10.11.6.2
FC 165	It is not clear on what basis 'unlikely' has been determined for collisions in offshore waters. The data on offshore cetaceans don't exist to support that. And there has been no consideration of sperm whales, which were the most common species acoustically detected at the Sea Lion field suggesting they are relatively common there (acoustic findings in Hipsey *et al.,* 2013) and are also vulnerable to ship strike due to their behaviour? This should be amended. to 'Possible.' "The introduction of a 10 knot speed limit for the Falklands pMMA, in line with NOAA guidelines, is already considered as industry standard mitigation (Section 10.11.5)" Section 10.11.5 actually said that there wasn't any industry-standard mitigation?	Section 10.11.5 (Industry standard mitigation). states: 'As part of Navitas' operating procedures, speed restrictions will be applied to vessels entering the boundary of the inshore proposed Marine Managed Area (pMMA); as vessels approach the inshore pMMA boundary line the maximum speed permitted will be ≤10 knots.'. The initial impact assessment listed the likelihood of collision inshore as 'Possible'. However, Section 10.11.7 (Project-specific mitigation) states: 'To further reduce the risk of collisions in inshore waters, Navitas will limit vessel speeds to under 8 knots within Berkeley Sound.' In line with this the likelihood of occurrence is reduced to 'Unlikely'.	Section 10.11.5 Section 10.11.6.1

Ref.	Representation	Navitas response	Changes in Rev 4
		Further, 'Unlikely' has been applied as while whale strikes have occurred previously in the industry , there were none during previous exploration campaigns in the Falkland Islands in the same area. A number of controls would have to fail for this to occur (i.e., no watch keeping, not following speed restrictions etc.). Please refer to 10.11.6.1. Therefore, Navitas stand by the assessment. This section will be revised to include sperm whales.	
FC 166	"Additionally, during transit in Berkeley Sound, there will be two qualified Seabird and Marine Mammal Observers (SMMOs), most likely posted to the OSVs and they will advise the Ship's Master on the bridge of the need for evasive action. The OSVs are the most common vessels transiting Berkeley Sound to pick up equipment from the LTVs." Again, this doesn't take into account other vessels like launches that might be running to/from the LTVs, and it doesn't help at night. As stated above, vulnerable inshore aggregations of SRW occur in winter when night comprises two-thirds of a 24 hr period and MMOs will only be effective for the other third. These extra efforts are appreciated, but the reductions in vessel speed are the single most effective method especially in winter. • "Mariners should be made aware of the issue and how it relates to the Falkland Islands, educational materials, such as posters, will be produced to be displayed on the bridge of contracted vessels (see IFAW (2013) see Figure 10-50 below for example)" FC has already produced a poster (in Spanish and English) in liaison with Fortuna that outlines the Code of Conduct for FI waters and is available for use for awareness etc. Please contact us if you would like a PDF or to modify that to suit. • "On all vessels a lookout should be posted while transiting areas of high cetacean abundance" This is rather ambiguous. How are areas of high cetacean abundance going to be determined in real-time, and who is going to be the lookout? And of course this is no use at night.	It is agreed that the speed reductions are the most effective mitigation here. Thank you, Navitas would appreciate the information poster for distribution on project vessels. The Falkland Islands Code of Conduct will be followed and added to this section. In terms of reporting, this will be discussed and agreed with FIG.	Section 10.4.1.1 Section 10.11.3 Section 15.6.2.1.3 Section 15.6.2.1.4

Ref.	Representation	Navitas response	Changes in Rev 4
	• "If whales are spotted, speed should be reduced and animals given a wide berth." FI guidance should be followed to specify these distances. See the FI Code of Conduct. • "In addition to Navitas incident reporting and investigation, any incidents of collisions with marine mammals will be reported to FIG and the IWC" It would be nice if FC could be included in this loop, as the main organisation working with whales in the FI and producing Code of Conduct guidance. Near-misses (i.e., where whales pass <50 m from a ship, or where ships make diversions to avoid them) should also be logged/reported, in order to better understand risk. Same comment for P868. Additionally, FC may be able to attend dead whales floating at sea in the Berkeley Sound area (or subsequently washed up) and properly assess the nature of the injury, which could be useful to inform future risk assessments for industry.		
FC 167	"SMMOs coupled with the reduction to 8 knots within Berkeley Sound will reduce the likelihood of collisions between cetaceans and vessels from 'Possible' to 'Unlikely'." Most of the collisions evidenced in the inshore FI to date have been at low speed or while vessels are manoeuvring (see previous list). So the likelihood of contact is probably slightly decreased by reducing speed, but the chances of that contact then resulting in serious injury/death is what is significantly reduced. As such, this should probably remain 'Possible' (it makes no real difference to the assessment outcome anyway). As mentioned before, SMMOs might be reasonably useful in summer when daylight is long, but in winter their effectiveness is greatly limited by darkness.	Noted, no amendments proposed.	N/A
FC 168	"Sei and right whales are a common sight throughout the inshore waters of the Falklands during the summer and autumn but a complete survey is yet to be undertaken." Again, omission of eight years of data in inshore waters, including Berkeley Sound. Inshore SRWs are in winter, not summer. And again, what about sperm whales in the Sea Lion area, whose vessel collision assessment has not been mentioned.	Noted. The text will be amended. accordingly.	Section 10.11.4.3 Section 10.11.10

Ref.	Representation	Navitas response	Changes in Rev 4
FC 169	Small cetaceans and vessel collision risk inside Stanley Harbour at FIPASS/TDF both need to be considered in this Table, since dolphin mortality from vessel strike has been documented within Stanley Harbour.	Noted, see FC 153 above.	N/A
FC 170	Since fur and feathers were tested here, it could have been possible to also include baleen plates testing here, as mentioned on P1057. See Werth *et al.* (2019) for experiments with oil on whale baleen.	The EMMP workshop (April 2019) noted that 'The risk to marine mammals may lie in those whales that feed on the surface using baleen, but no data exist to assess the risk, and experimental evidence might be unethical to collect.' Given difficulties in trying to import seal pelt to the oil testing laboratory in France, Navitas imagines it will be very difficult to preserve whale baleen plates and transport them to the laboratory for testing. Navitas will review the Werth *et al.,* paper and incorporate into the EIS, but notes that Sea Lion is far from a typical crude so experiments with Sea Lion crude might yield different results.	Section 12.1.4.2.5.2
FC 171	The sei whale KBA is mentioned here, but the IMMAs are not.	Noted, the non-statutory KBA and IMMA will be added.	Section 7.5.2.3.5
FC 172	"Each recovery unit would have a boom encounter width of 15 m and a single skimmer capable of recovering 30 tonnes per hour (if that much oil is encountered by the boom) and could operate at a wave height of up to 2 m" Perhaps some information should be added here to clarify what proportion of time at the Sea Lion Field over a year has wave heights less than 2 m where recovering spilt oil would be plausible. Is there a Plan B for when it isn't? Would the incoming recovery vessels from South America/Africa have capacity to operate in higher sea states?	Thank you for your comment. Appendix 2 of the preliminary OPEPS identifies the oil spill response assets for each stage of the Sea Lion Development Phase 1 & 2. Oil spill response vessels can operate in high sea states, but they are reliant on the deployment of dedicated spill response equipment. As such the attendant vessels are not the limiting factor. According to the 'Metocean Criteria for the Sea Lion Development. Vol 2 ' (Premier Oil, 2015), wave height will exceed 2m *c.* 55% of the time. Therefore, mechanical recovery will often be challenging in South Atlantic sea states.	Section 5.11.1.2.3

Ref.	Representation	Navitas response	Changes in Rev 4
		However, as detailed both in the EIS and the Preliminary OPEPs, laboratory tests (by CEDRE) indicate that, given the nature of the Sea Lion crude, allowing for weathering and natural dispersion may often represent the optimal response approach and this will occur faster in the very metocean conditions which could prevent deployment of the response equipment. Recovery equipment will be available on station and would be deployed whenever conditions allowed. Please refer also to ED 190.	
FC 173	"Although the assumed response has a very modest effect and recovers 6.3 % (2,231 tonnes) of the oil…" At only 6.3% recovered, 'low/poor' might be a more realistic description.	6.3% is at the upper bound of actual recovery rates experienced during a review of 30 large oil spill incidents - Etkin and Nedwed (2021), which concluded that 2-6 % mechanical recovery is experienced in practice.	N/A
FC 174	Endangered blue whales are forgotten again. • "…marine mammals are not considered significantly at risk due to the semi-solid nature of the waxy crude…" Not sure why this makes them not at risk, since lunge- or skim-feeding baleen whales could presumably ingest such matter due to their indiscriminate feeding techniques. • The areas mentioned in 'Coastal' are also part of a KBA, and two IMMAs for whales which is not acknowledged. In particular, this area is used heavily by SRWs during winter.	Navitas will update the text accordingly.	Table 1.3 Table 7.57 Section 7.5.2.3.5
FC 175	The colour coding and overall risk assessment values used in these Tables is very confusing because it isn't clear why the final column has completely different verdicts to the descriptive text. Presumably this has been described somewhere in the preceding 1100+ pages, but it's not reasonable to have expected people to memorise it. The Table legends should make it clear why this is or refer the reader back to the relevant section with the explanation. As it stands, it is very difficult to comprehend	Navitas is not entirely sure it understands the concern raised. There is no expectation for the reader to memorise any text, but the basic methodology is outlined clearly in Chapter 8. Table 12.9 shows the risk assessment of a subsea blowout. This is tabulated owing to the number of receptors considered. There are no conclusions on this in the preceding text. The	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		table first indicates the impact (sensitivity of receptor x severity of effect) should it occur, which may be, for example, Moderate, and then factors in the likelihood of the blowout occurring which lowers the overall risk. The narrative preceding the table (Section 12.1.6.1.3) simply indicates the worst-case risk identified.	
FC 176	How is it possible that terrestrial tourists possibly noticing a small amount of oil on the coast (described as being 'very unlikely to come to their attention') is deemed to be of 'Moderate risk significance', but marine mammals that live in the immediate area of a spill are deemed 'Very Low risk significance'. This allocation of relevant importance should be reconsidered.	**Initial consultation response:** This will be revisited and the sensitivity of the marine mammals revised upwards. The high sensitivity assigned to tourists is based on the perception of an oil spill, which may impact the tourism economy. **Post-consultation comment:** Navitas has re-examined this concern and stand by the original assessment. The marine mammal sensitivity is high in the coastal region but is lower offshore as there is less potential for actual exposure to a crude spill given the space available. The assessment in relation to tourists is based upon their sensitivity to the negative *perception* of a spill rather than about them ever having sight of an oil spill, should one occur.	N/A
FC 177	"Cetaceans are more vulnerable to inhaling toxic vapour and are less affected by contact with the skin (Section 12.1.4.2.5)." The text in Section 12.1.4.2.5 does not support this statement – it merely describes both possibilities and does not assign relative importance. Recent papers from the Deepwater Horizon spill show that oil can adhere to cetacean skin, with unknown effects. Same comment as Table 12.11 re. how the overall risk significance can be deemed higher for land-based tourists than it is for Endangered marine mammals at the actual spill site.	Thank you for your comment. This is noted and the text will be clarified, the very different nature of the Sea Lion crude to that of the Deepwater Horizon means it is likely to have a different interaction with marine mammals, where ingestion is more likely. Please see FC 176 above.	Section 12.1.4.2.5.2

Ref.	Representation	Navitas response	Changes in Rev 4
FC 178	"There is no indication that the presence of a rig attracts associating marine mammals, although they could be attracted by potential prey species that may shelter near the rig." Incorrect, evidence is available online, for example: o Delefosse M, Rahbek ML, Roesen L, Clausen KT. Marine mammal sightings around oil and gas installations in the central North Sea. Journal of the Marine Biological Association of the United Kingdom. 2018;98(5):993-1001. doi:10.1017/S0025315417000406 ohttps://onlinelibrary.wiley.com/doi/full/10.1111/gcb.16134 ohttps://periodicos.ufsc.br/index.php/biotemas/article/view/2175-7925.2009v22n3p247	Text will be amended to include indirect impacts.	Table 12.13
FC 179	"While Oil Spill Response (OSR) equipment will be carried on the ERRV / MRSV and AHTS / ERRV offshore …in reality it is unlikely to be effective in the prevailing offshore weather conditions of the Sea Lion Field…oil spill response is not considered effective in respect of the largest events" Much of the discussion of OSR earlier can be negated by this statement that it would be ineffective.	While prevailing metocean conditions are likely to limit opportunities for effective deployment, Navitas is committed to ensuring that appropriate oil spill equipment is available so that in the unlikely event of a spill every effort can be made to minimise its impact.	N/A
FC 180	Same comment about terrestrial tourists being categorised of higher residual risk significance than Endangered marine mammals that are present at the immediate site of the spill.	**Initial consultation response:** This will be revisited and the sensitivity of the marine mammals revised upwards. The high sensitivity assigned to tourists is based on the perception of an oil spill, which may impact the tourism economy. **Post-consultation comment:** Please see response to comment FC 176.	N/A
FC 181	"The seasonal distribution of potential receptors in the NFB is reasonably well understood but further research is required to improve our knowledge of species distributions, and these are acknowledged as data gaps" We disagree, the seasonality of cetacean receptors at the NFB is not well understood.	Reasonable is a relative term and there are data from the field from at sea surveys and indeed PAM. A precautionary approach has been taken in the assessment where there are gaps.	N/A
FC 182	Apart from marine mammals being listed as a potential receptor in the list in 12.2.3, and the summary in Table 12.23, there seems to be no actual	The sensitivity of the receptor (marine mammals) is rated 'High' as 'A species with IUCN Endangered of	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	detailed consideration of the potential impacts of a marine diesel spill on marine mammals in Berkeley Sound. In Section 12.2.4.2 then it states that the majority of receptors have been considered in the offshore oil spill section (12.1), but this isn't adequate for marine mammals because the sensitivity in Berkeley Sound is significantly higher. The Sound is both a KBA and an IMMA based on its whale sensitivities, and foraging Endangered sei whales would be directly exposed and also indirectly exposed because oils accumulate within prey species (Werth *et al.,* 2019). The modelled spill areas in Figs 12-45 and 12-46 overlap with whale foraging areas.	Vulnerable status has notable presence in the zone of influence of the project'.	
FC 183	The fin whale hotspot fallacy in Berkeley Sound is repeated again here. However, southern right whales need to be added here as a KES in Berkeley Sound, as a species of regional conservation concern. • "Although it is possible that MGO from a spill of this size will not come into direct contact with any marine mammals, which occur in relatively low densities, this is not certain" This is incorrect. Berkeley Sound supports high densities of sei whales and SRWs. It would be surprising if a MGO spill inside Berkeley Sound did not come into direct contact with a marine mammal. • "Given the modest volatility of MGO, marine mammals could be susceptible to inhaling hydrocarbons upon surfacing to breath" In fact one of the most likely impacts would be accidental ingestion while sei whales are lunging or skimming to capture prey, both at the surface and subsurface. Same comment for Table 12.2.4 (P1166).	Section 7.4.6.3.1.6 (Fin whales) states that 'There are two apparent hotspots of fin whale sightings in inshore waters; one to the west of the Islands and the other in Berkeley Sound (Frans and Augé, 2016).' However the narrative goes on to state that Weir *et al.* (2017) refuted this as mistaken sightings. Southern right whales are also listed in Section 7.4.6.3.1.6. The sentence will be amended. to remove 'relatively low densities'. Section 12.1.4.2 details the nature of the impact to the key receptors of an oil spill. Section 12.2.4.2 describes the nature of the impact to additional inshore receptors. Section 12.1.4.2.5 (on marine mammals) will be updated to include ingestion of oil during lunge feeding as an example (should references be available for this) and Section 12.2.3 will be updated to refer specifically to the common receptors described in 12.1. [A recent set of tests involving whale baleen and six	Section 12.1.4.2.5.2

Ref.	Representation	Navitas response	Changes in Rev 4
		petroleum-based oils (Werth *et al.,* 2019) indicated that whale baleen is oleophobic and does not adsorb oil, and that oil is readily rinsed from the baleen by flowing water. There was minimal wrinkling or peeling of the baleen's cortical keratin layers in the tests and filter porosity was not appreciably affected. Oil ingestion risks remain although particle capture studies suggest potentially greater danger to mysticetes (baleen whales) from plastic pollution than oil.] Werth Alexander J., Blakeney Shemar M. and Cothren Adrian I. 2019Oil adsorption does not structurally or functionally alter whale baleenR. Soc. Open Sci.6182194 http://doi.org/10.1098/rsos.182194	
FC 184	"Should the monitoring of impacts indicate that the significance of the impacts and risks predicted in the EIS are not appropriate, and / or that mitigation is not effective, a revised mitigation measure and / or monitoring regime will be required." This may not be realistic. It is not clear how quickly monitoring would show impacts and how quickly after that would something change to address those impacts.	Regular review of the monitoring programme and results of the monitoring will be undertaken to see if any trends are emerging and the EMMP adapted accordingly.	N/A
FC 185	It is not clear how seabirds have ended up being rated as higher sensitivity to underwater noise than marine mammals. This doesn't make logical sense.	Seabirds are considered as having 'High' sensitivity. Initial impact to marine mammals assessed as 'Moderate' (sensitivity 'High' x severity 'Minor'). This demonstrates two ways in which the assessment leads to an EMMP action, either through high sensitivity coupled with uncertainty (in this instance seabirds) or through significant impact coupled with uncertainty (marine mammals), see Section 15.3.1.	N/A
FC 186	"Marine mammal observations prior to and during operations at the Sea Lion location and on Transits" Is the 'prior to' going to involve some targeted marine mammal surveys before anything happens? The data gap regarding	In accordance with the EMMP, SMMOs will be on board a number of the Sea Lion Offshore Assets. They will join the assets once they are on hire and in the	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	offshore cetacean occurrence at the Sea Lion field is a quite considerable one, and the little data that does exist is old.	area. The AHTS will commence their operations prior to the arrival of the MODU and SMMOs will be on board at this time.	
FC 187	The information in this Table is rather vague and it isn't easy to understand what is being proposed. But some of these are over-ambitious and unlikely to actually be achievable in practice. For example, "Investigate - Any adverse noise-related behaviour of marine mammals". There should be a plan/idea as to how that will be assessed before the surveys start, so that data collection can be steered accordingly. Identifying cetacean behavioural changes and linking them to an activity is extremely difficult and even dedicated research studies with ample resources and personnel often don't manage to do it (see all of the conflicting literature on marine mammals and noise impacts). And it takes a lot of time (several years) because of the need for adequate sample sizes to prove cause-effect. The likelihood of a behavioural response being identified by two SMMOs who aren't located on the noise-generating platform is virtually negligible. Also, the stated management action of "Scale back noisy activity" isn't viable – as part of the environmental approach then the project should already have scaled back noisy activities to the lowest levels needed to achieve the project goals, as that is standard industry best practice (and the ALARP approach stated in this EIS). "Adjust timing of operations" is also likely to be unrealistic in practice because industrial operations are constrained by weather and availability of platforms (and associated costs). We don't have better suggestions for handling this, the fact that offshore marine mammals will be disturbed by noise is probably a given side-effect of the project. But we do think that the stated Management Thresholds and Actions won't be achievable in practice with the resources that are being applied. • This table relates to 10.4 Offshore underwater noise. Where is the table for Inshore underwater noise and consideration of impacts in the sei whale foraging ground in Berkeley Sound? Especially the cumulative impacts? Why isn't this in the EMMP?	Navitas believes that noise generating activities have been avoided or scaled back as far as is reasonably practicable. The summary EMMP tables were prepared in discussion with stakeholders in the April 2019 EMMP workshop. The published workshop report notes that 'once the FDP has been approved and sanctioned, the EMMP will be transferred into a live document which will provide detail on: - Specific roles and responsibilities - Timelines, deadlines and 'frequency of execution' for actions identified - Progress and completion throughout the life of the field.' The workshop report proposes that an advisory committee including individuals with relevant expertise in the subjects being monitored will help draw up the specifications in any scope of work...and would also be able to comment on the results of the monitoring.' The EMMP workshop determined that effects of underwater noise on marine mammals inshore 'were considered by the [EMMP] workshop to be now outside the scope of the EMMP' due to the elimination of inshore ship-to ship crude oil transfers	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		from the development plan. Nonetheless Chapter 10.5 is being revised. Please see also FIFD 54.	
FC 188	• "SMMOs on board vessels periodically covering all seasons with particular focus at the time of year when animals are concentrated in the area of ship movements." It is not clear what this means. There are few data available for the NFB to show when animals would be concentrated in the area of ship movements. • "Reaction - Reduce vessel speed near marine mammals not attracted to the vessel" This is not clear. Presumably, if they are attracted to the vessel then they would be at higher risk of collision not lower. It would be better to simply commit to following the existing FI Code of Conduct which makes these things much clearer – dolphins approaching the vessel do not result in a reduction of speed but it is requested that vessels maintain their heading (or amend it only slowly) while there are dolphins around the vessel so that the animals have time to respond and maintain distance from the propellers. Also, something needs to be added here regarding vessels coming alongside at FIPASS/TDF with regard to dolphins, because there will be Commerson's dolphins in that area likely to approach the vessels while they manoeuvre alongside and already a documented example of a dolphin being killed during one such manoeuvre. • "Adaptation - Add marine mammal detection systems (e.g., infra-red camera systems); adjust timing of operations; consider use of deterrents" This would need to be tested on higher whale densities in Berkeley Sound probably before accepted as viable offshore. Reliable mitigation for vessel collision is currently to reduce overall speed and avoid sudden changes in both heading and speed. A commitment for project vessels to follow the existing Code of Conduct would address a lot of this.	Navitas will amend the EIS text to ensure that it refers to the Cetacean Code of Conduct and Navitas' commitment to adhere to it for all cycles of the Sea Lion Phase 1 and 2 Development. Navitas notes that it is already committed to vessel speeds in Berkeley Sound and Port William that are lower than those recommended by the Code of Conduct. Falkland Islands Company			
FIC 1	Sea Lion Environmental Impact Statement We have reviewed the above document and congratulate Navitas Petroleum on the breadth and depth of the analysis carried out, particularly as regards the potential impact of the project on Stanley and Berkeley Sound.	Thank you for your comments.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	While everyone would prefer that fossil fuels are eliminated sooner rather than later, it is generally accepted that they will continue to be required for the foreseeable future. Given this backdrop of demand, it is clearly better that oil continues to be supplied by responsible democracies, rather than leaving it to less desirable regimes around the globe. It is also notable that the Falkland Islands can help the UK maintain its energy security in a time when North Sea production is declining. The development of these oil reserves will also help to secure the financial future of the Falkland Islands by both directly and indirectly boosting the economy. Clearly, there are a number of further steps to go through as part of ensuring that the development is delivered responsibly, but we are encouraged by the thoroughness of the environmental impact statement and remain supportive of the process.		
Falkland Islands Fisheries Department			
FIFD 1	the following statement is unclear: << A mismatch in bathymetry and currents data can result in 'dead zones' near the seabed, which could adversely affect subsea discharges.>> Presumably, what was meant is that mismatch adversely affects the modelling of subsea discharges - ?	Thank you for the comment. The bathymetry in the area is well understood. The Sea Lion area was mapped using multibeam techniques as described in : Rockhopper Plc.,2012. Sea Lion Development Environmental Baseline Survey Scope of Work, 25-Jan-2012. Rockhopper Exploration Plc. Document Rev03 120125. Gardline. 2012. Sea Lion Field Development. North Falklands Licence Areas. PL032, PL033 and PL04. March and April 2012. Environmental Baseline Survey Report. Prepared for Rockhopper Exploration Plc. Reference: 9030.1. The FIFD 1 quote is taken out of context of the wider	Section 7.3.5.4

Ref.	Representation	Navitas response	Changes in Rev 4
		EIS narrative, the whole section states, "The bathymetry data supplied by BMT is precisely the same data that was used in the hydrodynamic modelling to produce the ocean currents dataset as discussed in section 7.3.3. This is important since it results in a perfect match between bathymetry and seabed currents data. [This is important to note because if there were] A mismatch in bathymetry and currents data can result in "dead zones" near the seabed, which could adversely affect subsea discharges."	
FIFD 2	<<…most likely to interact with oil and gas activity in Berkeley Sound, is the giant kelp…>> Why?	As stated, in 7.4.2.2.1.1, this is because 'This species is one of the largest (growing up to 60 m in length) and most abundant of the brown algae found around the coast of the Falkland Islands (van Tussenbroek, 1989).'	N/A
FIFD 3	<<Tree Kelp … have an order of magnitude greater biomass than Giant Kelp (*Macrocystis pyrifera*). If confirmed, … (P. Brickle *pers. comm.*)>> So how well is the biomass known?	*Lessonia* spp. are likely to have a biomass that is an order of magnitude greater that Macrocystis. This is based on observation and also what is known about Macrocystis biomass. However the biomass of Lessonia remains unknown.	N/A
FIFD 4	<<[Green algae] are anecdotally highly diverse and will be subject to study on how refugia (like the Falkland Islands) in the last glacial maximum contributed to this diversity>> Will be subject to study by who? Study in relation to oil?	This is part of the baseline description and provides context. The work is part of a PhD studentship and also a collaboration with South American Institutions and BAS. A reference will be added to the post-consultation EIS (Emma Beaton, 2019)	Section 7.4.2.2.2
FIFD 5	In the second paragraph, this sentence seems to be incomplete: << This suggests that of those taxa with a 50 % or greater predicted probability of being present in the area, are likely to be low density (not in aggregations) and / or rare, given that they went undetected in the Gardline (2013a) survey. >>	This will be amended to: This suggests that of those taxa with a 50 % or greater predicted probability of being present in the area, these taxa are likely to be low density (not in	Section 7.4.3.2.3

Ref.	Representation	Navitas response	Changes in Rev 4
		aggregations) and / or rare, given that they went undetected in the Gardline (2013a) survey.	
FIFD 6	<< This study will inform a marine invasives species monitoring program, as recommended at the EMMP workshop. >> Any information on the scope or timeline of the monitoring program?	See Section 15 EMMP for further details on monitoring.	N/A
FIFD 7	<< … parts [of NS] are heavily trawled throughout the year for finfish and skates. >> Skate trawling is no longer active.	Thank you for your comment. This is noted and agreed. Skates are no longer targeted but are caught as by-catch. The narrative will be amended for clarity.	Section 7.4.4.2.1.1
FIFD 8	<< The abundance of southern rock cod has increased several-fold in recent years, and it is currently the most abundant finfish on the Falkland Islands shelf and has become one of the most important finfish fisheries in the Falkland Islands (FIG, 2013c). >> This is obsolete. Rock cod has decreased considerably since 2013, and it is no longer the most abundant groundfish or important catch.	Noted and agreed. Hake is the most abundant. Rock cod still remain important but are not reported as by catch accurately. The text will be amended for clarity.	Section 7.4.4.2.3.2
FIFD 9	<< Although the JNCC Seabirds At Sea Team (SAST) surveys are 24 years old, it is unlikely that broad-scale animal distribution and movement patterns have changed significantly. >> It is important to stress that SAST seabird & marine mammal data was not only collected opportunistically, but were mostly recorded by a single observer (White et. al, 2002). In addition, throughout the years ecosystem changes have occurred, fish stocks have reduced, megafauna populations have recovered, and interactions with offshore human activities have increased. Considering the Falkland Islands are a hotspot for seabirds and marine mammals, in order for FIG to apply best practice for planning, mitigating and monitoring impacts of the Sea Lion Field, the collection of new data is required. Surveys must be carried out independently and applying the best scientific methodology and technology available: standardised sampling for megafauna (transects and distance-sampling), include a team of eight observers to work on shifts, specialised equipment (big eyes, infrared	Thank you for the comment. Navitas will collect data through SMMOs on vessels developing the field in the three years pre First-Oil and also collect acoustic data where / when practical too.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	cameras, multi-frequency acoustic array), and a PAM (passive acoustic monitoring) team.		
FIFD 10	<< In order to ensure that the JNCC SAST data provided an appropriate dataset on which to base the environmental impact assessment, POEPL commissioned Genesis to undertake a review of the data (Genesis, 2017). >> Considering the Falkland Islands are a hotspot for seabirds and marine mammals, FIG needs to apply best practice for planning, mitigating and monitoring impacts of the Sea Lion Field. In consequence, independent evaluations of the data and the EIA are a must.	FIG DMR has commissioned independent reviews of the EIA/S from the Offshore Petroleum Regulator for Environment and Decommissioning (OPRED) and the Scottish Association of Marine Science (SAMS) and may choose to comment further. See also FIFD 9.	N/A
FIFD 11	<< With permission from Falklands Conservation (FC) and JNCC, the SAST survey data was re-examined to highlight the species recorded in the vicinity of the Sea Lion area. >> Contradicts what is stated on page 4 (Acknowledgements).	Thank you for your comment. This is noted and the acknowledgments will be checked.	Acknowledgements Section 7.4.5.2.1.1
FIFD 12	inconsistent use of the common name <<southern sea lion>>, elsewhere it is <<South American sea lion>>.	Thank you for your comment. This is noted and the text will be checked for consistency.	Section 7.4.6.1.2
FIFD 13	Black browed albatross: besides the local breeding population of black-browed albatross, the South Georgia population also occurs in the Falkland Islands (Frankish *et al.,* 2020a). The black-bowed albatross from South Georgia is an ACAP Priority Population (>10% of the global total for each species and declining >3% per annum) (Phillips *et al.,* 2023).	Thank you for your comment. This is noted and reference to other BBA populations will be added.	Section 7.4.5.2.2 Table 7.17 Section 7.4.5.3.2 Table 7.23
FIFD 14	White chinned-petrel: there is a recent tracking paper that links movements of the WCP South Georgia population to the FI (Frankish *et al.,* 2020b).	Thank you for your comment. This is noted and Navitas will add the reference.	Section 7.4.5.2.2 Table 7.17 Section 7.4.5.3.2 Table 7.23
FIFD 15	Northern royal albatross: there are tracking papers that link movements of the NRA breeding sites in New Zealand to the FI (Nicholls *et al.,* 2002, 2005; Bose *et al.,* 2023).	Thank you for your comment. This is noted and Navitas will add the reference.	Section 7.4.5.2.2 Table 7.17 (sources added)
FIFD 16	Grey-headed albatross: besides being IUCN-Endangered, since 2011 the grey-headed albatross from South Georgia is an ACAP Priority Population	Thank you for your comment. This is noted and Navitas will add the reference.	Section 7.4.5.2.2

Ref.	Representation	Navitas response	Changes in Rev 4
	(Phillips *et al.,* 2023). Tracking research links movements of the SG population to the FI (Clay *et al.,* 2016)		Table 7.17 (sources added)
FIFD 17	Wandering albatross: besides being globally Vulnerable, the wandering albatross from South Georgia is locally Endangered (Jiménez *et al.,* 2016). In addition, since 2011 the WA from SG is an ACAP Priority Population (Phillips *et al.,* 2023). Fine-scale research links the SG population with FI waters (Carneiro *et al.,* 2022) and supports previous research in the FI (Otley *et al.,* 2006).	Thank you for your comment. This is noted and Navitas will add the reference.	Section 7.4.5.2.2 Table 7.17 (sources added)
FIFD 18	Black-browed albatross can dive to 19 m (Guilford *et al.,* 2022). And, the table does not include WCP from SG.	Thank you for your comment. This is noted and Navitas will amend the table.	Table 7.17 Table 7.23
FIFD 19	The last paragraph omits that SG populations of BBA, GHA and WA are ACAP Priority Populations.	Thank you for your comment. This is noted and Navitas will amend text and add SG populations.	Section 7.4.5.2.2
FIFD 20	White-chinned petrel: should include the size of the colony in Kidney Island; omits the fact that most of the individuals seen in the FI are from SG.	Thank you for your comment. This is noted and Navitas will amend text to include size and reference to White-Chinned population on Kidney Island.	Section 7.4.5.3.2 (White chinned petrel) Table 7.23
FIFD 21	omits GHA, WA, WCP and BBA from SG.	**Initial consultation response:** Likely Table 7.13 not 7.32. Note the table highlights ' Metadata from https://data.seabirdtracking.org/dataset. ' Hence, while data exists for the species listed, it may not have been deposited in the seabird tracking database. Navitas will re-check and amend where relevant. **Post-consultation comment:** Navitas reviewed the relevant table (Table 7.23). WA and GHA were not added as they occurred in very low abundances. In addition, it would have not been possible to discern whether WCP or BBA were from the Falkland Islands or South Georgia. Please note that the table references above are incorrect. Table 7.23 summarises the inshore bird species.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
FIFD 22	Omits ACAP Priority Population of BBA from SG. Black-browed albatross can dive to 19 m (Guilford *et al.,* 2022).	Please see response to FIFD 18.	N/A
FIFD 23	Omits WCP population from SG.	Please see response to FIFD 21.	N/A
FIFD 24	<< In 2019, the FIFD changed the way in which observed seabird mortalities were extrapolated to total mortalities in the fleet by including a 3:1 assumption of 1 mortality for every 3 heavy contacts observed based on Parker *et al.* (2013). >> FIFD did not change the way in which observed seabird mortalities were extrapolated to total mortalities in the fleet. Because in 2019 observer seabird dedicated effort was <2% and no seabird mortality was observed, possible minor injury contacts were used as a mortality proxy. Consequently, estimated seabird mortality numbers are precautionary.	Thank you for your comment. This is noted and the text will be amended for clarity.	Section 7.4.5.5.1
FIFD 25	<< "ACAP is a daughter agreement to the Convention on the Conservation of Migratory Species of Wild Animals (CMS), which the Falkland Islands are signatories to." >> The U.K is a direct signatory to both ACAP and CMS, not the FI. However, these do fully/partially extend to some UKOTs.	Thank you for your comment. This is noted and the text will be amended to reflect this.	Section 7.4.5.5.2
FIFD 26	Omits that in 2011 ACAP identified nine seabird Priority Populations for conservation, which represent >10% of the global total for each species and are declining >3% per annum. These include South Georgia populations of the WA, BBA, and GHA (Phillips *et al.,* 2023). In addition, the WA is locally Endangered (Jiménez *et al.,* 2016).	Thank you for your comment. This is noted and the text will be amended to reflect this.	Section 7.4.5.2.2 Section 7.4.5.5.2
FIFD 27	<< It is generally considered that there are insufficient data available to describe the foraging and breeding areas, seasonal distribution and abundance, and diet of most marine mammal species in the Falklands… Nonetheless, the available data is sufficient to indicate likely species presence on a seasonal basis. Both the visual and acoustic survey methods described below have recognised limitations which need to be acknowledged. However, datasets have been used in a complementary manner to provide a better overall picture. >> Regarding the acoustic data collected during one year (August 2012-August	Thank you for the comment. The AMAR data were collected over a period of a year. However, although old, the SAST did detect some beaked whales. Please see FC comment on the AMAR methodology (FC 129). Navitas believes it has been precautionary in our assessments. In addition, Navitas will be deploying SMMOs in the field three year pre First-Oil.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	2013), the usual sampling rate of the autonomous recorders (48Hz) was too low to collect beaked whale vocalizations, which are the most vulnerable cetaceans to anthropogenic noise (Taylor *et al.,* 2000; Prideaux, 2016; Harding & Cousins, 2022). Beaked whale vocalizations energy peaks range between 35-45 Khz (Rafter *et al.,* 2021); in addition, only 5% of the recordings were analysed (Hipsey *et al.,* 2013).		
FIFD 28	<<minke whale>> refers here to the Antarctic minke whale (*B. bonaerensis*), however White *et al.,* 2002 refers to the dwarf minke whale (*B.acutorostrata*). The document must clarify that the FI are in the distribution range of both species, which at sea are undistinguishable and which can also be confused with the pigmy right whale (*Caperea marginata*) (Otley, 2012). So, under the term <<minke whale>> could be at least three different species.	Thank you for your comment. This is noted and the text will be amended to reflect this.	Section 7.4.6.2.1.4 (Minke whale)
FIFD 29	omits the fact that the Falkland Islands are a beaked whale hotspot (MacLeod & Mitchell, 2006). Although beaked whale habitat normally occurs in deep waters (≥1000 m), Otley (2012) suggested that in the FI beaked whales do use shallower waters, which is known to occur elsewhere (Filatova *et al.,* 2024). S. 7.4.6 also omits to mention that beaked whales are highly vulnerable to anthropogenic sound, which can displace the animals from foraging areas, cause permanent damage, or cause incidental mortality (Barlow & Gisiner, 2006; Weilgart, 2013; Joyce *et al.,* 2018; Feyrer *et al.,* 2024). However, quantifying impacts in open sea is extremely difficult, as the arrival of carcasses to the shore depend on environmental features and human population density (Faerber & Baird 2010; Williams *et al.,* 2011; Prado *et al.,* 2013).	Thank you for your comment. This is noted and the text will be amended to reflect this.	Table 7.28 Section 10.4.4.4.5
FIFD 30	Beaked whales: all the information from Hyperoodon and Mesoplodon sightings should be included in the same paragraph. On this page it is omitted that sightings of Hyperoodon were carried out at the N, NE and E of the FI (White *et al.,* 2002).	The hyperoodon refers to seasonal variability, while the mesoplodon explains the difficulty in identifying beaked whale to species level - hence the need to separate into different paragraphs. Navitas will	Section 7.4.6.2.1.4

Ref.	Representation	Navitas response	Changes in Rev 4
		update the location of southern bottlenose whale sightings.	
FIFD 31	Omits to define “large whale species”. In the text this is also not defined.	The figure text will be clarified to explain that large whale species refers to unidentified large whales.	Section 10.11.4.3.2 Table 7.31
FIFD 32	<< During this period an increased but small number of >> Incomplete sentence.	Thank you for your comment. This is noted and the typo will be amended.	Section 7.4.6.2.1.2
FIFD 33	Fin whale: following Lanfredi, 2012, add Herr *et al.,* 2022 (large fin whale foraging groups in Gerlache Strait)	Thank you for your comment. This is noted and this reference will be added.	Section 7.4.6.2.1.4
FIFD 34	Southern bottlenose whale: should be together with Mesoplodon under the title <<beaked whales>>. The text omits that Hyperoodon sightings by White *et al.* (2002) took place in the N, NE, and SE of the FI.	Please see response to FIFD 30. These are separated on the basis of data availability. Specifically, one species has seasonal data, while the other are unidentified species of Mesoplodon. Text regarding location of sightings will be added.	Section 7.4.6.2.1.4
FIFD 35	Unidentified beaked whales (*Mesoplodon* spp.): Ziphiids (beaked whales) include genus Hyperoodon, Ziphius, Berardius, Mesoplodon, and Indopacetus, of which the first four have been recorded in the Falkland Islands (Otley *et al.,* 2011). The sentence “Beaked whales (*Mesoplodon* spp.)” is not correct. << All sightings occurred in waters over 1,000 m deep, with the majority coming from the region of the Falkland Trench to the south-east of the Islands >>. Although *Mesoplodon* sightings from White *et al.* (2002) took place in waters over 1000m deep, Otley (2012) suggested that in the FI beaked whales do use shallower waters; beaked whales can specialise in the use of coastal habitat (depth <300m) (Filatova *et al.,* 2024). Hyperoodon sightings by White *et al.* (2002) took place in the N, NE, and SE of the FI. << Stranding records indicate that a number of *Mesoplodon* species could be present within Falkland Islands waters (Otley *et al.,* 2012) >> The correct reference is Otley *et al.,* 2011. The text omits to say that the Falkland Islands are a beaked whale hotspot (MacLeod & Mitchell, 2006) and that beaked whales are highly vulnerable to	Thank you for your comment. This is noted and the text will be updated.	Section 7.4.6.2.1.4 Section 10.4.4.4.5

Ref.	Representation	Navitas response	Changes in Rev 4
	anthropogenic sound, which can displace the animals from foraging areas, cause permanent damage, or cause incidental mortality (Barlow & Gisiner, 2006; Weilgart, 2013; Joyce *et al.,* 2018; Feyrer *et al.,* 2024). Quantifying impacts in open sea is extremely difficult, as the arrival of carcasses to the shore depend on environmental features and human population density (Faerber & Baird 2010; Williams *et al.,* 2011; Prado *et al.,* 2013).		
FIFD 36	<<The acoustic monitoring survey recorded an unidentified odontocete species (toothed whale; including killer whale and dolphins).>> This sentence is not correct. The killer whale is a dolphin species; the term "toothed whale" includes the sperm whale, beaked whales, dolphins, and porpoises.	Thank you for your comment. This is noted and the text will be amended.	Section 7.4.6.2.1.4 (Hourglass dolphin)
FIFD 37	<< (*Arctocephalus* species) >> The text should mention the actual scientific names of species included in this term.	Thank you for your comment. This is noted and australis and gazella will be added.	Section 7.4.6.2.2.1
FIFD 38	Southern right whale. << Widespread in the southern hemisphere >>. The distribution is circumpolar in the Southern Hemisphere. << Growing population breeds off the coast of Argentina in September, migrates to Southern Ocean in the summer >> is not correct. The southern right whale breeds between July-November in Península Valdés (Argentina) and Santa Catarina (Brazil) (Danilewicz *et al.,* 2016; Mandiola *et al.,* 2019; Renault-Braga *et al.,* 2022) Antarctic minke whale: << Globally, the most common of the rorquals >> is not correct. Southern Hemisphere distribution (Cooke *et al.,* 2018). Dwarf minke whale (*Balaenoptera acutorostrata* subspecies). Omitted in the whole report. Distribution in mid and lower latitudes of the Southern Hemisphere, up to 69º (Cooke, 2018). Pygmy right whale (Caperea marginata). Omitted in the whole report. Circumpolar distribution, between 30-55ºS (Cooke, 2018a).	**Initial consultation response:** Thank you for your comment. This is noted and the table will be updated. **Post-consultation comment:** Table 7.28 has been updated. However, dwarf minke and pygmy right whales were not considered prevalent enough to warrant inclusion within the summary table.	Table 7.28

Ref.	Representation	Navitas response	Changes in Rev 4
	Beaked whales: only contains one beaked whale species (*Hyperoodon*). The table omits the rest of available information (i.e., unidentified beaked whale species.) Sei whale: << …. progress can be followed by 'fluke prints' left on the surface in the animal's wake >>. That is a common feature with other whale species, not exclusive for sei whales.		
FIFD 39	Antarctic minke whale (*Balaenoptera bonaerensis*): These are sympatric species; impossible to distinguish them at sea. White *et al.,* reported all their sightings as *B. acutorostrata*. The term <<minke whale>> should either include all the species, or clarify that under the term "small whale species" there could be at least three species: *B. acutorostrata*, *B. bonaerensis*, and C. marginata. Otley (2012) also states that the 3 species were not differentiated during JNCC surveys. Minkes stranded in the FI were also not differentiated to species level (Otley 2012).	Thank you for your comment. This is noted and the text will be clarified.	Section 7.4.6.2.1.4 (Minke whale)
FIFD 40	Killer whale: Here omits that there are likely to be resident populations. Seen year-round from longline vessels fishing to the north-east of the Sea Lion Field (Yates & Brickle, 2007). Orcas are occasionally seen from Loligo trawlers (FIFD unpublished data).	Thank you for your comment. This is noted and the Yates and Brickle reference will be added sightings to North of the NFB will be clarified in the text.	Section 7.4.6.2.1.4 (Killer whale)
FIFD 41	Right whale, Antarctic minke whale, Dwarf minke whale, Pygmy right whale, Sei whale: see comments on Table 7.2.8.	Thank you for your comment. This is noted and the table shall be updated accordingly. See also FIFD 38.	Table 7.28
FIFD 42	<< As during the 2015 exploration drilling campaign, Navitas will develop and implement a BSMP … >> <<Detailed monitoring requirements have been established during the Environmental Monitoring and Management Plan workshop (Chap. 15).>> It would be useful to see some details of what the 2015 BSMP provided. Chap. 15 does not provide any real detail.	The Sea Lion Phase 1 & 2 Biosecurity Management Plan will be developed after project sanction and prior to the commencement of operations. This will build upon the 2015 exploration Biosecurity Management Plan. The EMMP advisory group will be invited to review and input in to the draft Biosecurity Management Plan prior to its finalisation and issue.	N/A
FIFD 43	In this section the document omits to provide information on each step on the Field development and operation, including the types of equipment to be used, the number of each equipment to be used, and the characteristics	Detail on the full operation is given in the development description, Chapter 5, which is referenced in section 10.4.	Section 10.4.1.1 Section 10.4.5.1

Ref.	Representation	Navitas response	Changes in Rev 4
	of the noise to be generated by each of them. << Underwater noise will be generated in the Sea Lion Field throughout the Development and will result from the use of vessels. >> This sentence is incorrect. Besides shipping and vessel traffic, the development and operation of the Sea Lion Field might imply the production of underwater noise by different types of equipment, like: -seismic surveys; -high power sonar (SBES, MBES, boomers, etc.); -explosions; -drilling; -position transponders; -separators, injectors, pumps; -production maintenance. << The properties of sound in water (range and speed of travel) are exploited by many marine animals as a means of communication, navigation and detecting prey or predators. Sound travels at approximately 1,500 m/s in water (about five times faster than in air) and low frequency sound can propagate over hundreds to thousands of kilometres, although the effective range of most biological functions is tens of kms. >> Marine wildlife does not exploit the properties of sound in the water, but actually rely on sound for vital life functions, including communication, prey and predator detection, orientation and for sensing surroundings. Species living in the marine environment are adapted to the natural sound (ambient noise), biological (marine animals) and physical processes (earthquakes, wind, ice and rain). Sound propagation in the water is complex and requires many variables to be carefully considered before it can be known if a noise-generating activity is appropriate or not. It is inappropriate to generalize sound transmission without fully investigating propagation in the actual place.	No seismic surveys are planned, no high power sonar will be used and no explosives are planned to be used in drilling, unless stuck pipe occurs but in this instance explosives would be downhole. Transponders will not be required to site the FPSO or MODU. During construction, transponders may be used to site subsea equipment - these will be used for short period and removed once the subsea construction phase is complete. This will be noted in the section. Also note that the underwater noise modelling is being refined and will be presented in the next iteration of the EIS. See FIFD 54.	

Ref.	Representation	Navitas response	Changes in Rev 4
	<< Human-made (anthropogenic) noise in the marine environment can interfere with these processes and is recognised as having the potential to cause harm to marine animals. Consequently, under-water noise is regarded as a form of pollution. >> Because of diverse activities, in the last century human-made (anthropogenic) noise in the marine environment has increased (Prideaux, 2016). The term "harm" must be specified (e.g., physical, physiological, behavioural impacts). It is known that wildlife exposed to elevated or prolonged anthropogenic noise can suffer direct injury and/or temporary or permanent auditory threshold shifts. Noise can mask important natural sounds, such as the call of a mate, or the sound made by prey or predator. Anthropogenic noise can also displace wildlife from important habitats. These impacts are experienced by a wide range of species including finfish, crustaceans, cephalopods, pinnipeds, sea turtles, and sharks (Prideau et al, 2016).		
FIFD 44	Omits the Convention of Migratory Species (CMS), which has published Family guidelines on EIA for marine noise generating activities. All the marine mammal and seabird species, the porbeagle, and their prey are covered by CMS. Regarding pinnipeds and cetaceans, the FI has cetacean and pinniped Action Plans approved by EXCO, which highlight the following actions: 1) To assess and manage acoustic disturbance – including the application of appropriate licence conditions under the Offshore Minerals Ordinance. To assess and manage physical disturbance and development activities such as aquaculture, oil pollution and exploration and extraction industries, including the application of environmental impact assessment where appropriate.	Thank you for your comment. This is noted and will be added	Section 10.4.1.1
FIFD 45	Because sound exposure can cause mortality, injury to tissues, affect the physiology of living beings, damage to the auditory system, masking of biologically important sounds, and behavioural changes (feeding, breeding, spawning, migration, displacement from ecologically important areas) (CMS, 2017), the Falkland Islands needs to develop new policy regarding Mineral	Navitas refers the respondent to FIG DMR regarding their policy on noise. Note the EIS does include propagation modelling, please see section 10.4.4.4.2.	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	Resources. This new and specific policy should require the EIA to include propagation modelling. The noise models need to be confirmed by acoustic measurements in the field. The EIA needs to describe the methods chosen to reduce or baffle unnecessary high frequency noise, taking account of the noise spectrum before and after the addition of the mitigation measures. Cumulative effects from multiple temporally overlapping or consecutive surveys need to be considered. It is important to mention that the UK permitting systems also requires a detailed impact assessment to support the applications that clearly specifies the potential impacts (OSPAR, 2020). Also, Following CMS (2017), Prideaux (2016) and Weilgart (2023), this section omits to provide a comprehensive description of: 1) Each of the equipment's to be used; 2) The noise to be generated by each of the equipment's (intensity and frequency); 3) The occurrence of activities like seismic surveys and explosions, with detailed information on equipment, type of explosive, sound intensity level in water @ 1 m, frequency range, and number of detonations and interval time; 4) Description of noise counter measures, as bubble curtains, noise dampers and cofferdams, including a description of technology, best environment practice (BEP), or best available technology (BAT); 5) Identification of other activities having an impact in the region during the planned activity, accompanied by the analysis and review of potential cumulative or synergistic impacts. The EIA needs to provide an explanation of all activity technologies available and why each proposed technology is chosen, including consideration of noise-free installation methods. The EIS needs to specify the total duration of each proposed activity; the proposed timing of operations (i.e., season and time of day, during all weather conditions); sound intensity level (dB peak to peak) in water @ 1 metre and frequency ranges.	No seismic surveys are planned but please note cumulative modelling has been undertaken in section 10.4.4.4.3.2 showing the noise from all activities (drilling, production vessels and offtake vessels at once). Navitas note the OSPAR 2020 guidelines suggested are primarily for 'noise mitigation measures to be applied during pile-driving as well as alternative low noise foundation concepts especially for offshore wind turbines'. As no pile driving is proposed, it is not felt these are most appropriate for the Sea Lion development activities. The vessels modelled and their noise profiles are provided in Table 10.26. No seismic surveys or explosions are planned. Well completion approach now utilises Open Hole Gravel Pack (OHGP) rather than TCP guns. Please also note that the underwater noise modelling is being refined and will be presented in the next iteration of the EIS. See response to FIFD 54.	

Ref.	Representation	Navitas response	Changes in Rev 4
FIFD 46	Moderately intense low frequency noise can cause severe acoustic trauma and mortality in cephalopods. Effects have also been seen in zooplankton lobsters and epibenthos, among others (Harding & Cousins, 2022).	Thank you for your comment. This is noted and the reference will be added and included.	Section 10.4.4.2 Section **Error! Reference source not found.** Section 10.5.6.2
FIFD 47	The EIA focus on the sound pressure, however fish and invertebrates are more susceptible to particle motion (Prideaux, 2016; Popper & Hawkings, 2018; Harding & Cousins, 2022).	Thank you for your comment. This is noted in sections 10.4.4.3.1.1 and 10.4.4.3.2.1. Please note the noise chapters are being revised and updated. Please also refer to FIFD 54.	Section 10.4.4.4.2.1 Section 10.4.4.4.3.1 Table 10.19
FIFD 48	<< An SEL threshold of injury of 202 dB re 1µPa2s was agreed on by the panel (SAIC, 2011). The threshold found for the marbled murrelet was applied here to estimate the underwater noise impacts to diving seabirds.>> The threshold of 202 dB is not appropriate. Hansen *et al.* (2020) demonstrated that the common murre elicits a behavioural response at 110 dB re 1 mPa, similar to the sound levels that affect the harbour porpoise. In addition, it has been published that penguins response to seismic surveys within 100km of their colony, penguins avoiding their preferred foraging areas, which made them increase their foraging effort (Pichegru *et al.,* 2017).	The 202 dB threshold is used as an injury threshold, not a disturbance (behavioural change threshold), Navitas will review the papers suggested. Please note the noise chapters are being revised and updated. Please also refer to FIFD 54.	Section 10.4 Section 10.5
FIFD 49	<< Anthropogenic sources of sound in the ocean can disturb marine mammals, evoking behavioural responses, similar to the response to predator risk, and can trigger physiological stress responses (Tyack, 2008; Rolland *et al.,* 2012). >> Impacts of anthropogenic sounds include much more than behavioural responses and stress. Anthropogenic noise can cause physiological damage and mortality, being beaked whales extremely vulnerable (Taylor *et al.,* 2000; Barlow & Gisiner, 2006; Hildebrand, 2005; Prideaux 2016; Weilgart 2013; Joyce *et al.,* 2018; Chollewiak *et al.,* 2017).	Thank you for your comment. This is noted and this will be added in revised Sections 10.4 and 10.5. Please also refer to FIFD 54.	Section 10.4 Section 10.4.4.4.5 Section 10.5
FIFD 50	This section of the document also omits the fact that the Falkland Islands are a beaked whale hotspot (MacLeod & Mitchell, 2006). Although beaked whale habitat normally occurs in deep waters (≥1000 m), Otley (2012) suggested	Thank you for your comment. This is noted and Section 10.4.6.3.2 will be amended to clarify data gaps associated with beaked whales, which are	Section 10.4 Section 10.4.4.4.5 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	that in the FI beaked whales do use shallower waters, which is known to occur elsewhere (Filatova *et al.,* 2024). In addition, this section of the document omits to mention that beaked whales are highly vulnerable to anthropogenic sound, which can displace the animals from foraging areas, cause permanent damage, or cause incidental mortality (Taylor *et al.,* 2000; Barlow & Gisiner, 2006; Weilgart, 2013; Joyce *et al.,* 2018; Feyrer *et al.,* 2024). However, quantifying impacts in open sea is extremely difficult, as the arrival of carcasses to the shore depend on environmental features and human population density (Faerber & Baird 2010; Williams *et al.,* 2011; Prado *et al.,* 2013).	vulnerable to disturbance. Please note the noise chapters are being revised and updated. Please also refer to FIFD 54.	
FIFD 51	<< Of the species of cetacean present in the NFB (Section 7.4.6.2), many are capable of diving to depths in excess of 450 m, although due to the difficulties of working with these animals in an oceanic environment, the maximum dive depths of many species remain unknown. >> There are plenty of research on diving capabilities of teutophagic cetaceans. The sperm whale, the pilot whale, beaked whales and orcas are extreme divers, with deeper and longer foraging dives than any other mammal species (Tyack *et al.,* 2006; Schorr *et al.,* 2014; Towers *et al.,* 2019). Following habitat utilisation of beaked whales elsewhere, it is presumed that sighted individuals from fishing vessels operating in the Falklands might be residents (e.g., Gowans *et al.,* 2000; MacLeod & Zuur 2005; McSweeney *et al.,* 2007; Falcone *et al.,* 2009).	Thank you for your comment. This is noted and Navitas will update the section with references and dive depths from other locations. Please note the noise chapters are being revised and updated. Please also refer to FIFD 54.	Section 10.4 Section 10.4.4.4.5 Section 10.5
FIFD 52	<< Further, it should be noted that behavioural changes in response to anthropogenic noise, such as moving away from an area for a short period of time, changes in dive-time, masking of communication signals or echolocation clicks for short periods, do not necessarily result in detrimental effects on the animals involved. A reaction lasting less than 24 hours, and not recurring on subsequent days, was not regarded as particularly severe by Southall *et al.* (2007). >>	Agreed, this will be added in revised section. Please see response to FIFD 54.	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	Impacts of anthropogenic sounds include much more than behavioural responses and stress. Anthropogenic noise can cause physiological damage and mortality, being beaked whales extremely vulnerable (Taylor *et al.,* 2000; Barlow & Gisiner, 2006; Hildebrand, 2005; Prideaux 2016; Weilgart 2013; Joyce *et al.,* 2018; Cholewiak *et al.,* 2017).		
FIFD 53	<<The injury thresholds for each marine mammal group have been reviewed and updated by the National Marine Fisheries Service (NMFS, 2018) and Southall *et al.* (2019) and are summarised in Table 10.24.>> The SEL metrics reported by NOAA (2018) and Southall *et al.* (2019) only account for the cumulative exposure to one source in the hearing range of an individual. They do not consider the cumulative or aggregate effect of multiple sources. NOAA (2018) provided advice on how to combine multiple datasets and determine appropriate surrogates when little or no data exists. Southall *et al.* (2019) stated some important assumptions and limitations for the PTS and TTS thresholds that are proposed. They reported that the TTS and PTS thresholds are derived using median values of available data in several areas. However, they reported that impacts may relate to variability in susceptibility of individuals and the context of exposure scenarios. As such, single threshold criteria underestimate potential effects for some or in some scenarios and overestimate effects for others, the extent of each potential outcome depending on the degree of individual variability as well as key contextual aspects of exposure. The exposure criteria should therefore be used as a guide to predict the potential for PTS and TSS, but not used as an absolute. NOAA (2018) also reported that thresholds do not represent the entirety of an effects analysis, but rather serve as one tool to help evaluate the effects of noise produced during a proposed action on a marine mammal. Other aspects that should be considered within an overall assessment of risk include behavioural impact thresholds, auditory masking assessments and evaluations to help understand the ultimate effects of an impact on an individual's fitness and on populations.	Thank you for your comment. This is noted and Navitas will ensure these caveats are clarified. Please note the noise chapters are being revised and updated. Please also refer to FIFD 54.	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
FIFD 54	The noise-generating modelling presented in the EIA does not provide enough information to provide decision makers with credible and defensible information. The available modelling is not based in local propagation features. In consequence, the document neither identifies the acoustic footprint of the noise that will be generated in the Sea Lion Field, nor provides levels of noise propagation to make informed decisions. New modelling should be carried out following CMS Guidelines on Environmental Impact Assessment for Marine Noise-generating Activities (Prideaux 2016; CMS 2020): 1. Independent, scientific modelling of noise propagation should be impartially conducted. a) Models chosen should be peer-reviewed, scientific source models (as opposed to industry black box models); b) Modelers should have enough knowledge of, and experience with, the models they are using. Modellers should understand the physics of under-water noise propagation to ensure the correct models are used and that the results are accurate and make physical sense; c) Modelling results should be reviewed by subject matter experts, and experienced modellers with a strong theoretical understanding of underwater acoustics. 2. Propagation models should be: a) based on accurate input data, and for seismic surveys specifically the official calibration figures supplied by the survey vessel to be charted; b) able to accommodate the activity noise frequencies, the water depth, seabed topography, temperature and salinity, and spatial variations in the environment. Model methodology/s used should be stated;	The modelling was conducted by independent experts using models developed in house (by the independent consultant). However, further modelling techniques have since been developed and as such Navitas has chosen to revise and update this entire section. Please note that the sources of noise originate from the rig and a number of vessels that will be operating in the area. There is no pilling or other source of impulsive sound; anchors will be suction piled as opposed to impact piling. Navitas are confident the impact assessments are valid but has committed to updating this assessment with results from the new modelling now available.	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	c) specific to the source, region and environmental conditions. d) based on accurate input data including seismic source data and environmental data, such as: - geo-acoustic properties, including bottom sediment types and their layer depths for the region to be modelled, ideally down to several hundred metres into the bottom. - bathymetry mapping grid resolution greater than 450m - seasonally relevant Sound Speed Profiles (SSPs), salinity, temperature and depth data (in tabulated form). e) chosen based on the treatment of environmental conditions, with an appropriate rationale for the modelling choice provided in the modelling report. f) given special consideration for fiords and deep-water canyons and may require high-resolution 3D models. g) biologically relevant and able to handle a wide range of frequencies, including very high and very low frequencies, regardless of the proponent's frequency focus. The computational difficulty of modelling very high frequencies is not a reason for disregard. 3. Propagation modelling should include: a) the received sound levels at given distances from the noise source to determine propagation loss. b) full frequency bandwidth of a proposed anthropogenic noise source. c) the intensity/pressure/energy output within that full range. d) the principal or mean/median operating frequency of the source(s). e) the same season/weather conditions as the proposed activity accounting for local propagation features (depth and type of sea bottom, local propagation paths related to thermal stratification, SOFAR or natural channel characteristics). f) sound propagation and cumulative exposure data that is appropriate to		

Ref.	Representation	Navitas response	Changes in Rev 4
	the full range of concurrent noise generating activities. These should include separate modelling of each noise generating activity (i.e., shipping, support vessels, sonar, seismic surveys), as well as a cumulative model of all these activities combined. g) appropriate single shot modelling that is correctly reprehensive of the survey region. Biologically important sub-regions may require additional focus. h) representation of cumulative exposure over time (i.e., 24 hours). i) acoustic ground-truthing of the chosen model (to ensure model credibility). 4. Propagation modelling reports should demonstrate: a) propagation from point source out to a radius where the noise levels generated are close to natural ambient sound levels. b) particle motion propagation to assess the impact on invertebrates and fish species. c) proposed exclusion zones designed for the protection of specific species and/or populations should be identified and mapped and should demonstrate how noise will not propagate into these areas, taking into consideration the local propagation features. d) border thresholds will not be breached for exclusions zones and biologically important areas. e) that all modelling assumptions are clearly stipulated and comprehensively justified.		
FIFD 55	Besides shipping and vessel traffic, the development and operation of the Sea Lion Field might imply the production of underwater noise by different types of equipment, like: -seismic surveys; -high power sonar (SBES, MBES, boomers, etc.); -explosions; -drilling; -position transponders;	See response to FIFD 43.	Section 10.4.1.1 Section 10.4.5.1 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	-separators, injectors, pumps; -production maintenance. However, the EIA omits to provide a comprehensive description of the equipment, the activities, the individual noise and accumulated noise that will be produced in the Sea Lion Field. In Section 10.4.5 <<Industry standard mitigations >> the EIA only includes vessel noise, and wrongly says that "there are no industry-standard mitigation measures specifically designed to reduce the impact of vessel noise on fauna". The CMS in June 2023 published Best Available Technology (BAT) and Best Environmental Practice (BEP) for Mitigating Three Noise Sources: Shipping, Seismic Airgun Surveys, and Pile Driving – Technical Series No. 46 (Weilgart, 2023). The EIA omits to provide a comprehensive description of: each of the equipment's to be used; the noise to be generated by each of the equipment's (intensity and frequency); the occurrence of activities like seismic surveys and explosions, with detailed information on equipment, type of explosive, sound intensity level in water @ 1 m, frequency range, and number of detonations and interval time; description of noise counter measures, as bubble curtains, noise dampers and cofferdams, including a description of technology, best environment practice (BEP), or best available technology (BAT); identification of other activities having an impact in the region during the planned activity, accompanied by the analysis and review of potential cumulative or synergistic impacts.		
FIFD 56	Moderately intense low frequency noise can cause severe acoustic trauma and mortality in cephalopods. Effects have also been seen in zooplankton lobsters and epibenthos, among others (Harding & Cousins, 2022). The EIA focus on the sound pressure, however fish and invertebrates are more susceptible to particle motion (Prideaux, 2016; Popper & Hawkings, 2018; Harding & Cousins, 2022). The threshold of 202 dB is not appropriate	Thank you for your comment. This is noted and he underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections of the EIS are also being updated with relevant citations suggested during the public consultation and with	Section 10.4 Section **Error! Reference source not found.** Section 10.5 Section 10.5.6.2

Ref.	Representation	Navitas response	Changes in Rev 4
	for seabirds. Hansen *et al.* (2020) demonstrated that the common murre elicits a behavioural response at 110 dB re 1 mPa, similar to the sound levels that affect the harbour porpoise. In addition, it has been published that penguins' response to seismic surveys within 100km of their colony, penguins avoiding their preferred foraging areas, which made them increase their foraging effort (Pichegru *et al.,* 2017). Regarding marine mammals, impacts of anthropogenic sounds include much more than behavioural responses and stress. Anthropogenic noise can cause physiological damage and mortality, being beaked whales extremely vulnerable (Taylor *et al.,* 2000; Barlow & Gisiner, 2006; Hildebrand, 2005; Prideaux 2016; Weilgart 2013; Joyce *et al.,* 2018; Cholewiak *et al.,* 2017). The exposure criteria should therefore be used as a guide to predict the potential for PTS and TSS, but not used as an absolute. NOAA (2018) also reported that thresholds do not represent the entirety of an effects analysis, but rather serve as one tool to help evaluate the effects of noise produced during a proposed action on a marine mammal. Other aspects that should be considered within an overall assessment of risk include behavioural impact thresholds, auditory masking assessments and evaluations to help understand the ultimate effects of an impact on an individual's fitness and on populations.	consideration for the comments received. Please also refer to FIFD 54.	
FIFD 57	<< Each vessel will have its own individual 500 m exclusion zone. >> Meaning exclusion from any other vessels being anchored within 500 m, or traversing within 500 m? Does this help to mitigate underwater noise?	Yes, exclusion from any other vessel being anchored within that 500m or from traversing that 500m exclusion zone. Exclusion zones are not proposed as mitigations to the effect of underwater noise but for vessel safety.	N/A
FIFD 58	<< The goal was a phase-out of discharge of these chemicals by 1st January 2017, and this was largely achieved >> Meaning it was achieved in general globally, or in the Falkland Islands particularly, and if so how much is <<largely>>?	The phase out of Substitution chemicals is required under OSPAR Recommendation 2006/3 on 'the environmental goals for the discharge by the offshore industry of chemicals that are, or which contain, substances identified as candidates for substitution'. The OSPAR Convention is a legal agreement that guides international cooperation to protect the	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		marine environment of the North-East Atlantic. The OSPAR Convention's contracting parties include: Belgium, Denmark, Finland, France, Germany, Iceland, Ireland, Luxembourg, The Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and United Kingdom. In the UK, operators have to report annually (production) and per project (for drilling/workovers etc) on their progress in selecting non-Substitution chemicals and where non-substitution chemicals are still used, or alternatives are not yet available, this must be justified.	
FIFD 59	The CMS in June 2023 published Best Available Technology (BAT) and Best Environmental Practice (BEP) for Mitigating Three Noise Sources: Shipping, Seismic Airgun Surveys, and Pile Driving - Technical Series No. 46 (Weilgart, 2023). This report demonstrates that the regulation of vessels speed, routes, and avoidance of steaming parallel to the coast comprise best practice for shipping and reduce the noise footprint, mitigate collisions with whales, reduces fuel consumption and greenhouse emissions. It is crucial BAT and BEP are enforced in the Sea Lion Development.	Thank you for your comment. This is noted and vessel speed and maintenance of vessels are included in mitigations for noise reduction and speed reduction is included as a mitigation for minimising the risk of collision with marine mammals. Navitas will also follow the Falkland Islands Cetacean Code of Conduct. The EIS will be amended so that the Code of Conduct is added to the guidelines.	Section 10.4.1.1 Section 10.11.3 Section 15.6.2.1.3 Section 15.6.2.1.4
Falkland Islands Maritime Authority			
FIMA 1	1.3.1 – Regulatory Overview (page 30). Maritime Ordinance 2017 should be listed.	Thank you for your comment. This is noted and will be amended.	Section 1.3.1 Section 3.1.7.3
FIMA 2	2.2.3.2 – Installation (page 76). 'FIG Marine Authority' (and other name variations) should be read as 'Falkland Islands Maritime Authority' throughout the document.	Thank you for your comment. This is noted and will be amended throughout.	Section 2.2.3.1 and throughout document
FIMA 3	3.1.7.1 – International treaties and legislation relevant to the Falkland Islands. To note that the following international conventions listed have not yet been extended to the Falkland Islands by the UK:	Thank you for your comment. This is noted and will be amended.	Section 3.1.7.1

Ref.	Representation	Navitas response	Changes in Rev 4
	a. International Convention on Maritime Search and Rescue 1979. b. International Convention on the Control of Harmful Anti-fouling Systems on Ships 2001. c. International Convention for the Control and Management of Ship's Ballast Water and Sediments 2004 . Notwithstanding the issue of extension, under the Convention all vessels flagged to signatory states are required to hold certification confirming compliance with performance standard D-2 and to hold onboard an approved Ballast Water Management Plan.		
FIMA 4	3.1.7.3 – Falkland Islands national legislation. Maritime Ordinance 2017 should be listed.	Thank you for your comment. This is noted and will be amended.	Section 3.1.7.3
FIMA 5	3.2.8 – Emergency Response. An FIG Integrated Offshore Emergency Response (IOER) plan is currently (July 2024) in draft and will be shared with Navitas to ensure coherence with their Emergency Response Plans.	Noted thank you, Navitas look forward to collaborating with FIG on Emergency Response to ensure integrated plans. Navitas does not propose an amendment to document.	N/A
FIMA 6	3.2.18.1 – Sea Lion Field Northern Development Area management plans. FIMA looks forward to working with Navitas on the Harbour Management Plan (HMP).	Noted thank you for the comment.	N/A
FIMA 7	4.5.9 – Oil Spill Offshore. This section discounts dispersants and skimmers as viable options to respond to offshore oil spills because the oil is too waxy. No alternative options are offered here, although a return to the subject is promised later in the Statement.	Dispersants and oleophilic and weir skimmers are not considered suitable for this crude type. For Sea Lion crude, the CEDRE 2017 report states that 'oleophilic skimmers should not be recommended, as well as weir skimmers'. However, the report indicates that belt skimmers and nets would be appropriate. Weir skimming devices have been selected to respond to MGO spills. This equipment is specified in the Preliminary OPEPs submitted to FIG for review. Please see section 12.1.1.1.3 and the OPEPs for more detailed information. See also DMR 55. The text regarding the use of skimmers will be clarified in the relevant sections of the EIS.	Section 4.5.9

Ref.	Representation	Navitas response	Changes in Rev 4
FIMA 8	5.4.3 – Mobile Offshore Drilling Unit (MODU). Clarity needs to be established regarding how and by whom the 500m exclusion zone around the MODU (required under the Offshore Minerals Ordinance 1994) will be enforced. There will also be requirements to amend hydrographic publications and disseminate the information.	A dedicated ERRV (Emergency Response and Rescue Vessel (also known as "standby vessel") will be on standby at all times and ward off incoming 3rd party vessels and ensure no infringement of the 500m zone will occur. Vessel entry into the 500m zone will be controlled by permit and in accordance with the MODU Marine Operations Manual and MODU Safety Case. It is expected that marine activity close to the MODU will significantly reduce once the installation is on location and the relevant authorities and marine maps are updated.	N/A
FIMA 9	5.5.1 – Large Transport Vessel support. a. The indicative Large Transport Vessel (LTV) anchorages are noted. Final positions will be determined during future meetings between Navitas, FIMA, pilotage providers etc. b. Similarly to 5.4.3 above, clarity needs to be established regarding how, by whom and under what powers any 500m exclusion zone around the LTVs in Berkeley Sound will be enforced. There will also be requirements to amend hydrographic publications and disseminate the information. c. In order to put appropriate harbour management plans in place, more detail will be required on the LTVs themselves and activities likely to be associated with them, including the types of vessels rafting up, the frequency and duration of visits – and activity associated with visits such as the transfer of fuels, chemicals and large cargo. d. More detail is required on how will these vessels be serviced with regard to the discharge of food wastes, sullage and other discharges.	These are all good points. Navitas shall work closely with FIMA throughout the planning and execution stages of the development to ensure that: - final positions for the LTV anchorage sites are agreed and well communicated to mariners and other users of the sea - Activity Specific Operating Guidelines (ASOGs) are developed for the vessels operating in the area - FIMA is advised of all vessels planning to operate in the area - FIMA is advised of the activities and equipment / product transferred between vessels.	Section 5.5.1

Ref.	Representation	Navitas response	Changes in Rev 4
FIMA 10	5.11.1.1 – Port facilities. Although the majority of berthing activity will be centred on the Temporary Dock Facility (TDF) the wider impact of much increased maritime traffic using Stanley Harbour, Port William and Berkeley Sound needs to be fully examined to ensure de-confliction with other key users, adequate resourcing of harbour operations (anchorages, berths, pilotage, tugs) and ultimately the safe management of harbour operations.	Please refer to Section 11.2 Other users of the sea inshore for further detail on the planned use of the TDF and vessel movements within Stanley Harbour and Berkeley Sound. Navitas will work with FIMA as plans develop. As noted in the response to FIMA 9, Navitas agrees with these comments and is keen to work closely with FIMA throughout the planning and execution of the development.	N/A
FIMA 11	5.11.1.1.1 – The Temporary Dock Facility (TDF). This section makes reference to a requirement to increase the depth of water at the TDF. Falkland Islands legislation currently lacks provisions to support dredging operations however FIMA are liaising with AG Chambers over future legislative requirements.	The Falkland Islands planning process (including EIA) will be followed. Navitas will prepare a planning application and associated EIA as directed by the FIG Planning Department. Planning Permission was previously awarded to dredge an additional 0.5 m along the TDF berthing face but has now expired. Navitas will liaise with FIG Planning and FIMA, and the AG's Chambers as necessary, throughout.	N/A
FIMA 12	5.11.2 – Use of vessels. It is acknowledged that the figures cited assume a maximum number of vessels to provide a worst-case for impact and risk. That said, the estimate of total extra vessel 'days' for Stage 1 is 5,373 over 31 months, equating to an average of 5.6 extra vessels per day and for Stage 2 the total is 7,072 over 35 months, equating to an average of extra 6.5 vessels per day. The impact of this increase in traffic on harbour control, pilotage services, harbour launch provision, tug support, anchorages and berths needs to be fully scoped, understood and planned for, including the allocation by FIG of adequate resources to ensure harbour operations can be safely conducted.	As noted in the response to FIMA 9, Navitas agrees with these comments and is keen to work closely with FIMA throughout the planning and execution of the development. These numbers have significant contingency built in and Navitas will refine these requirements should approvals be granted.	N/A
FIMA 13	5.11.3.2 – Search and Rescue (SAR) exercises. Close liaison between Navitas and the FI SAR Committee will be required in order to ensure coherence with the FI SAR Strategy and FI SAR Plan, both updated in June 2024.	Agreed - Navitas looks forward to working closely with FIG in this regard.	N/A
FIMA 14	7.6.2 – Sensitivity of north Falkland coastline to offshore oil (Crude/diesel) spills.	Part a. In the very unlikely event of an oil spill, each spill	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	a. Whilst assessing the north Falklands coastline (particularly on East Falkland) as the most likely site of coastal contamination, this section however goes on to highlight the need for prioritization in response to any spill, saying: 'A pragmatic compromise will need to be reached that balances the importance of a site with the level of resources that are required. This may mean that some important sites may not be tackled in favour of other more accessible sites…'. The lack of alternative suggestions regarding further mitigation indicates that more work is required on this issue. b. Contamination of the north Falklands coastline would clearly be most likely in the event of consistent northerly winds. Whilst noting that any oil would take a number of days to reach the north Falklands coastline, those same northerly (rotor-inducing) winds are likely to impact on the arrival of responders from overseas in the event of a major spill.	would be considered on a case-by-case basis with a net environmental benefit analysis (NEBA) completed. The preliminary OPEPs and the work completed in the EIS are illustrative examples based on historical metocean and weather datasets and volume / type of oil assumptions but would be refined should such an incident occur. Part b. This is a valid point. However, the likelihood of sustained Northerlies (for over 30 days) is not expected and the resources (both equipment and personnel) to manage a response in the event of international support delay is available on the islands.	
FIMA 15	7.7.3.2 – Other users of Berkeley Sound and the east coast. Although this section acknowledges the role of Berkeley Sound in support of the fishing industry, it does not fully capture how busy the Sound can be during successful fishing seasons. For example, in March 2024 there were as many as 7 reefers, 2 tankers and 30+ fishing vessels in the Sound on a daily basis.	Noted, thank you a 'pers. comm' observation will be added to this effect to reflect the busy period noted in March 2024.	Section 7.7.3.2
FIMA 16	7.7.4.1.3 – Port facilities in Berkeley Sound. Although routinely used by the fishing industry for transhipping, Berkeley Sound is also regularly used by vessels of all kinds for shelter in adverse weather conditions. All vessels crossing the Reporting Line report to 'Stanley Port Control', not the Fisheries Department.	Thank you for your comment. This is noted and will be amended.	Section 7.7.4.1.3
FIMA 17	10.7.1.1 – Relevant legislation. Part 14 of the Maritime Ordinance 2017 (Dumping and Deposits at Sea) should be listed under 'Relevant Falklands legislation'.	Thank you for your comment. This is noted and will be amended.	Section 10.7.1.1
FIMA 18	10.7.1.1.5 – The PON 8 and oil sheen reporting. In addition to the Department of Mineral Resources (DMR), all oil sheen reports should also be made to FIMA. Further reporting guidance is contained within the NOSCP.	Thank you for your comment. This is noted and will be amended. Navitas note that the preliminary OPEPs submitted to FIG acknowledge that PON 8	Section 10.7.1.1.5

Ref.	Representation	Navitas response	Changes in Rev 4
		notifications/oil sheen reports will also be made to FIMA	
FIMA 19	10.11.5 – Industry-standard mitigation measures (to reduce the risk of collisions between vessels and marine animals). The reference to Navitas' operating procedures to limit maximum vessel speeds to 10 knots or less in certain areas is welcome and will complement existing procedures which see FIMA promulgating warnings and advisory speed limits in Port William and Berkeley Sound if whales have been reported in the vicinity.	Thank you for your comment. Navitas note that project specific mitigation reduces speed further to 8 knots at the entrance to Berkeley Sound. This is expected and reasonable and shall form part of the Vessels operating procedure and Area Specific Operations Guidelines (ASOGs).	N/A
FIMA 20	11.1.1.1.1 - Navigational Compliance. The expansion of Rule 7 to include reference to Automatic Identification System (AIS) should be removed or amended., as the current wording implies that it can be used as a stand-alone collision avoidance system. AIS can however be used with discretion and in combination with other systems and/or visual tracking.	Thank you for your comment. This is noted and will be amended.	Section 11.1.1.1.1
FIMA 21	11.1.1.1.2 – Offshore Exclusion Zones (safety zones). a. If retained, 'Notes to Mariners' should be changed to read 'Notices to Mariners'. b. Instead of the bulleted list in this paragraph, suggest replace with 'details of exclusion zones to be promulgated *via* Maritime Safety Information (MSI) under Coastal State obligations'. This wording will ensure that all means of promulgation are covered, not just those listed.	Thank you for your comment. This is noted and will be amended as per point b.	Section 11.1.1.1.2
FIMA 22	11.1.2.3 – Additional vessels. The phrase "while at sea, all Navitas project vessels which are not at anchor will maintain 24hr watchkeeping using radar, AIS and visual sightings" suggests (likely unintentionally) that Navitas project vessels at anchor will not maintain 24hr watches, which they are required to do under COLREGS 1972.	Thank you for your comment. This is noted and was not the intention. The text will be amended accordingly.	Section 11.1.2.3
FIMA 23	11.1.5.3 - Vessel operations. There is much emphasis on AIS in mitigating the risk of collision, which is relevant but AIS, if fitted, must be used in concert with the use of radar and visual lookout.	Thank you for your comment. This is noted and will be clarified.	Section 11.1.5.3

Ref.	Representation	Navitas response	Changes in Rev 4
FIMA 24	11.2.2.2.2 – LTV presence in Berkeley Sound. As noted in this section, final positions for the LTVs will be determined during future meetings between Navitas, FIMA, pilotage providers etc.	Thank you for your comment. This is noted and agreed.	N/A
FIMA 25	11.2.4.4.1 – Exclusion Zones. Clarity needs to be established regarding how, by whom and under what powers any 500m exclusion zone around the LTVs will be enforced.	Thank you for your comment. This is noted. Please see above response to comment FIMA 8. The potential for an exclusion zone and how this will be managed will be discussed with FIMA (notice to mariners, guard vessel, etc.) The future approach to selecting the final LTV locations, and determining the specifics of any proposed exclusion zone in consultation with FIMA will be noted in the post-consultation EIS.	Section 11.2.2.2
FIMA 26	11.2.4.4.1.1 – Reduced anchorage availability. Aside from bunkering and trans-shipment operations, vessels also use Berkeley Sound for shelter in adverse weather. Sheltering vessels will not always anchor.	Thank you for your comment. This is noted and will be amended.	Section 11.2.4.4.1.1
FIMA 27	11.2.5.2 – Vessel Operations. Navitas' harbour management plans for hydrocarbons-related shipping will be developed in close cooperation with FIMA, which exercises overall control of shipping movements in Stanley Harbour under the Harbours and Ports Ordinance 2017.	Thank you for your comment. This is noted and agreed.	N/A
FIMA 28	11.2.6.1.1 – Disturbance to other users within Stanley Harbour. Assessing the severity of the effect of additional vessels fuelling at FIPASS as 'Minor' may underplay the level of disturbance during busy periods in the fishing and cruise ship seasons, especially if a dedicated fuel line is not added to the TDF. In addition, a greater understanding is required regarding the capacity of those delivering pilotage services to cope with increased demand.	A dedicated fuel line from Stanley Services tank farm to the TDF is planned therefore it is expected that Navitas' use of FIPASS will be very limited. The comment on pilotage services is well noted and Navitas will work closely with FIMA and the pilotage service throughout the planning period and during operations to ensure that the service is not overwhelmed and that additional capacity can be sourced as required.	N/A
FIMA 29	11.2.6.1.2 – Loss of anchorage space due to exclusion zones in Berkeley Sound. To say that Berkeley Sound is 'largely unregulated' is not true. Although anchorages have not hitherto been formally allocated in the Sound, vessels are still required to make entry and departure reports and whilst	Thank you for your comment. This is noted and will be amended.	Section 11.2.6.1.2

Ref.	Representation	Navitas response	Changes in Rev 4
	using it vessels are subject to the same general regulatory regime as those using Port William and Stanley Harbour.		
FIMA 30	11.2.6.1.3 – Potential positive impact of the presence of Phase 1 and 2 Vessels. Noted and very welcome. When plans are mature enough, FIMA will be keen to learn what tug capability Navitas may deploy to the Stanley Harbour area.	Navitas shall keep FIMA advised of the vessels it has chartered and their capabilities.	N/A
FIMA 31	11.2.6.2.1 – Collisions in Stanley Harbour. Although the seasonal nature of traffic using Stanley Harbour is acknowledged elsewhere in the EIS, the phrase in this section “it will remain a relatively quiet port” is an over-generalization. Risks of collision need to be measured against the busy periods for the fishing and cruise ship industries when the port is anything but quiet.	Thank you for your comment. This is noted and the text has been amended to 'A relatively quiet port with notable busy periods during cruise ship and fishing seasons'. The precautionary approach of this assessment does include assessing the risk of collisions at busy times.	Section 11.2.6.2.1
FIMA 32	11.2.9.2 – Berkeley Sound. Although the context of the statement is understood, it is not correct to say “any vessel at anchor effectively has an exclusion zone around it”.	Thank you for your comment. Navitas will clarify the text.	Section 11.2.9.2
FIMA 33	11.2.10.4 – Monitoring required. Agreed.	Noted	N/A
FIMA 34	12.1.1.1 – Legislation relevant to oil and diesel spills. Under Falkland Islands Legislation, reference should be made to the Maritime (Ship to Ship Transfer) Regulations 2023, which came into force on 30th November 2023.	Thank you for your comment. This is noted and will be amended.	Section 12.1.1.1
FIMA 35	12.1.1.1.1 – National Oil Spill Contingency Plan (NOSCP). The NOSCP will need a root-and-branch review to ensure coherence between it and Navitas’ Oil Pollution Emergency Plan (OPEP), including clearly defining where responsibilities for shoreline protection and clean-up lie.	Thank you for your comment. This is noted and Navitas look forward to working with FIMA/FIG on this. Navitas has prepared and submitted preliminary OPEPs for FIG review (August 2024). Operational OPEPs will be completed and submitted to FIG for approval at least 6 months prior to commencement of operations.	N/A
FIMA 36	12.2.1.1 – Relevant legislation. As highlighted under 12.1.1.1, reference should be made to the Maritime (Ship to Ship Transfer) Regulations 2023.	Thank you for your comment. This is noted and will be amended.	Section 12.2.1.1
FIMA 37	12.2.7 – Project-specific mitigation measures. Close coordination between Navitas and FIMA over harbour management plans will be key. Bunkering	Thank you for your comment. This is noted and agreed.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	operations will also need to conform to the provisions of the Maritime (Ship to Ship Transfer) Regulations 2023.		
FIMA 38	12.3.4.1.3 – Vessel approaches. The point has been made earlier in this response but the phrase in this section "by international standards the harbour is not regarded as a busy port and collisions and groundings should be readily avoidable" down plays how crowded the port can get during busy periods for the fishing and cruise ship industries. It also does not take into account the significant impact of strong winds on the likelihood of groundings, as manifested in the grounding of the reefer FRIO CHIKUMA in April this year.	Please see response to comment FIMA 31 above.	Section 12.3.4.1.3
FIMA 39	12.3.5.2 – Vessel approaches. Already noted under earlier sections but – agreed - close coordination between Navitas and FIMA over harbour management plans will be key.	Thank you for your comment. This is noted and agreed.	N/A
FIMA 40	12.3.10 – Confidence. There is no need to rely on 'collective memory' regarding fuel spills, collisions and groundings, as official records are held by FIMA dating back to the 1990s. These can be made available to Navitas in support of further reporting.	These records have now been provided by FIMA and will be utilised to update the EIS.	Section 12.3.10
Fortuna Ltd. Group			
FOR 1	It is noted that the intention now is for 'direct offtake' at the oil field with no STS operation for crude oil in Berkeley Sound. There is a requirement for 2-3 large transport vessels (LTV), with exclusion zones, for up to c 13 months. Berkeley Sound is the main harbour used for seasonal *Illex* squid transhipment operations. Reliance on a range of services from Stanley supporting these transhipments means there are no realistic alternatives. The EIS assesses that the loss of anchorage space due to the LTVs will be low impact, which we hope will prove to be the case. We also hope that there will be no great impact or restriction on *Illex* transhipping operations which take place on a 24/7 basis.	These are all good points. Navitas shall work closely with FIMA and consult with FIFCA throughout the planning and execution stages of the development to ensure that: - final positions for the LTV anchorage sites are agreed and well communicated to mariners and other users of the sea - Activity Specific Operating Guidelines (ASOGs) are developed for the vessels operating in the area The LTVs (and 500m radius exclusion zones around both vessels) will take up 1.349% of the area of Berkeley Sound so are not considered to pose a significant impact to other users of the area.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		Of note: there will only be two LTV's in Berkeley Sound at any time.	
FOR 2	The EIS states that 'over-trawlable' subsea infrastructure is not considered necessary due to water depth and lack of fishing activity. That may be now, but it is not necessarily the case for ever. There are areas fished now which were not fished 30 years ago. This links to decommissioning as whilst the Sea Lion exclusion zones are in place trawling should only be at some distance. Once the site is abandoned/decommissioned it will be another matter. It is indicated that the decommissioning plan/commitment is a separate exercise and for the future. Our view is that the approach to decommissioning should be made clearer now and that the seabed should not be left fouled.	The Sea Lion subsea infrastructure will remain within exclusion zone whilst the field is operational. In accordance with Falkland Islands Government legislation decommissioning is subject to a separate EIA but it should be noted that the regulations state once a field is decommissioned all subsea infrastructure shall be removed, consequently there would be no requirement for overtrawlable structures. See also DGN 3.	N/A
FOR 3	Page 464: There are 3 charts showing valid fishing areas. Chart b) may be correct for finfish, but chart c) is not correct for *Illex* (it looks like a duplicate of b). The valid area for *Illex* covers a different area and includes and extends beyond the Sea Lion location. It is recognised that fishing for *Illex* does not extend to the full extent of the valid licence area for *Illex* licences. However, *Illex* fishing and *Illex* migrations occur closer to the Sealion area than portrayed by this chart.	Thank you for your comment. This is noted and the corrected charts will be placed in the post-consultation EIS. Additional information demonstrating the location of *illex* fishing in relation to the Sea Lion Field was presented in the FIFCA EIS presentation and will be published in the post-consultation EIS. The information demonstrates that there is no fishing overlap but vessels do occasionally transit over the Sea Lion field area.	Section 7.5.1.4 Figure 7-107
FOR 4	Page 484: The paragraph on the Falkland Islands economy characterises the fishing economy as "in 1990, the bulk economic activity shifted to the sale of fishing licences to foreign vessels" & "income from license fees fluctuates". It is noted that the EIS is quoting from other publications, but it is an obsolete characterisation which sells the FI fishing industry short. FIG Treasury data and other sources will show that corporate tax take from FI fishing companies is a very significant revenue stream but which also reflects the wider economic activity of FI fishing companies, investment and operation of FI registered vessels as well as partnering with overseas companies and vessels. A summary of GVA/GDP is added below showing that the fisheries sector accounts for *c.* 60%.	Navitas is required to assess oil spill financial liability and provide this as a separate regulatory submission to FIG for review and approval. This includes assessment of the worst-case impact on the Falkland Islands environment and economy (including specific fisheries and tourism analysis incorporating information from case studies from elsewhere and Falkland Islands specific information). This requires Navitas to demonstrate that it will have sufficient insurance in place to cover the assessed worst-case cost of oil spill response and clean up and the	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	The important point is that if there is an activity or accident which has a negative impact on the fishery in terms of magnitude it is not a few foreign licence fees at stake it could be a serious chunk of the entire FI economy.	financial impact on broader industry and the Islands economy.	
FOR 5	*Illex* (or Argentine Shortfin squid) are one of the most significant resources in the Southwest Atlantic and seasonally in FI conservation zones. The major potential pollution events of a blow-out or loss of FPSO cargo are indeed hopefully highly unlikely. There is some overlap between the *Illex* distribution both in FI zones and on high seas with the modelling of oil dispersion from those pollution events. In view of the significance of the *Illex* resource it is considered that there might have been more scope to model the potential interaction of *Illex* and oil. The table at page 1154 does capture the potential severity of impact to a degree. A spill which affects part of the fishery might have a wider reputational impact, or wider spread measures and restrictions due to a precautionary approach.	See response to FOR 4. In addition to this, within the Oil Spill Financial Liability Assessment actual and reputational damage as well as long term marketing impact have been considered thus demonstrating the maximum level of compensation (and therefore Navitas' insurance) to cover such an (albeit highly unlikely) event.	N/A
Falkland Islands Government Health and Safety			
H&S 1	Hazardous waste legislation is devolved in the UK and these amended. regs are only used in Scotland. Does this mean that all hazardous waste exported to the UK will arrive into Scotland, otherwise reference needs to be made to the Hazardous Waste (England & Wales) regulations 2005 as well.	If waste does need to be transported back to the UK, it is expected that it will arrive in Scotland and be managed / treated / disposed of in Scotland as was the case in the previous exploration drilling campaigns.	N/A
H&S 2	Oily wastewater will usually be classified as either EWC 13:05:07* or possibly 19:08:10* (if arising from a registered waste treatment facility) both of which are Absolute Hazardous Waste entries in WM3. In this case, how can it be discharged to foul sewer under a consent (particularly as there are currently no treatment facilities on the islands)?	The post-consultation EIS will clarify that onshore oily waste water will not go into the Stanley sewerage system. Onshore operations which may result in oily water discharge will be completed in a bunded area which will contain the oily water, this will then be treated, incinerated or dealt with away from the sewerage network and shall align with Navitas' Waste Management Procedure. It is understood that the FIG Stanley Incinerator will be operational by end 2026. This aligns with Navitas'	Section 10.10.2.2.1 Table 10.86 Section 10.7.2.8

Ref.	Representation	Navitas response	Changes in Rev 4
		operational schedule. Should the FIG Stanley Incinerator not be available Navitas would: 1. Store the waste in suitable containers onshore until the FIG incinerator is once again available; or 2. Store the waste in suitable containers onshore until offshore treatment on board either the MODU or FPSO is available 3. Store the waste in suitable containers onshore until a suitable volume is ready for export under the Basel Convention to the UK. Waste oils from this process shall always be candidates for re-use, incineration is a secondary solution.	
H&S 3	The disposal option for the aerosol and gas cylinder waste stream identifies Hazardous Landfill as one of the options: Most of this waste stream will be classed as “Flammable” (as propane is usually used as the propellant gas nowadays) and all flammables are banned from landfill disposal under the Landfill Directive (Article 5(3)b).	Understood, these waste streams will not go to landfill, the text in the chapter will be checked for clarity in the post-consultation EIS.	Section 10.10.4.4.1 Table 10.86
H&S 4	The disposal option for the hazardous electrical waste stream identifies Hazardous Landfill and Recovery (which is usually EfW) as the options: Waste electronics and electrical equipment is classed as “WEEE”, and the current UK WEEE regulations legally require all such waste to be diverted from landfill or incineration (which means producers of WEEE in any form have a responsibility to recycle and reuse any electrical waste where possible).	Understood, these waste streams will not go to landfill, text in the chapter will be checked for clarity in the post-consultation EIS.	Table 10.86
H&S 5	The disposal option for the non-hazardous electrical waste stream identifies Hazardous Landfill and Recovery (which is usually EfW) as two of the three options: As above, waste electronics and electrical equipment is classed as “WEEE”, and the current UK WEEE regulations legally require all such waste to be diverted from landfill or incineration (which means producers of WEEE in any form have a responsibility to recycle and reuse any electrical waste where possible).	Understood, these waste streams will not go to landfill, text in the chapter will be checked for clarity in the post-consultation EIS.	Table 10.86

Ref.	Representation	Navitas response	Changes in Rev 4
H&S 6	The disposal option for the oily water waste stream identifies Treat to Sewer as the option: Are sewage treatment facilities available on the islands, if not, then this should be, treat to registered discharge (covering discharges that go direct to a controlled water source). The consent limits are likely to be different in this case (and it would probably not be allowed).	Onshore oily waste water will not go into the Stanley sewerage system. This will be clarified in the post-consultation EIS. Onshore operations which may result in oily water discharge will be completed in a bunded area which will contain the oily water, this will then be treated, incinerated or dealt with away from the sewerage network and shall align with Navitas' Waste Management Procedure. It is understood that the FIG Stanley Incinerator will be operational by end 2026. This aligns with Navitas' operational schedule. Should the FIG Stanley Incinerator not be available Navitas would: 1. Store the waste in suitable containers onshore until the FIG incinerator is once again available; or 2. Store the waste in suitable containers onshore until offshore treatment on board either the MODU or FPSO is available 3. Store the waste in suitable containers onshore until a suitable volume is ready for export under the Basel Convention to the UK. Waste oils from this process shall always be candidates for re-use, incineration is a secondary solution.	Section 10.10.2.2.1 Table 10.86
H&S 7	Footnote 3 states that: “Any food waste returning to the supply base, for example if offshore macerators are not working, would be incinerated unless future opportunities arise in collaboration with FIG for composting of such resources”: Will this be classified as International Catering Waste (ICW)? which would then be classed as a Cat I Animal By Product (ABP). If this is the case, then it would need to comply with additional controls for storage, transport, and disposal.	Understood.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
Individual representations			
IND1 1	I am responding to your request for input to the public consultation on the Environmental Impact Statement (EIS) for the Sea Lion Field Northern Development Area, Phase 1 and 2, as published on your website (both the Non-Technical Summary and full document). I am sending this response to the consultation as a private individual and not on behalf of any organisation. In summary, my conclusion it that this project carries the risk of an accidental oil discharge resulting in severe environmental damage that would undermine the twin pillars of the current prosperity and future economic growth in the Falkland Islands, namely your Fisheries and Tourism industries. The current high GDP per capita of the Falkland Islands and its potential for further growth would be placed at risk in order to develop a new oil sector that will be a transient source of income. Furthermore, in the event of an oil discharge potential damage to the environment in the South Atlantic risks undermining your relationships with countries bordering that ocean. I give details of my analysis below.	Risk of oil spills are described in the document and the potential impact to tourism and fisheries is considered. Navitas is also required to assess oil spill financial liability and provide this as a separate regulatory submission to FIG for review and approval. This includes assessment of the worst-case impact on the Falkland Islands environment and economy (including specific fisheries and tourism analysis incorporating information from case studies from elsewhere and Falkland Islands specific information) and requires Navitas to demonstrate that it will have sufficient insurance in place to cover the assessed worst-case cost of oil spill response and clean up and the financial impact on broader industry and the Islands economy.	N/A
IND1 2	The risk that concerns me most is that of an unconstrained well blow out and oil release, similar to the 2010 Deepwater Horizon incident in the Gulf of Mexico. The industry has learnt from that incident by improving well design to reduce the risk of an unconstrained release of oil and by deploying well capping stacks in established oil producing regions so that a release can be contained quickly. The issue for the Falkland Islands is that as a new oil production region the specialized equipment needed to deal with an incident would need to be transported there after a problem has occurred.	Navitas will ensure industry best practice mitigation measures to minimise the risk of an uncontrolled release to oil. Capping Devices that can be transported by air in the event of an incident are readily available. Analysis of the location and number of capping devices available indicates that a capping device could be deployed to contain a well blow out at the Sea Lion field within 14 days, with 21 days being the worst-case expected scenario.	N/A
IND1 3	Section 1.7.4.3.1 'Accidental releases of crude oil or MGO to sea offshore' on page 38 of the Non-Technical Summary looks at the above risk but does not go into detail. For the details you need to go to Section 12.1 'Accidental and chronic oil pollution offshore' starting on page 1073 of the full EIS. Table 12.3 indicates that the assumed worst-case scenario for the duration of oil	Navitas is required to assess the potential impact of an oil spill event on the Falklands environment and economy and demonstrate to the Government that it will have sufficient insurance in place to cover this liability should an oil spill event occur. Revenues that	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	release from a well blow out is 21 days, based on the time taken to transport (by air) and deploy a well capping stack (details in Table 12.7). In reality there could be other complicating factors such as the need to extinguish fires on rigs and clear debris from a damaged wellhead so a capping stack can be deployed. Models of the dispersion of the released oil indicate it primarily moving in a Northern direction based on prevailing currents and wind (see for example Figure 12-4 on page 1110). The potential severity of the effect of a well blow out on the human population of the Falkland Islands *via* its impact on Fisheries and Tourism is considered to be 'High' but when the likelihood of occurrence is taken into account ('Unlikely') the overall risk significance is reduced to 'Moderate' (see Table 12.9). There are two major problems with using the above conclusions in the EIS to support development of the Sea Lion project. First, the GDP per capital of the Falkland Islands is relatively high by international standards but income from Fisheries and Tourism are significant contributors to this prosperity and its future growth (State of the Falkland Islands Economy 2020). Risking the viability of the two most promising sectors of the economy and the foundation of future prosperity of the Falkland islands to develop a third sector, that will provide only transient income, would be an unwise trade off.	would arise from the Sea Lion Phase 1 and 2 development would enable FIG to secure long term economic sustainability and insulate the Islands from the fluctuations in income associated with fishing and tourism.	
IND1 4	Second, the projected dispersion of any oil released in a Northern direction due to prevailing currents and wind, and away from the coast of the Falkland Islands, may seem like a positive. However, the countries in the region that the Falkland Islands has key relationships with may not see it that way as the potential environmental impacts in the wider South Atlantic would be severe, damaging international relations.	The oil spill modelling suggests that oil waxlets would disperse and degrade in the water column. Likelihood of oil beaching in detectible quantities is very low. Oil spill modelling indicates that by the time any oil crosses a transboundary line it would likely be undetectable with waxlets small and spread out, see Section 12.1.4.4.2.	N/A
IND1 5	In the interest of balance I note that the project design includes a gas injection well and associated gas compression facilities on the FPSO vessel in order to eliminate the routine flaring of produced gas during normal production (Table 1.1). There is therefore no reason to conclude that the carbon intensity of oil production in this project will be high by global standards. I will leave it to others to comment on links between oil	Thank you for your comments. Navitas notes the comment that there is no reason to conclude that the carbon intensity of oil production in this project will be high by global standards.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	production from a specific non OPEC+ project, such as this, and any incremental global oil consumption with associated carbon emissions. The above analysis and views are entirely my own. My conclusion is that this project is not in the long-term interest of the people of the Falkland Islands.		
IND2 1	Throughout the entire EIS there is a extreme lack of up to date data gathering and in date evidence provision.	Navitas will provide a table of new data acquired. This will be provided as an appendix to the post-consultation EIS.	Appendix 4
IND2 2	Table 4.4 Page 118, (Tanker Manoeuvring and Maintaining appropriate positioning) The reported simulation of 30 knots of winds and 3 meter seas show a total lack of understanding and knowledge of the seas and wind conditions often prevailing within the Sealion production area again showing total lack of any real time and up to date research.	Navitas strongly disagrees with this statement. Site specific metocean data collected over a 3 year period alongside the creation of a detailed metocean model drawing upon all the available datasets for the region demonstrates that the metocean conditions at the Sea Lion Field are similar to the UK Central North Sea. This modelling demonstrates that there will be sufficient berthing availability for direct offtake operations to be conducted safely.	N/A
IND2 3	No new up to date and accurate bird species data is evident for any of the inshore and offshore areas of operation, why was not survey work conducted within the areas by the company to show a commitment to having the correct UpToDate datasets not data from up to 20 years out of date. The environment has changed immensely in the last 10 years and the old data set information is now not current. The bird strike information is from 2015 and totally out of date.	There are new data from the GAP project, specifically tracking data. Regarding occurrence and distribution. The importance of the Patagonian Shelf around the Falkland Islands, as foraging habitat for seabirds and marine mammals and static ocean features that are associated with enhanced primary productivity. Baylis *et al.* (2019) highlights that for nine-species tracked, the probability of occurrence is highest on the Patagonian Shelf, shelf slope and the Burdwood Bank (Fig 7-53, pg. 360). These findings are similar to the at-sea distribution presented for the same species (White *et al.,* 2002). This is likely to reflect productivity on the Patagonian Shelf, being linked to the Patagonian Shelf, slope and Burdwood Bank (static features, associated with predictable areas of	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		enhanced productivity) (e.g., Fig 7-35, pg. 293). Based on the predictive models, and knowledge of local oceanography, the importance of the Patagonian Shelf around the Falkland Islands is unlikely to have changed over the past 24 years, hence animal distribution is still likely to be associated with the Patagonian Shelf. Regarding abundance: The statement specifically relates to the distribution and movements of animals. Data gaps remain for both Falkland Islands breeding species, and migratory visitors. Filling data gaps will improve our understanding of occurrence and distribution.	
IND2 4	10.1.6.1.2 page 603 the used data is not up to date and why did the company not carry out a full survey of the sealion field area of operation covering the entire year to get a full and in-depth analyses of all the species that do live and migrate through this area as this part of water in the FOCZ has very rich waters so attracts birds and whales at different times of the year.	Passive acoustic monitoring (PAM) data has been collected at the Sea Lion Field for one year. Whenever vessels associated with Sea Lion Field geotechnical, geophysical, seismic, exploration and appraisal operations have been in the area seabird and marine mammal observers (SMMOs) have been on board and collected data. These datasets, alongside other regional data (e.g., the GAP project with a large investments from both industry and government) have been compiled to inform this environmental impact assessment. It is understood however, that there are data gaps and this has been risk assessed through the EIA and the precautionary principle applied. In the EMMP Navitas has committed to continuing data collection within this area in order to verify the validity of the impact assessments and inform ongoing management and mitigation.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
IND2 5	10.1.6.1.3 page 604 this statement is very wrong that the sooty shearwaters only congregate at the entrance of Berkeley sound these birds use the entire length and breadth of Berkeley sound both in the early morning and evening when departing and returning to their nesting site. So being 10 kilometres from kidney is not a Low impact it is still a high one and all other bird species that are found in Berkeley sound also can be found in all areas, the tankers at anchor will impact highly with all flying bird species while at anchor in the sound, again no study has been conducted by the company on the abundance or areas of travel of birds within Berkeley sound showing yet again a total lack of concern for the wildlife environment.	Thank you for the comment. Observation by a number researchers suggest the greatest loafing abundances are in the region of Cochon and Kidney Islands during dawn and dusk. The sensitivity of the receptor is high because they represent a significant proportion of the biogeographic population (i.e., >1 % of the South Atlantic population). Navitas' operations in Berkeley Sound are limited to two anchored LTVs (not tankers) in clearly designated areas and the offtake of their cargo (infrastructure) over a period of 13 months. Navitas welcome the respondent to review the research on the benthic, birdlife, inter-tidal, coastal sensitivity which has been completed by the Company should they so desire.	N/A
IND2 6	10.1.6.2.1 page 605 How can the company say that single and multi bird strikes within the sealion field be low when they have not conducted any bird species or abundance of birds across a 12 month time scale, this again shows a total lack of interest or ability to gather the correct data and information for the EIS.	Thank you for the comment. Data are available from SAST surveys and other sources at the Sea Lion Field and in Berkeley Sound. See Chapter 7. The EMMP workshop report (April 2019) notes that workshop attendees (including environmental NGOs, independent experts and FI Fisheries Department) concluded that 'bird strikes caused by light attraction, where they occur tend to be very episodic and thus difficult to detect and monitor. There were no offshore bird strikes during the exploration and appraisal campaigns in the Sea Lion area and very few made during observations by FIFD in brightly-lit squid jigger fleet in waters to the north of the Falkland Islands.' Further surveys using qualified SMMOs will be conducted over 3 years before First-Oil. Of note, the presence of vessels in Berkeley Sound is limited to	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		two vessels for a total of 13 non-consecutive months and Navitas will also develop a Bird Strike Action Plan as part of the EMMP (Chapter 15).	
IND2 7	10.1.6.2.3, 10.1.6.2.4 pages 606,607 again the company has shown that there is no survey data conducted within Berkeley sound that they have not even commissioned an up to date and relevant survey when they knew that there was a big data gap in a very sensitive seabird area, having the impact as low yet again shows total lack of any concern for the wildlife environment of Berkeley sound with endangered species known to use the area intensely when breeding.	Thank you for the comment. Please see Ch7. Bird surveys in Berkeley Sound were conducted in all four seasons over a period of two years. Also note that the activities in Berkeley Sound are limited to two vessels over a period of 13 months. Navitas will also establish a Bird Strike Action Plan that includes Berkeley Sound and the Sea Lion Field.	N/A
IND2 8	The fishing industry has had very minimal shipping activity within Berkeley sound over the last 10 years which will have resulted in limited light pollution within the seabird breeding times.	Data from FIFD and FIMA would suggest that Berkeley Sound is regularly used by vessels, and Navitas would not consider it to have 'minimal shipping activity'.	N/A
IND2 9	10.5.6.1.3 page 703,704 the statement that transiting vessels will have a short duration of noise pollution time when entering Berkeley sound is not correct as once the vessels are anchored they will still emit large amounts of noise from the vessel into the water Colum from generators, also there will be significant noise from traveling launches and other supply vessel going to and from the vessels while they are moored. This additional traffic has not even been mentioned so having a slight as a disturbance is again showing total lack of understanding of the whale types who are present within Berkeley sound a anticipated kbi for Sei whales who are extremely sensitive to any additional noise levels.	When at anchor and not offloading their cargo, the LTVs will maintain one generator to keep the ship's facilities running but otherwise they will be on the anchor, weather vaning, minimising the noise they produce. When offloading they will be fully powered to enable safe operations etc. This will be acknowledged in the revised underwater noise section which will be included in the-post-consultation EIS.	Section 10.5
IND2 10	Table 10.35 under mitigation/prevention/control there is Project specific none proposed why is the company not actively looking at all additional ways to address these headlines with a project specific proposal thus actually showing that the known noise disturbance is being worked on and reduced not that it is being ignored.	No mitigations are proposed here as the potential impacts from two vessels anchoring in Berkeley Sound for up to 13 months have been assessed as 'Low' and 'Very low'	N/A
IND2 11	There is no UpToDate data or even any sign of the company attempting to establish the extent of the whale population and species types that will be highly effected within Berkeley sound and also the FICZ FOCZ of operations for the proposed oil field, no study or area information gathering work has	Thank you for the comment. Please note: Navitas (previously POEPL) invested significantly in data gathering to inform the environmental baseline of the Sea Lion Field and	Section 7.4.6

Ref.	Representation	Navitas response	Changes in Rev 4
	been carried out and this part of the EIS feels like an after thought the whale populations and species around the Falkland islands and the waters are increasing and this is widely known (with over 8 years of comprehensive study by Falkland Conservation) but the company has shown little or no regard to this information or even reaching out to get the up to date and relevant information to actually make any risk assessment and mitigation works for the whale and dolphin populations.	inshore areas relevant to the proposed development. The Hipsey report gathered Sea Lion specific data over a 14-month period. Please note, given the limited operations now proposed in Berkeley Sound (i.e., no inshore transfer and only two vessels anchored for a non-consecutive period of 13 months) the EMMP workshop screened out the need for further Berkeley Sound Marine Mammal data. The baseline information was up to date at the time of writing and will be updated further as part of the post-consultation submission process. Navitas is committed to further data collection - see Chapter 15. The FIG 2016 guidance states that the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained. When carrying out the risk assessment data gaps can be taken into account and within the EIS are factored into the precautionary approach and the confidence ratings within the EIS.	
IND2 12	I fully support and agree with all of the Falkland conservation EIS reply statement, the entire Navitas EIS is not fit for purpose.	Navitas strongly disagrees with this statement. We refer the reader to the responses to Falklands Conversation (FC) comments.	N/A
IND3 1	The EIS indicates that in the majority of the oil spill scenarios considered the impact on squid and the associated fisheries would be “Low” or “Very Low”, with the exception of Scenario 1, where the impact is assessed as “Moderate”. I believe this is an underestimation of the sensitivity of the squid species that inhabit Falklands waters. Please find my detailed comments below: 1. Baseline biological information is incomplete or inaccurate	Thank you for the comment. Navitas will amend the text with new information from Chemshirova *et al.* (2023). Their abundances are likely to be low during that period. Arkhipkin *et al.* (2012), based on data from 13,044 commercial bottom and pelagic trawls between 2000 and 2010 mainly within the FCMFZ, and from 1,272 research trawls taken between 1999 and 2011 reports that they are 'practically absent	Section 7.4.4.2.2.2 Section 7.4.4.2.3.2

Ref.	Representation	Navitas response	Changes in Rev 4
	Sections 7.4.4.2.2.2 and 7.4.4.2.3.2. Table 7.9. Argentine shortfin squid: This table contains inaccurate information regarding the presence of this species in the Northern Slope habitat zone, namely it characterises this species as "Absent" in Winter, which is incorrect. The annual Falkland Islands Fisheries Department groundfish survey reports from July surveys show that this species persists throughout the region. Moreover, the individuals that are found during these periods are juveniles, which are more susceptible to possible environmental impacts of the project. Recent research has also highlighted the importance of these seemingly small assemblages of squid which help maintain the species' flexibility and adaptivity to adverse environmental conditions (Chemshirova *et al.,* 2023). The omission of this information leads to the underestimation of importance of these individuals and thus subsequently an underestimation of the possible impact of the development on this commercial species, valuable to the Falkland Islands fisheries	from the Patagonian Shelf and slope'. Also note that the assessment is based on a combination of the sensitivity of the receptor, severity of the effect and the likelihood of occurrence. Which in the case of oil spill is unlikely. Please see Chapter 8 on methodology. Navitas is required to assess oil spill financial liability and provide this as a separate regulatory submission to FIG for review and approval, this assessment was issued to FIG in August. This includes assessment of the worst-case impact on the Falkland Islands environment and economy (including specific fisheries analysis incorporating information from case studies from elsewhere and Falkland Islands specific information) and requires Navitas to demonstrate that it will have sufficient insurance in place to cover the assessed worst-case cost of oil spill response and clean up and the financial impact on broader industry and the Islands economy.	
IND3 2	Section 7.4.4.3 This section states that a summary of the ecology of each species is provided - "their seasonal abundances in relation to the Berkeley Sound Area, their seasonal spawning migrations and their principal diet." However, in the relevant section (7.4.4.3.2.1) when discussing "Loligo (Patagonian long-finned squid)" only superficial mention of "zooplankton" is made with regards to diet, despite extensive research on the topic being widely available (Büring *et al.,* 2022; Jones *et al.,* 2023). The summary also omits recent literature that highlights the importance of D. gahi as a keystone species in the Falkland Islands ecosystem (van der Grient, 2023; Büring *et al.,* 2024). The lack of information presented in this section leads to further misconceptions that result in the environmental impact of the development being underestimated.	Thank you for the comment. Navitas will update the text where relevant. The Büring *et al.,* 2024 and Jones *et al.,* 2023 papers were not available at the time of writing. Additional detail has been added on loligo diet, however, as this is a layman's summary it is felt adding detail on the stable isotopes using gladii (the subject of Jones et al) is too detailed for this EIS.	Section 7.4.4.3.2.1

Ref.	Representation	Navitas response	Changes in Rev 4
IND3 3	2. Misrepresentation of fishing activity relating to jigging and trawling vessels Section 7.7.3.1.1 The statement made here: "However, further analysis of Vessel Monitoring System (VMS) data indicates that most of the vessels reporting catch in this square were in fact fishing elsewhere." There doesn't seem to be any evidence presented to support this. Furthermore, whilst the subsequent sentence acknowledges the variability of *Illex* catches and the connection between high catches in the relevant grid square and years of high *Illex* abundance, the conclusion is drawn that "the area is rarely fished". This is an erroneous conclusion, one of the key characteristics of the *Illex* fishery is the inter-annual fluctuations frequently associated with environmental drivers (Chemshirova *et al.,* 2021). The current impact assessment subsequently minimises the possible effects the development may have by completely ruling out the possibility of the fishery utilising the same areas simply on the basis of population fluctuations.	Thank you for the comment. Navitas has also analysed AIS data and it is clear that the *Illex* fleet fish on the shelf break and sometimes report either their midday or midnight positions in the relevant grid square XFAK but do not fish in there. The AIS data corroborates the VMS data. Navitas is required to assess oil spill financial liability and provide this as a separate regulatory submission to FIG for review and approval, this assessment was issued to FIG in August, 2024. This includes assessment of the worst-case impact on the Falkland Islands environment and economy (including specific fisheries and tourism analysis incorporating information from case studies from elsewhere and Falkland Islands specific information) and requires Navitas to demonstrate that it will have sufficient insurance in place to cover the assessed worst-case cost of oil spill response and clean up and the financial impact on broader industry and the Islands economy.	N/A
IND3 4	3. Underwater noise - Offshore - omissions of recent relevant literature: Section 10.4.4.3.1 This section aims to assess the effect of the noise generated by the project on the invertebrates with a focus on squid. However, recent and relevant research on the topic is omitted. Recent literature investigating the effect of anthropogenic noise in the range of 20 - 1000 Hz shows negative effects on *Doryteuthis pealeii* feeding behaviour (Jones *et al.,* 2021). The proposed project's estimated noise level is <1000 Hz, this falls within the range investigated by the previously cited study. Furthermore, this section states "...commercially exploitable aggregations of squid are not known to occur within the area of the Sea Lion Field…", this also serves to underestimate the impact of the development as addressed in point 2 above.	Thank you for your comment, the underwater noise modelling is currently being re-run to more accurately reflect Navitas' proposal for the Sea Lion field and Berkeley Sound. These sections are also being updated with relevant citations suggested during the public consultation. See FIFD 54.	Section 10.4 Section 10.4.4.2 Section **Error! Reference source not found.** Section 10.5 Section 10.5.6.2

Ref.	Representation	Navitas response	Changes in Rev 4
IND3 5	4. Ecotoxicity tests not performed on cephalopods and effects of contamination not fully considered. Section 12.1.4.1.1.1 and Section 12.1.4.2.3.2 The ecotoxicity tests of the crude oil only investigated the effects on embryonic zebrafish. This is insufficient evidence for potential impact on squid eggs, which differ significantly from a freshwater fish. Additionally, there were no tests performed on any of the paralarval/juvenile stages which are more vulnerable than egg masses or adults for two reasons: a) they are not as mobile as adults and often subject to current transport; and b) previous studies on O. pallidus showed that newly hatched animals were more sensitive to the toxic effects of crude oil (Long & Holdway 2001). Overall, the omission of this information and lack of testing further leads to the inaccurate assumption that crude oil would have negligible effect on newly hatched individuals, again underestimating the risk and impact of the development. Furthermore, there is an omission of research that clearly shows that molluscs including cephalopods are more susceptible to polycyclic aromatic hydrocarbons due to their reduced ability to metabolise these compounds, thus leading to higher likelihood of bioaccumulation compared with other organisms (Lacoue-Labarthe *et al.,* 2016; Rodrigo & Costa, 2017). This further serves to minimise the negative impact that the potential development may have on squid populations.	Thank you for the comments. These are noted. See response to IND10 1. An oil spill is an unplanned risk and impact that could be caused by multiple stakeholders - not just the oil industry. Additional data acquisition will not change mitigation, but may help better predict effects of a spill event. Navitas would consider participating in research effort to explore oil spill effect on squid egg masses. Ecotoxicity tests using Sea Lion crude were carried out on zebra fish eggs at the CEDRE laboratory. It was not possible to transport and import Falkland Islands squid eggs to France and maintain their integrity to enable lab testing. The CEDRE report notes that 'Concerning the toxicity of the oil on fish eggs, no acute toxicity was observed. A slight subacute toxicity (larval malformation <3%) was noted for the highest concentrations (between 29% and 100% of the water saturated with PAHs).' The concentrations employed in the lab testing are highly precautionary being far greater than the concentrations that would be expected in a spill event, and the crude would form solid masses on contact with the sea-water, limiting potential for contamination. While not fully understood, the current thinking is that the major spawning grounds are on the Eastern sea-board, whilst it is also acknowledged that loligo may spawn all round the Falklands: it is important to note that in a spill event the modelling suggests that none of the oil reaches these areas. In the worst deterministic case the modelling suggests that oil might reach the northern coast in extremely low concentrations.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
IND3 6	5. Incomplete information on *D. gahi* life span Section 12.1.4.2.3 This section makes the case for the life span of all squid being only one year, thus any effects of a spill would be minimal. This is inaccurate. Recent research found that a proportion of the population lives longer than one year (Jones *et al.,* 2019). This means that any adverse effects could be magnified across time and space. This again leads to the incorrect conclusion that the impact of the development on the squid population in the region would be minimal.	Thank you for the comment. Navitas will update the text stating this; however, it should be noted that the majority of loligo only live for ~ one year. The Jones *et al.* (2019) paper is on super bull males. The results suggest that superbulls provide temporal connectivity and arise through phenotypic plasticity, likely providing connectivity (between cohorts) as a side effect of body shape and size rather than a genetically selected advantage. Please note that they represent a small proportion of the population.	Section 12.1.4.2.3.1
IND3 7	6. Underestimation the wider effect on squid population dynamics Section 12.1.4.2.3. This section does state that squid are sensitive to environmental conditions, but omits the fact that whilst the general short life span of squid (see point 5) may limit bioaccumulation, squid populations can be very volatile. Therefore, once knocked out of equilibrium there is a risk of the population entering a boom and bust cycle, which can be very damaging for squid fisheries in the long term (Rodhouse 2008). Again, I believe this section underestimates the extent of the impact of this development by not considering or presenting key aspects of squid biology.	Thank you for the comment. Considering the nature of the oil and the likelihood of a large spill / blow out Navitas has been precautionary. Navitas is required to assess oil spill financial liability and provide this as a separate regulatory submission to FIG for review and approval, this assessment was issued to FIG in August. This includes assessment of the worst-case impact on the Falkland Islands environment and economy (including specific fisheries and tourism analysis incorporating information from case studies from elsewhere and Falkland Islands specific information) and requires Navitas to demonstrate that it will have sufficient insurance in place to cover the assessed worst-case cost of oil spill response and clean up and the financial impact on broader industry and the Islands economy.	N/A
IND3 8	7. Omission of cephalopod biology and recent research on the effects of oil contaminants on cephalopods Section 12.1.4.2.3 All squid species perform vertical diel migrations, this makes them more susceptible to the adverse effects of contaminants from an oil spill (Sutton et al, 2022). Furthermore, due to these migrations, they are more likely vectors of the transfer of said contaminants (Arkhipkin,	Thank you for the comment. Both these papers are the subject of Macondo oil spill which is very light non-viscous volatile crude which is in great contrast to the Sea Lion crude. The latter is buoyant and will be solid due it is pour point. The modelling also shows that it will be carried in a north easterly direction for	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	2013). Previous work on investigation of oil spill contaminants has shown that the exposure of squid to these contaminants has been previously underestimated (Romero *et al.,* 2020). Additionally, the duration of the exposure of said contaminants was also longer than previously expected (Romero *et al.,* 2020). Finally, this again contributes to the overall underestimation of the potential risks associated with the proposed development.	the most frequent metocean conditions. Navitas has been precautionary in the risk assessment. All matters to do with fisheries have been assessed as significant. Navitas is required to assess oil spill financial liability and provide this as a separate regulatory submission to FIG for review and approval, this assessment was issued to FIG in August, 2024. This includes assessment of the worst-case impact on the Falkland Islands environment and economy (including specific fisheries analysis incorporating information from case studies from elsewhere and Falkland Islands specific information) and requires Navitas to demonstrate that it will have sufficient insurance in place to cover the assessed worst-case cost of oil spill response and clean up and the financial impact on broader industry and the Islands economy.	
IND3 9	8. No commitment of investigation of D. gahi spawning grounds. Section 1.6.1.1.2 Identifies the lack of information on D. gahi spawning grounds as a "key data gap". Section 7.2.4.1 it is stated that "the prevalence of these bottom-attached masses remains unclear". However, there is no evident commitment or attempt made to investigate this further, beyond some of the shallow surveys near Berkley Sound. This is insufficient, and contributes to the prolonged underestimation of the impact of this development on the squid populations in the Falkland Islands.	There is no inshore transfer of oil in the current project proposal: the activity in and nearshore is restricted to vessels transiting between Stanley and Berkeley Sound and the Sea Lion field. In addition there will be two LTVs in Berkeley Sound for a duration of 13 months. and in the unlikely event of an oil spill the modelling undertaken determines that very little oil arising from an offshore spill would reach the near shore. Navitas discussed the possibility of testing loligo eggs but it was not possible to keep them alive and get them to the CEDRE laboratory in France. Navitas has been precautionary in the risk assessment. Please also see response to IND 3 10.	N/A
IND3 10	Recommendations Based on the analysis described above, I do not recommend the	The industry committed through GAP to support research into loligo spawning grounds. At that time	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	commencement of the project. Further studies should include establishing up-to-date and baselines for the squid populations of the region; obtaining accurate locations of the possible spawning sites for D. gahi and performing ecotoxicity tests on squid egg masses, paralarvae and juveniles.	Premier was intending on crude oil transfer in Berkeley Sound; this is no longer the case. An oil spill is an unplanned risk and impact that could be caused by multiple stakeholders - not just the oil industry. Navitas would consider participating in research effort to explore oil spill effect on squid egg masses. Ecotoxicity tests using Sea Lion crude were carried out on zebra fish eggs at the CEDRE laboratory. It was not possible to transport and import Falkland Islands squid eggs to France and maintain their integrity to enable lab testing. Additional data acquisition will not change mitigation, but may help better predict effects of a spill event. Navitas is required to assess oil spill financial liability and provide this as a separate regulatory submission to FIG for review and approval, this assessment was issued to FIG in August, 2024. This includes assessment of the worst-case impact on the Falkland Islands environment and economy (including specific fisheries and tourism analysis incorporating information from case studies from elsewhere and Falkland Islands specific information) and requires Navitas to demonstrate that it will have sufficient insurance in place to cover the assessed worst-case cost of oil spill response and clean up and the financial impact on broader industry and the Islands economy.	
IND3 11	Conclusion In conclusion, the proposed oil drilling project may have a significant effect on local cephalopod populations. I urge the Falkland Islands Government and the Members of the Legislative Assembly to carefully consider these factors before making a final decision.	The Sea Lion Field is not a significant area of cephalopod migration - as such, fishing in the area is minimal. Navitas will provide additional clarity on the location of the fishery in relation to the Sea Lion field in the post-consultation EIS.	Section 12.1 Section 12.2

Ref.	Representation	Navitas response	Changes in Rev 4
		As detailed in the EIS an oil spill event would be highly unlikely and is heavily mitigated against. Should such an event occur Navitas' Oil Spill Financial Liability Assessment (issued to FIG in August 2024) details the coverage that Navitas will have in place to compensate stakeholders affected by a spill. Laboratory testing has shown that Sea Lion crude has prolonged buoyancy, low solubility, low polycyclic aromatic content and relatively low toxicity which would likely limit the biological effect on squid. Biological recovery is likely to occur in one year. The Financial Liability Assessment notes however that a spill event would likely have a marketing impact, such that stakeholder compensation would be required.	
IND4 1	There will be significant carbon emissions as a result of the burning of oil produced. There is little commitment to offsetting these emissions. FIG have frequently pushed their environmental credentials and a desire for net zero but appear happy to contribute significant amounts of CO_2 to the atmosphere without proper offsetting in place.	The subject of Emissions is extensively detailed in Section 10.9 of the EIS. Navitas remains committed to exploring opportunities to further reduce its emissions; an example of this is the Emissions Reduction Action Plan (ERAP) for the Floating Production Storage Offtake (FPSO) during the Front End Engineering and Design (FEED) project and will continue throughout the life-cycle of the Sea Lion Field. Carbon and biodiversity offsetting opportunities require further evaluation and research to define the level of offsetting that can be achieved locally. Navitas is committed to complying with FIG's offsetting guidelines and policies. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting	Section 10.9.7 Section 10.9.11

Ref.	Representation	Navitas response	Changes in Rev 4
		fund. It would not be possible for Navitas to control the use of the product once it has been sold or monitor and manage emissions, thus the end user's emissions will be their responsibility to monitor, manage and offset; their scope 1 & 2 and will be considered our scope 3. A conservative assumption of Navitas' Scope 3 sold emissions (all being combusted) were included in the EIS.	
IND4 2	There is likely to be significant impacts on wildlife and there is still a lot of data missing on this (EIS even acknowledges there are data gaps) - imo far more robust data should be in place. Falkland's tourism and lifestyle is very much based around wildlife. Risking this by potentially going ahead without full data in place is very concerning.	Please note that under FIG's guidance (FIG, 2016) the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are dealt with in the risk assessment. Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken.	N/A
IND4 3	Going ahead with a huge oil development such as this appears at odds with FIGs commitments to net zero. Indeed it is likely to lead to the Falkland Islands having the highest CO_2 emissions per head anywhere in the world (we cannot and should not wash our hands of the emissions created once the oil has been exported)	Thank you for your comment. This is noted. However, it is not for Navitas to comment on FIG policy and would refer this comment to FIG.	N/A
IND4 4	There is little information on how the oil will be decommissioned if/when it becomes uneconomical.	Falkland Islands legislation requires Navitas to fund full decommissioning and to ensure that all infrastructure is designed so that it can be fully decommissioned. FIG will undertake assurance to ensure that adequate funds for decommissioning are in place throughout life of field. Please also refer to DGN 3.	N/A
IND4 5	Although spill risks are mentioned there is little information on how specific species will be affected	Note there are three chapters on oil spills and details on species affected, see sections 12.1, 12.2 & 12.3.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
IND4 6	Impacts on cetaceans in Falklands waters have not been fully explored. Much of the data is inadequate and the latest information has not been used/taken into account as far as I can see (for example impact of noise on cetaceans or entanglement issues do not appear to have been fully explored)	Underwater noise impacts on cetaceans inshore and offshore are covered in section 10.4 and 10.5. . The lines that will be placed in the water for the Sea Lion project include flowlines, risers and anchor chains. All of these are substantial and solid pieces of equipment, which Navitas believe poses a very low risk of entanglement to marine mammals. However, it is recognised that whale entanglement in anchor chains does occur, so a Whale Entanglement Management Plan will be put in place. Further detail on entanglement will be included in section 10.11. See also FC 82, FC 88).	Section 10.4 Section 10.5 Section 10.11.2.2
IND4 7	The EIS identifies over 30% of negative impacts as moderate or upper moderate - this includes atmospheric emissions (which in the middle of a climate crisis to me seems completely unacceptable - especially with no commitment to offsetting as above), collision with marine mammals (which is an unacceptable risk imo) and introduction of invasive species (we have seen the impact invasive species have had on many islands and how they have decimated seabirds. We have also seen the impact earwigs have had in Stanley - do we really want to have a moderate risk of this occurring?). It also lists competition for freshwater resources as upper moderate - with a drying climate and water scarcity likely to get worse this is deeply concerning.	Navitas has been very precautionary in all the impact and risk assessments. Risk of collision with marine mammals is not a risk specific to the oil industry but is present in relation to all marine traffic. Navitas has committed to vessel speeds below those recommended by guidance in order to minimise the risk to as low as reasonably practicable (Section 10.11.7). The impact for invasive species introduction is rated highly because of the impact that would arise if it were to actually occur despite all the preventative measures. Competition for freshwater is rated highly currently as the assessment has conservatively assumed that the planned increases to freshwater catchment and treatment will not be in place. If FIG makes these planned investments then the rating for this impact will decrease. In the event of a water shortage the project would be lowest priority for freshwater -	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		community and other industry needs would come first.	
IND4 8	The table (page 32) mentions competition for accommodation as an "upper moderate" risk. Housing in Stanley is already in short supply and prices high. There is a very real risk that people will be pushed into poverty by increasing rents (there are already a number of examples of rents rising due to people anticipating increased demand - houses are being bought by big companies with the intention of renting to oil for huge sums). As well as potential increase in poverty there is the very real risk of homelessness/people leaving the islands due to lack of affordable accommodation. This has not been addressed in the EIS beyond a brief mention in the table.	Sea Lion Phase 1 & 2 requirements and housing supply will be discussed further in the Socio-economic impact assessment. Navitas is committed to provision of increased housing to meet Sea Lion Phase 1 & 2 demand and to working closely with FIG to assist in the monitoring and management of this potential adverse impact, which extends beyond the potential Sea Lion Phase 1 & 2 development, and is a feature of Falkland Islands economic growth generally.	N/A
IND5 1	In reviewing the presented Environmental Impact Statement (EIS), several fundamental issues emerge that call into question the adequacy of the document for its intended purpose: 1. The EIS is Not Fit for Purpose: The current EIS fails to meet the necessary standards for a thorough and reliable assessment of the proposed project's environmental impacts. It lacks the comprehensive detail and rigor required to make informed decisions about the project's viability and its long-term effects on the environment. The gaps and deficiencies in the document suggest that it is not fit for purpose and requires significant revision.	The EIS meets international best practice and with regards to gaps it is important to note that under FIG's guidance (FIG, 2016), the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are dealt with in the risk assessment. Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken.	N/A
IND5 2	2. Carbon Emissions and Lack of Commitment to Offsetting: The EIS inadequately addresses the project's contribution to carbon emissions and fails to present a clear commitment to offsetting these emissions. Given the global urgency of combating climate change, the absence of a robust carbon management and offsetting plan is a critical oversight. The project must include specific targets and strategies for reducing and offsetting carbon emissions to align with international climate goals and to be consistent with FIG Guidance.	The subject of Emissions is extensively detailed in Section 10.9 of the EIS. Navitas are committed to exploring opportunities to further reduce emissions and to offsetting. Carbon offsetting opportunities require further evaluation and research to define the level of offsetting that can be achieved locally. Offsetting approach is being confirmed with FIG and	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		will be consistent with FIG legislation, policy and guidance. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	
IND5 3	3. Impacts on Wildlife and Data Gaps: The EIS presents significant data gaps concerning the potential impacts on local wildlife. These gaps and outdated data hinder the ability to assess how the project may affect vulnerable and endangered species and ecosystems. The document lacks a comprehensive analysis of the risks to wildlife, particularly concerning habitat disruption, pollution, protected areas. Addressing these data gaps through further research and ongoing monitoring is crucial for protecting biodiversity. Most of the data is over 10 years old. In example, I would like to highlight the lack of current data regarding Southern right whales, species that have been seen increasingly since 2017 and occurs persistently over the years, showing a clear use of Falklands Islands Waters. No current data published has been included in the EIS.	Thank you for the comment. There are lots of examples of recent data including tracking data from the GAP project and indeed more recently. New references will be added to the text and as with the response to the comment IND5 ,1 under FIG's guidance (FIG, 2016) the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are dealt with in the risk assessment. Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken.	N/A
IND5 4	4. Decommissioning and Spill Risks: The EIS inadequately addresses the risks associated with decommissioning and potential spills. A detailed and enforceable decommissioning plan must be included, along with a robust spill response strategy. Historical evidence indicates that spills can cause long-lasting damage to ecosystems, and the current EIS does not provide sufficient assurances that such risks will be effectively managed and the responsibility should not be passed to Falkland Islands Government.	Decommissioning is subject to a separate EIS. Navitas is legally obliged to decommission offshore infrastructure. See DGN 3. Spills are covered in sections 12.1, 12.2 and 12.3. Risks are managed in accordance with accepted industry best practice. Preliminary Oil Pollution Emergency Plans have been submitted to FIG along with a document that assesses potential financial liability associated with oil spill events (including the potential impact on fishing and tourism) and demonstrates that Navitas will have sufficient	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		funding/insurance cover in place to cover liability arising. Navitas recognises that the Polluter Pays Principle will be enforced, as such liability arising will not fall to FIG.	
IND5 5	5. Incomplete Legal Framework for Environmental Governance: In addition to the concerns above; the existing legal framework is insufficient to ensure effective environmental governance in the context of this project. Current regulations do not provide adequate safeguards or enforcement mechanisms to protect the environment from potential harm. Strengthening the legal framework is essential to ensure that environmental risks are properly managed and mitigated.	Navitas has submitted the Field Development Plan (FDP) and Environmental Impact Statement (EIS) in accordance with FIG's current legislative framework. Navitas continues to work with FIG and its key contractors to ensure that its arrangements are aligned with industry best practice and FIG's planned changes to legislation. Navitas expects that FIG will comment separately on the EIS public consultation representations which cover FIG's Oil Readiness and planned legislation.	N/A
IND5 6	In summary, the presented EIS is inadequate and requires substantial revisions to address its deficiencies. The document falls short in its assessment of environmental impacts, lacks alignment with both local and international environmental legislation, and fails to provide sufficient safeguards against potential risks. A more rigorous, detailed, and legally compliant EIS is essential for responsible decision-making and for the protection of the environment in the Falkland Islands.	ExCo 118/24 confirmed that the EIS submitted for public consultation was legislatively compliant. The document also meets international and more specifically UK best practice.	N/A
IND6 1	My knowledge of the oil industry is limited, but after reading the EIS and spending some time researching, slightly more knowledgeable than a few weeks ago. I read the non-technical EIS summary and found it a comprehensive risk assessment profile. Historically oil around the Falkland Islands could be thought of as 'political,' oil has featured in strategies and decisions made by British and Argentine governments since at least the 1960s, swinging from wanting/keeping sovereignty of the Falkland Islands to war; always simmering below the surface. This hampered oil development, but now, with advanced technology and political changes, the time is right.	Thank you for your comments. In answer to your questions: 1. Navitas is working closely with FIG and the local business community to ensure that all stakeholders are prepared for the Sea Lion Development. This public and private dialogue will continue throughout the planning and execution stages of the development. 2. In August 2024 Navitas submitted its Carbon & Biodiversity Offsetting Fund Strategy to FIG. Once the strategy is agreed by all parties application for local	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	The fishing industry, despite fears, has not wiped out our marine species; in fact, whales are thriving. Once the platforms and measures for species protection is in place I doubt there will be any difference than the present fishing fleet effect, regarding movements, light at sea at night, or with careful management, noise. There always will be damage/change, as there is with anything humans undertake. Species adapt to the environment. Is FIG sufficiently prepared with essential services - electricity, water, sewage, waste management and accommodation? I have not heard or read anything that gives me confidence that FIG is prepared. I also think sending ash/waste to landfill in UK, or anywhere else, is unacceptable, a facility should be built on the islands. Offsets usually refer to like-for-like [replanting a forest or replacing natural features]. The Falkland Islands are different in natural features, the replacement of a stand of rock, part of a stone run, or beach tidy would be superficial, practicality is needed. I hope the internal fund will go toward these services. It will be interesting to learn how emissions can be offset. How much say will FIG have in what happens to 'our' oil, will they have any influence. Falkland Islanders now have the right to self- determination, to freely pursue economic development and freely dispose of natural wealth and resources, written in our Constitution and endorsed by the UN. Yet…I expect, apart from a percentage per barrel and tax revenue FIG will not have any influence in a wider sense; probably wishful thinking for anything more and this development will go the way of other bonanzas. Is Navitas Petroleum an ethical company? How do/did Navitas view/choose their investors for the Sea	and international offsetting projects will be welcomed. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund. 3. Sea Lion crude will be sold on the open international market (subject to trade embargoes, international sanctions etc.). 4. Navitas is an ethical company, the depth and detail of the Environmental Impact Statement is a clear example of this. Further information on Navitas can be gained on the company website: www.nativaspet.com. 5. Navitas is a publicly traded company and is subject to clear legislative rules and investment / investor requirements. 6. As above, in the response to question 5, Navitas is publicly traded. The Sea Lion Field Carbon & Biodiversity Offsetting Fund will illustrate the company's commitment to the energy transition. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund. 7. Navitas is unable to comment on the opportunities that FIG will be able to develop as a consequence of the Sea Lion revenues and this question would best be answered by FIG. 8. Navitas is unable to comment on the opportunities	

Ref.	Representation	Navitas response	Changes in Rev 4
	Lion/Rockhopper development? Israeli investors are eager for access to oil and gas assets. It would be abhorrent morally to humanity if the riches from our 'oil' filtered into weaponry and contributed to the genocide and wars in the Middle East. It would be more ethical if part of our fortune be put into resourcing and investing in technologies working for cleaner energy for that distant future when oil is no longer needed. The Falkland Islands have a small population, we will per capita be extraordinarily rich in the short term, but what of the future? Where is the Falkland Islands going- will we just go with the flow or have an ambitious goal and steer for it? I worry we might flounder. There is going to be many practical, social, political, and ethical issues to debate in the next few years. I support this development but would like to know what is envisioned for our long-term future by FIG, HMG and Navitas.	that FIG will be able to develop as a consequence of the Sea Lion revenues and this question would best be answered by FIG.	
IND7 1	Overview The Sea Lion development proposed by Navitas Petroleum Development & Production Ltd within their 2024 EIS is, in most respects, a further iteration of the Sea Lion development concept that has been underway since 2011. Although further work has been carried out optimising the understanding of the geological aspects, and on the technical aspects of the development, the major features of the project appear substantially unchanged to several previous iterations of the FPSO-based development, and in particular the most recent Sea Lion project proposed by Premier Oil within their EIS, accepted by FIG in 2020.	Agreed, the project is substantially unchanged with some improvements.	N/A
IND7 2	Project design and operation The project proposal appears substantially similar at a technical level to the previous projects, with a small number of material technical changes such as	Agreed, using a repurposed FPSO does reduce environmental impacts overall.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	the change to well completions and the change to a repurposed FPSO rather than a new build. I do not have any material observations on these changes, and do not believe they will substantially impact either the planned environmental impacts of the project, or the risks of an unplanned major impact arising. Some choices made (such as using a repurposed FPSO) may arguably reduce the overall environmental impact of the project by reducing the lifecycle footprint, and as long as critical technical and safety requirements are met, these do not appear to raise any specific concerns and are aligned with established industry practice elsewhere. Detailed technical and safety aspects are for FIG's external technical and safety advisers to review within the field development plan and relevant safety submissions, and are beyond the scope of the EIS consultation.		
IND7 3	Data and risk Some concerns have been expressed that environmental data used in the EIA process is outdated and that insufficient data has been gathered in recent years. FIG and oil companies jointly funded two projects of gap analysis and data gathering over a period of several years. It is always true that more data could be gathered, but FIG and stakeholders should aim to take a pragmatic approach to determining what is necessary versus what might be desirable, and in particular, make some judgement on whether further data, or improving on identified uncertainties, would be likely to have a material impact on any decision to proceed with the project. My view is that it would not be likely to impact that decision, because a precautionary approach has generally been taken where there are uncertainties.	Agreed - note FIG EIA Guidance re data gaps (Sections 3.13 and 3.18 in particular).	N/A
IND7 4	Planned environmental impacts – and the bigger picture The planned impacts of the project appear to be broadly aligned with previous iterations of the project. If the project is delivered using good oilfield practice then the planned impacts over the life of the project appear acceptable and in line both with previous iterations of the development, and with the impact that might be expected from this type of project delivered elsewhere.	Thank you for your comments. Navitas confirms that it is working within FIG's legislative framework (as illustrated by the Environmental Impact Statement process). This is closely aligned to the UK regulatory framework which is considered world leading. In addition Navitas is working closely with leading international contractors all of whom have significant industry experience and	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	Global climate change concerns and carbon emissions are of course a developing issue for all projects of this type, and managing mankind's impact on our planet will remain a major challenge for decades. In considering this, it is important to recognise that global emissions from hydrocarbons are produced by global oil and gas consumption which stems from the demand for, and usage of, the commodities. In common with most mobile and globally traded commodities, consumption levels are not particularly affected by whether specific production opportunities in specific locations are pursued. Reducing emissions is therefore ultimately a function of reducing consumption, which in turn will reduce production. It is also important to recognise that the transition to a low-carbon future will necessarily take time (likely to be 20 years or more) and that regardless of how much carbon sits within any future energy landscape, it is more than likely that manufacturing industry will still require substantial volumes of oil and gas into the distant future. The notion of "Just Stop Oil" is therefore an idealistic and impractical concept at every level, and none of the proponents of such an approach are able to articulate a credible alternative. In the event that the Falkland Islands declined to provide consent to the project's Field Development Plan (for any reason), that decision would not inherently mean that any less oil will be used worldwide, or that any less carbon would be produced into the global atmosphere. It simply means that demand for the commodity will be satisfied from new supply somewhere else, which might produce either more or less carbon emissions depending on the nature of that project. It simply cannot be predicted with any reliability. The impacts on individual national statistics such as the carbon emissions per capita of the Falkland Islands can be highly misrepresented, and should	most of whom are public traded and consequently openly demonstrate their environmental social governance (ESG) policies.	

Ref.	Representation	Navitas response	Changes in Rev 4
	therefore be discounted. Using per-capita metrics, we would be proposing to ban sheep farming in the Falkland Islands because the emissions of sheep methane per capita are probably easily the highest of any country in the world. Decarbonisation is a whole-planet problem which must eventually have a whole-planet solution to reduce demand and deliver alternative technologies wherever possible. The Falkland Islands cannot meaningfully influence either of those things with a decision on a single project. This means that the principal role of the Falkland Islands is to ensure that any projects that are operated within its jurisdiction meet criteria such as: • The project meets normal industry expectations for a responsible operator working in a developed country, and is delivered using recognised best practice and best available technology to minimise planned emissions and maximise efficiency and safety • The project is regulated to a high standard by the host Government throughout its life including ensuring proper decommissioning		
IND7 5	Unplanned environmental impacts Significant unplanned environmental impacts mainly arise from the risk of a major accident of some sort, and the EIS sets out a number of such cases which appear to have been chosen and described adequately. Managing unplanned impacts is very much a matter of prevention, by reducing all material risks to as low as reasonably practicable (ALARP).	Thank you for your comment. This is noted and agreed.	N/A
IND7 6	Human and economic impact The impact on the population of the Falkland Islands and the nature of economic opportunities are both fairly well understood. There is a natural alignment between delivering an efficient project by not deploying unnecessary people and resources to a remote project location, and minimising adverse socio-economic impacts on the Falkland Islands, and it appears that the project proponents intend to continue to operate in this way. In simple terms, nothing will be deployed here if it is not necessary for the project. Previous rounds of exploration activity have been shown to be	Thank you for your comments. Navitas confirms that the project has been designed to minimise adverse socio-economic impacts and optimise the benefits for the Falkland Islands stakeholders. A separate Socio-Economic Impact Assessment undertaken by an independent UK based consultancy with recent relevant experience in the	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	quite manageable for the Falkland Islands, with modest impacts but considerable opportunities, and the onshore impacts of a single development as proposed in this EIS is likely to be "exploration plus" – a little more of everything, and for a longer period, but still manageable. Additional concurrent phases of development activity, not described in this EIS, may require more careful consideration in the event that any arise. The overall economic impact on the Falkland Islands will be generally extremely positive. The author is aware that a detailed economic model was compiled by FIG and the previous operator for past project iterations, and it is assumed that this has been updated. FIG has an extensive wish list for capital investment and aside from offsetting commitments that the project sponsor may make, developing a new industry would allow FIG to invest substantially in moving the Falkland Islands further along the path towards net zero and energy independence as a country.	Falkland Islands will be issued to FIG in Q1 2025. Navitas is unable to comment on the opportunities that FIG will be able to develop as a consequence of the Sea Lion revenues.	
IND7 7	Decommissioning and response planning Ensuring thorough, safe, and financed decommissioning at the end of project life is essential to protect the Falkland Islands. It is normal for decommissioning at this point to be in the form of a broad commitment rather than detailed plans which can only be designed closer to end of field life, so the content of the EIS appears acceptable in this regard, and the applicant's commitments to remove all parts of the development above the sea bed are in line with expectations. Response measures to unplanned events, that will in due course be set out in the oil spill contingency plan / oil pollution emergency plan will also need careful review, alongside the financial capacity arrangements to support this response.	Thank you for your comment.	N/A
IND7 8	Regulatory framework It is unclear from the EIS what the current status is of revised legislative provisions to bring in the UK's 2015 Safety Case provisions, and the new Environment Case legislation. Although there is mention of the ongoing work	Thank you for your comment. This is noted and Navitas shall update the EIS text to clarify the licensing regulations that apply. Navitas has submitted the Field Development Plan	Section 3.1

Ref.	Representation	Navitas response	Changes in Rev 4
	in section 3.1.7.3.1, references within the EIS document only appear to be to existing/legacy legislative provisions with no indication as to the expected date of changes coming into force, nor of any expected transitional provisions to new legislation when it emerges. It is assumed that the Sea Lion project is intended and designed to comply with forthcoming legislative changes, as these should by now be well understood, with detailed legislative drafting having commenced several years ago following policy approval. Completing the update work on the Offshore Minerals Ordinance 1994 (and other related legislative provisions) remains essential, as does maintaining sufficient expertise within FIG to ensure robust and effective regulation throughout the project. It is noted that some earlier identified legislative priorities such as updating the Conservation of Wildlife & Nature Ordinance 1999 appear not to have progressed, and other public information suggests that this Ordinance has been deprioritised in favour of unrelated environmental legislation. The effect of this should be clearly understood by decision-makers prior to granting any final production consent. The EIS suggests that the relevant licensing legislation for the project is the Offshore Petroleum (Licensing) Regulations 1995. In fact the majority, perhaps all, of the Sea Lion development sits within Production Licence PL032, which was issued under the Offshore Petroleum (Licensing) Regulations 2000. This is a separate (if substantially similar) piece of legislation, not an amendment to the 1995 regulations as suggested. The two sets of regulations provide for different model clauses, fees, licence terms and other key differences, and co-exist in law to regulate different production licences. However, this error is administrative and not particularly material to the EIS content.	(FDP) and Environmental Impact Statement (EIS) in accordance with FIG's current legislative framework. Navitas continues to work with FIG and its key contractors to ensure that its arrangements are aligned with industry best practice and FIG's planned changes to legislation. Navitas expects that FIG will comment separately on the EIS public consultation representations which cover FIG's Oil Readiness and planned legislation.	
IND7 9	Summary The project set out in the Navitas Sea Lion EIS is substantially similar to that previously accepted by Executive Council in 2020, with some iterative design	Noted, thank you.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	changes that are relatively minor in terms of the overall project. The function of an EIS is to describe the impact of a project on the environment should it go ahead, so that this impact can be taken into account in making a final determination on the development plan that the applicant must also submit to gain consent for production operations. The submitted document adequately describes this, and the planned and unplanned impacts appear to be in line with what would be expected for a project of this type. The EIS therefore appears to be acceptable. Consideration of whether the environmental impact described for the project is ultimately acceptable when balanced against the wider risks and benefits of the project to the Falkland Islands falls within the process of final project approval, and the granting of consent to a Field Development Plan.		
IND8 1	Global warming and climate change due to burning of fossil fuels is at last recognised as undisputable fact The International Energy Agency said in 2021 ''If governments are serious about the climate crisis, there can be no new investments in oil, gas and coal, from now – from this year." I do not see how a responsible government can proceed with approving a new oil development at this stage in our planet's history.	Refer to RSPB 7.	N/A
IND9 1	1. Presentation, length, language and style This project represents the most significant development in the Falkland Islands in the past 40 years. Given the proposed commitment of the Falkland Islands Government and community to environmental stewardship, it is essential that this EIS document is accessible and comprehensible to a wide audience. In this regard, I have some initial comments on the presentation, language and style used in the Environmental Impact Statement (EIS). In the same manner as choosing to name the oil field "The Sea Lion Field", featuring a cover image of penguins on a pristine coastline is misleading and inappropriate. This approach seems intended to evoke a sense of	Sea Lion was the name given to the initial prospect identified by RKH. Navitas is keenly aware of the beauty and special nature of the Falklands environment and the cover image was photographed by a member of the Navitas team. Regarding the length of the document, this is a complex development project in an area where the baseline was previously not known very well. EIAs of *c.* 400-500 pages are generally appropriate for explorations EIAs as opposed to development EIAs in	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	environmental harmony that starkly contrasts with the true nature of the proposed development. Such imagery may lead the public and stakeholders to underestimate the potential ecological risks involved. The EIS should accurately reflect the serious environmental implications of this project, rather than attempting to soften its impact with misleading visuals and branding. The EIS document is significantly longer than comparable documents, which typically range between 400 to 500 pages. While the length itself is not an issue, the extensive contradictory statements, redundancy and verbosity in the text complicates the review process for stakeholders. For example, the routine inclusion of institutional information and acknowledgements for grants and funding is unnecessary within the main body of the document. There are also instances where information is mentioned for past, current and future studies that form no part of this EIS. These factors may discourage community members from reading the document, limiting the opportunity for widespread public engagement and input.	a new area. Other technical reviewers have complimented the structure and readability of the document.	
IND9 2	2. Failure to identify fish related data gaps and missed opportunities Section 7.2.4. Data gaps: It is concerning that the Falkland Islands Offshore Hydrocarbons Environmental Forum (FIOHEF) did not appear to identify a single critical data gap regarding the potential for impacts of oil development on fish populations in the northern slope area of the Falkland Islands, and area that is data poor. Given the vital role of fisheries in the Falkland Islands' economy and ecosystem, this appears to be a major oversight.	One aspect of scoping is to identify any data gaps and available data that could inform the assessment. This was not identified as a data gap in scoping.	N/A
IND9 3	Missed Opportunities: The Falkland Islands Government's Directorate of Natural Resources, Fisheries Department (FIFD), has conducted various surveys, including fisheries-independent demersal surveys from 2015 to the present. However, these surveys generally do not extend beyond the 200-250 m depth contour in the north of the Falkland Islands. The reason for this is that they cover the area in which shelf-based commercial fishing takes place. As a result, they do not cover the proposed development area, particularly the NS slope area (250-600 m), which remains critically data	Thank you for the comment and suggestion. Navitas would welcome such an opportunity for more data collection on the NS. Note that much of the data we have comes from Arkhipkin *et al.* (2012) and this review used data from 13,044 commercial bottom and pelagic trawls between 2000 and 2010 mainly within the FCMFZ, and from 1,272 research trawls	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	poor. The earlier consultations presented an opportunity to address these data gaps. By negotiating the inclusion of one to two additional days of sampling within the proposed development area, much-needed baseline data could have been collected, significantly enhancing the baseline for understanding of the local fish ecology and biology, setting a platform for ongoing monitoring and providing a more robust data collection strategy for assessing impacts.	taken between 1999 and 2011. Some of which were conducted on the NFB.	
IND9 4	3. Fish baseline data limitations The EIS for the proposed offshore oil development in the Falkland Islands waters presents significant shortcomings in its characterisation and presentation of baseline data for fish populations. Notably, it omits crucial updated information that could influence the assessment's accuracy. 3.1. Outdated and insufficient baseline data for fish populations Section 7.2: The baseline data for fish populations is reported to be sourced and collated through literature reviews. However, there seems to be a complete absence of current literature. Specifically, the median year from which references were sourced is 2012. There are no references cited in the section more recent then 2016. There has been an abundance of research undertaken with new findings on fish and cephalopod populations over the last decade. Given the significant ecosystem changes documented over this period (Laptikhovsky *et al.,* 2013; Arkhipkin *et al.,* 2023), the reliance on outdated data is concerning and undermines the relevance of the assessments. The EIS should incorporate recent research and extend its focus to include deeper waters adjacent to the proposed development to provide a comprehensive and accurate assessment of the potential environmental impacts.	Thank you for the comment Navitas will update the text where relevant. The Laptikhovsky *et al.* (2013) is cited and referenced and Navitas will update the text with the Arkhipkin *et al.* (2023) reference and indeed any new relevant literature.	Section 7.4.4.2
IND9 5	7.4.4.2.2.1: The seasonal abundances of fish and squid populations on the Northern Slope (NS) are based entirely on research undertaken by Arkhipkin *et al.* (2012b) using data acquired from mixed commercial fisheries and	Thank you for the comment. Arkhipkin *et al.* (2012b) represents the most comprehensive review to date and its intention was to show patterns in the	Section 7.2.4.1

Ref.	Representation	Navitas response	Changes in Rev 4
	research surveys between 1999 and 2011. While this research provides some foundational baseline data for the shelf area around the Falkland Islands, its use as the sole baseline for assessing the proposed development area and the wider Northern Slope (NS) zone is problematic for several reasons: Geographic, and Temporal Data Gaps: The study's sampling sites do not comprehensively cover the Northern Slope (NS) area, particularly the deeper waters where the proposed development and dispersal pathways occur. The limited spatial and temporal coverage undermines the ability to accurately predict species distribution and biomass trends across the NS. As described above, this data is also outdated given large changes that have occurred in the ecosystem. Methodological Flaws in Biomass Estimation: The study assumes uniform species distribution across different habitats, extrapolating data from sampled areas to unsampled ones. This assumption, coupled with the limitations of using CPUE as a biomass proxy (particularly from selective fishing gear and strategies), results in inaccurate biomass estimates, especially in under-sampled deeper waters. Inadequate Consideration of Species' Life-History Stages: The use of selective data from commercial fisheries and inappropriate biomass estimates negates the importance of non-targeted species and life-history stages, such as juveniles, adults, and spawning individuals. This gap, along with the other methodological issues, further compromises the accuracy of the abundance trends described for the NS area.	movement of nekton around the islands including the NS which covers the NFB. This is acknowledged as a data gap (added to section 7.2.4.1). In this regard our Risk Assessment for fisheries is precautionary.	
IND9 6	3.2. Specific comments on various fish populations My concerns particularly focus on the following aspects of fish populations in the area: Critical Life-History Stages of Skates: The data limitations significantly hinder understanding the life-history patterns and vulnerabilities of skate species, which are crucial for effective management and conservation.	Thank you for the comments. The Risk Assessment with regards to fisheries is precautionary. Also note that under FIG's guidance (FIG, 2016) the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are dealt with in the risk assessment.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	Foraging Areas for Migratory Fish: The EIS downplays the importance of foraging areas for key commercial and recovering fish stocks and lacks sufficient information to reliably assess and monitor the potential impacts of the proposed development on their distribution, biology, and abundance. Deep-Sea Vulnerability: The proposed development on the NS slope area intersects critical life-history stages and connectivity pathways of vulnerable deep-sea species. The potential impacts of the development on these should be considered in the EIS.	Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken.	
IND9 7	3.2.1. Critical life-history stages of skates The only skate species mentioned in any level of detail in the EIS is the yellownose skate (*Dipterus chilensis*). This species was redescribed five years ago as consisting of *D. chilensis* (only occurring in the Pacific), and *D. lamillai*, the warrah skate, thought to be endemic to Falkland Islands waters (Concha *et al.,* 2019). The proposed development area on the Patagonian shelf and slope is a globally recognized hotspot for skate species, with over 22 recorded species, including those of commercial significance (Arkhipkin *et al.,* 2012a, 2023). This region supports: Commercially important species*: Bathyraja brachyurops*, *B. albomaculata*, *B. griseocauda*, and *Dipturus lamillai*. Commercially valuable bycatch species: *Bathyraja cousseauae*, and *B. multispinis*. Smaller bycatch species and juvenile: These play crucial ecological role. Many of these species are keystone species essential for maintaining ecosystem stability. However, they are particularly vulnerable due to their long life spans, slow growth rates, and low fecundity (Grosell and Pasparakis 2021). Declines in abundance have been reported for several of these populations according to the IUCN (Winter and Arkhipkin 2022), with B. albomaculata listed as vulnerable, B. griseocauda as endangered, and D. lamillai, appearing to be endemic to the Falkland Islands (Concha *et al.,* 2019).	**Initial consultation response:** Thank you for the comments. Navitas will update the text where appropriate. The risk assessment with regards to fisheries is precautionary. Also note that under FIG's guidance (FIG, 2016) the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are dealt with in the risk assessment. Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken. **Post-consultation comment:** After review of the relevant sections, Navitas consider that sufficient information has been provided to enable the relevant assessments. In addition, the warrah skate (*D. lamillai*) is likely not endemic to the Falkland Islands. The species was described from a specimen captured in the Falkland Islands (Concha, *et al.*, 2019). This does not mean that warrah skate has limited range, simply that its range is not known.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	The proposed development is likely to overlap with areas crucial to these species, including during key life-history stages such as spawning and recruitment (Arkhipkin *et al.,* 2012a, 2023). The failure to delineate the areas during which these critical stages occur, and their overlap with the proposed development, represents a significant data gap (Lee *et al.,* 2022; Ramos *et al.,* 2023; Ramos *et al.,* 2024). Without precise identification and protection of recruitment, juvenile, and spawning areas— many of which likely coincide with the development site— the potential impacts on these vital skate populations cannot be accurately monitored, assessed, or mitigated. This oversight could result in irreversible harm to species that are already vulnerable or endangered.		
IND9 8	3.2.2. Foraging areas for commercially significant migratory fish species The proposed development area overlaps with critical foraging and migratory pathways for several commercially and ecologically significant fish species in the Falkland Islands. The Environmental Impact Statement (EIS) seems to downplay the importance of the Northern Slope area to these populations. This is likely due to the use of outdated references and data as described above. The following key species are of particular concern: Common hake (*Merluccius hubbsi*): Since 2015, common hake has become the dominant fish biomass around the Falkland Islands, surpassing rock cod and becoming the primary target of finfish fisheries. Observational data from FIFD research surveys suggests that a key feeding and migratory pathway occurs to the north of the Falkland Islands in waters deeper than 200 m (NS area), which overlaps with the proposed development area. Recent survey and commercial data suggest that the deeper waters are important for larger female individuals as they migrate to southern feeding areas in the SS and SEOS areas. However, baseline data to describe the full distribution range of common hake is not available, and their dynamics within Falkland Islands waters are poorly understood. Without this information, the potential impacts on these populations cannot be accurately monitored, assessed, or	Thank you for your comment. This is noted and the text will be updated where appropriate. The baseline here was informed by the most recent review in Arkhipkin *et al.* (2012). This paper was based on an analyses from 13,044 commercial bottom and pelagic trawls between 2000 and 2010 mainly within the FCMFZ, and from 1,272 research trawls taken between 1999 and 2011. Some of these were conducted on the NFB. Migration pathways are not likely to have changed since this work. However, the assemblage has changed dramatically due to a mixture of environmental change and over exploitation of rock cod and southern blue whiting, with hake now being the dominant commercial species. As described in Arkhipkin *et al.* (2012), hake is a shelf species and southern blue whiting is a shelf break species. The Sea Lion Field sits beyond the shelf break in 450 m on the deeper parts of the North Slope (NS). As noted by the commenter, there are some gaps in	Section 7.4.4

Ref.	Representation	Navitas response	Changes in Rev 4
	mitigated. This gap in research has been identified by the FIFD and must be addressed to prevent unintended consequences on this vital fishery. Blue whiting (*Micromesistius australis*): The proposed development area also intersects key feeding and migratory pathways for blue whiting, a species that has previously experienced a significant population collapse and is currently in recovery (Laptikhovsky *et al.,* 2013). This life-history stage, where blue whiting migrates and forage, is critical for their growth and subsequent spawning success (Busbridge *et al.,* 2020). Disruption to these pathways due to the proposed development could severely hinder their recovery, potentially leading to another population decline (McKeown *et al.,* 2017). Given the fragile status of blue whiting, continuous monitoring of their abundance and population structure in this area is essential. Baseline data is critical for assessing the impact of any changes resulting from the development to ensure that the species' recovery is not compromised.	knowledge. However not all gaps can be filled, practically, economically and logistically. Under FIG's guidance (FIG, 2016) the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are dealt with in the risk assessment. Therefore, the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken.	
IND9 9	3.2.3. Life-history stages of vulnerable deep-sea fish The proposed development area intersects with critical life-history stages of deep-sea species, such as the Patagonian toothfish (*Dissostichus eleginoides*) and ridge-scaled grenadier, both of which are highly vulnerable to anthropogenic and environmental pressures (Roberts 2002; Laptikhovsky 2011; Lee *et al.,* 2019). Patagonian toothfish (*Dissostichus eleginoides*) The EIS presents outdated information on the ecology and population structure of the Patagonian toothfish, failing to incorporate the latest research. Recent studies reveal that the development area directly intersects with key life-history periods and connectivity pathways, posing significant risks to the population's sustainability (Arkhipkin and Laptikhovsky 2010; Brown *et al.,* 2013; Lee *et al.,* 2018, 2021, 2022, 2024; Troccoli *et al.,* 2023; Kim *et al.,* 2024).	Please see comments and responses to IND9 10, IND9 11, IND9 12. Navitas will update the text and references with any new material.	Section 7.4.4.2.3.1

Ref.	Representation	Navitas response	Changes in Rev 4
IND9 10	Key findings related to the development area: Population discreteness: The EIS mentions a wide distribution around the sub-Antarctic. However, it fails to acknowledge the patchy distribution and discrete population structure that occurs across this wide distribution. Around the Falkland Islands the species consists of a discrete population consisting of contingents from Chile, Burdwood Bank, and local groups, arising through egg and larval dispersal (Laptikhovsky *et al.,* 2006; Rogers *et al.,* 2006; Arana 2009; Ashford *et al.,* 2012; Lee, B 2022; Arkhipkin *et al.,* 2022; Lee *et al.,* 2024). Species exhibiting such population structure are considered vulnerable, and the preservation of this diversity is crucial for ecological stability and resilience (Hilborn *et al.,* 2003; Schindler *et al.,* 2010). Egg and larval dispersal pathway: While there is no evidence to suggest that Patagonian toothfish spawn in the NS, eggs and larvae from southern spawning areas are dispersed northwards across the NS (Ashford *et al.,* 2012; Lee *et al.,* 2024). These would likely be susceptible to associated pollution risk and should be considered in the impact assessment. Adult site fidelity: The EIS describes a migratory life-history for adult Patagonian toothfish. Adult life-history stages exhibit strong site fidelity with no evidence of seasonal migratory behaviour (Brown *et al.,* 2013; Lee *et al.,* 2018, 2022; Troccoli *et al.,* 2023). A significant portion (75-95 %) of the population remains resident in deep-sea habitats adjacent to the proposed development area throughout their life. This means that any impacts from the development are likely to have long-lasting and potentially severe consequences for the population. Adult large-scale movements: A small percentage (5-25 %) of the population undertakes large-scale movements (home-range relocations) towards southern spawning grounds (Lee *et al.,* 2022; Troccoli *et al.,* 2023). The northern slope, adjacent to the development area, serves as a vital movement corridor linking northern deep[1]sea habitats (both in Falkland and High Seas waters) with these southern spawning grounds. Disruption to this movement corridor could hinder these essential migrations, potentially	Thank you for the comment. Navitas will update the relevant baseline section with more recent reference including Kim *et al.* (2024) on toothfish movement. Population discreteness: patchy distributions in species are inherent and acknowledged and we are fully aware of what is known about Patagonian toothfish to date, it is likely that some larvae and eggs are present in the area and are likely present around the whole Falkland islands. We feel this detail is perhaps beyond what is required for this EIA. This area is not well studied and there is little in the literature. Egg and larval dispersal: Again, there is little information in the literature on this, we know eggs and larvae come from a couple of sources (Burdwood Bank area and Diego Ramirez area) however large assumptions would have to be made about what is around the North Falklands basin. The Patagonian shelf is not a seamount. In the case of toothfish, they are inherently patchy but this is a scale dependent thing. They are caught everywhere in the fishery. Adult site fidelity: references added Large-scale movements: references added Recruitment and early ontogenetic movement: References added. We disagree that important nursery areas lie adjacent to development area. 'Adjacent' needs context and nursery area and the	Section 7.4.4

Ref.	Representation	Navitas response	Changes in Rev 4
	affecting reproductive success and the overall sustainability of the population. Recruitment and early life-history movements: Important nursery areas lie adjacent to the development area, with connectivity pathways that link these nurseries with adult deep-sea habitats, passing directly through the development area. Key nursery areas have been identified south of the Falklands (inshore of Beauchene), west (Jason Islands), and north (inshore of the development area) (Ashford *et al.,* 2012; Lee *et al.,* 2021, 2024). Recruitment into these areas shows strong temporal variability, occurring in sporadic pulses every 5-10 years (Arkhipkin and Laptikhovsky 2010; Lee *et al.,* 2021). This life-history aspect increases the vulnerability of the species. During their ontogenetic development, these nursery areas are linked to adult habitats in the north (offshore of the development area) and east by persistent connectivity pathways (Arkhipkin and Laptikhovsky 2010; Lee *et al.,* 2021, 2024). These downslope movements through the connectivity pathways are protracted, extending directly through the development area over a 4–10-year period. Protecting these nursery areas and connectivity pathways is essential for maintaining the sustainability of the species – and the proactive development of management measures has been a clear focus point by FIFD, particularly for implementation during years of high recruitment.	population structure of that needs to be clarified. Again this is considered too much detail for this EIS. Toothfish are distributed throughout the Patagonian shelf in deep water, in similar depths to the development but this is not the only location toothfish are found. Nursery areas are found around the FI, can the commenter provide some context on 'adjacent' to the development. The NFB is not the only connectivity pathway around the FI. This is a floating FPSO, which, in the context of the NFB is a small area. Adding more information on this will add to an already lengthy document	
IND9 11	Ridge-scaled grenadier (*Macrourus carinatus*) The EIS provides limited information on the ridge-scaled grenadier, a species with characteristics indicating high vulnerability (Lee *et al.,* 2019). This species is believed to consist of a single reproductive stock within the waters surrounding the Falkland Islands (401–1391 m) (Laptikhovsky 2011). Spawning occurs year-round, including within the proposed development area to the north of the Falkland Islands (Laptikhovsky *et al.,* 2008; Laptikhovsky 2011; Lee *et al.,* 2019). Given the ridge-scaled grenadier's restricted distribution and the year-round spawning within the development area, the potential impacts of the	Navitas has been precautionary with regard to fisheries. Please note that the rough-scaled grenadier is widely distributed around the Falkland Islands and the southern ocean and has wide spawning and reproductive distribution. There are spawning grounds around the Falkland Islands and so the Sea Lion field as an area is considered small within this wider distribution and any impact is likely to be short-lived and reversable with little impact to the overall population given the abundance and distribution.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	proposed activities on this vulnerable species warrant serious consideration. Failing to account for the species' life-history characteristics and habitat requirements could lead to significant, long-lasting impacts on its population viability.		
IND9 12	Table 7.10: The high abundance of Patagonian toothfish on the NS is the same throughout the year (not just restricted to Summer and Autumn). The high abundance of common hake on the NS is throughout the Autumn-Winter (not restricted to Summer). Survey data shows that kingclip is prevalent throughout the year. Ridge-scaled grenadier should be added to the table. Other important skate species should be included, such as *B. albomaculata*, *B. brachyurops*, *B. griseocauda*, *B. cousseauae*, *B. multispinis*. The catshark (Schroederichthys bivius) is another abundant species not considered in the EIS.	Fisheries species are considered collectively with the exception of the major target species. Note this is a summary. Navitas will update the table where appropriate. Much of these data were from Arkhipkin *et al.* (2012) which represents the most comprehensive review of this type to date. This work analysed seasonal changes in relative abundance and biomass of nektonic predators were analysed on the eastern Patagonian Shelf and continental slope.	Table 7.10
IND9 13	12.1.4.2.3.1 The following statement is inaccurate - "Typically, adult fish are not considered highly sensitive to impacts of oil spills." Adult fish are indeed capable of avoiding water with high hydrocarbon concentrations (Hjermann *et al.,* 2007), however, this does not negate their sensitivity to associated ecosystem and long-term effects. There are numerous references in this regard (Balk *et al.,* 2011; Ainsworth *et al.,* 2018; Cave and Kajiura 2018; Grosell and Pasparakis 2021). Just to provide two specific examples, an ecosystem model that was used to assess the impacts from the Deepwater Horizon oil spill of fish guilds suggested that the biomass of large reef fish decreased by 25-50 %, and large demersal fish by 40-70% (Ainsworth *et al.,* 2018). This was a result of the impacts on demersal foraging areas leading to starvation. Recovery in high turnover populations was predicted to occur within 10 years, but slower-growing populations over 30 years to fully recover. In another study in the North Sea (Balk *et al.,* 2011), haddock and Atlantic cod populations were shown to be under significant environmental stress due to the chronic effects of oil-related pollution, leading to reduced health, reproductive success, survival and subsequent declines of these fish populations.	Noted, thank you. These references will be reviewed.	Sections 12.1.4.2.3.1 & 12.1.4.2.3.2

Ref.	Representation	Navitas response	Changes in Rev 4
IND9 14	12.1.4.2.3.2 “Sea Lion crude on zebra fish (*Danio rerio*) eggs found that the crude is unlikely to impact these fish eggs in the event of a spill.” Zebrafish are a tropical, freshwater, highly adaptable species, capable of surviving and being reared in a wide range of conditions – thus the likely use of them as the species in these toxicity tests. However, this also makes comparisons with species in the Falkland Islands (a marine, temperate, cold-water environment) difficult. Specifically, warm-water organisms are more robust to toxicity test procedures compared to their cold-water counterparts, such as for example cod (Hjermann *et al.,* 2007).	Thank you for the comment. The Hjermann *et al.* (2007) paper review examines the effects of a hypothetical oil spill on fishes in this area, with a focus on effects on the egg and larval stage of the 3 dominating fish stocks: NE Arctic cod *Gadus morhua*, Barents Sea capelin *Mallotus villosus*, and Norwegian spring-spawning herring *Clupea harengus*. Data on egg and larval dispersal are not available for most species in the Falkland Islands. Zebra fish eggs are the standard laboratory test in ecotoxicology. These tests were done under laboratory conditions with Sea Lion crude. Zebra fish eggs are the standard laboratory tests because there are protocols for handling them and they survive well under laboratory conditions. These are why they are used as an analogue. Testing of cold water eggs would be extremely difficult for marine fish here in the Falkland Islands; although this has been done on research cruises for embryology experiments, the eggs do not survive well outside of their natural conditions and it would be very difficult to understand what factors are causing mortality in addition to any toxicological factors. The properties of Sea Lion crude are such that a toxicological impact on cold water fish eggs at the concentrations expected in a spill event and in cold water temperatures would be negligible at worst. See also responses to IND 3 5, IND 3 9 and IND 3 10.	N/A
IND9 15	5. Recommendations To address the significant concerns identified in the EIS, the following recommendations are proposed: Acknowledge and Address Data Gaps: The EIS should explicitly recognize and address the existing data gaps, especially concerning the critical life-history	Navitas believe gaps have been acknowledged and a precautionary approach has been taken. In addition, under FIG's guidance (FIG, 2016) the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	stages and habitat use of skates, migratory fish, cephalopods, and deep-sea fish. This acknowledgment is crucial for developing an accurate and comprehensive environmental impact assessment.	which they are dealt with in the risk assessment. Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken.	
IND9 16	Enhance Surveys: Initiate discussions and collaborate with the Falkland Islands Fisheries Department to include additional survey stations in the proposed development area. This will help address the substantial data gaps, particularly those related to the life-history stages and habitats of key species.	Thank you for the comment. Collaboration would be welcome and this can be discussed in the FIG proposed long-term monitoring plan.	N/A
IND9 17	Update Baseline Information in the EIS: Incorporate the latest research and data from surveys conducted by the Falkland Islands Government's Directorate of Natural Resources, Fisheries.	Thank you for the comment. Navitas will update the text with relevant references where appropriate.	Chapter 7
IND9 18	Improve Monitoring: Collaborate with relevant stakeholders to design and implement a comprehensive monitoring plan that specifically targets the NS area. This plan should aim to improve understanding and management of these ecologically significant regions, focusing on the species and habitats most at risk. Implementing these recommendations will help ensure that the EIS reflects the best available science and provides a framework for managing the environmental impacts of the proposed development.	Please refer to section 15.1, the EMMP included in the EIS details the actions and plans required to: • Measure and monitor the predicted and potential impacts (primarily the 'Severity of Effect') of the Development, • Check the efficacy of the project-specific mitigations in place, and • Address uncertainties, such as spatial / temporal data gaps, to increase the level of confidence in the impact / risk assessment. Should the monitoring of impacts indicate that the significance of the impacts and risks predicted in the EIS are not appropriate, and / or that mitigation is not effective, a revised mitigation measure and / or monitoring regime will be required. A workshop to consider the content of the EMMP was held and attended by 25 interested stakeholders, comprising FIG, POEPL, industry bodies and NGOs.	Chapter 15

Ref.	Representation	Navitas response	Changes in Rev 4
		The EMMP will be managed by a governance board consisting of representatives of FIG and Navitas, supported by an advisory forum including both non-technical stakeholders and relevant individuals with expertise in the subjects being monitored and managed.	
IND10 1	Notwithstanding the myriad of data gaps, inconsistencies and errors this document contains - as identified by a number of informed, professional parties and individuals - my comment here relates to the foolhardiness of opening up oil and gas fields in the Falklands. Our oil industry aspirations date back to the efforts of FIG civil servants in the early 1990s, when the role of the oil and gas industry in precipitating climate change and greenhouse gas emissions had not yet entered mainstream political consciousness, and certainly not that of the Falklands. 30 years on times have changed dramatically and it is now no longer seen to be politically or globally acceptable for a self-styled environmentally responsible country to be opening its doors to an industry that is widely acknowledged as the cause of human-induced environmental damage on a scale never seen before. To quote the statement from Falklands Conservation: "The International Energy Agency has stated that no new oil and gas fields should be opened if we are to achieve net zero emissions by 2050. This would be necessary to keep temperature rises under the safe 2°C limit, avoiding far more severe climate change effects on wildlife, ecosystems and people, including for the Falkland Islands. Opening a new oil field in the Falkland Islands would not align with this..." No matter how robust (or otherwise) the EIS statements are regarding environmental and social impacts, risks and sensitivities, and associated	Thank you for your comment. This is noted. However, Navitas considers these comments are for FIG consideration.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	proposed mitigation measures, they are of no relevance to the central issue which is we should not be part to the opening up of new oil and gas fields.		
IND11 1	Regulatory and Legal Framework The Falkland Islands is not ready for hydrocarbons production. Oil Readiness has languished, and whilst MLAs have re-prioritised work in recent months, this has not resulted in demonstrable revisions to the legislation and regulation required to oversee a production industry. The Department of Mineral Resources is under resourced and this consultation itself demonstrates that: "The EIS consultation process and further detailed review can be managed with current staff through reprioritisation of other activities. Future resourcing requirements for the regulation of offshore hydrocarbons are addressed in other ExCo papers." FIG has failed to adequately prepare for this EIS submission and is currently not able to regulate a hydrocarbons industry to international best practice. This is a significant risk to the Falkland Islands environment and brings risk of contingent liability to the UK Government. Whilst "It is considered that this EIS will generally be compatible with future planned legislation", this legislation is not in place, and Navitas cannot be held to legislation that is not in force. This risks legal challenge and future lawsuits if attempting to ensure higher standards are adhered to later. 10.2.1 of 118-24P states that the new environmental legislation will be in place by 2025 – this seems wholly unachievable when viewed against the FIG legislative program and the continued failure to move this project beyond policy and drafting instructions. Without robust environmental legislation in place for the EIA process and proposed Environment Case (policy approved in 2018), there are significant gaps in the current regulatory framework (e.g., lack of Polluter Pays and liability, identified gaps in the Conservation of Wildlife and Nature Ordinance) which have been highlighted for almost a	Navitas continues to work with FIG and its key contractors to ensure that its arrangements are aligned with industry best practice and FIG's planned changes to legislation. Navitas expects that FIG will comment separately on the EIS public consultation representations which cover FIG's Oil Readiness and planned legislation.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	decade. Commitments made by FIG to have best practice environmental and safety legislation in place prior to hydrocarbons development have not materialized.		
IND11	The ExCo paper that sought approval for public consultation on the EIS contains errors and had the incorrect version of the EIS appended (incorrect CO_2 emission figures) – the document approved by ExCo should be the document which is consulted upon – this failure to follow due process is concerning but consistent with FIG decision making in recent years.	The EIS was updated to present additional emissions data following publication of the ExCo paper that sought approval for public consultation. The updated EIS was subject to Public Consultation and will be considered by ExCo.	N/A
IND11 3	The EIS consultation process appears muddied, with the role of FIG as regulator and Navitas as developer unclear at times and occasionally appearing to carry direct conflicts of interest.	Navitas has followed FIG's EIA Guidance regarding the Public Consultation process.	N/A
IND11 4	The EIS is inconsistent with FIGs objective to 'reduce our carbon emissions, in order to ensure we act as a responsible global citizen' (Islands Plan 2022). FIG cannot continue to state that the environment is of great value and importance whilst taking actions that directly conflict with these statements. A hydrocarbons industry would be good for the economy, not the environment, it is that simple.	Thank you for your comment. This is noted. However, it is not for Navitas to comment on FIG policy and we would refer the representation to FIG.	N/A
IND11 5	The EIS is largely based on the previous Premier submissions, but with amendments to the development to cut costs (e.g., smaller repurposed FPSO and direct offtake to tankers of opportunity brings greater spill risks – FIG is currently not in a position to adequately control or regulate this oil spill risk).	Amendments to the former Premier proposals are not, as suggested, driven by cost considerations. The field development approach adopted by Navitas enables a more carbon intensity efficient approach to the development. Premier's proposal to utilise a larger FPSO would have led to utilisation inefficiencies in later field life as production declined. In addition, by redeploying an existing facility Navitas is removing the additional environmental impact arising from construction of a new vessel. There will, however, be considerable investment in upgrades and modifications to the candidate FPSO prior to its deployment to the Islands to ensure that it	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		is optimally configured for the Sea Lion Phase 1 & 2 development. Direct offtake to tankers of opportunity was a feature of the previous Premier proposal, and removes the need for double handling of cargos and the inshore spill risk which was associated with Premier's initial inshore transfer oil export concept. The Direct Offtake to tankers of opportunity is considered a connected activity - as such it will be regulated both under FIG's Offshore Safety legislation which it is anticipated will have been fully updated prior to operations commencing, and Falkland Islands Maritime Legislation. Navitas is committed to following international best practice for tanker operations, and will instigate extensive vessel vetting procedures prior to tankers being selected to offtake cargos.	
IND11 6	Whilst FIG has failed to bring in new legislation for this proposed development, Navitas has also failed to provide new data to inform their EIS submission. It is the responsibility of the developer to ensure that adequate, site-specific data is available for the proposed development. The GAP project (jointly funded) did populate some data gaps for use in environmental impact statements, but there remain outstanding pieces of work that are directly relevant to Sea Lion (such as impact of Sea Lion crude on pelts/feathers that Premier had previously committed to). The age of seabird data has previously been criticized. Data collection should be proportionate to the development, but Navitas does not appear to have directly undertaken any studies to inform this updated EIS.	Thank you for the comment. The age of the SAST data has been acknowledged and Navitas commit to collecting new data *via* SMMOs for three years pre First-Oil. The oil was tested extensively at a world leading laboratory in France (CEDRE). Many seabird feathers were tested. Fur seal pelts were not tested because import permits were not able to be obtained. Please refer to the EMMP Chapter 15. Efforts to acquire import permits (to France) will recommence and if acquired, testing of pelts is anticipated to occur between project sanction and First-Oil.	N/A
IND11 7	Carbon emissions and offsetting “Future operator-led direct and indirect offsetting in the Falkland Islands	Perhaps the use of the word 'Internal' has been misconstrued - the Fund will be funded internally, but	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	including carbon and biodiversity offsetting that includes Falklands-specific habitat restoration projects. To enable this, Navitas will create an internal fund which will initially be used to commission research and feasibility studies that lead to pilot offsetting schemes that can be expanded to enable large scale in-Falklands habitat restoration (Carbon sequestration) and biodiversity offsetting. Navitas will monitor opportunities to fund/undertake direct and indirect offsetting throughout Field Life." OPRED queried "How offsetting projects would be identified and managed" – this is still unclear in the EIS and remains an area of concern. Utilising an internal fund fails to demonstrate independent input and verification. FIG previously approved legislation for an Environment Trust to be put in place for this purpose (which has not been enacted). The Environment Trust proposal would prevent either a developer or FIG from utilizing the Fund for non-additional projects and instead would aim to achieve net environmental benefit.	the intent is that the oversight and governance will have FIG and Independent NGO representation as well as independent technical/environmental advisors. Navitas has prepared and submitted a briefing paper to FIG that outlines the intent of the fund. Navitas believe that this aligns with FIG policy and legislative requirements. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	
IND11 8	The carbon emissions will dramatically increase the Falklands national emissions figures. That should be recognized and reflected in the context of the EIS, not just as a comparison to wider UK GHG emissions. Continuing to develop hydrocarbons is not in line with Net Zero aspirations, neither for the Falklands nor the UK, but would bring economic gain. The flaring base case appears to have increased from the previous Premier submission, with associated increases in emissions, is this increase justified?	Section 10.9.4.3.1 sets the context for the Falkland Island emissions. Comparison to Falkland Islands emissions is presented in Section 10.9.4.5.1. POEPL did not specifically itemise flaring that may result from unplanned process upsets and Navitas has included this potential, with a highly conservative (high) estimate. The only flaring POEPL referred to is that associated with commissioning and they estimated 862 t/d *vs.* the 389.2 t/d estimated by Navitas (Table 10.63). Navitas are committed to a zero routine flaring philosophy (Section 5.8.4.4) and flaring emissions are not higher than those proposed by POEPL.	N/A
IND11 9	If the EIS is to be accepted, then conditions should be applied including consultation on proposal for environmental monitoring plans, offsetting, oil spill plans.	Thank you for your comment. This is noted. However, Navitas is unable to comment on what controls (if any) FIG should place on the project's acceptance. It	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	Ultimately, the Falklands is not oil ready and whilst there may be substantial economic gain on the horizon, is it worth the risk if we can't prevent our national resources and environment? It is laudable to be aiming at international best practice, but we aren't there, and we don't have the resources to get there any time soon.	should, however, be noted that: 1. Conditions can be applied to any acceptance. 2. Navitas has already committed to an Environmental Management and Monitoring Plan, a Carbon & Biodiversity Offsetting Fund and has issued preliminary OPEPs to FIG These examples indicate the 'best practice' that is already being applied to the development. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	
IND12 1	1) Social effect - competition for resources 1.1 – Housing Sections 7.7.4.5.1 and 11.3.6.1.2 of the EIS recognise the risk of competition for resources as a social impact as "low" and sensitivity of the effect as "minor" - this assessment significantly underestimates the real-world implications that such competition is likely to have on the community. The EIS does not present extensive quantitative data on the real issue of the effect of increased cost of housing on the community, and there is substantial anecdotal evidence from past instances where oil development was anticipated. In these cases residents have reported sharp increases in rental prices and sale prices of properties as a direct consequence of the speculative behaviour of businesses. Land-banking has continuously exacerbated the housing crisis, driving up accommodation costs for both purchase of land and for private rental. These impacts disproportionately affect vulnerable populations of the islands, who may be priced out of their homes or face a sharp drop in quality of life due to rent increases and a lack of options for alternative residence due to the	Socio-economic aspects of the development (e.g., house prices etc.) were scoped out of the EIS in agreement with FIG (Section 6.2.2.1) whereas social impacts, such as competition for resources were scoped in, which is captured in the FIG EIA Guidelines. A socio-economic impact assessment will consider pressure on housing (both supply and demand and potential house price/rental inflation, construction constraints) in more detail. The socio-economic monitoring and management plan will monitor impacts throughout the project life-cycle and enable Navitas and FIG to explore potential mitigations and management actions as the project matures. Issues associated with land availability and housing are relevant to Falkland Islands economic development in general and not specific to the Sea Lion phase 1 & 2 development.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	sudden surge in demand. The experiences shared by those who lived through previous cycles of oil development are crucial indicators that should not be overlooked or downplayed. While these impacts may not always be fully captured in statistical data, they reflect genuine hardships which the community may face, and thus, the potential severity of these social impacts deserves a more thorough and realistic assessment in the EIS. The EIS also significantly overlooks the increased demand for tradespersons driven by the oil industry. This surge in demand will likely reduce the speed at which new residential properties can be constructed in the Falklands—a region already grappling with limitations on how quickly housing can be built. The current shortage of tradespersons is a known issue, and the influx of oil-related work will only exacerbate this problem. As tradespersons gravitate toward the more lucrative opportunities in the oil sector, the availability of labour for residential construction will decrease, slowing down the rate at which new homes can be built. This shift will also drive up the cost of labour, as tradespersons become accustomed to higher rates of pay from the oil industry. Consequently, even those who can afford the already increasing housing prices may struggle to find available builders, further intensifying the housing crisis. Moreover, this situation will disproportionately affect individuals and families who cannot compete with the higher wages offered by the oil sector. The increased cost of construction services will make it even harder for them to afford new homes, potentially leading to greater inequality in housing access and worsening the existing housing shortage. The EIS fails to account for these dynamics, which are crucial in understanding the full scope of the oil project's impact on the local housing market.		

Ref.	Representation	Navitas response	Changes in Rev 4
IND12 2	1.2 – Electricity The EIS also appears to underestimate the potential impact of increased competition for electricity (section 11.5), which poses a significant risk to the Falkland Islands' already outdated power infrastructure. The current electricity grid and power station are operating beyond their optimal capacity, and the additional demand generated by the project will place an even greater strain on these systems. As the demand for electricity rises, the burden on existing generators will likely accelerate the need for their replacement. The government's current approach to infrastructure funding involves passing a portion of the costs for depreciation and replacement onto the public. This model suggests that the increased strain on the electricity system will not only drive up the immediate costs of electricity but will also result in a continuous cycle of rising expenses for consumers. These costs could escalate further if the new generators are not promptly replaced, especially given the logistical challenges associated with the Falklands' remote location. Moreover, any delays in replacing or repairing generators could exacerbate the situation, leading to potential outages or further price hikes. The EIS does not fully account for these risks, which could have far-reaching consequences for the local population. The assumption that new generators will be readily available or that upgrades will be seamlessly implemented underestimates the complexities involved in such a remote environment as the Falklands. This could lead to a significant and sustained increase in electricity costs, disproportionately affecting residents and businesses alike. None of these issues are addressed by measures offered such as off-peak power utilisation and sustainable design, as there will always be an increased burden on the electricity supply resource of the Falklands, and therefore the above issues of reduced service periods and stress on existing staff and systems.	Competition for electricity is assessed as 'Upper Moderate', to reflect this issue. FIG have confirmed increased power will be available by the start of operations and Navitas will work closely with FIG to ensure their energy needs can be met without compromising the community's needs. Cost of electricity to the consumer is controlled by FIG.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
IND12 3	1.3 - Water access and infrastructure capacity The issue of water access is another area where the Environmental Impact Statement (EIS) appears to underestimate the potential strain on existing infrastructure. The current water system in the Falkland Islands is already operating at full capacity, struggling to meet the demands of the population and existing industries. While the EIS acknowledges that work is planned to upgrade and expand the water infrastructure, these upgrades are primarily designed to accommodate a gradual increase in the population and typical industrial and commercial growth. However, the scale of development associated with the oil industry far exceeds the projections on which these upgrades are based. The oil project, along with the necessary ancillary developments—such as new residential properties, higher industrial water usage, and other significant infrastructure projects—will demand a much greater increase in water capacity than currently planned. Even if the proposed water infrastructure developments are completed on time and reach their expected capacity, they would likely only just meet the needs arising from this natural growth. Adding the significant additional demands from the oil industry could push the water system beyond its limits almost immediately upon completion. This scenario raises serious concerns about the sustainability and resilience of the water supply. The potential for delays or shortfalls in the planned upgrades could lead to severe water shortages, further exacerbated by the increased demand from oil-related activities. The EIS does not appear to fully account for these risks, nor does it provide a comprehensive plan to address the additional pressure that oil development would place on the water infrastructure. If the capacity of the water system is reached or exceeded, this could result in rationing, increased costs for consumers, or the need for emergency infrastructure investments, all of which would have significant social and	Competition for water resources is assessed as Upper Moderate, reflecting the challenge, and notes that without changes to the current water system Sea Lion will exceed Stanley's capability to produce water in Stage 1. Navitas are working with FIG to ensure the water system will be suitable for Sea Lion development and have included a trickle feed and other water saving measure (e.g., all vessels arriving with water makers and loaded with potable water, seawater being used for drilling) to minimise water usage. Navitas has provided FIG with projected requirements, and FIG expects to be able to accommodate these. The SIA will build upon the commentary already included in the EIS re water, electricity etc.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	economic impacts. It is essential that the true scale of water demand from the oil industry and associated developments is accurately assessed and factored into the planning and execution of infrastructure projects to avoid a critical shortfall.		
IND12 4	1.4 - Fuel and bunkering, economic stability as affected by fuel stocks The Environmental Impact Statement (EIS) acknowledges that Stanley Services Limited stocks fuel according to demand. However, it fails to fully consider the broader implications of this practice on the local economy and the community's cost of living. As Stanley Services adjusts fuel pricing based on the ratio of what remains in the tanks to what needs to be restocked, any increase in demand—such as that driven by the oil industry—would have a significant and potentially destabilising impact on fuel prices. With the advent of the oil project, fuel demand will likely fluctuate more dramatically, particularly during peak periods of oil-related activity. This increased and unpredictable demand would lead to more frequent and potentially sharper adjustments in fuel prices. The community, already sensitive to fluctuations in the cost of living, would face a rolling impact as fuel costs rise more rapidly and unpredictably. This volatility would not only affect household budgets, particularly for kerosene and diesel, which are critical to daily life, but also complicate financial planning for businesses and government projects alike. For government and commercial entities, the unpredictability in fuel costs could lead to inaccurate economic forecasting and budgeting, causing delays or cost overruns in key projects. For the average resident, the increased cost of fuel would ripple through the economy, affecting the prices of goods and services that depend on fuel for transportation and production. This could lead to a less predictable and more challenging economic environment, where the cost of living becomes increasingly difficult to manage, particularly during periods of heightened oil activity.	Thank you for your comment. Navitas has spoken with Stanley Services Ltd (SSL). They have commented that 'the comments are factually inaccurate with both domestic fuel and bunker fuel prices having separate pricing mechanisms with one not reliant on the other but are based around world fuel prices. As part of the fuel license agreement between FIG & SSL, SSL has to keep minimum stocks of certain grades for domestic fuel. The minimum stock level is calculated on average sales, any large change in sales will have a negligible impact on pricing and if anything larger sales will assist in keeping prices lower for domestic fuel grades. Bunker fuels are treated differently and there is no requirement for any minimum stock levels. However, an increase in bunker fuel sales will more likely have a minimal positive effect in reducing domestic fuel prices rather than raising them'.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	The EIS does not adequately address these potential economic impacts, nor does it propose measures to mitigate the increased volatility in fuel prices that would result from the oil industry's influence on fuel demand. It is crucial that these factors be taken into account to ensure that the economic well-being of the Falklands community is protected in the face of such significant developments.		
IND12 5	1.5 - International flights The proposal to monitor use of existing airlinks for potential impact is not sufficient to address the potential impact of additional use of the flights. While it is asserted that charter flights could be used by oil companies at various points, it is not addressed that there will be a profit incentive for Navitas to use the existing airlinks where possible. This will have substantial negative impact, with room for a rolling impact in various scenarios. Additional use of existing airlinks, even if it is not considered significant by oil interests, would not have to be high to have a substantial impact on availability of flights for both members of the public travelling to and from the islands for holidays - or visits to home countries for migrants. Existing airlinks already operate at capacity, and in the case of the existing South America link a heavier push on existing capacity is likely to increase prices - either affecting the cost to consumers or the cost to government, indirectly affecting residents by tax revenue usage. Additionally, the airbridge connection also operates at capacity, and is regularly delayed. At this time there are regular cases where residents are waitlisted when there are delays causing merged flights, causing significant expense to travellers and major inconvenience to local businesses and government. With additional strain on capacity to the airbridge such delays would only cause more significant clashes and frustration, longer waitlists, and disproportionately affect those who are least able to afford the delays - particlarly as those who are prioritised on waitlists are senior government	The usage of both the Airbridge and LATAM is discussed in section 7.7.4.3. The impact assessment is covered in Section 11.6. Airlinks will be discussed further in the socioeconomic impact assessment. The current stretch/difficulties regarding air links are keenly understood. The difficulties associated with existing air links noted in the comment explain why Navitas has committed to its own charter flight during the development, SIMOPs and production phases of the Sea Lion development. Currently Navitas would not be able to run its operations using the existing airlinks given both the limited seat availability and waitlisting arrangements, and that an international airframe needs to remain on the ground for sufficient time for the helicopters to complete the offshore crew change. Navitas will work closely with FIG and BFSAI prior to operations to ensure that its charter flight operations can be accommodated at Mount Pleasant International Airport. Oil industry charter flights were accommodated at MPA during previous exploration campaigns.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	officers and BFSAI staff. Each of these issues could face yet more compounded negative effects which are not given due significance as the Mount Pleasant Complex has a majorly limited capacity for inbound and outbound flights. As such, even were charter flights used this would limit the windows in which delayed flights could enter and depart the islands, leading to greater delays, frustration for then public, and expense for government and local businesses and residents.		
IND12 6	2) Effect on quality of life for Falklands residents The basis of pursuing the establishment of an oil industry, it is asserted, is to be able to fund work and projects to increase quality of life for Falklands residents. Here I highlight a number of areas which show that there are a range of areas of negative effect for quality of living in the Falklands. 2.1 – Access to employment It is often asserted that the introduction of an oil industry will improve employment and provide funds for a range of infrastructure projects for the Islands. These claims are universally made for oil projects in various countries, and have been shown to be false. It has been shown that for migrants oil has no positive effect on likelihood of employment, and that the effect on hired jobs in both high and low oil regions of hydrocarbon exporting nations is significant negative (Sigal, 2016). Also, areas where oil is located over time tend to suffer from lower economic growth and lower per capita incomes than the rest of the country, greater dislocations, higher environmental and health hazards, and higher levels of conflict. Economically, petroleum fails to offer long-term sustainable employment alternatives at the local level, but it can seriously disrupt pre-existing patterns of production. The promise of new jobs that new oil exploitation seems to offer typically attracts large numbers of migrants to an exploitation area. The rapid influx	The comments are noted. They are out of scope for the EIS (Section 6.2.2) however this they are covered in the Social Impact Assessment (SIA). It should also be noted that the full employment situation in the Falkland Islands mean that the Islands are distinct from other studies. FIG maintain a local content code of practice. The Sea Lion SIA will detail employment mitigations and a Social Effects Monitoring and Management Programme (SEMMP) will monitor effects and determine appropriate management action throughout the development lifecycle.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	of people and the higher relative salaries of oil project workers inflate the local prices of key goods and services, bringing about a significant increase in the cost of living, even for those who do not share in the benefits of an oil project (Karl, 2007) This effect is particularly visible in communities which have any presence of farming. Universally where oil is introduced farming activity, by employment numbers and production, falls significantly (Sigal, 2016).		
IND12 7	2.2 – Effects on health The effect of oil exposure in a nation for health is even more drastic. Presence of disabilities, both at birth and by injury, increase significantly – and offspring survival rate drops (Sigal, 2016). This has been shown to be the case even when controlling for levels of education and base levels of public healthcare in the area. The only exception for this is where oil is introduced in an area where there is a pre-existing range of private healthcare options in the area – and even in this case there is only a slightly less significant increase in proportion of disabilities by injury, and a less significant decrease in offspring survival rate, and in both cases, only for the highly educated and higher earners, (Sigal, 2016). It was also found that there were significant effects on the health of resident populations where oil is extracted, increasing the presence of various health complications, including asthma, bronchitis, asthma related complications, and lung-condition related deaths - for the United States resulting in a $77 billion direct cost in total health impacts (Buonocore, et al, 2023).	These effects noted in the publication referenced (Sigal, 2016) do not appear relevant to the Sea Lion Phase 1 & 2 Development in which oil is produced offshore and away from human populations. Potential impacts to human health will be considered further in the socioeconomic impact assessment.	N/A
IND12 8	2.3 - Noise pollution The Environmental Impact Statement (EIS) presents an analysis of the potential noise impact from oil activities in areas such as Berkley Sound, Stanley, and regions closest to the port. However, the data and assumptions underlying this analysis are fundamentally flawed. The studies cited in the	Noise surveys were undertaken to understand the baseline levels of noise around Stanley and Berkeley Sound, see section 7.7.5.1.1, as this is indeed a quieter soundscape than an urban environment. The sensitivity of the receptor (human population) is	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	EIS largely reference noise levels considered acceptable in urban environments—areas that already experience a significant degree of background noise. These studies fail to account for the unique context of the Falklands, where many areas, particularly those affected by the oil project, are rural with much lower levels of pre-existing ambient noise. The EIS does not adequately consider the heightened sensitivity of both the resident population and local wildlife to noise disturbances in these quieter, more natural environments. In rural settings like those around Berkley Sound and Stanley, even small increases in noise levels can have disproportionately large effects. The noise data provided in the EIS is not only inappropriate for the Falklands context but also risks severely underestimating the potential disruption caused by oil-related activities. Wildlife in these areas, which is accustomed to a relatively quiet environment, may experience significant stress and behavioural changes due to the sudden and sustained increase in noise. Similarly, residents who are used to low ambient noise levels could face considerable discomfort, sleep disturbances, and other negative health effects, which are not accurately reflected in the urban-centric studies referenced in the EIS. In the particular case of heavy vehicle noise, as has been better tested in regard to aircraft, ambient noise is usually dominated by road traffic noise and community noise (Fields, 1992). Fields suggests that levels of ambient noise may have little effect on reactions to aircraft noise. Nevertheless the responses from the focus groups in the study of Heaver (2002) and those of Diamond *et al.* (2000) suggest that those in areas with high ambient noise level are less annoyed by an additional source than those in an otherwise quiet environment (Sanchez *et al.,* 2015). Lim *et al.* (2008) concurred, finding that subjective responses to aircraft noise decreases with increasing background noise levels.	assessed as being Moderate within the assessment and Navitas will conduct noise monitoring once into operations and monitor and respond to all complaints.	

Ref.	Representation	Navitas response	Changes in Rev 4
	In short, the data used to assess noise impact is not just inadequate—it is fundamentally misaligned with the conditions of the Falkland Islands. The EIS must take into account the lower baseline levels of ambient noise and the greater sensitivity of both humans and wildlife in these rural areas - and take into account the lower difference in noise level required to cause a stress response. Without this adjustment, the true severity of the noise impact cannot be accurately assessed, potentially leading to a gross underestimation of the environmental and social costs associated with the project. It is important to note that as this information is incorrectly founded, the effects can be severe. Once ambient noise levels exceed what a population are accustomed to, the health effects can be severe. Increased noise can lead to significant sleep disruption and psychological distress, which can, in turn, elevate the risk of cardiovascular problems and weaken the immune system. Studies have shown that in areas where there's a sudden and sustained rise in noise levels, the frequency of hospitalizations often increases due to these stress-related health impacts. A consistent increase in noise disturbances can have profound and lasting effects on community health and well-being (Mucci, 2020).		
IND12 9	2.4 - Lack of stability in post-oil scenarios The Environmental Impact Statement (EIS) fails to address the critical issue of what will happen to the Falklands in a post-oil scenario or during periods of oil market instability. The EIS overlooks the potential long-term risks associated with becoming heavily reliant on the oil industry. History has shown that when regions or industries become dependent on oil, they are vulnerable to severe economic disruptions if oil reserves dwindle, if there are fluctuations in global oil prices, or if the industry declines for other reasons. A downturn in the oil market can lead to widespread job cuts, leaving many people unemployed and leading to a range of social issues, including increased homelessness and poverty as has been seen in Aberdeen and	Such effects are outwith the scope of the EIS - potential impacts on employment and quality of life will be considered further in the socioeconomic impact assessment. The Social Effects Monitoring and Management Plan can monitor potential impacts throughout the Phase 1 & 2 development lifecycle.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	other cities which developed an oil reliance. Businesses that thrive during the oil boom may struggle or close down entirely when the industry contracts, resulting in a loss of economic diversity and resilience. Additionally, infrastructure investments made to support the oil industry may become underutilised or abandoned, leading to a deterioration of public assets and a further strain on government resources. The domino effect of an economic downturn in a post-oil scenario can be devastating, with negative impacts spreading across various sectors and deeply affecting the community's quality of life. The EIS does not adequately consider these risks or propose strategies for mitigating them. While it may be challenging to fully predict and plan for a post-oil future, it is essential that the government takes a cautious and forward-looking approach, ensuring that the Falklands is not left vulnerable to the boom-and-bust cycles often associated with oil dependency. The potential consequences are too significant to ignore, and a more robust plan is necessary to ensure long-term stability and sustainability for the Falklands		
IND12 10	3) Falklands Government functionality 3.1 - Global perceptions of the Falklands The Falkland Islands have long marketed themselves as a place where "nature is still in charge." This branding is not just about attracting tourists who come to experience the unique wildlife, including penguins, seals, and whales, but also plays a crucial role in the Islands' political narrative on the global stage. The Falklands are presented as responsible custodians of this part of the South Atlantic, committed to preserving the natural environment for future generations. This image is integral to the Islands' efforts to garner international support for self-determination, particularly during engagements with the United Nations and other global bodies. By positioning the Falklands as a region that prioritises environmental stewardship, legislators have successfully leveraged this perception to build political alliances and strengthen the case	Thank you for your comment. This is noted. However, it is not for Navitas to comment on FIG policy and approach to public diplomacy.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	for maintaining autonomy. However, the development of oil and the associated environmental risks could seriously undermine this carefully cultivated image. The global perception of the Falkland Islands as a pristine, environmentally conscious region is at risk of being tarnished by the realities of oil extraction and the environmental impacts that accompany such activities. If the project proceeds without adequately addressing these concerns, it could damage the Falklands' reputation, leading to a loss of credibility in both tourism markets and international political arenas. Moreover, any negative environmental outcomes could diminish the appeal of the Falklands to eco-conscious travellers, which would have direct economic consequences. This would not only affect the tourism sector but also weaken the Islands' ability to use their environmental record as a tool in political diplomacy. It is essential that these potential impacts on global perception are given serious consideration in the Environmental Impact Statement, as they could have long-lasting effects on the Falklands' economic and political standing.		
IND12 11	3.2 - Public infrastructure support and wider functionality The development of the oil industry in the Falklands is likely to introduce significant challenges to the functionality of the Falklands government, particularly in terms of public infrastructure support. One key concern is the increased use of the air bridge between the Falklands and the UK. With oil-related activities increasing demand for air travel, there will likely be longer delays for government officers travelling to and from the Falklands. These delays could hinder the efficiency of government operations, reducing the ability of officers to respond promptly to critical issues. Moreover, the longer and less reliable travel times may deter potential recruits from moving to the Falklands, as well as dissuading current residents from staying, exacerbating the challenges of maintaining a skilled and stable workforce within the government.	Thank you for your comment. This is noted. However, it is not for Navitas to comment on matters regarding FIG policy and infrastructure investment.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	In addition to the strain on travel infrastructure, the oil industry will place an additional burden on the Falklands' already strained public works sector. The increased use of roads for transporting oil-related materials and personnel will accelerate the wear and tear on the road network. Given that the road works team within public works is already operating at maximum capacity, this added pressure will likely lead to delays in essential road maintenance and other public works projects. The ripple effect of these delays could extend to other critical infrastructure as previously mentioned, such as electricity, water access, fuel and bunkering, housing, and healthcare services, all of which are already facing capacity challenges. The EIS does not fully address these potential impacts, which could severely compromise the government's ability to maintain and develop the infrastructure necessary to support both the oil industry and the wider community.		
IND12 12	4) Method of consultation of EIS I would also like to make known my significant concern in regards to the Non-Technical Summary and the presentation of this document. While I understand the necessity of simplifying information to increase likelihood of responses by members of the public, I feel that the document overly condenses and simplifies various areas and at times even downplays areas of significant risk with the possibility of misleading stakeholders and members of the public who may not have time to read the large complete EIS. While there is little specific response that can be made in regard to this, I would urge that legislators and officers thoroughly consider the high barrier for complete responses which exists for members of the public in regard to the EIS, as almost all but those who would have professional capacity and reason to read the complete EIS; or those who have no significant	Navitas followed FIG EIA guidance on the Public Consultation process.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	professional or personal time commitments, would have time to review and respond to the complete EIS. This being the case, I would urge that Legislators in particular consider the views of their electorate when considering the EIS and it's responses - and do their best to imagine the views of the electorate who may be effected in the future by the decision to pursue hydrocarbons, and would not have had the opportunity to respond to this document, either due to capacity, age, commitment, or fear of negative consequences from their employer or future prospective employers - especially due to the heavily politicised view which is taken of anti-oil stanced individuals.		
IND12 13	5) Acceptability of risk While I do not claim to have expertise in environmental science, biology, or related fields, I am deeply concerned about the lack of attention given to what is considered an acceptable level of risk by the government. The Falkland Islands have long been promoted as a place where nature is in charge, a region that values environmental stewardship and care for its unique ecosystems. Given this, I strongly believe that the burden of what is deemed an acceptable level of environmental risk should be extremely low. The EIS, however, proposes risk levels that range from moderate to high, which are simply not acceptable by any reasonable standard for a place that prides itself on environmental preservation. These mixed moderate, upper moderate, and high-risk assessments should not be allowed to progress unchecked. It is vital that the government upholds the principles of environmental care that have long been associated with the Falklands. Allowing such significant risks to move forward would not only undermine these values but could also lead to irreversible harm to the very environment that the Falklands has committed to protecting.	Thank you for your comment. This is noted. Navitas followed a robust EIA methodology (Chapter 8) and applied the precautionary principle in accordance with FIG EIA guidance.	N/A
IND12 14	Conclusion In conclusion, I believe that the proposed oil drilling project is ill advised from a social perspective, environmental perspective, and from the	Thank you for your comment. This is noted. However, it is not for Navitas to comment on FIG policy.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	perspective of the functionality of government. I also believe that it would be completely misaligned with the Falklands Government goals and responsibility of the Falklands Government and people to contribute to the global environment and - as the Islands Plan states: "reduce our carbon emissions in order to ensure we act as a responsible global citizen."		
IND13 1	Response to the public circulation of the Navitas Petroleum Environmental Impact Statement Thank you for the opportunity to comment, I do so having acute regard for over 4 decades of personal time spent lobbying for the opportunity, which thankfully now lies within grasp. Let us not be blind-sided by a biased environmental rant, sans substance. 30 years ago following due public consultation, FIG launched the First-Oil licensing round in London. There were no dissenting voices, and even Falklands Conversation, then present, did not express objection. In May 2010, Rockhopper Exploration discovered the Sea Lion field. It has taken 14 years to embrace the real possibility of an emerging new industry; it is a once-in-a-generation opportunity. The Sea Lion Environmental Impact Statement (EIS) issued by Navitas Petroleum for consultation, requires responsible consideration of the opportunities, risks and impacts, both positive and negative. The EIS is in accordance with the Islands Plan 2022–2026, that states "This Assembly will… progress extractive industries in an environmentally conscious way." The EIS recognises other relevant FIG policies involved in decisions making and consultation, include those charged with protecting the environment and biodiversity, and climate change. In the Falklands, especially across the rural communities, we all see the impacts of global climate change. We all have our part to play in combating this, through restoration, and the development of Sea Lion will provide the financial resources to fast track land management, best scientific led bio-diversity restoration, and healing of the landscape.	Thank you for your comments.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	The inconvenient reality is that oil has to be a declining part of the energy mix during the Energy Transition in the coming decades. We use oil to fly to and from the Falklands, heat and light our homes, fly FIGAS to boost tourism, take winter vacation, encourage marine tourism, drive vehicles and power fishing vessels, cargo and cruise ships. It is hypocritical therefore, for anyone, and especially Falklands Conservation, to state that whilst we use oil, it should be produced elsewhere, often with lower environmental and ethical standards, by corrupt and dictatorial regimes. Without an air bridge and UK land, sea and air security commitment to the Falklands, we would soon become an irksome remnant of a bygone era. Having lived through the Falklands darkest economic times with little future potential, I cannot recommend any return to such an era. The EIS has identified the risks, and mitigations, with few residual planned negative impacts. This is because oil development is mainly a contained, sub-surface activity. The biggest risks are from unexpected incidents. A modern, high quality development will minimise the risk of such an event. The EIS mitigations show that this can be done. As an example, the likelihood of oil beaching in the Falklands is assessed as 'Low'. The industry will bring with it sea and air units to daily underpin any risk which might surface, and commitments to call in the mobilisation of time critical international resources in the unlikely event of spillage. No other industry, working within the Falklands environment, provides such safeguards. Risks of development are recognised and managed elsewhere, as in the UK, which has 120 producing oil sites, including new sites under development, and from where the Falklands has modelled its offshore Health, Safety and Environment legislation. Even environmentally conscious Norway, has 90 oil-producing sites, and an unimaginable sovereign wealth fund to prepare for the future without fossil fuels. For risk of development to be acceptable in the UK, then it should be acceptable in the Falklands. We have one environment, which we need to protect, but also we desperately need to restore the terrestrial element of our environment – it should not be a simplistic excuse, as Falklands Conservation posits, not to		

Ref.	Representation	Navitas response	Changes in Rev 4
	sustainably develop our economy for the benefit of future generations health, wealth and education, and land restoration. We have a duty to promote, protect and nurture our environment. For some years, I have been in the field restoring Falklands' habits and trying to reduce the loss of peat land, and the only party to have undertaken a first and only ground-truthing survey in one sector of the Falklands. The rural community, called Camp, leads by example having invested substantially in renewables, significantly reducing fossil fuel use. Stanley will energy transition over some years with weighty reserves cost implications. The Falklands are fragile in many ways. Nationally we have experienced the severe financial and social impacts of the long-term decline in the Falklands' historically dominant sector, wool producing. Responsibly, the Falklands needs to diversify its economy. We cannot rely forever on maintaining current financial reserves – they stand to dwindle. Our standard of living and the services we currently enjoy, substantially depend on a single, underpinning activity, fishing. Fishing also has a significant impact on the marine environment. FIG scientifically monitors the fisheries and makes fishery management decisions. Many of the risks in the EIS also are relevant to existing marine activities. Nationally we will be able to educate, train, and employ future generations of home- grown environmentalists, naturalists and future land managers, from an oil industry, which hitherto has not been possible due to lack of commitment and finance. Investing in home-grown talent, educated in our current restricted setting, pursuing further education in the scientific arena, fills a waiting vacuum. Today's students should become our scientific advisors of the future. Political lobbying for the Falklands to have its oil and gas regime commenced decades ago. Let us not cast aside prior strategic thinking and vision done at that time, and our nation's economic future, because of some pseudoscience pedalled by Falklands Conservation. [Redacted personally identifying information], I interpret its 57-page response as nothing short of a rant, whilst on the other hand it annually has arms gleefully outstretched to		

Ref.	Representation	Navitas response	Changes in Rev 4
	receive tens of thousands of £s, of taxpayers funded subvention. Double standards, worthy of public criticism, if not a PAC review. Some years ago the Falklands bunker supplier revealed that >1million tonnes of marine diesel had been transferred in Berkeley Sound, this figure fell short of including all transfers for reefer and jiggers for prior decades. It is therefore wrong of Falklands Conservation to finger the Sea Lion development assets as having the only capability of striking a whale. The Falklands has a National Oil Spill Contingency Plan (NOSCP), but on page 10 of the Falklands Conservation response, oil spills only get one paragraph out of 57 pages! The NOSCP is based on being proportionate to the risk, and at the moment, does not consider oil production, so to make reference to it as Falklands Conservation has done, is misleading or at best, naïve. The Falklands equivalent to the Merchant Shipping Act already provides the basis for a Falklands equivalent to the UK SOSREP with the powers of intervention - but why bother mentioning that when Falklands Conservation appear unaware of Chapter 4 of the Ordinance: Liability for Oil Pollution, or Chapter 5: International Oil Pollution Compensation Fund. To say the EIS is not fit for purpose, reckons with a biased ranting response, which does not even name the author(s). Fast-forward from 1995, we are fortunate to be able to comment on this development EIS in a transparent way. I endorse the well thought through EIS and its focus on delivering the best mature environmental protection against known and likely risks to enable development, while delivering a sustainable future for upcoming generations across both our terrestrial and marine environments.		
IND14 1	Response to Environmental Impact Statement: The Sea Lion Field Northern Development Area As an member of public I am writing to express my profound concerns regarding the Environmental Impact Statement (EIS) for the Sea Lion Field Northern Development Area. As an individual and a Marine Biologist with extensive experience at sea, I have briefly reviewed the EIS and found	Thank you for your comments, the underwater noise chapters are being revised and Navitas will be sure to review the paper suggested. See FIFD 54.	Section 10.4 Section 10.5

Ref.	Representation	Navitas response	Changes in Rev 4
	several critical issues that I believe warrant immediate attention. 10.4.4.3.2.1 Fish hearing thresholds The EIS appears to have been finalized prior to the publication of critical research that directly relates to the project's potential impacts. Specifically, paper Anthropogenic noise disrupts early-life development in a fish with paternal care - ScienceDirect, presents findings that were not considered in the EIS. This study indicates that anthropogenic noise can lead to a decrease in egg number and a reduction in yolk sac size in fish. These findings have direct implications for fish populations, particularly in sensitive habitats such as those around the Falkland Islands. The observed effects in the study- namely, reduced egg numbers and smaller yolk sacs- suggest significant developmental disruptions that could impact fish survival rates and population dynamics. Such disruptions are particularly concerning for species with critical early-life stages and could exacerbate the adverse impacts on fish populations predicted in the EIS.		
IND14 2	1.7.3.1.1 Direct offsetting: The EIS outlines various options for offsetting but does not specify a clear, actionable plan for addressing the carbon emissions resulting from oil extraction, production, and combustion. Given the significant carbon footprint that the project will likely contribute-particularly in the context of the Falkland Islands' relatively high per capita emissions-it is crucial that a definitive strategy for carbon offsetting be established. Considering the Falkland Islands' remote location and limited resources, offsetting measures may indeed be challenging. Without a clearly defined and robust plan for compensation, the environmental impact of the Sea Lion oil field could be substantial. It is essential to have a detailed, written commitment to offsetting that includes calculations and strategies tailored to the unique circumstances of the Falkland Islands. The EIS includes examples such as reforestation in nearby areas where	Thank you for your comment. This is noted. The example of reforestation provided in EIS section 8.11.2.1 was not intended to refer to the Falkland Islands, it was included to provide an example of what would constitute direct or 'like-for-like' offsetting. Please also refer to the response to comment IND 11 7.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	construction has cleared trees. We are clearly not talking of Falkland Islands and EIS is clearly lacking seriousness and commitment for offsetting. Specific, context-appropriate offsetting strategies should be developed rather than relying on generalized examples that may not address the unique environmental and logistical challenges of the region. Given the lack of a clear and actionable plan for offsetting, and the specific challenges posed by the Falkland Islands' remote location, I recommend that permission for the Sea Lion oil field extraction and further oil exploration be put on hold until a comprehensive and feasible offsetting plan is developed. This plan should include detailed calculations and strategies that are specifically tailored to the conditions and capabilities of the Falkland Islands.		
IND14 3	Spatial Overlap with Fishing Licences: The proposed Sea Lion oil field is situated within the geographical boundaries of fishing areas designated under B licence.	Thank you for your comment. This is noted and is discussed in Section 7.7.3.1.1.1, which details the fishing activity within that licence and notes the low levels of fishing in the area and the specific square in which Sea Lion is located.	N/A
IND14 4	And finally, I would like to express a significant concern regarding the Falkland Islands preparedness for potential accidents related to oil exploration. The remoteness of the Falkland Islands, coupled with their limited resources, raises serious doubts about the ability to mount a prompt and adequate response in the event of an environmental incident.	Navitas has prepared and submitted its preliminary (Pre-FID) OPEPs to FIG for their review and approval. These shall be finalised prior to the commencement of operations. Navitas is proactively committed to mitigating the risks of such an event from occurring. Navitas Petroleum Development and Production Ltd. (formerly POEPL) has invested significant resources in understanding Sea Lion crude behaviour and the metocean environment in order to predict the potential impacts on wildlife and inform optimum spill response equipment. Extensive Tier 1 and Tier 2 response equipment has been specified and will be available on the support vessels, and stored in the Supply yard. Tier 3 Spill Response will be supported	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		by specialist oil spill and wildlife response agencies with resources (equipment and manpower) available to respond at very short notice. The oil spill response arrangements are not reliant on the NOSCP and associated resources. The preliminary OPEPs have been prepared in order to interface appropriately with the NOSCP (as required and stipulated in the NOSCP) and Navitas has committed to regular engagement, training and joint spill response exercises with FIG to ensure that a spill response can be effected appropriately.	
Royal Society for the Protection of Birds			
RSPB 1	SEA LION FIELD DEVELOPMENT PHASES 1 & 2, ENVIRONMENTAL IMPACT STATEMENT (EIS) 2024 CONSULTATION RESPONSE The RSPB welcomes the consultation offered by the Falkland Islands Government and offers comments with the aim of contributing to the shared objective of environmentally sensitive economic development. We offer these comments from the perspective of UK and international policy. This contribution builds upon RSPB consultation responses to oil Environmental Impact Assessments in the Falklands over several decades. The RSPB's view is that, due to the five reasons outlined below, the EIS is insufficient to currently meet the standard of an environmentally safe development and should be resubmitted once FIG's more robust planned governance framework is in place. The comments outlined below are not exhaustive.	Please see responses below.	N/A
RSPB 2	1)The proponent's baseline data survey work has major shortcomings a)The incorporation of new pinniped and avian data is welcome. This helps narrow risk and current uncertainty in impacts upon vulnerable seabird and marine mammal populations. It helps identify the presence of a number of species. However, it is our view that inadequate effort has been made between the exploration and extraction applications to survey offshore	Navitas disagrees that the baseline data survey work has major shortcomings. The RSPB comment suggests that additional data should have been gathered in the time available between exploration and extraction. Navitas	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	baseline ecological data on birds and cetaceans. It remains hard to understand why these known gaps could not have been filled by the proponent in the time available.	Development and Production Limited, formally POEPL, has invested considerable resources both independently and *via* the industry-FIG funded 'GAP' project to acquire and analyse data, including seabird and cetacean data, to inform the baseline. While some of this data was available in time to inform exploration Environmental Impact Assessments, it was not commissioned for the exploration stage, but was commissioned specifically to inform the baseline for the purposes of the development impact assessment. While the Seabirds at Sea Team dataset is old, this has been analysed alongside and is complemented by other more recent data and the data is considered valid for the purposes of the risk assessment. There are some data gaps in the SAST dataset, which are acknowledged in the EIS. FIG EIA Guidance states that 'the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they address the gaps in the risk assessment' and where there are data gaps a risk may be increased to reflect the higher level of uncertainty. To update the seabirds at sea dataset would require a multi-year, multiple vessel survey effort across the entire Falklands offshore area. It is considered that this is beyond the scope of an individual operator. The EMMP Workshop considered the (post-regulatory approval/project sanction) data acquisition, monitoring and management	

Ref.	Representation	Navitas response	Changes in Rev 4
		requirements at all stages of the project life-cycle. The workshop concluded that it would be useful to collect further [seabird] data opportunistically from vessels associated with the Sea Lion development, but that a wider data collection effort to update seabird information was beyond the scope of the EMMP.' It was also decided in the EMMP workshop not to monitor seabird populations ashore 'due to the difficulty of attributing any change to activities in the Sea Lion field.' Despite it being suggested by the EMMP workshop that a wider [seabird] data collection effort was beyond the scope of the EMMP, Navitas has committed in the EIS to collaboration with FIFD in this regard post sanction (Section 10.1.10.1).	
RSPB 3	b)Surveys in the 'zone of influence' –a key concept in EIA – are important. Wider tracking data for species is helpful to help build a partial picture. However, this is not a substitute for rigorously designed surveys. In the North Sea, offshore windfarm developers are expected to provide comprehensive data on bird distribution and movements (as well as data on other animals' distribution and movements) over a two-year period and often over potentially very large areas, prior to submitting consent applications. Developers typically undertake offshore distribution and movement pattern surveys, often at considerable cost. This is done so ahead of project approval, with full knowledge of potential associated risks to that development. The need for up-to-date baseline data is also a required under North Sea oil EIA regulations (Statutory Instrument 2020 No. 1497). c)One of the principal reasons for the recognition of the need for up-to-date survey work is that evidence from around the world suggests that seabird populations are changing in their distribution and abundance, including in the sub-Antarctic1. Given the global importance of this marine region to	The context here is that the Sea Lion field is the only one in the Falklands Islands that is currently being looked at for development and it is not reasonable, practically or financially for a single operator to undertake this work in isolation. This work is more appropriate for a collaboration of industry and FIG. Navitas Petroleum Development and Production Limited (previously POEPL) has invested considerable sums in data gathering alongside investment in the GAP project. See also response to RSPB 2.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	seabird populations, and potential risks from oil developments, similar data would be expected to be presented.		
RSPB 4	d)We commend the use of precautionary risk categories. However, the use of these categories has limits if rigorous and up-to-date baseline information fails to be presented. These data gaps ensure there is unnecessary uncertainty regarding the significance of impact on receptors. Consequently there is insufficient confidence in the targeting and efficacy of any mitigation measures that are proposed for individual species that may have different behavioural or lifecycle characteristics e.g., are they vulnerable to light pollution, do they form seasonal local aggregations etc..	The assessments in in the EIS are precautionary and all consider gaps in the data. Under FIG's guidance (FIG, 2016) the applicant should not be accountable for data gaps that could not reasonably have been filled, but more for the way in which they are dealt with in the risk assessment. Therefore the presence of justifiable data gaps does not make an EIS unfit-for-purpose, as long as these are acknowledged and explained and indeed a precautionary approach is taken.	N/A
RSPB 5	e)A compounding concern is that much of the North Falkland Basin east of the drill site has no SAST data in sensitive months, a significant data gap, particularly when considering impacts from possible spill events.	Thank you for the comment. This gap is acknowledged in the document. Note that Navitas will deploy SMMOs on vessel operating in and from the field for a period of three years pre-First-Oil.	N/A
RSPB 6	f)Best practice Environmental Impact Assessment, for example presented by the UK Government2, considers the use of baseline data gathering once consent has been given, or as part of a 'consent condition' to be poor practice. This would include the deferral of baseline data collection to the Sea Lion Environmental Monitoring and Management Plan. This has the potential to put decision makers in a difficult position as engineering plans are advanced, leverage is reduced and development plans therefore less likely to be altered later as the costs would be potentially much higher. g)It is therefore our view that the avian data presented does not allow FIG to make sufficiently informed decisions on potential impacts and therefore methods of possible mitigation of impacts in engineering or operational procedures.	See response to comment RSPB 2, 3, 4 and 5.	N/A
RSPB 7	2)Carbon emissions from unabated development of the Sea Lion field a)The International Energy Agency has highlighted the risk of new long term oil developments to the safe limits described in the UNFCCC Paris Agreement:	The subject of emissions is transparently and extensively detailed in Section 10.9 of the EIS. Navitas is committed to exploring opportunities to further reduce its emissions; an example of this is the	Section 10.9.7.1 Section 10.9.4.4.4 Section 10.9.4.4.5

Ref.	Representation	Navitas response	Changes in Rev 4
	To align with a 1.5 °C scenario, these [industry] emissions need to be cut by more than 60% by 2030 from today's levels and the emissions intensity of global oil and gas operations must near zero by the early 2040s. [...] In a scenario that hits global net zero emissions by 2050, declines in demand are sufficiently steep that no new long lead-time conventional oil and gas projects are required3. b)The estimated unabated carbon emissions outlined in the EIS are approximately 9 million tonnes from production and >111 million tonnes from combustion of the oil. Extraction is proposed to extend beyond 2050, the deadline for net zero. This, alongside the lack of credible offsetting plans (see below), ensure that this development is not compatible with environmentally safe development. c)The proponent has publicly stated a desire to further develop the basin with no mention of emission abatement plans4. If this were to happen unabated, the unfavourable emissions scenario would be significantly compounded.	Emissions Reduction Action Plan (ERAP) for the Floating Production Storage Offtake (FPSO) vessel during the Front End Engineering and Design (FEED) project. Navitas also commits to seeking further emissions reduction initiatives throughout the life-cycle of the Sea Lion Field. EIS Section 10.9.4.4.4 notes that currently expected emissions from Sea Lion are 17.9 $kgCO_2e$/boe. This section also notes that 'when the personnel transportation, drilling and vessel emissions are excluded to enable like-for-like comparison with UKCS emissions reported to the NSTA, the carbon intensity is estimated to be 14.2 $kgCO_2e$/boe (section 10.9.4.5.4).' Consequently, Sea Lion will bring oil to market at a carbon intensity lower than the UK average for an FPSO (36 $kgCO_2e$/boe for FPSOs of 11-25 years of age and 20 $kgCO_2e$/boe for FPSOs of 0-10 years old), indicating that the development is comparatively efficient. This is without the additional emissions reduction measures that will be considered in Front End Engineering Design (FEED) and the Emissions Reduction Action Plan (ERAP). Were the development not to be sanctioned, oil would be sourced from the international market from existing, declining fields with a likely higher carbon intensity. With regards to offsetting, Navitas is committed to	**Note:** the estimates mentioned in the response column have subsequently reduced following changes to the gas conversion rate in response to Xodus 46. Section 8.11

Ref.	Representation	Navitas response	Changes in Rev 4
		offsetting significant impacts. Local offsetting will be prioritised over international schemes. Carbon and biodiversity offsetting opportunities require further evaluation and research to define the level of offsetting that can be achieved locally. Navitas' offsetting strategy has been detailed in a paper which was issued to FIG in August 2024; this will be further discussed and agreed with FIG and will be consistent with FIG legislation, policy and guidance. Navitas does not consider it is possible to give more information on credible potential offsetting plans with a path to physical delivery, including pilot projects, until further research has been undertaken. EIS section 8.11.2.2 states that at this stage it has not been possible to develop potential indirect offsetting projects to the level of maturity required by the EIA guidance, and it cannot make ad hoc commitments to indirect offsetting projects that are not fully understood. 8.11.4 states that 'As feasibility of various potential operator-led direct and indirect offsetting initiatives cannot be confirmed prior to research, analysis and development, Navitas is not in a position to specify offsetting required by the 2016 FIG Offsetting Guidance at this time. Given this, Navitas will initiate a Falklands-specific fund which will initially address and inform the feasibility of large scale carbon and biodiversity offsetting through commissioned research and investigation. It is intended that following this feasibility stage, Navitas will provide funding to the viable projects identified in order to discharge its offsetting obligation.' Note that some potential indirect offsetting initiatives are indicated at	

Ref.	Representation	Navitas response	Changes in Rev 4
		8.11.2.2 but this list is not exhaustive. It is not clear at this stage which of these potential projects would achieve the greatest environmental benefits. Furthermore, at the scale required to achieve meaningful offsetting, these projects may require environmental and socio-economic impact assessment in their own right. The majority of the land in the Falkland Islands is in private ownership, so landowners will need to be content to embrace the offsetting projects proposed. It is difficult to contemplate that landowners can commit to supporting such offsetting initiatives prior to regulatory approval and sanction of the project and prior to there being additional clarity on the environmental benefits such projects will achieve. For these reasons, it was not possible to confirm offsetting initiatives at this stage. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	
RSPB 8	3)Bird strike a) The EIS states (p.605): The Sea Lion Development is 220 km offshore, in an area that supports relatively low seabird densities throughout the year, and therefore it is not considered likely that multiple bird strikes will occur on a regular basis. It is our view that the avian survey data has not been presented to allow the proponent to ensure this statement's veracity (see above). b) The category of 'low' sensitivity of the seabird receptors impacted by artificial light and flares would therefore be unable to be verified. c) The EIS suggests that With regard to the likelihood of a multiple bird-strike	a) Although there are some temporal gaps in the SAST data Navitas believe that it has been precautionary in the risk assessment. Diurnal albatrosses and petrels (i.e., active during the daytime) are less likely to be involved in light induced bird-strikes than birds that are active at night. b) The low sensitivity refers to sea birds that will be vulnerable to light at night – for example prions etc. Most of these are listed as 'least concern' under the	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	event occurring, such a strike is likely to occur less than once per year but more than once in 10 years (p.606). Again, our view is that the data presented are insufficient to be able to make this statement with reliability and therefore the planned mitigation are potentially unreliable. d) Species that are listed as potentially susceptible to bird strike (section 10.1.4.3.1.4 p.599) have not been surveyed at the field site and data presented do not substitute for well-designed surveys that would test for bird strike susceptibility as is found in survey work for offshore wind in the North Sea when conducted to high standard. e) The EIS states that Navitas has limited control over third-party vessels (table 10.6) and proposes minimal stipulations in relation to bird strike. All contractors should apply relevant standards as part of the development. Good practice would see this built into contracts. f) Where insufficient data is available and considering this region is of global significance for seabird populations, good practice would assume a precautionary approach. However, the proposed mitigation measures presented offer few investments beyond industry standard practice. Few Innovative proposals for mitigation are made. These should include the use of radar, modified protocols during high risk periods at key times of the year, Clear sky lighting and other proven methods to reduce the impacts of the development, all part of a structured and internationally expert-reviewed plan.	IUCN red list. c) Thank you for the comment. Our assessment is based on evidence available and the likely taxa affected. The area will be surveyed post sanction and 3 years prior to First-Oil and the data generate here will improve Navitas' Bird Strike Action Plan. d) See response in c). Note that further data will be collected by SMMOs in the field three years pre First-Oil.The EMMP workshop concluded that 'a wider data collection effort to update seabird information was beyond the scope of the EMMP.' The context here is that the Sea Lion field is the only one in the Falklands Islands that is currently being looked at for development and it is not reasonable, practically or financially, for a single operator to undertake this work in isolation. This work is more appropriate for a collaboration of industry and FIG. Navitas has indicated its desire to collaborate with FIFD to collect area wide multi-year data - see section 10.1.10.1. e) With the exception of the CTT's, third party vessels on direct hire to the Sea Lion development will be part of the Bird Strike Action Plan with monthly bird strike reports sent to FIG. Lighting on vessels will be outwith Navitas' control and will be governed by safety regulations, although all in-field vessels will be asked to optimise lighting and utilise on site mitigations e.g., black out blinds etc. f) Thank you for the comment. Navitas will develop a	

Ref.	Representation	Navitas response	Changes in Rev 4
		Bird Strike Management Plan for all operations in Berkeley Sound and at the Sea Lion Field. Navitas has committed to exploring whether further mitigations can be applied during Front End Engineering Design, but as these project specific mitigations cannot yet be confirmed they have not been factored into the residual impact assessment.	
RSPB 9	4)Carbon and biodiversity offsetting proposals are not yet viable a)The proponent has put forward possible options in relation to offsetting carbon and biodiversity impacts under various scenarios. However, as freely identified in Table 8.9 (p.552) the plans are not sufficiently advanced to be able to show viability. b)FIG's Hydrocarbons Environmental Impact Assessment Guidance states that Whilst the EIS is not itself necessarily the basis for implementing or enforcing the mitigation, it should demonstrate that the proposed mitigation is realistic 5 . The proposals do not fulfil FIG's standard currently. This critical part of the EIS appears to have been presented prematurely.	Offsetting is the final step in the mitigation hierarchy. Navitas is committed to offsetting significant impacts. FIG guidance requires local offsetting to be prioritised over international schemes. Carbon and biodiversity offsetting opportunities require further evaluation and research to confirm viability and define the level of offsetting that can be achieved locally. This feasibility stage is underway, but requires data acquisition over a number of years. Where direct offsets are not available, Navitas will undertake indirect offsetting (EIS section 8.11.2.2). Navitas' offsetting strategy has been detailed in a paper which was issued to FIG in August 2024; this will be further discussed with FIG and will be consistent with FIG legislation, policy and guidance. See also commentary on offsetting in response to RSPB 7. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	N/A
RSPB 10	5)FIG's planned environment regulation regime is incomplete and therefore not yet 'oil-ready' a)FIG has recognised the need to improve regulation for the environment in order to secure safe standards of environmental governance and to address	Navitas notes this comment. Navitas expects FIG to address responders' comments on legislative matters separately.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	potential conflicts of interest as would be found in other jurisdictions such as the UK. b)In 2013 ExCo approved plans to separate the environmental regulatory function from the licencing function to avoid any potential conflicts (ExCo paper No. 70/13). This function is separate in the UK's North Sea regime. Whilst there is currently no evidence of any real conflict arising between licensing and safety regulation there are potential conflicts of interest between these functions, and most modern oil regimes separate the regulation of licensing/production from the regulation of safety and environmental matters (indeed in other regimes separation of these functions has followed major safety incidents (Piper Alpha in the UK and Macondo in the USA)). […] The Islands would be wise to learn from this experience and avoid some of the mistakes made elsewhere. This will ensure that the inherent conflict of interest between issuing economically and commercially valuable production licences and the approval of safety and environmental practices is avoided, and will better ensure the protection of the unique environment of the Islands and the safety of its inhabitants and transient workforces6. c)This recommendation has not been completed. The licencing authority is now considering the approval of the EIS. Arguably the licencing authority is now faced with this potential conflict. d)In the same paper there was the following commitment: That ExCo confirm that new legislation and guidance is needed to compel operators to submit an 'Environmental Case'. This recommendation has not been completed. e)In 2020 ExCo paper 97/20 noted The wider Falklands environmental regulatory framework has been noted as a concern for the UK Government in relation to the offshore Sea Lion development; and there is a need to demonstrate substantial progress regarding a number of items of legislation including the CWNO [Conservation of Wildlife and Nature Ordinance] in advance of project sanction. […] The FI wildlife legislation is dated and inappropriate for the globally significant wildlife supported by the Islands		

Ref.	Representation	Navitas response	Changes in Rev 4
	and includes little guidance for dealing with breaches. As the EIS correctly points out there are no equivalent 'Disturbance licences', so it is difficult for developers to know what the next steps are to be compliant with legislation and policy. f) In 2017 ExCo approved plans (ExCo paper 5/17) to put in place a 'polluter pays' law: The proposed legislation seeks to extend the focus of those onto prevention as well as remediation by placing an obligation on operators to take necessary steps to prevent environmental damage, and giving FIG suitable powers to issue specific directions. This is in line with the UK Environmental Damage (Prevention and Remediation) Regulations 20157. This recommendation has not been completed. g)If FIG logic is to be followed, the environmental governance framework is not yet sufficiently complete to approve the current EIS to a sufficiently safe governance standard.		
Seafish (Falklands) Limited			
SEAFISH 1	Discharge of drill cuttings – Looking for reassurance that this activity won't interfere with squid – what is the previous relevant literature in this area? It would be helpful to show the discharge of cuttings from the drilling and their spread across the seabed.	Navitas does not anticipate any impact from drill cuttings on squid life-cycles. As indicated in Section 10.6 the footprint of the cutting piles is very small in comparison to the extent of the habitat available. Further, spawning grounds for *illex* are off the southern coast of Brazil and the eggs are pelagic. The impacts of drill cuttings and discharges on fish and squid are captured in Section 10.6.4.2.5.	N/A
SEAFISH 2	Mobile Offshore Drilling Unit – The scale of the necessary exclusion zone around the FPSO and associated underwater infrastructure is not clear. There is a 500m zone and a 1,275m zone referenced, but also references to other items at the site that require exclusions zones as well. A map outlining the total area that will be closed to fishing vessels would be ideal.	Section 5.4.3 on the MODU makes reference only to the 500m exclusion zone around the MODU Section 5.5.4 on the arrival and positioning of the FPSO makes reference to the 1,275m exclusion zone around the FPSO Section 11.1.2.2 on Disturbance to other users provides a figure showing the combined offshore exclusion zones. Navitas is unclear as to where the confusion lies.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		A 500m exclusion zone is required around the MODU whilst drilling. A similar 500m zone is upheld for the SURF vessels whilst they are completing their workscopes. Once the FPSO is in steady state production a 1,275m exclusion zone will be established. The increase in distance is required as it covers a greater amount of subsea infrastructure to that of the MODU or the SURF vessels. Notices to Mariners will be issued each time the MODU moves and once the FPSO is located. Navitas has also committed to working closely with FIMA and regularly advising FIFCA. A field detail (albeit not to scale) is included in Section 1.4, this provides a detail of how the surface and seabed will look in steady state production. Charts with the Sea Lion Field infrastructure and offshore assets will be provided to other users of the sea prior to operations commencing. Please also refer to the response to FOR 3.	
SEAFISH 3	How is the size of the offsetting fund set, is there a risk that Fisheries are asked to contribute to this in the future? Is there any precedent for this happening in other jurisdictions?	Navitas issued its Carbon & Biodiversity Offsetting Fund strategy to FIG in August 2024. The size of the offsetting fund will be agreed in conjunction with FIG. Navitas has specified that this fund will be related only to the Sea Lion field. Previously FIG's proposed Environment Fund was designed by FIG in consultation with stakeholders with the view that it could service offsetting contributions /ambitions of industries beyond oil and gas in future. Any regulation requiring broader industry contribution is a decision for FIG,	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		consequently Navitas cannot offer any further comment on this matter. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	
SEAFISH 4	How are the international tankers that collect the oil for export regulated and what is the risk level of an accident with one of them in or around FI waters? What routes will they be using for transit in FI waters?	Thank you for your comment. Tankers are vetted according to the criteria noted in section 5.10, which includes (but is not limited to): - Compliance with MARPOL 73/78 - Validity of SOPEP - Compliance with IMO Ballast Water requirements - Biofouling management - All CTTs must be double-hulled - Must be equipped with 8 wire mooring lines on fixed drums - The CTT will have aft towing bits with a minimum 80 tonne SWL (Safe Working Load). - Will have an amidships crane with minimum SWL of 15 T with a 4.5 m outreach; - Manifolds will be fully compliant with OCIMF recommendations; - Must have helicopter landing / winching area. Risks of collisions are assessed in a bespoke collision risk assessment report by Anatec (2024), which is reported in section 11.1 and oil spill risks are assessed in section 12.1. With regards to the routes that the CTTs are likely to take this is, as yet unknown as the CTTs will be	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		chartered from the international market. However, it is reasonable to expect that the CTTs will enter the Sea Lion field from the north or northeast as most they are expected to come from the Americas or the African continent.	
Uplift			
UP 1	1. We write in response to the consultation by the Department for Mineral Resources regarding the Environmental Impact Statement (EIS) for the Sea Lion Field Development. The EIS has been submitted by Navitas Petroleum Development and Production Ltd (Navitas) who intend to develop Phase 1 and 2 of the field with Rockhopper Exploration (Rockhopper). 2. Uplift is a UK-based not-for-profit research organisation that supports a rapid transition from oil and gas production on a timeline consistent with a safe climate. We are interested in and concerned about the proposal to	Thank you for your comments. Responses to the questions and commentary by Uplift are addressed in the responses below.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	develop a new oil extraction project in the Falkland Islands as a UK overseas territory due to its impact on the climate and incompatibility with UK climate obligations. 3. In reviewing the Sea Lion Development EIS, we consider that it fails to comply with the requirements of the relevant Falkland Islands legislation1; with the UK's and the Falkland Islands' international legal obligations; and with Falkland Islands Government (FIG) guidance2. We consider that the EIA fails to properly assess the environmental impacts of the development, in particular a meaningful assessment of the development's transboundary and cumulative climate impacts. Our comments will set out our concerns about how the EIS falls short in the following areas: a. Combustion emissions. b. Production emissions. c. Mitigation and offsetting of significant environmental impacts. d. Other international legal obligations.		
UP 2	Combustion emissions are not "outwith the control" of the developer 4. The EIS incorrectly concludes that the combustion emissions from the Sea Lion Development are outwith the control of the developer. The atmospheric emissions associated with the combustion of the sold product are identified as "Upper Moderate" in terms of significance, but are described as "outwith Navitas' control" (EIS, Section 16.4, page 1290). 5. The UK Supreme Court recently held in the case of Finch v Surrey County Council3 that the Environmental Impact Assessment (EIA) for an oil extraction project must assess the effect on climate of the combustion of the oil to be produced, and rejected the reasons for disregarding those impacts as flawed (Finch, paragraph 178). 6. The argument that combustion emissions are outwith the control of the developer was expressly rejected by the court. At paragraph 103 of the decision, the Supreme Court held that: "The combustion emissions are manifestly not outwith the control of the site operators. They are entirely within their control. If no oil is extracted, no combustion emissions will occur. Conversely, any extraction of oil by the site operators	Please note: Navitas included the worst-case emissions resulting from the product once sold, however, it remains the case that there is currently no guidance regarding estimation or assessment of such emissions. The narrative will be reworded to state that "Once the oil is produced and sold, it is beyond the ability of Navitas to determine where, when and how the end-use emissions will be created and thus Navitas has very little ability to influence these aspects." The arguments made in the Finch *vs.* Surrey County Council case are understood by Navitas, including the statement that emissions from the sold product are within Navitas' control in that they could be prevented if Navitas chose not to produce the oil in	Section 10.9

Ref.	Representation	Navitas response	Changes in Rev 4
	will in due course result in GHG emissions upon its inevitable combustion. It is true that the time and place at which the combustion takes place are not within the control of the site operators. But the effect of the combustion emissions on climate does not depend on when or where the combustion takes place. Those factors are irrelevant to the size and significance of the environmental impact". 7. The EIS notes that the environmental legislation that applies to oil and gas in the Falkland Islands is based upon the regulatory requirements for the UK Continental Shelf, and that legal compliance and preparation of required consents would be based on current FIG legislation, where it exists, and with reference to UK legislation and guidance (EIS, Section 1.3.1, page 30). We consider the UK Supreme Court ruling in Finch on the correct interpretation and requirements of the EIA process to be relevant and instructive to the Department for Mineral Resources when considering whether this EIS from Navitas is satisfactory. 8. In our view, consistent with that of the UK Supreme Court, the significant combustion emissions that would inevitably result from Sea Lion Development are manifestly not outwith Navitas' control.	the first place. However, this EIS is in support of the FDP which is actively seeking approval to develop the oil field and produce the oil and gas. To this end, the EIS presents an assessment of the environmental and social impacts and risks of doing so. It is then the decision of FIG, to determine whether or not the impacts and risks, alongside the associated EMMP, are considered to be tolerable when balanced against the economic and social gains. Navitas continue to work closely with FIG as their legislative framework develops.	
UP 3	Inadequate identification and assessment of combustion emissions 9. While maintaining that the combustion emissions are outwith their control, Navitas does state that those emissions were estimated for P10, P50 and P90 production cases on the assumption that 100% of the product would be combusted. The figure for those combustion emissions is not provided in the EIS, thereby failing to properly identify and assess the significant effects of the development in the EIS in a clear manner that the general public can understand, as required by the regulations and relevant guidance. 10. Instead, Navitas states that the Sea Lion production per day for a P50 case "represents only 0.03 % of global daily emissions" (EIS, Section 1.7.4.2.4, page 53). For the purposes of the EIS, the only relevant scenario is the P10 case, which would reflect the worst-case impacts. By using the P50 case, the EIS has failed to assess the worst-case impacts as required by	9. The combustion emissions associated with the sold product, assuming 100% combustion, are stated for each of the P10, P50 and P90 cases in 10.9.4.4.8. 10 & 11. The comparison of the total emissions to the daily global demand is not intended as anything other than a means of providing perspective in the context of global demand. Navitas will amend the narrative and present the P10, P50 and P90 case as a percentage of the global demand instead of just the expected P50 case. 12. As emissions are a global impact, the contribution of project in the context of global demand is an appropriate comparison to make. The comparison is not intended to hide the fact that the emissions are	Section 10.9

Ref.	Representation	Navitas response	Changes in Rev 4
	the legislation and guidance. 11. Assessing the combustion emissions as a percentage of global daily emissions is not a meaningful or informative measure for the purposes of EIA, nor is it in line with legal and regulatory requirements or Falkland Islands guidance. 12. A comparison with a global daily average, or even with the UK daily average emissions, is not sufficient for the purposes of the EIA. Comparing emissions to a global total in a manner which will necessarily result in the emissions from a particular project representing a small proportion of that total are neither instructive nor reflective of their true environmental impact.	considered significant, as is indicated by both the Moderate and Upper Moderate impact assessment outcomes provided.	
UP 4	13. We recommend that the assessment of combustion emissions must include an assessment of all quantifiable impacts including the impact on temperature increase, extreme weather events, and whether there is room within the carbon budget for meeting the 1.5°C temperature goal for these further emissions. Rather than comparing one project to a global daily total of emissions, there are a number of more appropriate and telling benchmarks that could be assessed to present the impact in a manner that the general public will understand. a. FIG Guidance on Hydrocarbons Environmental Impact Assessment dated 7 July 2016 (EIA Guidance 2016) states that FIG need to know how the industry will increase emissions in comparison to other local sectors and that "an assessment of atmospheric emissions compared with FI emissions figures is required" (EIA Guidance 2016, paragraph 3.15). This comparison is not provided by Navitas in the EIS. There is insufficient environmental information provided to properly and meaningfully assess the impacts of the combustion emissions. b. The decision of the UK Supreme Court in Finch noted that the direct production emissions in that case were calculated as a proportion of total UK carbon budget, allowing the effects to be described in that context as "negligible" when compared to the national total. However, the court notes that, had it been included, the figure for the combustion emissions would	Thank you for your comment. It is impossible to determine the impact of a single project on climate change parameters such as temperature and weather events. a. An assessment of atmospheric emissions compared with Falkland Islands emissions figures is provided in Section 10.9.4.5.1 (footnote 72) and is referenced in the impact assessment in Section 10.9.6.1.1. While the EIA Guidance suggests that FIG needs to know how the industry will increase emissions in comparison to other local sectors, and that FIG can provide data (FIG EIA Guidance 3.15), FIG Environment was not able to provide sufficiently detailed data to enable any meaningful sectoral comparisons to be made. 10.9.4.3.1 notes that the Falkland Islands emissions do not include emissions from international aviation and shipping and that these and other omissions must be taken into account when making direct comparisons. It states further that all comparisons between the Phase 1 & 2 emissions and Falkland Islands emissions must be	Section 10.9.4.5.1

Ref.	Representation	Navitas response	Changes in Rev 4
	have been nearly two orders of magnitude greater and "could not have been dismissed as 'negligible' in that way" (Finch, paragraph 82). c. The EIS should not just calculate and identify the total combustion emissions, but also assess whether there is room for those emissions in the global carbon budget for meeting the 1.5C temperature goal. Projected CO_2 emissions from existing fossil fuel infrastructure, without additional abatement, would exceed the remaining global carbon budget for 1.5°C4. Therefore, any new fossil fuel developments need to be matched by production reductions elsewhere to avoid fossil fuel oversupply and breaching the goals of the Paris Agreement. The EIS makes no attempt to prove these emissions would be substitutive rather than additive. d. The decision of the UK Supreme Court in Finch highlighted the importance of the production gap, i.e., the difference between countries' planned fossil fuel production and global production levels consistent with limiting global warming to 1.5°C or 2°C. The UK Supreme Court notes that the general picture is that many governments continue to support, finance and expand fossil fuel production, even though such policies are "irreconcilable with global climate commitments", referencing the UNEP Production Gap Report 2023 (Finch, paragraph 142). e. The EIS does not make any reference to the production gap and the wider significance and environmental impact of expanding fossil fuel production to which the Sea Lion project would contribute. The fact that such expansion is recognised by expert bodies and the UK Supreme Court as irreconcilable with global climate commitments is not addressed in the EIS. f. The impacts of atmospheric emissions are necessarily cumulative and must not be assessed in isolation. As the International Tribunal for the Law of the Sea (ITLOS) made clear in its recent Advisory Opinion on Climate Change and International law5, in the context of pollution of the marine environment from anthropogenic GHG emissions, "planned activities may not be environmentally significant if taken in isolation, whereas they may produce significant effects if evaluated in interaction with other activities" (ITLOS Advisory Opinion, paragraph 365).	caveated. Noting these caveats, in 10.9.4.5.1, Navitas has provided an assessment of the Phase 1 & 2 development in comparison to Falkland Islands emissions using the data available (see footnote 72). b. Navitas does not conclude that the emissions associated with the development, production or of combustion of the sold product are negligible, and this is indicated throughout the assessment chapter and in all summaries. c - f. This is not the role of a single operator that does not have view of all sources of emissions from projects that are sanctioned, or in the process of being sanctioned. The cumulative impact of emissions is global and long-term and is the driver behind the numerous international instruments in place to manage and reduce global emissions while ensuring sufficient fossil fuel is available to meet demands during the transition to sustainable energy. .	

Ref.	Representation	Navitas response	Changes in Rev 4
UP 5	Production emissions 14. The EIS compares the development's production emissions to the total UK carbon budgets, which is not a legally or scientifically relevant metric by which to assess the significance of their environmental impact. A comparison between the direct emissions from the Sea Lion Development and the projected future UK direct emissions is shown in Table 10.71 of the EIS, showing the Sea Lion production emissions as relatively small percentages of the annual allowance of the UK's 4th, 5th and 6th carbon budgets. This comparison is included to "provide a context within which to assess the 'severity of effect'" (EIS, 10.9.4.5.5, page 833). 15. However, calculating the impact as a percentage of a national or global budget will necessarily always show any individual project making a small contribution to the total, and is not a meaningful comparison on which to base an assessment of environmental impact. Even if the Sea Lion emissions did contribute to the UK's carbon budgets, this assessment is meaningless without indicating how much of that budget has already been used by existing or other planned developments. 16. Nor is the comparison with the UK carbon budgets or a UK total emissions in line with the requirements of the FIG Guidance, which explicitly requires a more local comparison with the Falkland Islands emissions figures (EIA Guidance 2016, 3.15). The annual emissions are demonstrated in the context of Falkland Islands emissions in Table 10.70 based on 2021 emissions data. It is unclear why the EIS uses 2021 data when more recent data is available, and casts doubt on whether the EIS is based on the most up to date environmental information as required by the guidance. In using that baseline of 2021 emissions, the Sea Lion development being responsible for 65% of the Falkland Islands emissions represents a very significant environmental impact. This is the most legally relevant comparison for the Department for Mineral Resources to consider. 17. An assessment of Sea Lion's production emissions as a percentage of all emissions from UK Overseas Territories would also be more instructive than a comparison to the UK's carbon budgets - which based on the figures	14 & 15: Navitas recognises that the contribution of any project taken in isolation will amount to a small percentage of aggregated emissions and does not claim that the small percentage contribution leads to a negligible impact. The sensitivity of the atmosphere as a receptor is recognised to be Very High as indicated in Section 8.5.2.1.1 and the overall impacts associated with the emissions are rated as Moderate and Upper Moderate. Mitigations to minimise the impacts are built-in to the basis of design and all emissions will be recorded and monitored. When the worst-case carbon intensity of the project is compared with that provided by the NSTA, as shown in Section 10.9.4.5.4, they are shown to be less than the UKCS average, even when using the lower P90 production rate and including all other emissions which are not factored into the NSTA data e.g., personnel transportation, vessels and drilling emissions. 16. Comparison with the Falkland Island emissions is presented in Section 10.9.4.5.1 and is referred to in Section 10.9.6.1.1. The 53 % contribution is acknowledged as being high but this also needs to take account of the fact that the data set provided by FIG is currently incomplete and does not include emissions from aviation, large-scale fishing, shipping or previous offshore O&G activity, all of which are significant contributors. The data used are the most current data (at the time of writing) supplied by FIG in January 2024. 17 & 18: It is recognised that the UK Carbon Budgets do not yet include emissions from all OT/CD's (see	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	provided would be approximately 10% of production emissions from UK Overseas Territories party to the UK's ratification of the UN Framework Convention on Climate Change (UNFCCC)6. 18. However, if Navitas and the Department for Mineral Resources consider the UK carbon budgets to be a relevant measure, then the mechanisms for meeting those carbon budgets should also be considered. The UK government has committed, within the North Sea Transition Deal (NSTD) to specific targets for the offshore oil and gas industry, which seek to achieve a 50% reduction in greenhouse gas emissions by 2030 against a 2018 baseline within the sector7. The EIS does not demonstrate that Sea Lion would be consistent with the NSTD emissions targets, nor the clear direction of travel in UK oil and gas policy that it reflects.	response to DMR 231) but in the absence of any other benchmark, and with the ITCU commitment to progress their inclusion, the UK budgets are used at this time. Should budgets for OT/CDs be established, these will be used in future. Whichever benchmark is used for comparison, Navitas conclude that the emissions are a significant impact, as all emissions now are, and the decision falls to FIG on whether or not these can be considered tolerable in balance with the potential gains. As a single operator, it is not for Navitas to determine how much of a carbon budget has been used already, or will be used by all other future projects, and nor are such data available to them. The UK Government is a statutory consultee to FIG and it is the role of FIG, in consultation, to determine the fate of the proposed project in full consideration of the environment and social impacts.	
UP 6	19. As Navitas appear to consider the UK as a relevant comparator, the comparatively high carbon intensity of Sea Lion's production emissions when assessed against UK oil and gas should also be considered. Emissions estimates based on Phase 1 and 2 of the Sea Lion development indicate a carbon intensity of 25.8-35.2 kg CO_2 equivalent per barrel of oil produced (EIS, 1.7.4.2.4). Navitas seek to downplay this poor operational emissions performance by comparing the carbon intensity of this new development to existing, producing FPSO-developments operating in the North Sea (EIS, 10.9.4.5.4 and 10.9.4.3.2.3). 20. In fact, the carbon intensity for the Sea Lion development is significantly higher than the average for UK offshore oil and gas (19.8 kg CO_2/boe in 20228, 26-58 % less than Sea Lion). Recent Environmental Statements approved in the UK have had average emissions intensities significantly below the UK average. The proposed Sea Lion development also has an	The average stated by NSTA and used for comparison in the EIS is based on *actual* intensities of just the production phase for the fields (and excludes personnel transportation, vessel use and drilling), whereas the Sea Lion EIS necessarily has to report potential worst-case. Emissions intensity for the Sea Lion 'current expected case' is 17.9 kgCO_2e/boe for the whole development at the P50 production case. In order to align with the methodology for emissions reported to the NSTA, it is necessary to consider the production phase only (i.e., excluding the personnel	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	intensity significantly above the global average (18 kg CO_2/boe) and median (22 kg CO_2/boe). 21. The Sea Lion development would therefore perform poorly against UK standards and the NSTD metrics, and would be unlikely to pass the North Sea Transition Authority's effective net zero test for new developments. We note that FIG has no equivalent mechanism to the NSTD or an effective net zero test, suggesting lower standards of regulatory governance compared to the UK. Given that the EIS acknowledges that the regulatory regime is based on that of the UKCS and will look to UK legislation and guidance where the FIG regime is silent (EIS, Section 1.3.1, page 30), we recommend that the Department for Mineral Resources implement their own effective net zero test as part of the approval process for new developments, including Sea Lion.	transportation, vessels and drilling emissions); the current expected emissions intensity is below the UK average at 18.2, 14.2 and 13.1 kgCO_2e/boe at the expected P90, P50 and P10 production cases, respectively.	
UP 7a	Mitigation and offsetting 22. The Offshore Minerals Ordinance 1994 requires the EIS to describe the measures that are envisaged to eliminate or reduce significant adverse effects, remedy those effects if possible, and offset them. FIG Guidance requires that mitigation and off-setting measures "should not be hypothetical or unrealistic, but measures which the applicant is proposing to use and is confident will be practicable and effective within the local context" (EIA Guidance 2016, paragraph 3.22). The EIS should demonstrate that the mitigation is realistic (EIA Guidance 2016, paragraph 3.22). There are a number of impacts and risks of concern that cannot be mitigated at all, or for which the EIS proposes mitigations which are not realistic. It is concerning that a number of environmental impacts and risks remain significant, with no mitigation or offsetting identified.	These comments are noted. 1. Navitas is committed to offsetting impacts that are significant. 2. This includes the offsetting of impacts that are uncertain or intermittent. 3. The EIS does not propose offsetting for unplanned impacts (e.g., full inventory loss of oil from the FPSO). 4. Table 8.9 refers to direct offsetting opportunities of impacts that are assessed to be significant (moderate or above). 5.Where direct offsets are not available, Navitas will deploy indirect offsetting. This will be clarified in Table 8.9 in the post-consultation EIS. 6.EIS Section 8.11.4 explains that offsetting projects that benefit the Falkland Islands environment will be prioritised over international schemes; this is in line with FIG guidance. 7. FIG has developed further offsetting guidance since	Section 8.11.2.2 Table 8.9

Ref.	Representation	Navitas response	Changes in Rev 4
		their EIA Guidance 2016 was published. This includes the option of contribution to an environmental fund to directly commission, manage and oversee offsetting projects. 8. Navitas is funding additional research in order to be confident that the offsetting measures currently under consideration will be practicable and effective within the local context. 9. Navitas' Offsetting approach will align with FIG's Policy and Legislation. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund.	
UP 7b	23. The EIS acknowledges that a number of environmental risks "remain significant" even after consideration of both base-case and project-specific mitigations. These include the risk of bird strikes due to artificial light and risk of collision between marine mammals and vessels, which remain "Moderate", and others including the impacts from atmospheric emissions associated with combustion of the oil remaining "Upper Moderate" (EIS, Table 1.6, page 51).	Navitas note these comments.	N/A
UP 7c	24. There are a number of significant impacts for which no realistic mitigation or offsetting can be identified. Table 8.9 shows that no realistic direct offsetting of the bird strike or injury to marine mammals from collision could be identified. In relation to the impacts of atmospheric emissions, Table 8.9 notes that there are no emissions trading schemes in the Falkland Islands and that other carbon offsetting initiatives have been identified but require further research and analysis "to determine their efficacy and the quantum of potential offset prior to such initiatives being taken forward". As for indirect	Navitas will update Table 8.9 in the post-consultation EIS to ensure it is clear that where there is no direct offset identified, indirect offsetting will be undertaken. Please refer to EIS Section 8.11.2.1 on indirect offsetting. Feasibility of various identified potential direct and indirect offsetting initiatives cannot be confirmed without further research, analysis and development. Navitas is committed to funding the required	Table 8.9

Ref.	Representation	Navitas response	Changes in Rev 4
	offsetting, Navitas accepts that they have not been able to identify indirect offsetting projects to the level of maturity required. It is not satisfactory that some of the most significant environmental impacts remain without mitigation or offsetting, notwithstanding the questionable efficacy of offsetting as a strategy to mitigate emissions.	feasibility studies, empirical data gathering and pilot programmes to inform the feasibility of large-scale carbon and biodiversity offsetting. Navitas' Offsetting approach will align with FIG's Policy and Legislation. **Note:** Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund. Please see response to comment UP 7e.	
UP 7d	25. Where project-specific mitigations are identified to reduce some risks, those mitigations are not realistic and the downgrading of risks in this way without clear mitigation or off-setting plans undermines the precautionary approach.	It is not clear what examples are being referred to here. Navitas believes that the EIS presents a thorough and robust assessment, that project-specific mitigations are realistic, and the precautionary approach has been applied appropriately.	N/A
UP 7e	26. While the combustion emissions that would occur when Sea Lion's oil is burned are included in the EIS, to the limited extent that they are described only as a percentage of the global daily average, there is no attempt to mitigate, eliminate, reduce, or offset their significant environmental impacts.	Navitas' offsetting strategy has been detailed in a paper which was issued to FIG in August 2024. Navitas is committed to comply with FIG legislation, policy and guidance. Following regulatory approval, Navitas will implement a dedicated carbon and biodiversity offsetting fund that will be financed by contributions from Navitas and governed by a steering group comprising Navitas, FIG and NGO stakeholders and technical advisors. The performance of Navitas' offsetting programme will be reported.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
		Note: Since the public consultation FIG has developed its offsetting policy and Navitas has agreed to contribute to the environment trust fund rather than a Sea Lion specific carbon and biodiversity offsetting fund. Please note that once the oil is produced and sold, the title transfers and then it is beyond the ability of Navitas to determine where, when and how the end-use emissions will be created, and thus Navitas has very little ability to influence these aspects. Please also refer to UP 2.	
UP 8	Other international legal obligations 27. The UK must report its emissions, plus those Crown Dependence and Overseas Territories which have had the UK ratification of the UNFCCC extended to them, under the UNFCCC process. The UK has extended its ratification of the UNFCCC to the Falkland Islands9. While the Paris Agreement has not been extended to the Falkland Islands, it is clear that Navitas consider it to be relevant legislation, and the UK may consider extending the Paris Agreement to other Overseas Territories. The UK is already not on track to meet its Nationally Determined Contribution and will need to put forward additional plans for reduction emissions if this was to be extended to the Falkland Islands and the Sea Lion project is approved.	Navitas expects that FIG will comment separately on the EIS public consultation representations which concern FIG's Policy and Legal Obligations.	N/A
UP 9	28. The UK's status as a party to the UN Convention on the Law of the Sea (UNCLOS)10 extends to the Falkland Islands. UNCLOS includes obligations to adopt laws and regulations to prevent, reduce, and control pollution of the marine environment from land-based sources and from the atmosphere. Measures must include "those designed to minimize to the fullest possible extent" the "release of toxic, harmful or noxious substances from land-based sources" and pollution from vessels or installations at sea (UNCLOS, Article 194). 29. Article 194 of UNCLOS requires states to take "all necessary measures" to	Navitas notes this comment. Navitas expects FIG to address responders' comments on legislative matters separately.	N/A

Ref.	Representation	Navitas response	Changes in Rev 4
	prevent, reduce and control pollution of the marine environment from "any source". The recent unanimous Advisory Opinion of ITLOS confirms that anthropogenic GHG emissions constitute pollution of the marine environment and that the obligation to take all necessary measures applies to such pollution (ITLOS Advisory Opinion, paragraph 197). 30. The ITLOS Advisory Opinion makes clear that the obligations under UNCLOS are not satisfied by simply complying with the obligations and commitments of the Paris Agreement (ITLOS Advisory Opinion, paragraph 223). Rather, it seems that "all necessary measures" requires, at the very least and only as a minimum, compliance with those emissions reductions obligations. 31. We recommend that the Department of Mineral Resources should aim to go beyond the bare minimum compliance with its obligations under the legislation and its regulatory regime if it hopes to comply with its obligations under UNCLOS. It is clear following the ITLOS advisory opinion that states and signatories must take very significant action to prevent pollution from any source, including greenhouse gas emissions, to comply with their UNCLOS obligations.		
UP 10	Conclusion 32. We consider the EIS for the Sea Lion Development to be inadequate and the project unfit for approval in light of its excessive emissions, which have not been adequately assessed or disclosed, as well as transboundary and cumulative impacts, including on the marine environment and the climate, which have not been properly assessed. 33. There is strong scientific evidence and consensus that new oil and gas production is not compatible with net zero emissions by 2050, which is the relevant target within the comparable UK regime, or with a 1.5°C or 2°C pathway. 34. On this basis, and the numerous inadequacies of the EIS, consent for the Sea Lion Development should not be granted.	Navitas notes this comment but disagrees with its conclusions. As detailed in the EIS, Navitas acknowledges the energy transition. Navitas has presented a field development plan which shall have a lower carbon per barrel intensity than the average North Sea production. Please refer to response to RSPB 7.	N/A
